Overview of the Manual

The LOOPS Library Modules Manual describes the Library Modules for Venue's Lisp Object-Oriented Programming System, LOOPS. These Library Modules, which can be loaded into Medley, provide additional functionality to LOOPS.

This manual describes the current release of the LOOPS Library Modules, which run under Medley.

Organization of the Manual and How to Use It

This manual is divided into chapters, with each chapter focussing on a particular Library Module. A Table of Contents is included to help you find specific material.

Conventions

This manual uses the following conventions:

- Case is significant in LOOPS and Medley. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- You need to use an Interlisp Exec to enter all exec expressions.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(_ self Selector Arg1 Arg2)

• Examples are shown in the Interlisp Exec and appear in the following typeface:

 $89 \leftarrow (\leftarrow \text{LOGIN})$

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form ClassName.SelectorName.

- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the LOOPS items (functions, methods, etc.) by using the following template:

- Purpose: Gives a short statement of what the item does.
- Behavior: Provides the details of how the item operates.
- Arguments: Describes each argument in the following format:

argument Description

- Returns: States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.
- Categories: A way to group related methods. For example, all the methods related to Masterscope on the class **FileBrowser** have the category Masterscope, not **FileBrowser**. This item appears only for methods.
- Specializes: The next higher class in the class hierarchy that contains a method with the same selector. For example, **RectangularWindow.Open** can specialize **Window.Open**. This appears only for methods.
- Specializations: The next lower class in the class hierarchy that contains a method with the same selector. For example, **Window.Open** is a specialization of **RectangularWindow.Open**. This appears only for methods.
 - Example: An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See the *LOOPS Reference Manual* for details.

Description/Introduction

Gauges are an important part of the LOOPS user interface for both developers and end users. Gauges assist in understanding the dynamic nature of the programs. This is in contrast to the more typical case of debugging programs using static means. In the creation of user-friendly interfaces, you can use gauges to display, in analog or digital form, various data that may be changing. Also, by employing active gauges, you can provide a convenient way to interact with a system.

One of the features of gauges is the ease with which you can use them in a system. In more traditional languages, if you want to understand how a variable is changing over the course of a computation, you must make modifications in your program wherever you want to begin or end the examination of a variable. Given the capabilities of active values used by gauges, you need only attach or detach a gauge to the data that you are interested in monitoring.

The following types of gauges are available:

- Meter; a circular instrument that wraps around any number of times.
- Dial; a bounded dial, like an automobile speedometer.
- LCD; a gauge that uses the entire window to display a value.
- Scale; a horizontal or vertical display of a gauge.
- ActiveScale; a scale that allows you to change the gauge value.

Gauges are an example of the combination of programming capabilities within LOOPS. The different types of gauges are defined within the context of an inheritance lattice. This allows the more general functionality and variables to be allocated to more general gauge classes, with specific functionality placed in more restricted classes. You can also see the use of mixins to add a small amount of functionality to several different classes of gauges.

Note: Mixins are classes that are used only in conjunction with another class to create a subclass.

The methods within gauges are built upon both function calling and message sending. Gauges are "attached" to objects through the mechanism of active values. Since gauges are built upon the mechanism of active values, gauges can only be attached to data within objects. It is not possible to use gauges to monitor any arbitrary Lisp variable.

Prerequisites

The default font for gauges is Modern 10.

Installation/Loading Instructions

Gauges are divided among several different files to allow you to load only those objects and functions that you need. The table below lists the files to load for each type of gauge. The filecoms for each file will try to load any other required gauge files from **LOOPSLIBRARYDIRECTORY**. The file GAUGES.DFASL and either GAUGEINSTRUMENTS.DFASL or GAUGEALPHANUMERICS.DFASL will always be loaded; other files may also be loaded.

- Gauge File to load
 - LCD GAUGEALPHANUMERICS.DFASL
 - METER GAUGEMETERS.DFASL
 - DIAL GAUGEDIALS.DFASL
 - SCALE GAUGESCALES.DFASL

ACTIVE SCALEGAUGEACTIVE.DFASL

Additionally, the file GAUGESELFSCALEMIXIN.DFASL can be loaded to add the class **SelfScaleMixin**, and GAUGEALARMS.DFASL can be loaded to add the class **AlarmMixin**.

To load the required files, first set the value of **LOOPSDIRECTORY** to include the directory where the gauges files are stored, then type the following expression in the Executive:

(LOAD 'FILENAME)

To load all of the gauges, load the file GAUGELOADER and then enter (LOADGAUGES). GAUGELOADER also sets the variables: GAUGEFILES and GaugeClasses.

(LOADGAUGES LDFLG SOURCES?FLG)

[Function]

Purpose:	Loads all the gauges.			
Behavior:	Assumes that all of the gauge files are on the LOOPSDIRECTORY search path.			
		e files will be loaded based upon the settings of <i>LDFLG</i> and <i>FLG</i> . A FILESLOAD expression is built up and evaluated.		
Arguments:	LDFLG	Can be NIL, PROP, or SYSLOAD. See the LDFLG discussion under loading in the <i>Interlisp-D Reference Manual</i> .		
	SOURCES?FLG Can be NIL or T. If NIL, this attempts to load the compiled files before trying to load the sources. If T, only the sources are loaded.			
Poturne:	Llood for side offect only			

Returns: Used for side effect only.

GAUGEFILES		[Variable]
	Behavior:	Initialized to (GAUGEACTIVE GAUGEALARMS GAUGEALPHANUMERICS GAUGEBOUNDEDMIXIN GAUGEDIALS GAUGEDIGIMETER GAUGEDIGISCALE GAUGEINSTRUMENTS GAUGEMETERS GAUGES GAUGESCALES GAUGESELFSCALEMIXIN)
GaugeClasses		[Variable]
	Behavior:	Initialized to (GaugeAV ActiveGaugeMixin Gauge AlarmMixin BoundedMixin SelfScaleMixin)
		Call (Browse GaugeClasses) to open a browser of all of the gauge classes.

Application/Module Functionality

This section describes the gauge classes and methods.

Gauge Classes

Class browser Meter RoundScale Dial ActiveHorizontalScale HSGraphics HorizontalScale (SSHorizontalScale Instrument HBarChart -- SSHBarChart StraightScale Gauge ActiveVerticalScale VSGraphi⋩ VenticalScale SSVenticalScale BarChart -- SSBarChart LCD SSDigiMete AlphaNumeric < DigiMeter LCDMixin DigiScale

This section describes the available gauges shown in the following browser.

Note: The browser does not include the optional mixin classes.

Within the class description of each class, the instance variables and class variables that are specializations only because they have different default values are not listed.

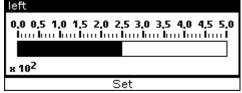

Name	Туре	Description
ActiveGaugeMixin	AbstractClass	A gauge class that allows you to set the value of the variable being monitored with the cursor, via a SET menu.
ActiveHorizontalScal	e Class	An active gauge that displays the value on a horizontal scale.
ActiveVerticalScale	Class	An active gauge that displays its value on a vertical scale.
AlarmMixin	AbstractClass	A mixin that adds alarm functionality to any gauge.
AlphaNumeric	AbstractClass	A gauge that gives an alphanumeric display of a value.

BarChart	Class	A gauge that displays more than one VerticalScale side-by
		side.
BoundedMixin	AbstractClass	Creates a bounded scale for displayVal ; to be used as a mixin for instruments.
Dial	Class	A bounded dial, like an automobile speedometer.
DigiMeter	Class	A gauge that displays both an LCD and a meter.
DigiScale	Class	A gauge that displays both an LCD and a horizontal scale.
Gauge	AbstractClass	A class for objects that present a dynamic graphical image of a LOOPS value.
GaugeAV	Class	An active value associated with a gauge.
HBarChart	Class	A gauge that displays more than one HorizontalScale side-by side.
HorizontalScale	Class	A labeled, bounded scale with a bar that fills to the right.
HSGraphics	AbstractClass	Gauge that is displayed in the form of a singe horizontal scale or bar.
Instrument	AbstractClass	A numeric gauge that is externally scaled by inputLower and inputRange and scaled internally by lower and range .
LCD	Class	Differs from AlphaNumeric in that the entire gauge window is the printing region.
LCDMixin	AbstractClass	Computes print region differently from LCD .
Meter	Class	A circular instrument that wraps around any number of times.
RoundScale	AbstractClass	Abstract Class for instruments with circular (arc) scales.
SelfScaleMixin	AbstractClass	Provides for the gauge to rescale according to the reading.
SSBarChart	Class	A self-scaling version of BarChart.
SSDigiMeter	Class	A self-scaling version of DigiMeter .
SSHBarChart	Class	A self-scaling version of HBarChart.
SSHorizontalScale	Class	Gauge that is displayed in the form of a single scale or bar which rescales itself accordingly.
SSVerticalScale	Class	Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.
StraightScale	AbstractClass	Abstract Class for instruments with straight scales.
VSGraphics	AbstractClass	Gauge that is displayed in the form of a single vertical scale or bar.
VerticalScale	Class	Gauge that is displayed in the form of a single vertical scale or bar.

ActiveGaugeMixin

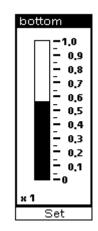

Description:	A gauge class that allows you to set the value of the variable being monitored with the cursor, via a SET menu.
MetaClass:	AbstractClass

Supers: Class Variables: Instance Variables:	Object None. cursor	The cursor to use when changing the scale; the default is NIL.
ActiveHorizontalScale		[Class]
Description:		auge that displays the value on a horizontal scale. This gauge value of the data it is connected with and allows you to change that be gauge.
MetaClass:	Class	
Supers:	ActiveGaug	geMixin, HorizontalScale
Class Variables:	None.	
Instance Variables:	cursor	Cursor to use when changing the scale; its property :initform is set to HorizontalAGCursor .
Example:	position the	ges have an attached menu at the bottom of the gauge. When you cursor over this menu and press a mouse button, the cursor the following shape:
		eft button is held down, the system tracks movements of the cursor es the value that the gauge is monitoring.

ActiveVerticalScale

Description:	Similar to ActiveHorizontalScale, except that a vertical scale is used.		
MetaClass:	Class		
Supers:	ActiveGaug	eMixin, VerticalScale	
Class Variables:	None.		
Instance Variables:	cursor	Cursor to use when changing the scale; its :initform property is set to VerticalAGCursor .	
Example:	Similar to A following sh	ctiveHorizontalScale. When setting, the cursor changes to the ape:	

AlarmMixin

[Class]

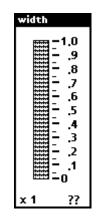

Description: A mixin that adds alarm functionality to any gauge. An alarm is defined as warning object that is set off when the value being monitored falls outside of the specified range. The gauge flashes and stays inverted when the alarm is tripped.

CAUTION

When a new class of gauges is created that will use the properties of **AlarmMixin**, **AlarmMixin** should be the first class on the Supers list of the new class. This guarantees that the **AlarmMixin.Set** method is invoked.

MetaClass:	AbstractClass		
Supers:	Object		
Class Variables:	MiddleButtonItems		
Instance Variables:	IowTripPoint Alarm is triggered when reading goes below this point.		
	hiTripPoint Alarm is triggered when reading goes above this point.		
	flashNumber Number of times alarm will flash when it is tripped.		
	flashInverval Interval in milliseconds between flashes.		
AlphaNumeric	[Class]		
Description:	This class contains some of the methods and data for the LCD classes. These gauges can display any type of character, letters, or numbers.		
MetaClass:	AbstractClass		
Supers:	Gauge		
Class Variables:	None.		

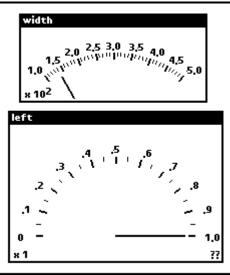

Instance Variables:	precision	Number of characters displayed in the reading. The default value is 5.
BarChart		[Class]
Description:	A gauge that	It can display more than one VerticalScale at once, side-by side.
MetaClass:	Class	
Supers:	VerticalScal	e
Class Variables:	None.	
Instance Variables:	maxLabelW	/idth Maximum width of labels on each bar. Default value is 0 which means no limit.
	scaleLeft	Offset within the gauge window from the left for the leftmost bar. Default value is 3.
	scaleBotto	m Offset within the gauge window from the bottom for all the bars. Default value is 30.
Example:	Here is a Ba the values 1	arChart showing the size and shape of a window. It is displaying 5, 21, 13, and 6.
	left bot x 10 ¹	-3.0 -2.5 -2.0 -1.5 -1.0 -0.0 tom height width
BoundedMixin		[Class]
Description:	BoundedM	s a super of the scale classes and Dial . If a gauge that has ixin as a super class tries to display a new setting that is outside of the gauge, the gauge will display the minimum or maximum propriate and place a "??" in the window.
MetaClass:	AbstractCla	SS
Supers:	Object	
Class Variables:	None.	
Instance Variables:	None.	
Example:	Here is a ve	rtical scale that displays a reading greater than its maximum.

Dial

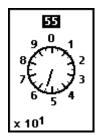

[Class]

Description:	A bounded dial, like an automobile speedometer.
MetaClass:	Class
Supers:	BoundedMixin, RoundScale
Class Variables:	None.
Instance Variables:	This class specializes the same instance variables as RoundScale.
Example:	The angle of the arc changes with the shape of the window.

DigiMeter

Description:	A gauge that combines both a meter and an LCD.
MetaClass:	Class
Supers:	Meter, LCDMixin
Class Variables:	None.
Instance Variables:	spaceForLCD Vertical space required by LCD within the gauge. Defaults to 30.
Example:	This DigiMeter is displaying 55.

DigiScale

Description:	A gauge that combines both a horizontal scale having no ticks and an LCD.
MetaClass:	Class
Supers:	HorizontalScale, LCDMixin
Class Variables:	None.
Example:	This DigiScale is displaying 63 with its scale set from 0 to 100.

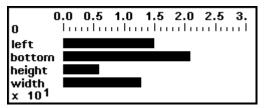

Gauge			[Class]	
	Description:	A class for objects that present a dynamic graphical image of a LOOPS value. This class provides most of the methods for using gauges.		
	MetaClass:	AbstractCla	ss	
	Supers:	Window		
	Class Variables:	LeftButton	tems Menu options associated with the left mouse button.	
		MiddleButt	onItems Menu options associated with the middle mouse button.	
	Instance Variables:	reading	External value of reading. The default value is 0.	
		containedI	AV Active value that connects the gauge to the data it is monitoring. It should be an instance of the class GaugeAV .	
		font	Font that is used by a gauge; default value is (Modern 10).	
		width	Width of a gauge; has property min, which specifies the minimum width for a gauge.	
		height	Height of a gauge; has property min , which specifies the minimum height for a gauge.	
GaugeAV			[Class]	
	Description:	An active va	lue that is associated with a gauge.	
	MetaClass:	Class		
	Supers:	LocalStateA	ctiveValue	

Class Variables:	None.	
Instance Variables:	gauge	The gauge connected to this active value.
	object	The object containing the variable associated with the active value.
	propName	The property name of the associated variable.
	type	Data type of the associated variable.
	varName	Name of the associated variable.
HBarChart		[Class]
Description:	A gauge tha side.	t can display more than one HorizontalScale at once, side-by
MetaClass:	Class	
Supers:	HorizontalSo	cale
Class Variables:	None.	
Instance Variables:	maxLabelW	/idth Maximum width of labels on each bar. Default value is 0 which means no limit.

scaleLeft

Offset within the gauge window from the left for the leftmost bar. Default value is 3.

Example: Here is an **HBarChart** showing the size and shape of a window. It is displaying the values 15, 21, 13, and 6.

HorizontalScale

[Class]

Description: A labeled, bounded scale with a bar that fills to the right.

MetaClass: Class

Supers: HSGraphics

Class Variables: None.

Instance Variables: None.

Example: This **HorizontalScale** is reading 350 on a scale from 0 to 500.

left		
0.0 0.5 1.0 1	5 2,0 2,5 3,0	3,5 4,0 4,5 5,0
han kan kan	հուհուհուհո	3,5 4,0 4,5 5,0 . http://www.ice.com
2		
x 10 ²		

HSGraphics

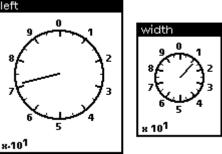

Description:	This class pr horizontal sc	ovides some of the methods for displaying the graphics of a ale.	
MetaClass:	AbstractClass		
Supers:	StraightScale		
Class Variables:	None.		
Instance Variables:	scaleBotton	n Bottom edge of scale in pixels. The default value is 10.	
	scaleLeft	Left edge of scale in pixels. The default value is 12.	
	scaleWidth	Width of inside of scale in pixels. The default value is 120.	
	scaleHeight	Height of scale in pixels. The default value is 15.	
Instrument		[Class]	
Description:	numerical da	provides additional methods and data for gauges that display only ita. This data is externally scaled by inputLower and , and scaled internally by lower and range .	
MetaClass:	AbstractClas	S	
Supers:	Gauge		
Class Variables:	None.		
Instance Variables:	ticks	Scale marks on the instrument; value is a number or NIL; smallTicks property indicates the number of smaller ticks between each large tick.	
	displayVal	Internal value relative to instrument.	
	range	Range for internal displayVal .	
	inputRange	Range for external reading.	
	lower	Lower bound for internal displayVal.	
	inputLower	Lower bound for external reading.	
	brushWidth	Scale factor for width of ticks, rays, and circles in pixels.	
	labels	The labels that will be displayed on the gauge.	
	labelScale	A dotted pair representing the sign and exponent of a reading.	
	spaceForLa	belScale Extra vertical space to display scale label.	
LCD		[Class]	
	Differe from		
LCD Description:	Differs from		

Description.	
MetaClass:	Class
Supers:	AlphaNumeric
Class Variables:	None.
Instance Variables:	None.

Example: This **LCD** is displaying the string "Mumble", and has been **Shape**dto 120 x 60.

LCDMixin	[Class]
Description:	Computes printing region differently from LCD so that an LCD may be added into another window.
MetaClass:	AbstractClass
Supers:	AlphaNumeric
Class Variables:	None.
Instance Variables:	precision Number of characters displayed in the reading; the default value is 3. Its property is readingRegion ; the default value is NIL.
	readingY Y position of bottom of reading. The default value is 7.
Meter	[Class]
Description:	A circular instrument that wraps around any number of times. It displays a sign and exponent in the lower left corner of its window.
MetaClass:	Class
Supers:	RoundScale
Class Variables:	None.
Instance Variables:	This class specializes the same instance variables as RoundScale .
Example:	The Meter on the left is displaying a negative value.
	left

RoundScale

Description:	Abstract Class for instruments with circular (arc) scales.
MetaClass:	AbstractClass
Supers:	Instrument
Class Variables:	None.
Instance Variables:	needleLength Radius of needle in pixels. The default value is 15.

	ne dive	Dedius of evolutions in the default value is 40	
	radius	Radius of arc in pixels. The default value is 10.	
	хс	x-coordinate window coordinate of center of arc. (See DRAWARC in the <i>Lisp Release Notes</i> .)	
	ус	y-coordinate window coordinate of center of arc. (See DRAWARC in the <i>Lisp Release Notes</i> .)	
SelfScaleMixin			[Class]
Description:	Provides fo	r the gauge to rescale according to the reading.	
MetaClass:	AbstractCla	SS	
Supers:	Object		
Class Variables:	None.		
Instance Variables:	lowScaleFa	actor Rescales if reading shrinks so that it will fit more than lowScaleFactor times in inputRange. The default value	ue is 5.
SSBarChart			[Class]
Description:	A self-scalir	ng version of BarChart.	
MetaClass:	Class		
Supers:	BarChart		
Class Variables:	None.		
Instance Variables:	None.		
SSDigiMeter			[Class]
Description:	A self-scalir	ng version of DigiMeter .	
MetaClass:	Class		
Supers:	DigiMeter		
Class Variables:	None.		
Instance Variables:	None.		
SSHBarChart			[Class]
Description:	A self-scalir	ng version of HBarChart.	<u> </u>
MetaClass:	Class		
Supers:	HBarChart		
Class Variables:	None.		
Instance Variables:	None.		
.			
SSHorizontalScale Description:	Gauge that rescales its	is displayed in the form of a single horizontal scale or ba elf accordingly.	[Class] r which

MetaClass:	Class
Supers:	VerticalScale
Class Variables:	None.
Instance Variables:	None.

SSVerticalScale

[Class]

[Class]

[Class]

Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.
Class
HorizontalScale
None.
None.

StraightScale

 Description:
 Abstract class for instruments with straight scales.

 MetaClass:
 AbstractClass

 Supers:
 BoundedMixin, Instrument

 Class Variables:
 None.

 Instance Variables:
 shade
 Shade of bar; numeric value from 0 to 65535. The default value is 65535, which is BLACKSHADE.

VerticalScale

Description:	Gauge that is displayed in the form of a singe vertical scale or bar.
MetaClass:	Class
Supers:	VSGraphics
Class Variables:	None.
Instance Variables:	None.
Example:	This VerticalScale is displaying the value .55 and has its Shade set to 1258.

-1.0 - 0.9 - 0.8 - 0.7 - 0.6 - 0.5 - 0.5 - 0.4 - 0.3 - 0.2 - 0.1 - 0.1 - 0.1 - 0.1

VSGraphics		[Class]
Description:	Similar to HSGraphics but for vertical scales.	
MetaClass:	AbstractClass	
Supers:	StraightScale	
Class Variables:	None.	
Instance Variables:	scaleBottom Bottom edge of scale in pixels. The default value is 12.	
	scaleLeft Left edge of scale in pixels. The default value is 15.	
	scaleWidth Width of inside of scale in pixels. The default value is 15	5.
	scaleHeight Height of scale in pixels. The default value is120.	

Gauge Methods

This section describes the available methods and functions which are used to manipulate gauges. In many cases, a particular gauge class specializes a method defined in the class **Gauge**. In this case, the specialized method definition is not explicitly defined; instead, this is noted in the Specializes/Specializations field of the description.

Name	Туре	Description
Attach	Method	Connects a gauge to an object.
Attached?	Method	Determines what the gauge is attached to.
ChangeFont	Method	Sets the gauge's instance variable font and updates the gauge.
Close	Method	Detaches the gauge and closes the window.
Destroy	Method	Destroys the gauge, detaching it first.
Detach	Method	Detaches the gauge from the variable it is attached to.
Reset	Method	Resets the gauge's instance variable reading .
SetScale	Method	Sets the scale for the gauge.
Shape	Method	Sweeps a new region.
ShapeToHold	Method	Shapes the gauge window to its smallest possible size.
Update	Method	Reinitializes the gauge and its display window to reflect the current state.

(← self Attach obj varName prop	Name type xOrPos y)	[Method of Gauge]
Purpose:	Connects a gauge to an object.	
Behavior:	Displays the gauge on the screen and associa <i>varName</i> of <i>obj</i> . If <i>propName</i> is specified, the variable's property. If <i>xOrPos</i> and <i>y</i> are not s appear which must be positioned to place the g	gauge will montior the pecified, a small box will
Arguments:	obj A pointer to the object to which the	ne gauge is to be attached.

	varName	The name of the instance variable, class variable, or method to which the gauge is to be attached.
	propName	If non-NIL, the gauge will be attached to this property.
	type	One of IV, CV, or METHOD, within the object being connected to the gauge. If NIL, it defaults to IV.
	xOrPos	A numerical value to specify where, in screen coordinates, the gauge will be placed on the display. If NIL, you are asked to place the gauge on the screen. This can be a number to specify the x coordinate or a position. If it is a number, also specify y .
	У	If <i>xOrPos</i> is not a position, this specifies the y coordinate in screen coordinates for the gauge.
Returns:	self	
Specializations:	the scale ma	ale.Attach has an additional <i>shade</i> argument so that the shade of ay be specified at the time the gauge is attached. The following rgument list for this method:
	(← (\$ instar xOrPos y)	nce OfHorizontalScale) Attach obj varName shade propName type
	additional la	methods for BarChart , HBarChart , and their subclasses take an <i>bel</i> argument. If no <i>label</i> argument is given, the bar is labeled with The <i>label</i> argument comes last, as follows:
	(← (\$ instar xOrPos y la	nce OfBarChart) Attach obj varName propName propName type bel)
(\leftarrow self Attached? don'tPrintFlg)		[Method of Gauge]
Purpose:	Determines	what a gauge is attached to.
Behavior:	containedlr	Fig is non-NIL this returns the value of the gauge instance variable AV . If <i>dontPrintFig</i> is NIL, the object and the varName the gauge to will be printed in an attached window.
Arguments:	don'tPrintFl	g Suppresses displaying what the gauge is attached to.
Returns:	NIL	
$(\leftarrow self ChangeFont newFont)$		[Method of Gauge]
Purpose/Behavior:	Sets the gau the gauge is	uge's instance variable font to <i>newFont</i> and updates the gauge. If s too small for <i>newFont</i> , it is reshaped.
Arguments:	newFont	A font in which to display the gauge's text.
Returns:	Previous va	lue of font .
$(\leftarrow \textit{self} Close)$		[Method of Gauge]
Purpose/Behavior:	Detaches th	e gauge and closes the window.
Returns:	CLOSED	
$(\leftarrow \textit{self Destroy})$		[Method of Gauge]
Purpose/Behavior:	Destroys the	e gauge, detaching it first before closing the window.

Returns:	NIL
(← self Detach)	[Method of Gauge]
Purpose/Behavior:	Detaches the gauge from the variable to which it is attached. This prints in an attached window that the gauge is being detached, and deletes all of the links connecting the gauge, active value, and object being monitored. Does not close the window.
Returns:	NIL
(← self Reset newReading)	[Method of Gauge]
Purpose/Behavior:	Sets the gauge's instance variable reading to <i>newReading</i> and updates the gauge. If the gauge is too small for <i>newReading</i> and it is SelfScaling, it is reshaped.
Arguments:	newReading Sets the instance variable reading to <i>newReading</i> , and updates the gauge without going through any intermediate steps.
Returns:	NIL if gauge is AlphaNumeric or RoundScale; otherwise self.
Specializations:	Alphanumeric.Reset, RoundScale.Reset
Example:	The following example causes the LCD to be redisplayed with the <i>newReading</i> :
	$13 \leftarrow (\leftarrow (\$ lcd1) Reset "New Title")$
$(\leftarrow self $ SetScale min max)	[Method of Gauge]
Purpose/Behavior:	Sets the scale for the gauge; computes the new scale values and redisplays if necessary.
Arguments:	min Lowest value on scale.
	max Highest value on scale.
Returns:	self
(← self Shape newRegion noUp	dateFlg) [Method of Gauge]
Purpose/Behavior:	If <i>newRegion</i> is NIL, you are prompted to sweep out a region which has a minimum sized based upon a min property of IV width and height:,min . If <i>newRegion</i> is non-NIL, it is first checked to guarantee that it is at least as large as width:,min by height:,min .
Arguments:	<i>newregion</i> List specifying the external coordinates of the window in which the gauge is displayed; list is of the form (left, bottom, width, height).
	noUpdateFlg If NIL, reshapes the gauge.
Returns:	NIL
Specializes:	Window
Specializations:	LCD , Meter , DigiMeter . Meter.Shape has an extra argument <i>ExtraSpaceFlg</i> . If T, this will allow you to shape a fairly arbitrary region for the gauge; if NIL, the meter is constrained to be close to a square. This latter behavior is what the user sees when trying to shape the meter from the window menu.

	BarChart, HBarChart , and their subclasses can only be freely Shape d in the direction their bars run (i.e., BarChart s can be Shape d vertically and HBarChart s can be Shape d horizontally). Their size along the other dimension is fixed by the number of values attached to the chart.
Example:	This example reshapes the gauge to a location where the lower left corner is at (10,100) a width of 50 and a height of 150.
	14←(← (\$ lcd1) Shape '(10 100 50 150))
(← self ShapeToHold)	[Method of Gauge]
Purpose/Behavior:	Shapes the gauge window to its smallest possible size based on width:,min and height:,min and redisplays the gauge.
Returns:	NIL
Specializations:	LCD.Shape
(← self Update)	[Method of Gauge]
Purpose/Behavior:	Reinitializes the gauge and its display window to reflect the current state.
Returns:	self
Categories:	Window

Examples

The typical use pattern for a gauge is to first create it, set the scale to the appropriate value, and attach it to the desired data.

To attach a horizontal scale to a LOOPS window, w1, first enter

```
15←(← ($ Window) New 'w1)
#,($& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 495))
16←(← ($ HorizontalScale) New 'hs1)
#,($& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))
```

17 \leftarrow (\leftarrow (\$ hs1) SetScale 0 500) NIL

Now make the connection.

 $18 \leftarrow (\leftarrow (\$ hs1) Attach (\$ w1) 'width GRAYSHADE) \\ #,(\$\& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))$

The following gauge appears and you are prompted to place it .

width
0.0 0.5 1.0 1.5 2.0 2.5 3.0 3.5 4.0 4.5 5.0 Tanakan karing barran karing barran barra
× 10 ²

The title of the gauge shows the instance variable being monitored.

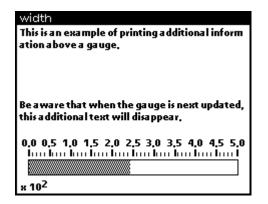

Gauges can be shaped larger. The graphics used to display scales do not change; extra white space is added to the top or right. You can use this space to print additional information, as follows:

19←(MOVETOUPPERLEFT (@ (\$ hs1) window)) {WINDOW}#372,7104

 $20 \leftarrow (PRIN1$ "This is an example of printing additional information above a gauge.

Be aware that when the gauge is next updated, this additional text will disappear." (@ (\$ hs1) window)) "This is an example of printing additional information above a gauge.

Be aware that when the gauge is next updated, this additional text will disappear."

Limitations

When a font is changed, a gauge occasionally needs to be updated to be correctly displayed.

Instruments can have only floating point numbers for labels, and cannot have integers.

[This page intentionally left blank]

Description/Introduction

Masterscope has been modified to provide for analysis of files created under the Koto or Lyric/Medley release of LOOPS. A full explanation of Masterscope can be found in the *Lisp Library Modules Manual*. In addition to the relations explained there, LOOPS defines the relations described in this chapter.

Note: Masterscope data base files created under Buttress Loops will not function properly in this release. Those data base files will have to be recreated.

Installation/Loading Instructions

- Load MASTERSCOPE from your Lyric/Medley library floppies according to its loading instructions. This should load the compiled files MASTERSCOPE, MSANALYZE, and MSPARSE.
- Load LOOPSMS.DFASL from wherever you installed the LOOPS Library Modules. This should load versions of MASTERSCOPE and MSPARSE that extend Masterscope to handle LOOPS constructs.

Relations

	LOOPS defines the following relations:	
Name	Туре	Description
SEND	Relation	Collects all places where the method is sent.
SEND SELF	Relation	Collects all places where the method is sent to self.
SEND NOTSELF	Relation	Collects all places where the method is sent to an object other than <i>self</i> .
GET	Relation	Locates all places where the value of an instance variable is retrieved.
GET CV	Relation	Locates all places where the value of a class variable is retrieved.
PUT	Relation	Locates all places where the value of an instance variable is set.
PUT CV	Relation	Locates all places where the value of a class variable is set.
IMPLEMENT	Relation	Locates all methods that specialize the given selector.
SPECIALIZE	Relation	Locates all methods that specialize the given selector and use \leftarrow Super in the body of the method.
OVERRIDE	Relation	Locates all methods that specialize the given selector and do not use \leftarrow Super in the body of the method.

USE IV	Relation	Used with an instance variable name to locate all places where the instance variable is used in a GET or PUT.
USE CV	Relation	Used with a class variable name to locate all places where the class variable is used in a GET or PUT.
USE OBJECT	Relation	Used with an object name to locate all places where the object is used.

SEND

[Relation]

Purpose/Behavior:	Used between method names and selectors to collect all places where the method is sent. For example, the form
	. WHO IS SENT BY 'Helicopter.Move
	works, but
	. WHO IS SENT BY Move
	does not work.
Example:	The following command allows you to edit all code that sends the message New .
	. EDIT ALL WHO SEND New
SEND SELF	[Relation]
Purpose/Behavior:	Used between method names and selectors to collect all places where the method is sent to <i>self</i> . Places where
	(\leftarrow self methodName)
	is found are collected, while places where
	(\leftarrow otherInstance methodName)
	is found are not.
Example:	The following command allows you to edit all code that sends the message Clear to self.
	. WHO SENDS SELF Clear
SEND NOTSELF	[Relation]
Purpose:	Same as SEND SELF , except the only places where the message is sent to an object other than <i>self</i> .
Example:	The following allows you to edit all code that sends the message Clear to any instance other than <i>self</i> .
	. SHOW ALL WHO SEND NOTSELF Clear
GET	[Relation]
Purpose:	Used with an instance variable name to locate all places where the value of the instance variable is retrieved. This relation can be used along with the SELF and NOTSELF modifiers.

	Example:	This command allows you to edit all code that gets the value of the instan variable width from an instance other than self and the value of the instan variable height from <i>self</i> .	
		. SHOW ALL WHO GET NOTSELF width AND GET SELF height	
GET CV		[Rel	lation]
	Purpose:	Same as GET , except that GET CV locates places where the value of the class variable is retrieved. This relation can be used with the SELF and NOTSELF modifiers.	9
	Example:	This command allows you to edit all code that accesses the value of the overlable height of <i>self</i> .	class
		. SHOW ALL WHO GET CVSELF height	
PUT		[Rel	lation]
	Purpose:	Used with an instance variable name to locate all places where the value the instance variable is set. This relation can be used along with the SEL and NOTSELF modifiers.	
	Example:	This command allows you to edit all code that sets the value of the instan variable width.	ice
		. EDIT ANY WHO PUT width	
PUT CV		[Rel	lation]
	Purpose:	Same as PUT , except locates places where a specified class variable is s This relation can be used along with the SELF and NOTSELF modifiers.	set.
	Example:	This command list all the sections of code that set the value of the class variable width for an instance other than <i>self</i> .	
		. WHO PUTS CV NOTSELF width	
IMPLEMENT		[Rel	lation]
	Purpose:	Used with a method name to locate all methods that specialize the given selector.	
	Example:	This returns a list of classes where the method Clear is defined.	
		. WHO IMPLEMENTS Clear	
SPECIALIZE		[Rel	lation]
	Purpose:	Used with a method name to locate all methods that specialize the given selector and use \leftarrow Super in the body of the method.	
	Example :	This command allows you to edit all the methods that are specializations Clear and use the \leftarrow Super form.	of
		. EDIT ANY WHO SPECIALIZE Clear	
OVERRIDE		[Rel	lation]
	Purpose:	Like SPECIALIZE above, except it locates all methods that specialize the given selector and \leftarrow Super is not used in the body of the method.	;

	Example:	This command allows you to edit all the specializations of Clear that do not make use of the \leftarrow Super form.
		. EDIT ALL WHO OVERRIDE Clear
USE IV		[Relation]
	Purpose:	Used with an instance variable name to locate all places where the instance variable is used in a Get or Put . It is equivalent to using the relation form of GET IVName or PUT IVName .
	Example:	This command allows you to edit all code that either sets or accesses the instance variable width .
		. EDIT ANY WHO USE THE IV width.
USE CV		[Relation]
	Purpose:	Used with a class variable name to locate all places where the class variable is used in a Get or Put . It is equivalent to using the relation form: GET CV CVName OR PUT CV CVName .
	Example:	This command allows you to edit all code where the class variable commonWindow is either set or accessed.
		. EDIT ANY WHO USE THE CV commonWindow
USE OBJECT		[Relation]
	Purpose	Uses an object name to locate all places where the object is used.
	Example	This command returns a list of all code where the object Window is used.
		. WHO USES THE OBJECT Window??

Limitations

Masterscope has several limitations:

- Names of methods must be quoted when used with Masterscope; for example, the method name Helicopter.Move must be entered as 'Helicopter.Move.
- The following expression will not find a call to GetValue when in a method :
 - . WHO CALLS GetValue

Masterscope does not record calls to **GetValue** and **PutValue** explicitly; it records them under the Get- relation along with calls of the form

 $(\leftarrow foo Get 'bar)$

Similarly, the following functions are recorded under relations instead of their names:

GetClassValue Get CV

PutClassValue GetClassIV PutClassIV

Put CV Get IV Put IV

If you want to find the explicit calls to Get/PutValue, use

- . WHO GETS ANY AND NOT SENDS Get
- Masterscope currently assumes calls to GetValue and similar accessors are accessing instance variables; i.e.,

```
(GetValue foo 'bar)
```

records an access to the instance variable **bar**. This is not necessarily the case; **bar** could also be a class variable.

• The methods and functions that create class and instance variables populate the appropriate **PUT NOTSELF** relations. For example, a function that does

 $(\leftarrow (\$ foo) AddCV 'bar)$

will be found by the query

. WHO PUTS CV NOTSELF 'bar

An exception occurs with the generalized \boldsymbol{Add} and \boldsymbol{Delete} method. For example,

(\$ foo) Add 'IV 'bar)

will not be noticed as accessing the instance variable bar.

Also, the templates for methods and functions that accept property lists generally only notice the first property. For example,

 $((\leftarrow(\$ foo) NewWithValues '((bar baz chain link sausage)))$

notices **baz** as a property, not a link.

Description/Introduction

In many knowledge-based systems, it is useful to represent knowledge as interconnected sets of instances. A virtual copy mechanism allows a network of instances to be viewed as a prototype which can be copied. The copy of the prototype is virtual in that the contents of each instance is not completely copied at creation time. Instead, it inherits default values from the prototype (also called the original), thus continuing to share the parts not modified in the copy. The copied network is virtual also in the sense that only those instances needed in the processing are copied.

A virtual copy of an object in the prototype network has the following properties:

- It responds to at least the same set of messages as the prototype object and in the same way; that is, a copy has the same procedural behavior that is defined for the prototype.
- A copy inherits variables and their values from the prototype, and continues to do so until an explicit change is made in the copy. At that point, the new value is stored in the copy and it stops tracking the prototype for that variable. A fetch operation on a value that is not stored locally either finds or creates a virtual copy of the value obtained from the prototype.

Installation/Loading Instructions

The implementation of virtual copies is contained in the file LOOPSVCOPY.LCOM. No other files are necessary.

Application /Module Functionality

A network of instances is tied together through the values of instance variables within each of the instances. Assume an object A has an instance variable x, the value of which is the object B. A virtual copy of A will also have an instance variable named x. The value of x in the copy will point to B if B is a shared object, or x may point to a copy of B if it is to be virtual. Changing the value of x in the copy will not change the value in the original.

Overview of Operation

By default, virtual copies share instance variables. This means that changing the value of an instance variable in the original will be tracked by the copy.

Virtual copies are implemented with two additional classes:

• VirtualCopyMixin

The class **VirtualCopyMixin** is a subclass of Tofu which contains two instance variables:

- % copyMap%
- % copyOf%

(These unusual names are used to avoid conflicts with any other instance variable names users may create.) This class contains several methods, most of which are required to implement virtual copies and are not used by a programmer.

Printing a virtual copy instance is a specialization of how regular instances are printed. All instances print as #,(\$& <class-name> UID). The class of a virtual copy is a dynamic mixin of the class **VirtualCopyMixin** and the class of the original object (see the *LOOPS Reference Manual* for more information on mixins). The virtual copy print function adds the name or unique identifier (UID) of the original object. For example,

#,(\$& (VirtualCopyMixin Container1) (JFW0.0X:.aF4.R>8.3) c1)

is a copy of the object named c1.

VirtualCopyContext

The class **VirtualCopyContext** has no methods and only one instance variable, **copyMap**. Instances are used as an argument for calls to **MakeVirtualMixin**.

Since copies can be made of copies, you often need to determine the original object of a chain of copies with the **UltimateOriginal** function.

0	perands	

This section describes the functions, methods, class variables, and instance variables that operate on virtual copies.

VirtualIVs		[Class Variable]
	Purpose/Behavior:	Helps specify a class whose instances may be made into virtual copies. The value of this class variable should be either the symbol ALL, or a list of instance variables contained within instances of the class. If the value is ALL, all objects pointed to by any of the instance variables will be copied. If the value is a list of instance variables, only the instance variables on this list will have their values copied. Other instance variable values will be shared between the copy and the original.
(MakeVirtualMixin x copyContextObj) [Function]		
	Purpose:	Creates a virtual copy of an object.

Behavior: Creates a dynamic mixin class combining the classes **VirtualCopyMixin** and the class of *x*. An instance of this resulting class is created and it is returned.

Arguments:	<i>x</i> An object to be copied; must have the class variable VirtualIVs as described above.
	<i>copyContextObj</i> Usually NIL; used internally by MakeVirtualMixin when it calls itself. It can be an instance of VirtualCopyContext if you are creating an instance that is intended to be part of a currently existing network of copies starting from another entry point. See description in Limitations below for a further explanation of this point.
Returns:	An object that is a copy of x.
Example:	Refer to the section, "Example."
% соруМар%	[Instance Variable of VirtualCopyMixin]
Purpose/Behavior:	A mapping of original nodes (which are objects) in a network to the copied nodes. This map is stored in an instance of the class VirtualCopyContext .
% copyOf%	[Instance Variable of VirtualCopyMixin]
Purpose/Behavior:	Within an instance that is a copy, the value of this instance variable is a pointer to the object that was copied.
(← self VirtualCopy?)	[Method of VirtualCopyMixin]
Purpose:	Determines if an object is a virtual copy.
Returns:	self
Categories:	Object, VirtualCopyMixin
соруМар	[Instance Variable of VirtualCopyContext]
Purpose/Behavior:	The value of this instance variable is a list of dotted pairs. The CAR of each pair is the original; the CDR, the copy.
(UltimateOriginal self)	[Function]
Purpose:	Determines what an object is ultimately copying.
Behavior:	If self is not a virtual copy, self is returned.
	If self is a virtual copy, this recurses through the value of the instance variable % copyOf% until it finds the original and returns it.
Arguments:	self A LOOPS object.
Returns:	self or what is at the top of self's copy chain.

Example

Create a class called test and edit it as shown.

```
44\leftarrow (\leftarrow ($ Class) New 'test)
#,($C test)
```

 $45 \leftarrow (ED 'test)$

SEdit # ,(\$C test) Package: INTERLISP	
((MetaClass Class Edited%:	; Edited 11-Dec-87 ; 16:50 by
)	
(Supers Object)	
(ClassVariables (VirtualIVs (atomCopy	listCopy objCopy)))
(InstanceVariables (atom NIL)	
(atomCopy NIL)	
(list NIL)	
(listCopy NIL)	
(obj NIL)	
(objCopy NIL))	
(MethodFns))	

Create an instance called t0 of this class and inspect it.

```
46 \leftarrow (\leftarrow (\$ \text{ test}) \text{ New 't0})
#,($& test (N<sup>^</sup>W0.1Y%:.;h.Lh9 . 556))
47 \leftarrow (\leftarrow (\$ \text{ test})
        NewWithValues
        (BQUOTE ((atom 1)
                        (atomCopy 2)
                        (list (a b c))
                         (listCopy (A B (\, (\leftarrow ($ test) New (QUOTE t1)))))
                         (obj (\backslash, (\leftarrow (\$ test) New (QUOTE t2))))
                         (objCopy (\, (\leftarrow ($ test) New (QUOTE t3))))))
#,($& test (N^W0.1Y%:.;h.Lh9 . 560))
48 \leftarrow (\leftarrow \text{IT SetName 't0})
#,($& test (N^W0.1Y%:.;h.Lh9 . 560))
49 \leftarrow (\text{INSPECT IT}]
{WINDOW}#52,51234
All Values of test ($ t0).
 atom
             1
 atomCopy 2
             (abc)
 list
 listCopy (A B #,($ t1))
             #,($ t2)
 obj
 objCopy
             #,($ t3)
Make a copy called t0copy and inspect it.
57 \leftarrow (\leftarrow (MakeVirtualMixin ($ t0))
    SetName
    (QUOTE t0copy))
```

58←(INSPECT IT) {WINDOW}#53,10150

All Values of (V	'irtualCopyMixin test) (\$ t0copy).
atom	NIL
atomCopy	NIL
list	NIL
listCopy	NIL
obj	NIL
objCopy	NIL
copyÓf	# ,(\$ t0)
CopyMap	#,(\$& VirtualCopyContext (N+W0.1Y%:.;h.Lh9 . 563))

Make the following changes to t0 and then reinspect t0copy.

```
60 \leftarrow (for iv in '(atom atomCopy list listCopy obj objCopy) as val in (LIST 11 22 '(a b c d) '(A B C) ($ t3) ($ t1)) do (PutValue ($ t0) iv val] NIL
```

 $\begin{array}{l} \texttt{61} \leftarrow (\texttt{INSPECT IT}) \\ \{\texttt{WINDOW}\} \texttt{\#53,10152} \end{array}$

All Values of (Vi	irtualCopyMixin test) (\$ t0copy).
atom	11
atomCopy	22
list	(abcd)
listCopy	(A B C)
obj	<i>i</i> , (\$ t3)
objCopy	#.(\$& (VirtualCopyMixin test) (N+₩0.1Y%:.;h.Lh9 . 565) t1)
copyÓf	# ,(\$ t0)
copyMap	#,(\$& VirtualCopyContext (N+W0.1Y%:.;h.Lh9 . 566))

The copied instance variables have not changed since they do not track changes in the original object.

Limitations

Some subtle issues are involved in building and using prototype structures so that the structure is preserved in the copied network. These involve how the network is typically traversed.

A general constraint is that all the links to any shared node in the prototype either all be marked as virtual variables, or none of them are. If they are all marked, then a single copy will be made and used. If none are, then the original object from the prototype will be used. Sharing with the prototype can be useful if this object is a repository for standard information that is independent of context. However, if this constraint is violated, the topology of the virtual copy will be different from that of the prototype.

In the simplest situation the network has a single entry node. In this case, a copy-map (see the section "Operands") can be created when the entry node object is first copied. After that all values are copied using this copy-map. The mechanism works well in this situation, even if there is sharing and there are cycles within the network.

At the other extreme, networks can have arbitrary connectivity, including multiple entries from outside the network, for example, from other networks or

non-objects. In this case, the following constraints are necessary to ensure correctness of the virtual copy mechanism.

The first constraint states that all access to the network must start through a copy of one of the nodes in the prototype. This condition is necessary because the criteria for copying are contained in the links from one object to another, not in the objects themselves, and a shared node could not specify a link to a node to be copied. This constraint ensures that all accesses from the outside will be copied if and only if that object would have been copied because of an internal link. Otherwise, an analogous situation would occur in which you could either reach a copy or the original node of the prototype itself depending upon which path you follow when the paths lead to the same node in the prototype.

The final constraint requires that all entries to the network should be passed the same copy-map if they are to share structure. The underlying concern in imposing these constraints is that a network be always copied the same way to maintain its topology regardless of where you start.

Suppose you want to make a virtual copy of a virtual copy, that is, to use a virtual copy of a network as a prototype itself. This is very useful if you are using a network to hold the state of a partial design and you want to try two alternative continuations of the design. Some hidden costs are associated with such multiple-level virtual copies.

Suppose further that a network N1 is used as a prototype and you make a virtual copy, N1-VC. Furthermore, N1-VC-VC is defined to be a copy of N1-VC. Values missing from N1-VC-VC are found in the corresponding object of N1-VC. If the value is missing there, the process recurs, and N1 is examined. If the value is to be a virtual copy, then this process will add a virtual copy in N1-VC, and then a second level copy in N1-VC-VC. This is necessary to preserve the semantics presented, but implies that many levels of virtual copy cannot easily do inexpensive incremental searches of a network.

Overview of the Manual

The Xerox LOOPS Library Modules Manual describes the Library Modules for Xerox's Lisp Object-Oriented Programming System, Xerox LOOPS (TM). These Library Modules, which can be loaded into your Xerox Artificial Intelligence Environment, provide additional functionality to Xerox LOOPS.

This manual describes the Lyric/Medley Release of the Xerox LOOPS Library Modules, which run under the Lyric and Medley Releases of Xerox Lisp.

Organization of the Manual and How to Use It

This manual is divided into chapters, with each chapter focussing on a particular Library Module. A Table of Contents is included to help you find specific material.

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- You need to use an Interlisp Exec to enter all exec expressions.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(_ self Selector Arg1 Arg2)

• Examples are shown in the Interlisp Exec and appear in the following typeface:

89_(_LOGIN)

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form ClassName.SelectorName.

- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

- Purpose: Gives a short statement of what the item does.
- Behavior: Provides the details of how the item operates.
- Arguments: Describes each argument in the following format:

argument Description

- Returns: States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.
- Categories: A way to group related methods. For example, all the methods related to Masterscope on the class **FileBrowser** have the category Masterscope, not **FileBrowser**. This item appears only for methods.
- Specializes: The next higher class in the class hierarchy that contains a method with the same selector. For example, **RectangularWindow.Open** can specialize **Window.Open**. This appears only for methods.
- Specializations: The next lower class in the class hierarchy that contains a method with the same selector. For example, **Window.Open** is a specialization of **RectangularWindow.Open**. This appears only for methods.
 - Example: An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See the *Xerox LOOPS Reference Manual* for details.

Directories and Files

The directory {ERIS}<Doc>Loops>Lyric>Beta>LibMods> contains the files for the manual. This directory has the following subdirectories:

{ERIS}<Doc>Loops>Lyric>Beta>LibMods>Z-ReleaseInfo> contains this file on writing conventions and a file on
production details.

Filenames describe the contents of the file. For example, the filename

{ERIS}<Doc>Loops>Lyric>Beta>LibMods>Gauges

contains the chapter on gauges.

Assemble the files in the following order for the manual:

{ERIS}<Doc>Loops>Lyric>Beta>LibMods>A1-TitlePage.tedit {ERIS}<Doc>Loops>Lyric>Beta>LibMods>A2-TOC.tedit {ERIS}<Doc>Loops>Lyric>Beta>LibMods>A3-Preface.tedit {ERIS}<Doc>Loops>Lyric>Beta>LibMods>Gauges.tedit {ERIS}<Doc>Loops>Lyric>Beta>LibMods>Masterscope.tedit {ERIS}<Doc>Loops>Lyric>Beta>LibMods>VC.tedit

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(_ self Selector Arg1 Arg2)

• Examples appear in the following typeface:

89_(_LOGIN)

• All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.

WRITER'S NOTES

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form ClassName.SelectorName.
- · Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

- Purpose: Gives a short statement of what the item does.
- Behavior: Provides the details of how the item operates.
- Arguments: Describes each argument in the following format:
 - argument Description
 - Returns: States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.
- Categories: A way to group related methods. For example, all the methods releated to Masterscope on the class **FileBrowser** have the category Masterscope, not **FileBrowser**. This item appears only for methods.
- Specializes: The next higher class in the class hierarchy that contains a method with the same selector. For example, **RectangularWindow.Open** can specialize **Window.Open**. This appears only for methods.
- Specializations: The next lower class in the class hierarchy that contains a method with the same selector. For example, **Window.Open** is a specialization of **RectangularWindow.Open**. This appears only for methods.
 - Example: An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags.

Style Sheet Addenda

Here are some guidelines I used when writing the LOOPS manuals. Items appear in rather random order.

- Avoid contractions.
- Avoid subscripts. Use WORD1 rather than WORD1 to avoid inconsistent line leading.
- Avoid wording that starts "Note that..." or "Notice that...". Either make it a note with correct format or eliminate the "Note that".
- Use semicolons rather than m-dashes.
- Each item in the template starts with an initial capital letter; e.g., "Describes..."
- The arguments are identical in the call and in the argument description.

- Parenthesies appear around expressions and square brackets appear around the name of the functionality.
- The arrow in the expression is the NS character ←, not _. These characters appear similarly when printed, but differently on the screen. See the section, "Special Notes and Cautions," for details
- A period appears after the word None, after argument descriptions, and Returns: item.
- Items are set to or return T (instead of true).
- · Menus contain options, not items or selections.
- You drag (not roll) the mouse to the right of a menu option to see its submenu.
- Use "above" and "below" when referrering to things in the same section, section numbers and names when referrering to things in the same chapter, and chapter numbers and names when referrering to things in another chapter.
- Please study the following style sheet carefully before you start to edit. The various appearances of active value and annotated values are especially crazy making.

These things appear in **bold**: class variables functions instance variables messages methods variables

ActiveValue - specific class/instance active value - general information activeValue - previous implementation of ActiveValue

annotatedValue - data type **AnnotatedValue** - specific class annotated values - general information

Bitmaps, Graphs, and Sketches

To do SEdit and Inspector examples for the manual, you need to reset your FONTPROFILE and scale the resulting windows to 0.8.

- -- In your Interlisp Executive, enter (DV FONTPROFILE)
- -- Edit the FONTPROFILE to be as follows. (some of this is probably overkill, but it does eliminate any suprizes)

-- In your Interlisp Executive, enter (FONTPROFILE FONTPROFILE) (SEDIT.RESET)

-- Make bitmaps of the resulting windows, and scale these bitmaps to 0.8

To get the pop-up menus (and their drag-through submenus) into a bitmap for using as an illustration:

--Move your type-in point to the exec window.

--Bring up your pop-up menu.

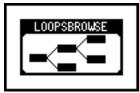

--control-G

--When the menu comes up, select Mouse *run. This will cause a break and spawn a new mouse process, so that the mouse continues to work.

--Move your type-in point to the tedit window.

--Shift-snap the menu image into the tedit window.

--Move the type-in point to the break window and type ^.

--To have your browser menus be a different font, type in your Interlisp Exec

(SETQ MENUFONT (FONTCREATE 'TERMNIAL 12 'BOLD))

--The global variable MENUFONT which is currently set to (HELVETICA 10 MRR).

--The menus that have already been created will still display this old font. Either recreate the browsers to force the menus to be recreated, or send a message to the browser

(_browser ClearMenuCache)

to force that browser to recreate its menus.

Special Notes and Cautions

Make sure you have changed the underscore to be a left arrow before loading and printing any files. To do this,

- Enter the following commands into your Executive:

```
(GETCHARBITMAP (CHARCODE _) '(MODERN 10 MRR))
(EDITBM IT)
```

- When the bitmap editor apears, delete the underscore and insert the following left arrow:

- Finally, enter the following commands into your Executive to store the pattern:

(PUTCHARBITMAP	(CHARCODE) '(MODERN 10 MRR) IT)
(PUTCHARBITMAP	(CHARCODE) '(MODERN 10 BRR) IT)
(PUTCHARBITMAP	(CHARCODE) '(TERMINAL 10 MRR) IT)
(PUTCHARBITMAP	(CHARCODE) '(TERMINAL 10 BRR) IT)
(PUTCHARBITMAP	(CHARCODE) '(TERMINAL 12 BRR) IT)

Description/Introduction

Gauges are an important part of the LOOPS user interface for both developers and end users. Gauges assist in understanding the dynamic nature of the programs. This is in contrast to the more typical case of debugging programs using static means. In the creation of user-friendly interfaces, you can use gauges to display, in analog or digital form, various data that may be changing. Also, by employing active gauges, you can provide a convenient way to interact with a system.

One of the features of gauges is the ease with which you can use them in a system. In more traditional languages, if you want to understand how a variable is changing over the course of a computation, you must make modifications in your program wherever you want to begin or end the examination of a variable. Given the capabilities of active values used by gauges, you need only attach or detach a gauge to the data that you are interested in monitoring.

The following types of gauges are available:

- Meter; a circular instrument that wraps around any number of times.
- Dial; a bounded dial, like an automobile speedometer.
- LCD; a gauge that uses the entire window to display a value.
- Scale; a horizontal or vertical display of a gauge.
- ActiveScale; a scale that allows you to change the gauge value.

Gauges are an example of the combination of programming capabilities within LOOPS. The different types of gauges are defined within the context of an inheritance lattice. This allows the more general functionality and variables to be allocated to more general gauge classes, with specific functionality placed in more restricted classes. You can also see the use of mixins to add a small amount of functionality to several different classes of gauges.

Note: Mixins are classes that are used only in conjunction with another class to create a subclass.

The methods within gauges are built upon both function calling and message sending. Gauges are "attached" to objects through the mechanism of active values. Since gauges are built upon the mechanism of active values, gauges can only be attached to data within objects. It is not possible to use gauges to monitor any arbitrary Lisp variable.

Prerequisites

The default font for gauges is Modern 10.

Installation/Loading Instructions

Gauges are divided among several different files to allow you to load only those objects and functions that you need. The table below lists the files to load for each type of gauge. The filecoms for each file will try to load any other required gauge files from **LOOPSLIBRARYDIRECTORY**. The file GAUGES.DFASL and either GAUGEINSTRUMENTS.DFASL or GAUGEALPHANUMERICS.DFASL will always be loaded; other files may also be loaded.

Gauge File to load

LCD GAUGEALPHANUMERICS.DFASL

METER GAUGEMETERS.DFASL

DIAL GAUGEDIALS.DFASL

SCALE GAUGESCALES.DFASL

ACTIVE SCALEGAUGEACTIVE.DFASL

Additionally, the file GAUGESELFSCALEMIXIN.DFASL can be loaded to add the class **SelfScaleMixin**, and GAUGEALARMS.DFASL can be loaded to add the class **AlarmMixin**.

To load the required files, first set the value of **LOOPSDIRECTORY** to include the directory where the gauges files are stored, then type the following expression in the Executive:

(LOAD 'FILENAME)

To load all of the gauges, load the file GAUGELOADER and then enter (LOADGAUGES). GAUGELOADER also sets the variables: GAUGEFILES and GaugeClasses.

(LOADGAUGES LDFLG SOURCES?FLG)

[Function]

Purpose: Loads all the gauges.
Behavior: Assumes that all of the gauge files are on the LOOPSDIRECTORY search path.
All the gauge files will be loaded based upon the settings of *LDFLG* and *SOURCES?FLG*. A FILESLOAD expression is built up and evaluated.
Arguments: *LDFLG* Can be NIL, PROP, or SYSLOAD. See the LDFLG discussion under loading in the *Interlisp-D Reference Manual*.
SOURCES?FLG
SOURCES?FLG
Can be NIL or T. If NIL, this attempts to load the compiled files before trying to load the sources. If T, only the sources are loaded.

Returns: Used for side effect only.

GAUGEFILES		[Variable]
	Behavior:	Initialized to (GAUGEACTIVE GAUGEALARMS GAUGEALPHANUMERICS GAUGEBOUNDEDMIXIN GAUGEDIALS GAUGEDIGIMETER GAUGEDIGISCALE GAUGEINSTRUMENTS GAUGEMETERS GAUGES GAUGESCALES GAUGESELFSCALEMIXIN)
GaugeClasses		[Variable]
	Behavior:	Initialized to (GaugeAV ActiveGaugeMixin Gauge AlarmMixin BoundedMixin SelfScaleMixin)
		Call (Browse GaugeClasses) to open a browser of all of the gauge classes.

Application/Module Functionality

This section describes the gauge classes and methods.

Gauge Classes

Class browser Meter RoundScale Dial ActiveHorizontalScale HSGraphics HorizontalScale (SSHorizontalScale Instrument HBarChart -- SSHBarChart StraightScale Gauge ActiveVerticalScale VSGraphi⋩ VenticalScale SSVerticalScale BarChart — - SSBarChart LCD AlphaNumeric < DigiMeter SSDigiMetei - LCDMixin DigiScale

This section describes the available gauges shown in the following browser.

Note: The browser does not include the optional mixin classes.

Within the class description of each class, the instance variables and class variables that are specializations only because they have different default values are not listed.

Name	Туре	Description
ActiveGaugeMixin	AbstractClass	A gauge class that allows you to set the value of the variable being monitored with the cursor, via a SET menu.
ActiveHorizontalScal	e Class	An active gauge that displays the value on a horizontal scale.
ActiveVerticalScale	Class	An active gauge that displays its value on a vertical scale.
AlarmMixin	AbstractClass	A mixin that adds alarm functionality to any gauge.
AlphaNumeric	AbstractClass	A gauge that gives an alphanumeric display of a value.

BarChart	Class	A gauge that displays more than one VerticalScale side-by side.
BoundedMixin	AbstractClass	Creates a bounded scale for displayVal ; to be used as a mixin for instruments.
Dial	Class	A bounded dial, like an automobile speedometer.
DigiMeter	Class	A gauge that displays both an LCD and a meter.
DigiScale	Class	A gauge that displays both an LCD and a horizontal scale.
Gauge	AbstractClass	A class for objects that present a dynamic graphical image of a LOOPS value.
GaugeAV	Class	An active value associated with a gauge.
HBarChart	Class	A gauge that displays more than one HorizontalScale side-by side.
HorizontalScale	Class	A labeled, bounded scale with a bar that fills to the right.
HSGraphics	AbstractClass	Gauge that is displayed in the form of a singe horizontal scale or bar.
Instrument	AbstractClass	A numeric gauge that is externally scaled by inputLower and inputRange and scaled internally by lower and range .
LCD	Class	Differs from AlphaNumeric in that the entire gauge window is the printing region.
LCDMixin	AbstractClass	Computes print region differently from LCD .
Meter	Class	A circular instrument that wraps around any number of times.
RoundScale	AbstractClass	Abstract Class for instruments with circular (arc) scales.
SelfScaleMixin	AbstractClass	Provides for the gauge to rescale according to the reading.
SSBarChart	Class	A self-scaling version of BarChart.
SSDigiMeter	Class	A self-scaling version of DigiMeter .
SSHBarChart	Class	A self-scaling version of HBarChart.
SSHorizontalScale	Class	Gauge that is displayed in the form of a single scale or bar which rescales itself accordingly.
SSVerticalScale	Class	Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.
StraightScale	AbstractClass	Abstract Class for instruments with straight scales.
VSGraphics	AbstractClass	Gauge that is displayed in the form of a single vertical scale or bar.
VerticalScale	Class	Gauge that is displayed in the form of a single vertical scale or bar.

ActiveGaugeMixin

Description:	A gauge class that allows you to set the value of the variable being monitored with the cursor, via a SET menu.
MetaClass:	AbstractClass

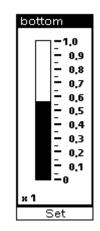

Supers:	Object	
Class Variables:	None.	
Instance Variables:	cursor	The cursor to use when changing the scale; the default is NIL.
ActiveHorizontalScale		[Class]
Description:		gauge that displays the value on a horizontal scale. This gauge value of the data it is connected with and allows you to change that be gauge.
MetaClass:	Class	
Supers:	ActiveGaug	eMixin, HorizontalScale
Class Variables:	None.	
Instance Variables:	cursor	Cursor to use when changing the scale; its property :initform is set to HorizontalAGCursor .
Example:	position the	ges have an attached menu at the bottom of the gauge. When you e cursor over this menu and press a mouse button, the cursor the following shape:
	While the la	T

While the left button is held down, the system tracks movements of the cursor and changes the value that the gauge is monitoring.

left		
0.0 0.5 1. I I) 1,5 2,0 2,5 3,0 3,5 4,0 	4.5 5.0
x 10 ²		
	Set	

ActiveVerticalScale

Description:	Similar to A	ctiveHorizontalScale, except that a vertical scale is used.
MetaClass:	Class	
Supers:	ActiveGauge	eMixin, VerticalScale
Class Variables:	None.	
Instance Variables:	cursor	Cursor to use when changing the scale; its :initform property is set to VerticalAGCursor .
Example:	Similar to A following sha	ctiveHorizontalScale. When setting, the cursor changes to the ape:

AlarmMixin

[Class]

Description: A mixin that adds alarm functionality to any gauge. An alarm is defined as warning object that is set off when the value being monitored falls outside of the specified range. The gauge flashes and stays inverted when the alarm is tripped.

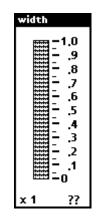

CAUTION

When a new class of gauges is created that will use the properties of **AlarmMixin**, **AlarmMixin** should be the first class on the Supers list of the new class. This guarantees that the **AlarmMixin.Set** method is invoked.

MetaClass:	AbstractClass	
Supers:	Object	
Class Variables:	MiddleButtonItems	
Instance Variables:	IowTripPoint Alarm is triggered when reading goes below this point.	
	hiTripPoint Alarm is triggered when reading goes above this point.	
	flashNumber Number of times alarm will flash when it is tripped.	
	flashInverval Interval in milliseconds between flashes.	
AlphaNumeric	[Class]	
Description:	This class contains some of the methods and data for the LCD classes. These gauges can display any type of character, letters, or numbers.	
MetaClass:	AbstractClass	
Supers:	Gauge	
Class Variables:	None.	

Instance Variables:	precision	Number of characters displayed in the reading. The default value is 5.
BarChart		[Class]
Description:	A gauge that	at can display more than one VerticalScale at once, side-by side.
MetaClass:	Class	
Supers:	VerticalScal	e
Class Variables:	None.	
Instance Variables:	maxLabelV	Vidth Maximum width of labels on each bar. Default value is 0 which means no limit.
	scaleLeft	Offset within the gauge window from the left for the leftmost bar. Default value is 3.
	scaleBotto	m Offset within the gauge window from the bottom for all the bars. Default value is 30.
Example:	Here is a B the values 1	arChart showing the size and shape of a window. It is displaying 5, 21, 13, and 6.
	left bot x 10 ¹	-3.0 -2.5 -2.0 -1.5 -1.0 -0.5 -0.0
BoundedMixin		[Class]
Description:	BoundedM	is a super of the scale classes and Dial . If a gauge that has ixin as a super class tries to display a new setting that is outside of of the gauge, the gauge will display the minimum or maximum propriate and place a "??" in the window.
MetaClass:	AbstractCla	SS
Supers:	Object	
Class Variables:	None.	
Instance Variables:	None.	

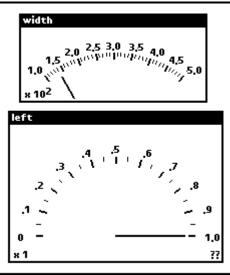

Example: Here is a vertical scale that displays a reading greater than its maximum.

Dial

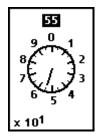

[Class]

Description:	A bounded dial, like an automobile speedometer.
MetaClass:	Class
Supers:	BoundedMixin, RoundScale
Class Variables:	None.
Instance Variables:	This class specializes the same instance variables as RoundScale.
Example:	The angle of the arc changes with the shape of the window.

DigiMeter

Description:	A gauge that combines both a meter and an LCD.
MetaClass:	Class
Supers:	Meter, LCDMixin
Class Variables:	None.
Instance Variables:	spaceForLCD Vertical space required by LCD within the gauge. Defaults to 30.
Example:	This DigiMeter is displaying 55.

DigiScale

Description:	A gauge that combines both a horizontal scale having no ticks and an LCD.
MetaClass:	Class
Supers:	HorizontalScale, LCDMixin
Class Variables:	None.
Example:	This DigiScale is displaying 63 with its scale set from 0 to 100.

Gauge		[Class]
Description:	A class for value. This	objects that present a dynamic graphical image of a Xerox LOOPS class provides most of the methods for using gauges.
MetaClass:	AbstractCla	SS
Supers:	Window	
Class Variables:	LeftButtonItems Menu options associated with the left mouse button.	
	MiddleButt	onltems Menu options associated with the middle mouse button.
Instance Variables:	reading	External value of reading. The default value is 0.
	contained	nAV Active value that connects the gauge to the data it is monitoring. It should be an instance of the class GaugeAV .
	font	Font that is used by a gauge; default value is (Modern 10).
	width	Width of a gauge; has property min, which specifies the minimum width for a gauge.
	height	Height of a gauge; has property min , which specifies the minimum height for a gauge.
GaugeAV		[Class]
Description:	An active va	alue that is associated with a gauge.
MetaClass:	Class	
Supers:	LocalStateA	ActiveValue

Class Variables:	None.	
Instance Variables:	gauge	The gauge connected to this active value.
	object	The object containing the variable associated with the active value.
	propName	The property name of the associated variable.
	type	Data type of the associated variable.
	varName	Name of the associated variable.
HBarChart		[Class]

Description: A gauge that can display more than one HorizontalScale at once, side-by side. MetaClass: Class Supers: **HorizontalScale Class Variables:** None. Instance Variables: maxLabelWidth Maximum width of labels on each bar. Default value is 0 which means no limit. scaleLeft Offset within the gauge window from the left for the leftmost bar. Default value is 3. Example: Here is an HBarChart showing the size and shape of a window. It is displaying the values 15, 21, 13, and 6. 0.0 0.5 1.0 1.5 2.0 2.5 3. O

HorizontalScale

[Class]

Description: A labeled, bounded scale with a bar that fills to the right.

MetaClass: Class

Supers: HSGraphics

Class Variables: None.

Instance Variables: None.

Example: This **HorizontalScale** is reading 350 on a scale from 0 to 500.

left	
0.0 0.5 1.0 1.5 2.0 2.5 3.0 3	3,5 4,0 4,5 5,0
han kan kan han han han ka	hoo hoo hoo l
× 10 ²	

HSGraphics

Description:	This class provides some of the methods for displaying the graphics of a horizontal scale.		
MetaClass:	AbstractClass		
Supers:	StraightScale	e	
Class Variables:	None.		
Instance Variables:	scaleBotton	n Bottom edge of scale in pixels. The default value is 10.	
	scaleLeft	Left edge of scale in pixels. The default value is 12.	
	scaleWidth	Width of inside of scale in pixels. The default value is 120.	
	scaleHeight	Height of scale in pixels. The default value is 15.	
Instrument		[Class]	
Description:	numerical d	provides additional methods and data for gauges that display only ata. This data is externally scaled by inputLower and , and scaled internally by lower and range .	
MetaClass:	AbstractClas	s	
Supers:	Gauge		
Class Variables:	None.		
Instance Variables:	ticks	Scale marks on the instrument; value is a number or NIL; smallTicks property indicates the number of smaller ticks between each large tick.	
	displayVal	Internal value relative to instrument.	
	range	Range for internal displayVal .	
	inputRange	Range for external reading.	
	lower	Lower bound for internal displayVal .	
	inputLower	Lower bound for external reading.	
	brushWidth	Scale factor for width of ticks, rays, and circles in pixels.	
	labels	The labels that will be displayed on the gauge.	
	labelScale	A dotted pair representing the sign and exponent of a reading.	
	spaceForLa	belScale Extra vertical space to display scale label.	
LCD		[Class]	
Description:	Differs from I	CDMixin in that the entire gauge window is the printing region.	

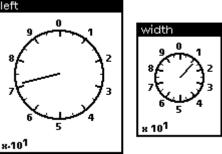

LCD

Description:	Differs from LCDMixin in that the entire gauge window is the printing region.
MetaClass:	Class
Supers:	AlphaNumeric
Class Variables:	None.
Instance Variables:	None.

Example: This **LCD** is displaying the string "Mumble", and has been **Shape**dto 120 x 60.

LCDMixin [Class] Description: Computes printing region differently from LCD so that an LCD may be added into another window. MetaClass: AbstractClass Supers: AlphaNumeric **Class Variables:** None. Instance Variables: Number of characters displayed in the reading; the default value precision is 3. Its property is **readingRegion**; the default value is NIL. Y position of bottom of reading. The default value is 7. readingY Meter [Class] Description: A circular instrument that wraps around any number of times. It displays a sign and exponent in the lower left corner of its window. MetaClass: Class Supers: RoundScale **Class Variables:** None. Instance Variables: This class specializes the same instance variables as RoundScale. Example: The **Meter** on the left is displaying a negative value. left

RoundScale

I

Description:	Abstract Class for instruments with circular (arc) scales.
MetaClass:	AbstractClass
Supers:	Instrument
Class Variables:	None.
Instance Variables:	needleLength Radius of needle in pixels. The default value is 15.

	radius	Radius of arc in pixels. The default value is 10.
	XC	x-coordinate window coordinate of center of arc. (See DRAWARC in the <i>Xerox Lisp Release Notes, Lyric Release</i> .)
	ус	y-coordinate window coordinate of center of arc. (See DRAWARC in the Xerox Lisp Release Notes, Lyric Release.)
SelfScaleMixin		[Class]
Description:	Provides for	r the gauge to rescale according to the reading.
MetaClass:	AbstractCla	SS
Supers:	Object	
Class Variables:	None.	
Instance Variables:	lowScaleFa	actor Rescales if reading shrinks so that it will fit more than lowScaleFactor times in inputRange. The default value is 5.
SSBarChart		[Class]
Description:	A self-scalir	ng version of BarChart.
MetaClass:	Class	
Supers:	BarChart	
Class Variables:	None.	
Instance Variables:	None.	
SSDigiMeter		[Class]
Description:	A self-scalir	ng version of DigiMeter .
MetaClass:	Class	
Supers:	DigiMeter	
Class Variables:	None.	
Instance Variables:	None.	
SSHBarChart		[Class]
Description:	A self-scalir	ng version of HBarChart.
MetaClass:	Class	
Supers:	HBarChart	
Class Variables:	None.	
Instance Variables:	None.	
SSHorizontalScale		[Class]
Description:	Gauge that rescales its	t is displayed in the form of a single horizontal scale or bar which elf accordingly.

MetaClass:	Class
Supers:	VerticalScale
Class Variables:	None.
Instance Variables:	None.

SSVerticalScale

[Class]

Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.
Class
HorizontalScale
None.
None.

StraightScale

[Class]

[Class]

Description:	Abstract class for instruments with straight scales.		
MetaClass:	AbstractClass		
Supers:	BoundedMixin, Instrument		
Class Variables:	None.		
Instance Variables:	shade	Shade of bar; numeric value from 0 to 65535. The default value is 65535, which is BLACKSHADE.	

VerticalScale

Description:	Gauge that is displayed in the form of a singe vertical scale or bar.
MetaClass:	Class
Supers:	VSGraphics
Class Variables:	None.
Instance Variables:	None.
Example:	This VerticalScale is displaying the value .55 and has its Shade set to 1258.

VSGraphics		[Class]
Description:	Similar to HSGraphics but for vertical scales.	
MetaClass:	AbstractClass	
Supers:	StraightScale	
Class Variables:	None.	
Instance Variables:	scaleBottom Bottom edge of scale in pixels. The default value is 12.	
	scaleLeft Left edge of scale in pixels. The default value is 15.	
	scaleWidth Width of inside of scale in pixels. The default value is 15	j.
	scaleHeight Height of scale in pixels. The default value is120.	

Gauge Methods

This section describes the available methods and functions which are used to manipulate gauges. In many cases, a particular gauge class specializes a method defined in the class **Gauge**. In this case, the specialized method definition is not explicitly defined; instead, this is noted in the Specializes/Specializations field of the description.

Name	Туре	Description
Attach	Method	Connects a gauge to an object.
Attached?	Method	Determines what the gauge is attached to.
ChangeFont	Method	Sets the gauge's instance variable font and updates the gauge.
Close	Method	Detaches the gauge and closes the window.
Destroy	Method	Destroys the gauge, detaching it first.
Detach	Method	Detaches the gauge from the variable it is attached to.
Reset	Method	Resets the gauge's instance variable reading.
SetScale	Method	Sets the scale for the gauge.
Shape	Method	Sweeps a new region.
ShapeToHold	Method	Shapes the gauge window to its smallest possible size.
Update	Method	Reinitializes the gauge and its display window to reflect the current state.

(← self Attach obj varName propName type xOrPos y)		[Method of Gauge]
Purpose:	Connects a gauge to an object.	
Behavior:	Displays the gauge on the screen and as <i>varName</i> of <i>obj.</i> If <i>propName</i> is sport variable's property. If <i>xOrPos</i> and <i>y</i> appear which must be positioned to place	ecified, the gauge will montior the are not specified, a small box will

Arguments: *obj* A pointer to the object to which the gauge is to be attached.

	varName	The name of the instance variable, class variable, or method to which the gauge is to be attached.
	propName	If non-NIL, the gauge will be attached to this property.
	type	One of IV, CV, or METHOD, within the object being connected to the gauge. If NIL, it defaults to IV.
	xOrPos	A numerical value to specify where, in screen coordinates, the gauge will be placed on the display. If NIL, you are asked to place the gauge on the screen. This can be a number to specify the x coordinate or a position. If it is a number, also specify .
	У	If <i>xOrPos</i> is not a position, this specifies the y coordinate in screen coordinates for the gauge.
Returns:	self	
Specializations:	StraightScale.Attach has an additional <i>shade</i> argument so that the shade of the scale may be specified at the time the gauge is attached. The following shows the argument list for this method:	
	(_ (\$ instan xOrPos y)	nce OfHorizontalScale) Attach obj varName shade propName type
	additional la	a methods for BarChart , HBarChart , and their subclasses take an <i>abel</i> argument. If no <i>label</i> argument is given, the bar is labeled with The <i>label</i> argument comes last, as follows:
	(_ (\$ instai xOrPos y la	nce OfBarChart) Attach obj varName propName propName type ibel)
\leftarrow self Attached? don'tPrintFlg)	[Method of Gauge]
Purpose:	Determines	what a gauge is attached to.
Behavior:	If <i>don'tPrintFlg</i> is non-NIL this returns the value of the gauge instance variable containedInAV . If <i>dontPrintFlg</i> is NIL, the object and the varName the gauge is attached to will be printed in an attached window.	
Arguments:	don'tPrintFlg Suppresses displaying what the gauge is attached to.	
Returns:	NIL	
(self ChangeFont newFont)		[Method of Gauge]
Purpose/Behavior:		uge's instance variable font to <i>newFont</i> and updates the gauge. If s too small for <i>newFont</i> , it is reshaped.
Arguments:	newFont	A font in which to display the gauge's text.
Returns:	Previous va	lue of font .
$(\leftarrow self Close)$		[Method of Gauge]
Purpose/Behavior:	Detaches th	ne gauge and closes the window.
Returns:	CLOSED	
(← self Destroy)		[Method of Gauge]
Purpose/Behavior:	Destrovs th	e gauge, detaching it first before closing the window.
	2000 yo u	

Returns:	NIL
(← <i>self</i> Detach)	[Method of Gauge]
Purpose/Behavior:	Detaches the gauge from the variable to which it is attached. This prints in an attached window that the gauge is being detached, and deletes all of the links connecting the gauge, active value, and object being monitored. Does not close the window.
Returns:	NIL
(← self Reset newReading)	[Method of Gauge]
Purpose/Behavior:	Sets the gauge's instance variable reading to <i>newReading</i> and updates the gauge. If the gauge is too small for <i>newReading</i> and it is SelfScaling, it is reshaped.
Arguments:	<i>newReading</i> Sets the instance variable reading to <i>newReading</i> , and updates the gauge without going through any intermediate steps.
Returns:	NIL if gauge is AlphaNumeric or RoundScale; otherwise self.
Specializations:	Alphanumeric.Reset, RoundScale.Reset
Example:	The following example causes the LCD to be redisplayed with the <i>newReading</i> :
	13_(_ (\$ lcd1) Reset "New Title")
$(\leftarrow self $ SetScale min max)	[Method of Gauge]
Purpose/Behavior:	Sets the scale for the gauge; computes the new scale values and redisplays if necessary.
Arguments:	min Lowest value on scale.
	max Highest value on scale.
Returns:	self
(← self Shape newRegion noUpd	dateFlg) [Method of Gauge]
Purpose/Behavior:	If <i>newRegion</i> is NIL, you are prompted to sweep out a region which has a minimum sized based upon a min property of IV width and height:,min . If <i>newRegion</i> is non-NIL, it is first checked to guarantee that it is at least as large as width:,min by height:,min .
Arguments:	<i>newregion</i> List specifying the external coordinates of the window in which the gauge is displayed; list is of the form (left, bottom, width, height).
	<i>noUpdateFlg</i> If NIL, reshapes the gauge.
Returns:	NIL
Specializes:	Window
Specializations:	LCD , Meter , DigiMeter . Meter . Shape has an extra argument <i>ExtraSpaceFlg</i> . If T, this will allow you to shape a fairly arbitrary region for the gauge; if NIL, the meter is constrained to be close to a square. This latter behavior is what the user sees when trying to shape the meter from the window menu.

	BarChart, HBarChart , and their subclasses can only be freely Shape d in the direction their bars run (i.e., BarChart s can be Shape d vertically and HBarChart s can be Shape d horizontally). Their size along the other dimension is fixed by the number of values attached to the chart.
Example:	This example reshapes the gauge to a location where the lower left corner is at (10,100) a width of 50 and a height of 150.
	14_(_ (\$ lcd1) Shape '(10 100 50 150))
(<i>← self</i> ShapeToHold)	[Method of Gauge]
Purpose/Behavior:	Shapes the gauge window to its smallest possible size based on width:,min and height:,min and redisplays the gauge.
Returns:	NIL
Specializations:	LCD.Shape
(← self Update)	[Method of Gauge]
Purpose/Behavior:	Reinitializes the gauge and its display window to reflect the current state.
Returns:	self
Categories:	Window

Examples

The typical use pattern for a gauge is to first create it, set the scale to the appropriate value, and attach it to the desired data.

To attach a horizontal scale to a Xerox LOOPS window, w1, first enter

```
15_(_ ($ Window) New 'w1)
#,($& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 495))
16_(_ ($ HorizontalScale) New 'hs1)
#,($& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))
```

17_(_ (\$ hs1) SetScale 0 500) NIL

Now make the connection.

18_(_ (\$ hs1) Attach (\$ w1) 'width GRAYSHADE)
#,(\$& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))

The following gauge appears and you are prompted to place it .

width
0.0 0.5 1.0 1.5 2.0 2.5 3.0 3.5 4.0 4.5 5.0 Tanakan karing barran karing barran barra
× 10 ²

The title of the gauge shows the instance variable being monitored.

Gauges can be shaped larger. The graphics used to display scales do not change; extra white space is added to the top or right. You can use this space to print additional information, as follows:

19_(MOVETOUPPERLEFT (@ (\$ hs1) window))
{WINDOW}#372,7104

20_(PRIN1 "This is an example of printing additional information above a gauge.

Be aware that when the gauge is next updated, this additional text will disappear." (@ (\$ hs1) window)) "This is an example of printing additional information above a gauge.

Be aware that when the gauge is next updated, this additional text will disappear."

width
This is an example of printing additional inform
ation above a gauge,
Be a ware that when the gauge is next updated,
this additional text will disappear.
0,0 0,5 1,0 1,5 2,0 2,5 3,0 3,5 4,0 4,5 5,0
han kan kan han han han kan kan han han h
× 10 ²

Limitations

When a font is changed, a gauge occasionally needs to be updated to be correctly displayed.

Instruments can have only floating point numbers for labels, and cannot have integers.

[This page intentionally left blank]

Description/Introduction

Masterscope has been modified to provide for analysis of files created under the Koto or Lyric/Medley release of Xerox LOOPS. A full explanation of Masterscope can be found in the Xerox Lisp Library Modules Manual, Lyric and Medley Releases. In addition to the relations explained there, Xerox LOOPS defines the relations described in this chapter.

Masterscope data base files created under Buttress Loops will not function properly in this release. Those data base files will have to be Note: recreated.

Installation/Loading Instructions

- · Load MASTERSCOPE from your Lyric/Medley library floppies according to its loading instructions. This should load the compiled files MASTERSČOPE, MSANALYZE, and MSPARSE.
- Load LOOPSMS.DFASL from wherever you installed the Xerox LOOPS ٠ Library Modules. This should load versions of MASTERSCOPE and MSPÁRSE that extend Masterscope to handle Xerox LOOPS constructs.

Relations

	Xerox LOOPS defines the following relations:		
Name	Туре	Description	
SEND	Relation	Collects all places where the method is sent.	
SEND SELF	Relation	Collects all places where the method is sent to self.	
SEND NOTSELF	Relation	Collects all places where the method is sent to an object other than <i>self</i> .	
GET	Relation	Locates all places where the value of an instance variable is retrieved.	
GET CV	Relation	Locates all places where the value of a class variable is retrieved.	
PUT	Relation	Locates all places where the value of an instance variable is set.	
PUT CV	Relation	Locates all places where the value of a class variable is set.	
IMPLEMENT	Relation	Locates all methods that specialize the given selector.	
SPECIALIZE	Relation	Locates all methods that specialize the given selector and use _ Super in the body of the method.	
OVERRIDE	Relation	Locates all methods that specialize the given selector and do not use _Super in the body of the method.	

USE IV	Relation	Used with an instance variable name to locate all places where the instance variable is used in aGET or PUT.
USE CV	Relation	Used with a class variable name to locate all places where the class variable is used in aGET or PUT.
USE OBJECT	Relation	Used with an object name to locate all places where the object is used.
SEND		[Relation]
Purpose/Behavior:	Used betwee method is s	een method names and selectors to collect all places where the ent. For example, the form
	. WHO IS	SENT BY 'Helicopter.Move
	works, but	
	. WHO IS	SENT BY Move
	does not wo	ork.
Example:	The followir New .	ng command allows you to edit all code that sends the message
	. EDIT AI	L WHO SEND New
SEND SELF		[Relation]
Purpose/Behavior:	Llood botwy	
r dipose/ Dellaviol.	method is s	een method names and selectors to collect all places where the ent to self. Places where
	$(\leftarrow$ self met	hodName)
	is found are	collected, while places where
	$(\leftarrow otherIns$	tance methodName)
	is found are	not.
Example:	The followir Clear to sel	ng command allows you to edit all code that sends the message f.
	. WHO SEN	IDS SELF Clear
SEND NOTSELF		[Relation]
Purpose:		END SELF, except the only places where the message is sent to
	-	her than self.
Example:		ng allows you to edit all code that sends the message Clear to any ner than <i>self</i> .
	. SHOW AI	L WHO SEND NOTSELF Clear
GET		[Relation]
Purpose:	the instance	an instance variable name to locate all places where the value of e variable is retrieved. This relation can be used along with the IOTSELF modifiers.

	Example:	This command allows you to edit all code that gets the value of the instance variable width from an instance other than self and the value of the instance variable height from <i>self</i> .
		. SHOW ALL WHO GET NOTSELF width AND GET SELF height
GET CV		[Relation]
	Purpose:	Same as GET , except that GET CV locates places where the value of the class variable is retrieved. This relation can be used with the SELF and NOTSELF modifiers.
	Example:	This command allows you to edit all code that accesses the value of the class variable height of <i>self</i> .
		. SHOW ALL WHO GET CVSELF height
PUT		[Relation]
	Purpose:	Used with an instance variable name to locate all places where the value of the instance variable is set. This relation can be used along with the SELF and NOTSELF modifiers.
	Example:	This command allows you to edit all code that sets the value of the instance variable width.
		. EDIT ANY WHO PUT width
PUT CV		[Relation]
	Purpose:	Same as PUT , except locates places where a specified class variable is set. This relation can be used along with the SELF and NOTSELF modifiers.
	Example:	This command list all the sections of code that set the value of the class variable width for an instance other than <i>self</i> .
		. WHO PUTS CV NOTSELF width
IMPLEMENT		[Relation]
	Purpose:	Used with a method name to locate all methods that specialize the given selector.
	Example:	This returns a list of classes where the method Clear is defined.
		. WHO IMPLEMENTS Clear
SPECIALIZE		[Relation]
	Purpose:	Used with a method name to locate all methods that specialize the given selector and use _Super in the body of the method.
	Example:	This command allows you to edit all the methods that are specializations of Clear and use the _Super form.
		. EDIT ANY WHO SPECIALIZE Clear
OVERRIDE		[Relation]
	Purpose:	Like SPECIALIZE above, except it locates all methods that specialize the given selector and _Super is not used in the body of the method.

	Example:	This command allows you to edit all the specializations of Clear that do not make use of the _Super form.
		. EDIT ALL WHO OVERRIDE Clear
USE IV		[Relation]
	Purpose:	Used with an instance variable name to locate all places where the instance variable is used in a Get or Put . It is equivalent to using the relation form of GET IVName or PUT IVName .
	Example :	This command allows you to edit all code that either sets or accesses the instance variable width .
		. EDIT ANY WHO USE THE IV width.
USE CV		[Relation]
	Purpose:	Used with a class variable name to locate all places where the class variable is used in a Get or Put . It is equivalent to using the relation form: GET CV CVName OR PUT CV CVName .
	Example:	This command allows you to edit all code where the class variable commonWindow is either set or accessed.
		. EDIT ANY WHO USE THE CV commonWindow
USE OBJECT		[Relation]
	Purpose	Uses an object name to locate all places where the object is used.
	Example	This command returns a list of all code where the object Window is used.
		. WHO USES THE OBJECT Window??

Limitations

Masterscope has several limitations:

- Names of methods must be quoted when used with Masterscope; for example, the method name Helicopter.Move must be entered as 'Helicopter.Move.
- The following expression will not find a call to GetValue when in a method :
 - . WHO CALLS GetValue

Masterscope does not record calls to **GetValue** and **PutValue** explicitly; it records them under the Get- relation along with calls of the form

(_ foo Get 'bar)

Similarly, the following functions are recorded under relations instead of their names:

GetClassValue Get CV

PutClassValue GetClassIV PutClassIV

Put CV Get IV Put IV

If you want to find the explicit calls to Get/PutValue, use

- . WHO GETS ANY AND NOT SENDS Get
- Masterscope currently assumes calls to GetValue and similar accessors are accessing instance variables; i.e.,

```
(GetValue foo 'bar)
```

records an access to the instance variable **bar**. This is not necessarily the case; **bar** could also be a class variable.

• The methods and functions that create class and instance variables populate the appropriate **PUT NOTSELF** relations. For example, a function that does

(_(\$ foo) AddCV 'bar)

will be found by the query

. WHO PUTS CV NOTSELF 'bar

An exception occurs with the generalized **Add** and **Delete** method. For example,

(\$ foo) Add 'IV 'bar)

will not be noticed as accessing the instance variable bar.

Also, the templates for methods and functions that accept property lists generally only notice the first property. For example,

((_(\$ foo) NewWithValues '((bar baz chain link sausage)))

notices **baz** as a property, not a link.

[This page intentionally left blank]

This file includes notes on the production of *Xerox LOOPS Library Modules Manual*, Lyric Beta Release. This manual is packaged with the *Xerox LOOPS Release Notes* and *Xerox LOOPS Reference Manual* to form one binder.

Writer: Raven Kontur Brewster

Printing Date: >>DA<< >>MO<< 1988

Files Needed

To edit or print the manual, make sure you have the following files loaded:

IMTOOLS SKETCH GRAPHER

Fonts Used

{ERIS}<LISP>FONTS>

Modern font 18-point bold 14-point bold 12-point bold 10-point regular 10-point italic 10-point bold

Terminal font 10-point regular

Printing Information

The manual was printed under a Lyric sysout on the Tsunami printer.

Artwork

• The cover page for the binder is in the file {ERIS}<Doc>Loops>Lyric>Beta>BinderCover.tedit.

Special Notes and Cautions

If you bring the file into a TEdit window to print it, you must first make sure your underscore character is redefined as a left arrow. See the file on conventions for details. This restriction does not apply if you use the Hardcopy option from the File Browser.

Description/Introduction

In many knowledge-based systems, it is useful to represent knowledge as interconnected sets of instances. A virtual copy mechanism allows a network of instances to be viewed as a prototype which can be copied. The copy of the prototype is virtual in that the contents of each instance is not completely copied at creation time. Instead, it inherits default values from the prototype (also called the original), thus continuing to share the parts not modified in the copy. The copied network is virtual also in the sense that only those instances needed in the processing are copied.

A virtual copy of an object in the prototype network has the following properties:

- It responds to at least the same set of messages as the prototype object and in the same way; that is, a copy has the same procedural behavior that is defined for the prototype.
- A copy inherits variables and their values from the prototype, and continues to do so until an explicit change is made in the copy. At that point, the new value is stored in the copy and it stops tracking the prototype for that variable. A fetch operation on a value that is not stored locally either finds or creates a virtual copy of the value obtained from the prototype.

Installation/Loading Instructions

The implementation of virtual copies is contained in the file LOOPSVCOPY.LCOM. No other files are necessary.

Application /Module Functionality

A network of instances is tied together through the values of instance variables within each of the instances. Assume an object A has an instance variable x, the value of which is the object B. A virtual copy of A will also have an instance variable named x. The value of x in the copy will point to B if B is a shared object, or x may point to a copy of B if it is to be virtual. Changing the value of x in the copy will not change the value in the original.

Overview of Operation

By default, virtual copies share instance variables. This means that changing the value of an instance variable in the original will be tracked by the copy.

Virtual copies are implemented with two additional classes:

VirtualCopyMixin

The class **VirtualCopyMixin** is a subclass of Tofu which contains two instance variables:

% copyMap%
 % copyOf%

(These unusual names are used to avoid conflicts with any other instance variable names users may create.) This class contains several methods, most of which are required to implement virtual copies and are not used by a programmer.

Printing a virtual copy instance is a specialization of how regular instances are printed. All instances print as #,(\$& <class-name> UID). The class of a virtual copy is a dynamic mixin of the class **VirtualCopyMixin** and the class of the original object (see the *Xerox LOOPS Reference Manual* for more information on mixins). The virtual copy print function adds the name or unique identifier (UID) of the original object. For example,

#,(\$& (VirtualCopyMixin Container1) (JFW0.0X:.aF4.R>8.3) c1)

is a copy of the object named c1.

VirtualCopyContext

The class **VirtualCopyContext** has no methods and only one instance variable, **copyMap**. Instances are used as an argument for calls to **MakeVirtualMixin**.

Since copies can be made of copies, you often need to determine the original object of a chain of copies with the **UltimateOriginal** function.

Operands

This section describes the functions, methods, class variables, and instance variables that operate on virtual copies.

VirtualIVs		[Class Variable]
	Purpose/Behavior:	Helps specify a class whose instances may be made into virtual copies. The value of this class variable should be either the symbol ALL, or a list of instance variables contained within instances of the class. If the value is ALL, all objects pointed to by any of the instance variables will be copied. If the value is a list of instance variables, only the instance variables on this list will have their values copied. Other instance variable values will be shared between the copy and the original.
(MakeVirtu	alMixin x copyConte	xtObj [Function]
	Purpose:	Creates a virtual copy of an object.

Behavior: Creates a dynamic mixin class combining the classes **VirtualCopyMixin** and the class of *x*. An instance of this resulting class is created and it is returned.

Arguments: x An object to be copied; must have the class variable VirtualIVs as described above.

copyContextObj

Usually NIL; used internally by **MakeVirtualMixin** when it calls itself. It can be an instance of **VirtualCopyContext** if you are creating an instance that is intended to be part of a currently existing network of copies starting from another entry point. See description in **Limitations** below for a further explanation of this point.

Returns:	An object that is a copy of x.
Example:	Refer to the section, "Example."
% соруМар%	[Instance Variable of VirtualCopyMixin]
Purpose/Behavior:	A mapping of original nodes (which are objects) in a network to the copied nodes. This map is stored in an instance of the class VirtualCopyContext .
% copyOf%	[Instance Variable of VirtualCopyMixin]
Purpose/Behavior:	Within an instance that is a copy, the value of this instance variable is a pointer to the object that was copied.
(← self VirtualCopy?)	[Method of VirtualCopyMixin]
Purpose:	Determines if an object is a virtual copy.
Returns:	self
Categories:	Object, VirtualCopyMixin
соруМар	[Instance Variable of VirtualCopyContext]
Purpose/Behavior:	The value of this instance variable is a list of dotted pairs. The CAR of each pair is the original; the CDR, the copy.
(UltimateOriginal self)	[Function]
Purpose:	Determines what an object is ultimately copying.
Behavior:	If self is not a virtual copy, self is returned.
	If <i>self</i> is a virtual copy, this recurses through the value of the instance variable % copyOf% until it finds the original and returns it.
Arguments:	self A Xerox LOOPS object.
Returns:	self or what is at the top of self's copy chain.

Example

Create a class called test and edit it as shown.

```
44_(_($ Class) New 'test)
#,($C test)
```

45_(ED 'test)

SEdit # ,(\$C test) Package; INTERLISP	
((MetaClass Class Edited%:	; Edited 11-Dec-87 ; 16:50 by
(Supers Object)	
(ClassVariables (VirtualIVs (atomCopy	/ listCopy objCopy)))
(InstanceVariables (atom NIL)	
(atomCopy NIL)	
(list NIL)	
(listCopy NIL)	
(obj NIL)	
(objCopy NIL))	
(MethodFns))	

Create an instance called t0 of this class and inspect it.

```
46_(_($ test) New 't0)
#, ($& test (N^W0.1Y%:.;h.Lh9 . 556))
47_(_ ($ test)
       NewWithValues
       (BQUOTE ((atom 1)
                       (atomCopy 2)
                       (list (a b c))
                       (listCopy (A B (\, (_ ($ test) New (QUOTE t1)))))
(obj (\, (_ ($ test) New (QUOTE t2))))
(objCopy (\, (_ ($ test) New (QUOTE t3))))))
#,($& test (N<sup>W0.1Y%:.;h.Lh9.560))</sup>
48 ( IT SetName 't0)
#,($& test (N^W0.1Y%:.;h.Lh9 . 560))
49 (INSPECT IT]
{WINDOW}#52,51234
All Values of test ($ t0).
atom
            1
atomCopy 2
             (abc)
 list
listCopy (A B #,($ t1))
obj #,($ t2)
            #,($ t3)
 objCopy
Make a copy called t0copy and inspect it.
57_(_ (MakeVirtualMixin ($ t0))
   SetName
```

58_(INSPECT IT) {WINDOW}#53,10150

All Values of (VirtualCopyMixin test) (\$ t0copy).
atom	NIL
atomCopy	NIL
list	NIL
listCopy	NIL
obj	NIL
objCopy	NIL
copyÓf	# ,(\$ t0)
Сорумар	#,(\$& VirtualCopyContext (N+W0.1Y%:.;h.Lh9 . 563))

Make the following changes to t0 and then reinspect t0copy.

```
60_(for iv in '(atom atomCopy list listCopy obj objCopy)

```

61_ (INSPECT IT) {WINDOW}#53,10152

All Values of (Vi	irtualCopyMixin test) (\$ t0copy).
atom	11
atomCopy	22
list	(abcd)
listCopy	(A B C)
obj	<i>i</i> , (\$ t3)
objCopy	#.(\$& (VirtualCopyMixin test) (N+W0.1Y%:.;h.Lh9 . 565) t1)
copyOf	# ,(\$ tØ)
copyMap	#,(\$& VirtualCopyContext (N+₩0.1Y%:.;h.Lh9 . 566))

The copied instance variables have not changed since they do not track changes in the original object.

Limitations

Some subtle issues are involved in building and using prototype structures so that the structure is preserved in the copied network. These involve how the network is typically traversed.

A general constraint is that all the links to any shared node in the prototype either all be marked as virtual variables, or none of them are. If they are all marked, then a single copy will be made and used. If none are, then the original object from the prototype will be used. Sharing with the prototype can be useful if this object is a repository for standard information that is independent of context. However, if this constraint is violated, the topology of the virtual copy will be different from that of the prototype.

In the simplest situation the network has a single entry node. In this case, a copy-map (see the section "Operands") can be created when the entry node object is first copied. After that all values are copied using this copy-map. The mechanism works well in this situation, even if there is sharing and there are cycles within the network.

At the other extreme, networks can have arbitrary connectivity, including multiple entries from outside the network, for example, from other networks or

non-objects. In this case, the following constraints are necessary to ensure correctness of the virtual copy mechanism.

The first constraint states that all access to the network must start through a copy of one of the nodes in the prototype. This condition is necessary because the criteria for copying are contained in the links from one object to another, not in the objects themselves, and a shared node could not specify a link to a node to be copied. This constraint ensures that all accesses from the outside will be copied if and only if that object would have been copied because of an internal link. Otherwise, an analogous situation would occur in which you could either reach a copy or the original node of the prototype itself depending upon which path you follow when the paths lead to the same node in the prototype.

The final constraint requires that all entries to the network should be passed the same copy-map if they are to share structure. The underlying concern in imposing these constraints is that a network be always copied the same way to maintain its topology regardless of where you start.

Suppose you want to make a virtual copy of a virtual copy, that is, to use a virtual copy of a network as a prototype itself. This is very useful if you are using a network to hold the state of a partial design and you want to try two alternative continuations of the design. Some hidden costs are associated with such multiple-level virtual copies.

Suppose further that a network N1 is used as a prototype and you make a virtual copy, N1-VC. Furthermore, N1-VC-VC is defined to be a copy of N1-VC. Values missing from N1-VC-VC are found in the corresponding object of N1-VC. If the value is missing there, the process recurs, and N1 is examined. If the value is to be a virtual copy, then this process will add a virtual copy in N1-VC, and then a second level copy in N1-VC-VC. This is necessary to preserve the semantics presented, but implies that many levels of virtual copy cannot easily do inexpensive incremental searches of a network.

This directory contains all the documentation for Xerox Loops in all its various incarnations. Directories are as follows: {ERIS}<Doc>LOOPS> - most general information {ERIS}<Doc>Loops>ProductionSpecs> - specs for all versions of Koto LOOPS {ERIS}<Doc>Loops>Koto>Final - Product Release for Koto LOOPS (Oct 87) {ERIS}<Doc>Loops>Lyric>Alpha - Alpha Lyric LOOPS (Jan 88) Most directories have the following subdirectories: Ref> - Reference Manual RelNote> - Release Notes LibMod> - Library Modules Manual (Lyric Release) LibPkg> - Library Packages Manual (Koto Release) UserMod> - Users' Modules Manual (Lyric Release) UserPkg> - Users' Packages Manual (Koto Release) And even further in the diectory maze, X-Index> - has IMPTR files and resulting index Z-ReleaseInfo> - holds more details on conventions and production details. This appendix describes how to install the LOOPS System files, Library Modules files, and Users' Modules files on the Sun Workstation.

Overview of the Distribution Kit

The distribution kit for LOOPS on the Sun consists of a single 1/4-inch tape cartridge. It contains the complete release in "tar" format and creates appropriate directories when its contents are extracted.

Preparation

Preparing to install LOOPS requires that the Medley release of Lisp is already installed and that adequate file space is available.

Before installing LOOPS, remember that

- the Medley 1.0, 1.1 or 1.2 release of Lisp must already be installed on your Sun Workstation;
- the complete LOOPS distribution requires about 1.2 MBytes of file space.

Installation

The software installation procedure shows the steps required for installing the Medley LOOPS software on a Sun Workstation with Medley already installed. Examples are given where appropriate. Only those users who are system administrators and have **root** privileges can install the LOOPS, Medley release.

Before starting software installation, remember that the LOOPS software requires about 1.2 MBytes of file space.

1. Log in under your username.

login yourname

prompt%

where yourname is replaced by your username.

2. Check for available space with the df command:

prompt% df

Filesystem	kbytes	used	avail	capacity	Mounted on
/dev/xy0a	7437	5470	1223	82%	/
/dev/xy0h	148455	4900	128709	96%	/usr/misc

3. Determine if you need to run su to make a directory for the distribution. If so, type in su:

prompt% **su**

4. Make a directory for the distribution. This directory should be named /usr/local/lde/loops. If you have enough space on the file system containing /usr/local/lde, then

prompt# mkdir /usr/local/lde/loops/

If you don't have enough space on /usr/local/lde, go to step 6.

5. Make yourself owner of this directory:

prompt# /etc/chown yourname /usr/local/lde/loops/

where yourname is your username.

6. If you don't have space on the file system which contains /usr/local/lde, but do have space somewhere else, for instance on /usr1, then make the directory there and link /usr/local/lde/loops to it:

prompt# mkdir /usr1/loops

prompt# /etc/chown yourname /usr/usr1/loops

prompt# ln -s /usr1/loops /usr/local/lde/loops

7. If you ran su, leave the privileged shell by typing:

prompt% exit

- 8. Insert the ¹/₄-inch cartridge tape, containing the LOOPS software, in the drive.
- 9. Connect to /usr/local/lde/loops:

prompt# cd /usr/local/lde/loops

10. Load the Medley software from tape. Indicate the appropriate device abbreviation for your tape by replacing **xx** in the example below with

ar for the Archive drive,

st for a SCSI tape drive.

This example shows the command entry sequence:

prompt# tar xvpf /dev/rxx0

As the software is loaded (a process that takes some time) the system prints a series of lines in the following form:

x ./system/LOOPS., 28552 bytes, 56 tape blocks

The x at the beginning of the line indicates that the file is being extracted from the tape.

This creates directories named:

/usr/local/lde/loops/system/

/usr/local/lde/loops/library/

/usr/local/lde/loops/users/

This is a good time to set the protection of the extracted directories and files so that the work group using LOOPS has at least read access to them.

- 11. Boot Medley Lisp.
- 12. Open an Interlisp Executive Window.
- 13. Make certain the time is set correctly.
- 14. Set the **DIRECTORIES** and **DISPLAYFONTDIRECTORIES** variables appropriately so the sysout can find your Lyric/Medley library and font files.
- 15. Make the LOOPS System directory your connected directory:

CONN {DSK}/usr/local/lde/loops/system/

16. Enter the following into your Exec:

LOAD(LOOPS)

A menu appears that looks like this:

Loops system Install from distribution Load into sysout

17. Select the menu option Install from distribution.

The following menu appears:

Loops directories	Click here when done
LOOPSDIRECTORY	{DSK} <lispfiles>LOOPS></lispfiles>
LOOPSLIBRARYDIRECTORY	{DSK} <lispfiles>LOOPS>LIBRARY></lispfiles>
LOOPSUSERSDIRECTORY	{DSK} <lispfiles>LOOPS>USERS></lispfiles>
LOOPSUSERSRULESDIRECTORY	{DSK} <lispfiles>LOOPS>RULES></lispfiles>

This menu shows the current (or default, if unset) values of the variables LOOPS examines when it loads things.

If you have installed LOOPS under /usr/local/lde/loops/ click the mouse on the menu items to set these directories to point where the tape was unloaded:

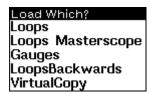

LOOPSDIRECTORY {dsk}/usr/local/lde/loops/system/ LOOPSLIBRARYDIRECTORY {dsk}/usr/local/lde/loops/library/ LOOPSUSERSDIRECTORY {dsk}/usr/local/lde/loops/users/ LOOPSUSERSRULESDIRECTORY {dsk}/usr/local/lde/loops/users/

As the last installation step, the installation tool automatically modifies the file LOOPSSITE, writes it out to the vaule of the variable **LOOPSDIRECTORY**, and compiles it.

When this step is finished, the first menu reappears:

Loops system Install from distribution Load into sysout

18. Select the menu option **Load into sysout** to load LOOPS into your system. The following menu appears:

19. Select **LOOPS** from the menu to load LOOPS from the location where you installed it.

Once LOOPS is loaded the LOOPS System menu reappears. To load one of the other LOOPS library or Users' modules, select the appropriate name in the Load Which? menu.

20. Position your mouse cursor anywhere on the screen except for the Load Which? menu, then press the left mouse button to exit the installation procedure.

Medley LOOPS is now installed on your Sun Workstation.

Loading After Installation

This section describes how to reload LOOPS into a newly started Lisp sysout after LOOPS has been previously installed.

- 1. Start up Medley on your Sun Workstation.
- 2. Open an INTERLISP Exec window.
- 3. Make sure **DIRECTORIES** points to a directory containing GRAPHER.LCOM, and **DISPLAYFONTDIRECTORIES** points to a directory containing the Helvetica display font files from your Lisp distribution kit.
- 4. Connect to the directory containing the LOOPS system files:

(CNDIR '{DSK}/USR/LOCAL/LDE/LOOPS/SYSTEM/)

5. Load LOOPS loader program:

(FILESLOAD LOADLOOPS)

6. Run the LOOPS loader program:

(LOADLOOPS)

This procedure loads only the LOOPS system files. Please see the manuals describing the LOOPS Library and Users' Modules for their loading procedures.

CAUTION

LOOPS uses the new compiler and its macrolet facilities. When LOOPS is loaded, it sets your ***DEFAULT-CLEANUP-COMPILER*** to **'CL:COMPILE-**

FILE. More information on this cleanup flag and the new compiler is available in the *Lisp Release Notes*, in your Medley Lisp kit.

Annotated Values and Active Values

In the previous chapters, IVs, CVs, and their properties have been treated as passive entities without structure. *Annotated values* are a way of associating behavior and annotations with variables. In keeping with the object oriented programming style of LOOPS, these annotations are objects. Annotation objects are called *active values*. When a variable containing an annotated value is accessed, a message is sent to the active value. This mechanism is dual to the notion of messages: messages are a way of telling objects to perform operations, which can change their variables as a side effect; active values are a way of accessing variables, which can send messages as a side effect.

This chapter first describes the structure and implementation of annotated values. Functions for explicitly dealing with annotated values are documented. Then the class ActiveValue is introduced and the standard protocol for active values is described. Next, the standard subclasses of ActiveValue are explained.

5.1. Annotated Values

5

LOOPS defines a new INTERLISP data type called annotatedValue. Each annotatedValue contains a single field. This field contains an object, the annotated value's active value. The standard variable access functions described in previous chapters (GetValue, PutValue, GetClassValue, PutClassValue) treat values that are annotated values specially. GetValue and GetClassValue do not return the annotated value. Instead, they send the contained active value a message, and return the result of that message. Similarly, if the current value of a variable is an annotated value, PutValue and PutClassValue operate by sending the contained active value a message.

type? annotatedValue value

[Macro]

Returns true if *value* is an annotated value, false otherwise. This is the standard way to test to see if a value is an annotated value.

create annotatedValue
$$\leftarrow object$$
 [Macro]

Creates a new annotated value with active value *object*. No checking of *object* is performed.

LOOPS2

fetch annotatedValue of *value*

Returns the active value contained in the annotated value *value*. If *value* is not an annotated value, generates an error.

replace annotatedValue of value with object [Macro]

Replaces the active value contained in the annotated value value with object. If value is not an annotated value, generates an error. No checking of *object* is performed.

 $\leftarrow AV av selector . args$

 \leftarrow AV is a message sending form that can be used with annotated values. (\leftarrow AV *av selector* . *args*) \rightarrow (\leftarrow (fetch annotatedValue of *av*) *selector* . *args*).

AnnotatedValue

Sometimes people forget to extract the active value from an annotated value, and they end up trying to use an annotated value as an object. Using the LispDataType feature, LOOPS takes care of this for you. Annotated values are considered to belong to the LOOPS class AnnotatedValue. If you send a message to an annotated value, the behavior is found in the class AnnotatedValue. There, the method for MessageNotUnderstood forwards the message off to the contained active value. Similarly, if you attempt to get an IV from an annotated value, the get ends up happening to the wrapped active value.

5.2. The Abstract Class ActiveValue

Active values follow a standard protocol that allow them to be used inside of annotated values.

In the description of methods for active values, the arguments *containingObj*, *varName*, *propName*, and *type* are used to describe the variable containing the active value. *type* is one of IV, CV, or NIL : a type of IV or NIL indicates that the variable is an instance variable or an instance variable property of containingObj; a type of CV indicates a class variable or class variable property of containingObj. If propName is NIL, the variable is either an IV or a CV, otherwise it is an IV or CV property with name *propName*. *containingObj* is the instance or class that contains the variable.

ActiveValue

[Abstract class]

The class ActiveValue captures the protocol followed by all active value objects. ActiveValue is an abstract class, so you cannot make instances of ActiveValue. Specializations of ActiveValue need to specialize the GetWrappedValueOnly and PutWrappedValueOnly methods. Methods that you want to specialize include AVPrintSource, GetWrappedValue, PutWrappedValue, WrappingPrecedence, and CopyActiveValue.

[Macro]

[Macro]

[Class]

5.2.1 Displaying Annotated Values

← *self* AVPrintSource

An annotated value determines how it will print out by sending the AVPrintSource message to the its active value. This message returns a form suitable for use by the INTERLISP function DEFPRINT. The result should be a pair of the form (*item1* . *item2*). *item1* will be printed using PRIN1, and then *item2* will be printed by PRIN2 (see the IRM description of DEFPRINT for more details).

The default method in ActiveValue returns the list

("#." \$AV className avNames (ivName value propName value ...) (ivName ...)...)

which will cause the annotated value to print out as

#.(\$AV className avNames (ivName value propName value ...) (ivName ...)...).

className is the name of the class of the active value. *avNames* is a list of names of *self*; the last element of *avNames* is the uid of *self*. The lists (*ivName value propName value ...*) describe the state of the IVs of the active value. Note that the uid of the active value is included in the printed form, so the identity of the active value object can be recovered. In this way, different annotated values can share the same active value, and have this sharing maintained across a dump/load-up.

\$AV className avNames . ivForms

AV is used to reconstruct a dumped annotated value. It returns a new annotated value whose active value is reconstructed from the *avNames* and *ivForms*.

5.2.2 Fetching and Replacing Wrapped Values

← self GetWrappedValue containingObj varName propName type [ActiveValue method]

The GetWrappedValue message provides a way to perform arbitrary actions when a variable is read. When GetValue (or GetClassValue) finds an annotated value in an instance, it does not return the annotated value. Instead, it sends the contained active value the GetWrappedValue message and returns the result of this message.

The default method in ActiveValue sends the message GetWrappedValueOnly to *self*. If this value is an annotated value, it is triggered by sending it the GetWrappedValue message, and the result is returned; otherwise the value is returned with no further processing.

 $\leftarrow \textit{ self } \texttt{GetWrappedValueOnly}$

Returns the immediate "local state" of the variable that is wrapped by the active value *self*. If this local state is a nested active value, it is not triggered. The default implementation causes an error by calling SubclassResponsibility.

[ActiveValue method]

[ActiveValue method]

[Special Form]

[ActiveValue method]

The PutWrappedValue message provides a way to perform arbitrary actions when a variable is set. When PutValue (or PutClassValue) attempts to replace an annotated value, it instead sends the contained active value the PutWrappedValue message.

The default method in ActiveValue checks to see if the current value is a nested active value by sending the GetWrappedValueOnly message to *self*. If the result is an annotated value, PutWrappedValue forwards the message on the the nested active value; otherwise it sends the message PutWrappedValueOnly to *self* and returns the result.

← *self* PutWrappedValueOnly *newValue*

[ActiveValue method]

Replaces the immediate "local state" of the variable that is wrapped by the active value *self*. The current local state is replaced. If the current value is a nested active value, it is not triggered. The default implementation causes an error by calling SubclassResponsibility.

5.2.3 Inheriting Active Values

Typical implementations of PutWrappedValue store the new value in the active value. However, if the active value is shared among different instances all these instances would see this change. In particular, if the active value is inherited from the class of the instance, all other instances of the class would see this change. This behavior is usually not desired. The GetWrappedValue method of active values is also free to alter the internal state of the active value, causing the same problem. To get around this problem, the annotated value is first copied, and this copy is stored in the instance. The CopyActiveValue method implements this copying. When GetValue or PutValue finds no local value, it first checks to see if the current value is an annotated value inherited from the class. If it is, it sends CopyActiveValue to the active value, and stores the result in the instance. The put or get then proceeds.

← *self* CopyActiveValue *annotatedValue*

[ActiveValue method]

annotatedValue is an annotated value that surrounds *self*. CopyActiveValue should return a copy of *annotatedValue*, containing a copy of *self*. It is possible, and in some cases desirable, for an implementation of CopyActiveValue to return *annotatedValue*.

The default behavior returns a new annotated value wrapped around a copy of *self*. IV values of self are not copied, the values are shared with the copy, except that IVs of self that contain annotated values are copied using the CopyActiveValue message.

5.2.4 Adding and Deleting Annotations

← self AddActiveValue containingObj varName
 propName type annotatedValue

[ActiveValue method]

Adds the annotated value *annotatedValue* to the variable specified by *containingObj*, *varName*, *propName*, and *type*. If *annotatedValue* is not specified or is NIL, *annotatedValue* defaults to a newly created annotated value containing the active value *self*. If the variable is already an annotated value, the AddActiveValue method uses the WrappingPrecedence message (below) to

determine if *annotatedValue* should be nested in the current annotated value or wrapped around it. The method returns *annotatedValue*.

← *self* WrappingPrecedence

Specifies where an annotated value containing *self* should be added to an existing annotated value. T means that this active value must go on the outside of any other annotated values. NIL means it must go on the inside. A number specifies a precedence: active values with larger WrappingPrecedence values go outside ones with smaller WrappingPrecedence values. If two active values have the same (numeric) WrappingPrecedence, the order is not determined. The default implementation of WrappingPrecedence returns 100.

← self DeleteActiveValue containingObj varName propName type [ActiveValue method]

Finds the first annotated value on the variable specified by *containingObj*, *varName*, *propName*, and *type* that has *self* as its active value and deletes it from that variable. Returns that annotated value if one was found, NIL otherwise.

← self ReplaceActiveValue newVal containingObj varName propName type [ActiveValue method]

It is sometimes desirable to replace an annotated value in a variable with some new value. (— *self* ReplaceActiveValue *newVal containingObj varName propName type*) replaces the annotated value containing *self* in the variable described by *containingObj, varName, propName*, and *type* with the new value *newVal*.

5.2.4 Manipulating Active Values

Some programs need to explicitly test and trigger active values. The following functions can be used to access IVs and CVs without triggering active values.

GetValueOnly *object varName propName*

GetValueOnly is the same as GetValue, except that GetValueOnly does not trigger any active values. GetValueOnly returns the immediate value of the variable. If this is not an annotated value, GetValueOnly returns the same value as GetValue. If there is no local value, the inherited value is returned. See also the function GetIVHere.

GetClassValueOnly object varName propName

ObjRealValue *object varName value propName type*

GetClassValueOnly is the same as GetClassValue, except that GetClassValueOnly does not trigger any active values. GetClassValueOnly returns the immediate value of the variable. If this is not an annotated value, GetClassValueOnly returns the same value as GetClassValue. *object* can be either an instance or a class.

If *value* is not an annotated value returns *value*, otherwise returns the value of $(\leftarrow AV GetWrappedValue object varName propName type)$. This macro is used by GetValue and

[*ActiveValue method*]

[Function]

[Macro]

[Function]

GetClassValue to trigger active values, and can be used by programs that explicitly test for active values.

PutValueOnly object varName newValue propName [Function]

PutValueOnly is the same as PutValue, except that PutValueOnly does not trigger any active values. PutValueOnly replaces the immediate value of the variable with newValue, even if the old value is an annotated value.

PutClassValueOnly object varName newValue propName [Function]

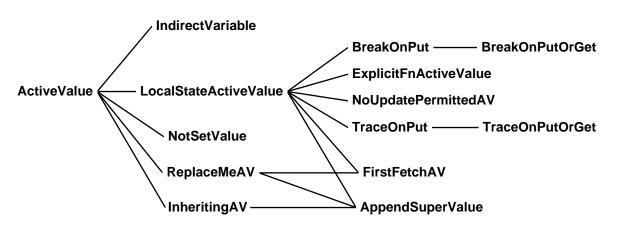

PutClassValueOnly is the same as PutClassValue, except that PutClassValueOnly does not trigger any active values. PutClassValueOnly replaces the immediate value of the variable with newValue, even if the old value is an annotated value. object can be either an instance or a class.

\leftarrow self HasAV? av

[ActiveValue method]

Returns true if the active value (or annotated value) av is nested inside in the active value self.

5.3. Specializations of ActiveValue

The ActiveValue Class Hierarchy

5.3.1 NotSetValue and Variable Inheritance

NotSetValue

[Variable]

LOOPS uses annotated values to trigger IV inheritance. When an instance is created, its IVs are initialized to contain (the value of) NotSetValue. NotSetValue is an annotated value whose active value is the prototype instance of the class NotSetValue. The class NotSetValue specializes the

default ActiveValue protocol to trigger IV inheritance. In this way GetValue does not need to do any special check to see if a value needs to be inherited — all it needs to do is see if the value is an annotated value. Note that GetValueOnly does need to do a special check for NotSetValue, but see the function GetIVHere.

NotSetValue form

Returns true if form evaluates to NotSetValue, otherwise false. (NotSetValue form) \rightarrow (EQ form 'NotSetValue). This is the approved way of testing a value to see if it is NotSetValue.

← *self* AVPrintSource

Returns the pair ("#." . NotSetValue). This causes (the value of) NotSetValue to print out as #.NotSetValue. This will be read in as the value of the variable NotSetValue.

[NotSetValue method]

If type is NIL or IV, this evaluates (*containingObj* IVValueMissing *varName propName* 'GetValue) and returns the result; if type is CV, evaluates ($\leftarrow class$ CVValueMissing varName propName 'GetValue) (where class is the class of containingObj if containingObj is an instance, else *containingObj* if it is a class) and returns the result; otherwise an error is generated. See the methods IVValueMissing and CVValueMissing on the class Object.

newValue propName type

If type is NIL or IV, this evaluates (*containingObj* IVValueMissing varName propName 'PutValue *newValue*) and returns the result; if *type* is CV, evaluates (← *class* CVValueMissing varName propName 'PutValue newValue) (where class is the class of containingObj if containingObj is an instance, else containingObj if it is a class) and returns the result; otherwise an error is generated. See the methods IVValueMissing and CVValueMissing on the class Object.

← *self* CopyActiveValue *annotatedValue*

Returns #.NotSetValue. There is only one NotSetValue.

← *self* WrappingPrecedence

Returns NIL. #.NotSetValue must always be on the inside of any sequence of nested active values.

GetIVHere object varName propName

If *propName* is NIL and there is a local value for the IV *varName* in the instance *object*, that value is returned. If *propName* is not NIL and there is a local value for the IV property *propName* of the IV varName in the instance object, that value is returned. Otherwise, if propName is NIL GetIVHere returns #.NotSetValue, and if propName is not NIL GetIVHere returns (the value of) NoValueFound.

[Macro]

[*NotSetValue method*]

[*NotSetValue method*]

[NotSetValue method]

[NotSetValue method]

[Function]

GetCVHere object varName propName

object must be a class. Returns the value of the class variable that is found in the class *object*. If none is found, then returns #.NotSetValue.

GetClassIV class varName propName

Returns the default value or property value of the instance variable *varName* in the class *class*.

PutClassIV class varName newValue propName

Stores *newValue* as the default value or property value of teh instance variable *varName* in the class class. If varName is not already local to the class, this will cause an error. Returns newValue.

5.3.2. Indirect Variables

In some applications it is important to be able to access values indirectly from other instances. For example, Steele [Steele80] has recommended this as an approach for implementing equality constraints.

IndirectVariable

Mumble.

5.3.3. ReplaceMeAV

The active value mixin ReplaceMeAV can be used when an active value should be replaced when a variable is first set.

ReplaceMeAV

Mumble.

5.3.4. LocalStateActiveValue

Many kinds of active values explicitly store the "real" value of the variable in an IV of the active value.

LocalStateActiveValue

Mumble.

5.3.5. InheritingAV

Some kinds of active values want to compute a value based on what would have been inherited if the active value had not been present. For example, it might be desired to append items onto an inherited value (see the class AppendSuperValue).

InheritingAV

Mumble.	

5.3.9. AppendSuperValue

The active value class AppendSuperValue can be used to append data to inherited values.

AppendSuperValue	[Class]
Mumble.	

[Class]

[Class]

5.3.10. ExplicitFnActiveValue

ExplicitFnActiveValue

ExplicitFnActiveValue explicitly store functions that will be triggered when the variable is fetched or replaced. They have three IVs: localState, getFn,and putFn. The localState is the "real" value of the variable (possibly a nested active value), the getFn and putFn are names of functions that are applied with standard arguments by the GetWrappedValue and PutWrappedValue methods. The getFn and putFn are called with arguments *containingObj*, *varName*, *oldOrNewValue*, *propName*, *activeValue*, and *type*. ExplicitFnActiveValue active values print out as #. (A *localState getFn putFn*), where the *localState*, *getFn*, and *putFn* are the values of the corresponding IVs of the active value.

5.4. Compatibility with older versions

The following existed in older versions of LOOPS, which had a different implementation of active values. They are provided for compatibility purposes only. New programs should not use them. They are not fully supported, and will not exist in future releases. The current implementations of these use the new active values. They are fully compatible with the older versions except where noted.

5.4.1. Old Style Active Values

LOOPS used to combine the notion of annotated value and active value. Variable annotations were instances of the INTERLISP datatype activeValue.

activeValue

In this version of LOOPS, the record activeValue is an access record that converts the three fields of the old active values to appropriate functions for accessing annotated values. Forms like (type? activeValue *form*) and (fetch localState of *activeValue*) will do the right thing. Reading in old style active values automatically converts them to annotated values wrapping an instance of the class ExplicitFnActiveValue.

unction]
unction]
unction
unction]
Ľ

[Class]

[Record]

PutLocalStateOnly <i>av newValue</i>	[Function]
Works just like in the old LOOPS.	
ReplaceActiveValue <i>av newVal self varName propName type</i> Works just like in the old LOOPS.	[Function]
MakeActiveValue <i>self varOrSelector newGetFn newPutFn</i> <i>newLocalSt propName type</i>	[Function]
Works just like in the old LOOPS, except that the interpretation of	

MakeActiveValue ignores the value of *newLocalSt*, and always creates a new active value. This is the behavior that the old MakeActiveValue produced when *newLocalSt* was Embed.

5.4.2. GetFns and PutFns

DefAVP <i>fnName putFlg</i>	[Function]	
Works just like in the old LOOPS.

ReplaceMe <i>self varname oldOrNewValue propName activeValue type</i> Works just like in the old LOOPS.	[Function]	
AtCreation self varname oldOrNewValue propName activeValue type	[Function]	
No longer works Instead you can use either the FirstFetch function or the finitForm property		

No longer works. Instead, you can use either the FirstFetch function, or the :initForm property of IVs.

5.5. Summary of Variable Access Functions

The following tables summarizes the available functions for variable access.

	Inherit/Trigger	Inherit/Don't Trigger	Don't Inherit/Don't Trigger
from instance	25		
IV	GetValue PutValue	GetValueOnly PutValueOnly	GetIVHere
CV	GetClassValue PutClassValue	GetClassValueOnly PutClassValueOnly	<n.a.> <n.a.></n.a.></n.a.>
from classes	3		
IV	<n.a.> <n.a.></n.a.></n.a.>	GetClassIV PutCIVHere	GetClassIVHere PutClassIV
CV	GetClassValue PutClassValue	GetClassValueOnly PutClassValueOnly	GetCVHere PutCVHere

Tailoring MasterScope

Extending analysis of functions

MasterScope maintains a number of tables describing how (analyzed) functions relate to other objects. The template keywords **TEST**, **PROP**, **FUNCTION**, etc. corespond to some of these tables. For a number of applications, the user would like to be able to define new template words and the database tables that go along with them.

(ADDTEMPLATEWORD WORD)

defines a new table to hold a new MasterScope relation. The name of the table will be **WORD**, and **WORD** can be used in function templates. This is a new function.

Functions are also provided to allow the user to access these new tables inside of a MasterScope command.

(MSADDRELATION RELATION TABLES)

defines a new relation for MasterScopes parser and command interpreter. For example, (MSADDRELATION ' (FETCH FETCHES FETCHING FETCHED)) could have been used to define the FETCH relation.

RELATION is a list of **ROOT PRESENT PARTICIPLE** and **PAST** conjugations of the new relation. **TABLES** is a list of MasterScope database tables that will be **UNION**ed to compute the new relation. (If **TABLES** is an atom it will be coerced to a list containing that atom. If the tables do not already exist, they will automatically be created by **ADDTEMPLATEWORD**). **TABLES** defaults to the **ROOT** of the relation.

(MSADDMODIFIER RELATION MODIFIERS TABLES) [Function]

defines a new modifier for the given relation. For example, the phrase **SET FREE** could have been defined by **(MSADDMODIFIER 'SET 'FREE '(SETFREE))**.

RELATION is a known MasterScope relation (either built-in or defined by **MSADDRELATION** above). **MODIFIERS** is a list of equivilent modifiers. **TABLES** is a list of MasterScope database tables that should be **UNION**ed to compute the new, modified relation. (If any of the tables do not exist, they will be created by **ADDTEMPLATEWORD**). This is a new function.

(MSADDTYPE TYPE TABLES HOWUSED SYNONYMS)

[Function]

[Function]

[Function]

2

tells MasterScope what it means to use an object of a given type. The phrase USE THE FIELD could be defined by (MSADDTYPE 'FIELD '(FETCH REPLACE)).

TYPE is the type of the object being described. The word **TYPE** can then be used in MasterScope commands. **TABLES** indicates how the relation **USE THE <TYPE>** ... is defined. **HOWUSED** is a list of verb describing how the type can be used. The above example not only lets you use the phrase **USE THE FIELD**, but also the phrases **FETCH THE FIELD** and **REPLACEUSE THE FIELD**. The default value of **HOWUSED** is **(USE)**. Finally, **SYNONYMS** is a list of synonyms for **TYPE**.

In addition to these new functions there are a number of other ways to tailor MasterScope.

Some MasterScope templates, for example (IF expression template1 template2) can compute the template to be used. These expressions can access the current form via the free variable EXPR. The free variable PARENT can be used to access the expression that contains the current expression. This has existed all along, but has not been documented.

ANALYZEUSERFNS

is a list each of whose elements is a function that will be **APPLY***ed to the name, definition, and the results of the MasterScope analysis of a function whenever it is analyzed. The result of each application becomes the new result of the MasterScope analysis.

The results of the MasterScope analysis is an ALIST associating relations (**BIND**, **CALL**, etc) with the coresponding data for the function. This can be used to compute relations that are determined by some global context. This has existed all along, but has not been documented.

(SETSYNONYM PHRASE MEANING -)

defines a new synonym for MasterScope's parser. Both **MEANING** and **PHRASE** are lists of words; anywhre **PHRASE** is seen in a command, **MEANING** will be substituted. For example, (SETSYNONYM 'GLOBALS '(VARS IN GLOBALVARS OR @(GETPROP X 'GLOBALVAR))) would allow the user to refer with the single word GLOBALS to the set of variables which are either in GLOBALVARS or have a GLOBALVAR property.

SETSYNONYM includes a small pattern match ability. A & in **PHRASE** will match any word; the word will be substitued for **N** in **MEANING** where **N** is the number of &'s which have been matched. For example, (**SETSYNONYM** ' (FOO & &) '(IN 1 OR ON 2)) will take FOO FIE FUM into IN FIE OR ON FUM. This is an old function, but the documentation (IRM p 13.20) was incomplete zspecifically the pattern match stuff was not mentioned.

Extending MasterScope commands

[Variable]

[Function]

DESCRIBELST

[Variable]

is a list each of whose elements is a list containing a descriptive string and a form. The form is evaluated (it can refer to the name of the function being described by the free variable **FN**); if it returns a non-**NIL** value, the description string is printed followed by the value. If the value is a list, its elements are printed with commas between them. For example, the entry ("types: " (GETRELATION FN ' (USE TYPE) T) would include a listing of the types used by each function. From the IRM, p 13.7.

MSCHECKFNS

[Variable]

is a list of functions that will be used to extend the **CHECK** MasterScope command. The **CHECK** command will **APPLY*** each function on **MSCHECKFNS** to the list of files being checked. This is new.

Analyzing new types of objects

This doesn't work yet.

(MSADDANALYZE PLURAL SINGULAR ANALYZEFN RELATIONS) [Function] defines a new type for MasterScope analysis. For example, (MSADDANALYZE 'CLASSES 'CLASS 'AnalyzeClass ??) will let you execute MasterScope commands like . ANALYZE ANY CLASS ON 'MYFILE and . WHAT CLASS DEFINES THE IV foo. The function ANALYZEFN should be a function of two arguments, the item name and the flag REANALYZE?, and should return an ALIST associating relation names to corresponding data for the object. This is a new function.

Need to do

(DUMPDATABASE) needs to store out all the new words, relation, etc.

Analyzing new types of things needs to store the info someplace, and **ERASE** needs to be able to find it.

Need a **FILEPKGTYPE** for the MasterScope words.

Proposal for Loops manual contents.

This ordering is based on the Interlisp Reference manual. Numbers in [[]]'s indicate the coresponding parts in the (new) IRM. Other comments are enclosed in []'s I envision a manual in a single binder, with large tabs marking the IRM volume separation, and smaller tabs for each chapter.

Just load the file LOOPS

Initial screen setup

Customer Support

Differences from old Loops

KnowledgeBases no longer a part of Loops

Functions ReadLeafObj, AllGlobalNames, RememberName, and GlobalName no longer exist

Variables WritingSummaryFlg, WritingLayerFlg, LeafInstanceFlg, FirstEnvFlg, OpenKBFiles, DefaultKBName, CurrentEnvironment, CurrentNameTable, and CurrentUIDTable no longer exist

Macro Modified no longer exists

Rules no longer a part of Loops

Rules are not distributed. If they are needed, they can be loaded by first recompiling them and then loading the file LOOPSRULES-ROOT. This replaces a few functions and methods in the standard system and then load the rules files.

Code cleaned up

Variables VarNameIndexes, PrintStatusWindow, and TTY no longer exit

Functions DC, de, ue, em, ei, ec, and file no longer exit

Macro @@ no longer exists. Change (@@ foo) to (@ ::foo), or even (@ foo)

Usermacros PU, UE, and EU no longer exist

The argument that controls updating in the window methods SetOuterRegion, SetRegion, Shape, and Shapel have all been changed to noUpdateFlg. They used to be a mixture of updateFlg and dontUpdateFlg.

The interpretation of the left, bottom, width, and height IVs in the class Window is now the same as Lisp windows: left and bottom refer to the lower left corner of the outside of the window, width and height refer to the outside dimensions of the window (including title).

The file LoopsMixin has been deleted. The classes DatedObject, IndirectObj, Node, Perspective, NamedObject, GlobalNamedObject, TextItem, VarLength, StrucMeta, ListMetaClass, TempClass, and Template no longer exist.

Old messages List and List! are now called ListAttribute and ListAttribute!. This change was required for future migration to

CommonLoops. The old methods for List and List! are still available in the LOOPSBACKWARDS file.

- The functions DebugLoops, LOOPSDIR, i/d, and TESTLOOPS have been removed from the system.
- The functions CheckDestroyedObjects and RemoveClassDef have been removed from the system.

I/O

- Support for reading in old style read macros (like #(localState getFn putFn) or #\$Mumble) is available in the file LOOPSBACKWARDS.
- UIDs are no longer strings. They are CONSes of session-id's and uid numbers.

Active Values

Most of the old functions for active values have been moved to LOOPSBACKWARDS. The functions GetLocalState, PutLocalState, GetLocalStateOnly, PutLocalStateOnly, ReplaceActiveValue, MakeActiveValue, and DefAVP are still around, and seem to work. The exception is MakeActiveValue — it now always EMBEDS.

Functions GetActiveValueGetFn, GetActiveValuePutFn, GetActiveValueLocalState, PutActiveValueGetFn, etc no longer exist. Replacements are available in the file LOOPSBACKWARDS.

NotSetValue is no longer ?—it is now an active value. This may require changes to any code that directly refered to ?.

Virtual Copies

The messages MakeCopy99, MakeCopyActiveValue99, MakeCopyList99, and MakeCopyObject99 in VirtualCopies have been renamed \Internal/MakeCopy, \Internal/MakeCopyActiveValue, etc

Method properties no longer exist

Function PushNewValue no longer defined. Instead, use CHANGETRAN.

Can't load new Loops files into old Loops.

Conversion of old Loops code to new Loops

Old code will need to be recompiled.

File LOOPSBACKWARDS

Function ConvertLoopsFiles

Future Directions

ARTIFICIAL INTELLIGENCE SYSTEMS XEROX LOOPS RELEASE NOTES XEROX LOOPS REFERENCE MANUAL XEROX LOOPS LIBRARY PACKAGES MANUAL LYRIC/MEDLEY RELEASE

ERRATA FOR THE LYRIC / MEDLEY RELEASE OF XEROX LOOPS

Please note the following corrections to the Lyric/Medley release of the manual and software. These descriptions and workarounds supplement the Lyric/Medley *Xerox LOOPS Release Notes*.

Notes and Cautions

Documentation comments in examples

Documentation props are now strings, as mentioned in the Lyric/Medley version of the *Xerox LOOPS Release Notes*. However, many of the manual's examples incorrectly show comments being used for documentation on methods, and instance and class variables.

Conversion of instance files

We have encountered a case where instance files from Koto LOOPS failed to load after conversion under Lyric/Medley LOOPS. This occurs when instances refer to each other (their IVs contain one another).

This type of instance file must be written out in the INTERLISP readtable, since only that readtable handles the "hash dot" reader macro used to write out a reference to an instance. After conversion of such files, place a MAKEFILE-ENVIRONMENT property on the file that will cause it to be written and read in the INTERLISP readtable.

GetIt for missing IV props

There is an inconsistency in **GetIt**'s behavior when retrieval of missing instance variable properties is attempted. If the object being retrieved from is an *instance*, this returns the value of **NoValueFound**, and triggers any active values. However, if the object being retrieved from is a *class*, **GetIt** returns the value of **NotSetValue**, and does not trigger active values. A workaround would be to check for both **NoValueFound** and **NotSetValue** as return values from **GetIt**.

LOOPS Rules

The User's Module "Rules" has changed to track differences between Koto and Lyric/Medley LOOPS. In Koto LOOPS, one could create RuleSets that were not methods; this is no longer possible. RuleSets can no longer reside "bare" in a FNS definition.

Several things follow from this change:

- RunRS no longer works.
- DefRSM is now the only way to create new RuleSets. The documented New method for the class RuleSet is used internally by DefRSM; software should no longer specialize or depend on it.
- The RuleSet method **CopyRules** no longer works. RuleSets can be copied using **CopyMethod**.

Converting Koto RuleSets

Converting older RuleSets to run in the Lyric/Medley release of Xerox LOOPS is a two-step process. The first step takes place in the Koto release of LOOPS; the second step occurs in the Lyric/Medley release of LOOPS.

While still running the Koto release of LOOPS, you must first pass preKoto RuleSets through the converter in the LOOPSBACKWARDS User's Module. This will upgrade the RuleSets to run in Koto LOOPS. RuleSets which reside in FNS must also be moved into methods at this time. A final ready-toconvert version of the RuleSet files should then be made.

After starting up the Lyric/Medley release of Xerox LOOPS any previously prepared Koto RuleSets can be passed through the converter in the CONVERSION-AIDS User's Module. Some types of Koto converted Buttress RuleSets will print out a message during conversion; these must then be rule-compiled, i.e. translated from RuleSet to executable code by sending the RuleSet the **RE** message and exiting the rule editor with **OK&LispCompile**.

After these steps all RuleSet formats will be correctly updated and the fully converted files can be made.

[This page intentionally left blank]

A. ACTIVE VALUES IN BUTTRESS LOOPS

In the Buttress version of LOOPS, the concept of active values was implemented differently. The current **ExplicitFnActiveValue** acts very much like the old active values, and is used to provide compatibility with existing Xerox LOOPS code. Most of the functions described in this chapter are found only in the LOOPSBACKWARDS user package, work as they did in the Buttress version of LOOPS, and should be used only to bring existing code into the current system.

Descriptions of the functionality in this appendix are written in terms of the new **ActiveValues** wherever possible.

The active value/annotated value system discussed in Chapter 8, Active Values, is a new implementation. Programs developed using the Buttress activeValue system automatically convert into the new system when loaded, using the **ExplicitFnActiveValue** capability described in Chapter 8, Active Values, and in this appendix.

Note: The following functions and records are maintained for compatibility purposes only; they are not fully supported and may not exist in future Xerox LOOPS releases. Programs that use these records and functions should be changed. The LOOPSBACKWARDS user package must be loaded for these functions to work.

A.1 Buttress System of ActiveValues

The Buttress LOOPS implementation combined the notions of annotated value and active value. To annotate a variable, the value was replaced with an instance of an Interlisp-D data type called activeValue, but there were no LOOPS classes with similar names and functions as there are now.

activeValue		[Record]
Purpose:		plementation of the active values concept. Specifically, the Lisp quivalent to the present annotatedValue.
Behavior:	An activeValue placed as the value of a variable invoked evaluation of code on access attempts rather than just returning a stored value.	
Field Names:	localState A place for data storage.	
	getFn	The name of a function applied when the program retrieves the value of a variable that contained an activeValue.
	putFn	The name of a function that was applied when the program replaces the value of a variable that contained an activeValue.
	the localSta	getFn or putFn fields is NIL, default actions returned or replaced ate , respectively. Nesting was accomplished by the localState of lue being itself an activeValue.

Purpose:Mimics the behavior of the Buttress-style active values and allows simple changes to the user code triggered by the ActiveValue mechanism.Behavior:Get accesses to the wrapped variable cause the getFn to be called, and P accesses cause putFn to be called. Enables the old style activeValues to loo like the new style without changing any functionality.Instance Variables:IocalStateA place for data storage.getFnThe name of a function applied when the active variable is reacputFnThe name of a function applied when the active variable	ExplicitFnActiveValue
accesses cause putFn to be called. Enables the old style activeValues to locality like the new style without changing any functionality. Instance Variables: localState A place for data storage. getFn The name of a function applied when the active variable is read	Purpose:
getFn The name of a function applied when the active variable is read	Behavior:
	Instance Variables:
putFn The name of a function applied when the active variable	
changed.	
(MakeActiveValue self varOrSelector newGetFn newPutFn newLocalState propName type) [Function]	(MakeActiveValue self varOrSel

Purpose:	Makes the value of some variable an active value.		
Behavior:	Creates a n	ew activeValue record and installs it according to the arguments.	
Arguments:	self	Object whose variable is changed to an active value.	
	varOrSelect	or Variable name or method selector where the data type activeValue is placed.	
	newGetFn a	and <i>newPutFn</i> If NIL, the old values of getFn and putFn are not overwritten. If T, the values of getFn and putFn are changed to NIL. Any other values are placed in the getFn and putFn fields of the activeValue.	
	newLocalSt	The value of this argument is ignored. A new ActiveValue instance is always created. The contents of localState is changed to the previous value of the variable or property being made active.	
	propName	Name of the property, if the active value is to be placed on a property list. This is NIL if the active value is associated with a variable or method.	
	type	Indicates the type of the variable <i>varNameOrSelector</i> . Must be one of IV (or NIL) for instance variable, CV for class variable, CLASS for a class property, or METHOD for a method property.	

(DefAVP fnName putFlg)			[Function]
Purpose:	Creates a t	emplate for defining an active value function.	
Behavior:	Creates a t	emplate and leaves you in the Interlisp-D function editor	
Arguments:	fnName	Name of the function.	
	putFlg	T indicates function is a putFn ; NIL indicates a getFn	
Returns:	The function	on name on exit from the editor.	

(GetLocalState activeValue self varName propName type)

[Function]

	Purpose:	Retrieves	data from	localState.
--	----------	-----------	-----------	-------------

- Behavior: Retrieves the value stored in the **localState** of *activeValue*. Nested active values will be triggered.
- Arguments: activeValue An ActiveValue.
 - *self* The object containing the **ActiveValue**.
 - *varName* The name of the variable were the **ActiveValue** is stored.
 - propName The name of an instance or class variable property. This is NIL if the **ActiveValue** is associated with the value of the variable itself.
 - *type* Specifies where the **ActiveValue** was stored. NIL means an instance variable, CV means class variable, CLASS means a class property, METHOD means a method property.
 - Returns: Contents of the **localState** field of *activeValue*.

(PutLocalState activeValue newValue self varName propName type)

[Function]

Purpose:	Data replacement.		
Behavior:		tores <i>newValue</i> in the localState field of <i>activeValue</i> . Nested active values ill be triggered.	
Arguments:	activeValue	An ActiveValue.	
	newValue	A new value to be stored in localState .	
	self	The object containing the ActiveValue.	
	varName	The name of the variable were the ActiveValue is stored.	
	propName	The name of an instance or class variable property. This is NIL if the ActiveValue is associated with the value of the variable itself.	
	type	Specifies where the ActiveValue was stored. NIL means an instance variable, CV means class variable, CLASS means a class property, METHOD means a method property.	
Returns:	The value of	newValue.	

(GetLocalStateOnly activeValue)

[Function]

Purpose:	Gets a value from localState without triggering any nested ActiveValue .
Behavior:	Retrieves the value stored in the localState field of the ActiveValue without triggering any nested ActiveValue .
Arguments:	activeValue The ActiveValue in which the getFn and putFn is found.
Returns:	The contents of localState.

(PutLocalStateOnly activeValue	newValue) [Function]
Purpose:	Puts a value into a localState without triggering any nested ActiveValues.
Behavior:	Replaces the value stored in the localState of <i>activeValue</i> without triggering any nested ActiveValue .
Arguments:	activeValue An ActiveValue.
	newValue Value used for the replacement.
Returns:	The value of <i>newValue.</i>

(ReplaceActiveValue activeValue newVal self varName propName type)

[Function]

- Purpose: In an object's variable which has an **ActiveValue** installed, overwrites *activeVal* with *newVal*, providing a way of removing an **ActiveValue**.
- Behavior: Searches arbitrarily deep nesting to replace the occurrence of *activeVal* with *newVal*. If no match is found in the list that is the value of the variable described by the arguments, an error is invoked.
- Arguments: *activeValue* The **ActiveValue** to be replaced.
 - *newVal* A new value to be stored in the object's variable.
 - self The object containing the ActiveValue.
 - *varName* The name of the variable were the **ActiveValue** is stored.
 - *propName* The name of an instance or class variable property. This is NIL if the **ActiveValue** is associated with the value of the variable itself.
 - *type* Specifies where the **ActiveValue** was stored. NIL means an instance variable, CV means class variable, CLASS means a class property, METHOD means a method property.
 - newValue Value used for the replacement.
 - Returns: Value of *newVal.*

A.2 getFns and putFns

In the Buttress version of LOOPS, where the only kind of active value was equivalent to **ExplicitFnActiveValue**, specialization of active values was done not the way it is in Xerox LOOPS, but by the equivalent of putting special purpose functions into the **getFn** and **putFn** instance variables. The following functions emulate the behaviors they had in the Buttress version, using the current **ActiveValue** mechanisms.

In all cases, the functions are installed in the **getFn** or **putFn** instance variable of an **ActiveValue**, and are called when an attempt is made to get or put the variable where the **ActiveValue** is stored. The arguments and values returned are irrelevant to the use of these functions.

Sun 3 & 4 LOOPS — 1/4" tar Tape Manufacturing Instructions

(Envos Internal Use Only)

- 1. Go to Tree (or any available Sun 3 with a tape drive on it), and log in.
- 2. Insert a blank ¹/₄-inch cartridge in the tape drive. You must use a 600foot tape.
- 3. Type the following commands (the text in bold):

tree%: cd /python/loops
tree%: makereleasetape

The system will type something like this:

You should have a tape in the cartridge drive already, and should be connected to the correct directory. Please verify that you are connected to the right place.

You are connected to:

/python/loops (or something ending in /python/pcl)

Type ^C to Abort

Type ^D to continue

- 4. Type control-D. The tape will now get written, followed by a message telling you that it is finished.
- 5. When the tape has finished moving (it rewinds automatically), remove it from the drive, and turn the write-protect tab to the "Safe" setting.
- 6. Label the cartridge and its container (green LOOPS labels). If those were the last 2 labels, make another 10 (Chuck's PC has the files).
- 7. Don't forget to log out.

Sun 3 & 4 LOOPS — 1/2" 9-Track 1600 bpi Manufacturing Instructions

(Envos Internal Use Only)

- 1. Go to python and load a ½-inch tape into its tape drive. Hit the "Density" button until the light next to "1600" is lit. You'll need to use a small reel of tape for this.
- 2. At python's console, log in as yourself.
- 3. Type the following commands (the text in bold):

python%: cd /python/loops

python%: maketape1600

The system will type something like this:

You should have a tape mounted on python's mag tape drive, and should be connected to the correct directory. Please verify that you are connected to the right place.

You are connected to:

/python/loops (or something ending in /python/pcl)

Type [^]C to Abort

Type ^D to continue

- 4. Type control-D. The tape will now get written, followed by a message telling you that it is finished.
- 5. When the tape has finished moving (it rewinds automatically), remove it from the drive, and remove the write-protect ring.
- 6. Label the tape (green Loops label). If that was the last label, make another 10 (Chuck's PC has the files).
- 7. Hit the "density" button on the tape drive until the light next to "Host" is lit.
- 8. Don't forget to log out.

- Object-oriented programming, in which information is organized in terms of objects. Every object belongs to a class, and the classes are arranged in an inheritance lattice which allows complex objects to be described simply. Objects communicate with each other by sending messages. When an object receives a message, it performs some action, which can include sending messages to other objects.
- Procedure-oriented programming, in which smaller subroutines build larger procedures and in which data and instructions are kept separate.
- Access-oriented programming, in which accessing a value triggers an action. This paradigm is useful to monitor certain values.
- Rule-oriented programming, in which programs are organized around recursively composable sets of pattern-action rules. These rules provide a convenient way to describe flexible responses to a wide range of events. This part of LOOPS is included in the users' modules.

As a new user of LOOPS, you first must become familiar with its terminology and with the fundamental concepts described by that terminology. This chapter presents the terminology and related concepts.

1.1 Introduction to Objects

This section shows the LOOPS hierarchy, called a lattice, in Figure 1-1, and describes the key terms in separate subsections. Terms appear in order of increasing complexity, with simpler terms described first and subsequent terms building on these simpler terms.

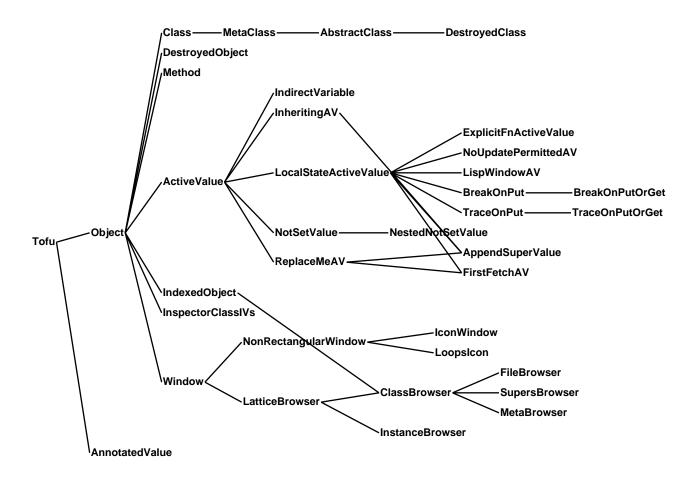

Figure 1-1. LOOPS Lattice

1.1.1 Object

As shown in Figure 1-2, an object is a structure consisting of data and a pointer to functionality that can manipulate the data. In procedureoriented programming, data and functionality are considered as separate entities.

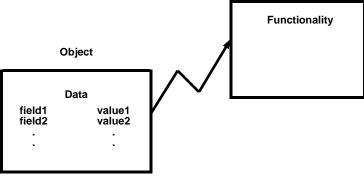

Figure 1-2. An Object

1.1.2 Message

Sending messages to objects provides an alternative to invoking procedures or calling functions. An object responds to a message by computing a value to be returned to the sender of the message, as shown in Figure 1-3. As a side effect, the data within an object may change during the computation. Messages contain a selector for the desired functionality. Messages may also contain arguments, as do procedures.

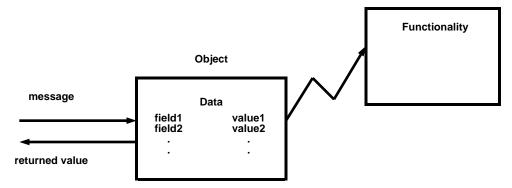

Figure 1-3. An Object Responding to a Message

1.1.3 Method

When an object receives a message, it determines what functionality it must apply to the arguments of the message. This functionality is called a method and is very similar to a procedure. A key concept that distinguishes methods from procedures is that in procedure-oriented programming, the calling routine determines which procedure to apply. In object-oriented programming, you determine the message to send and the object receiving the message determines the method to apply.

1.1.4 Selector

A message that is sent to an object contains a selector. The object uses the selector to determine which method is appropriate to apply to the message arguments. As shown in Figure 1-4, when an object receives a message with a specific selector, the object searches a lookup table containing selectors and methods to find the method associated with that particular selector.

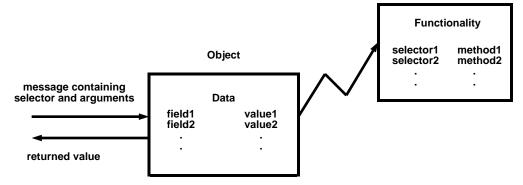

Figure 1-4. A Message Containing a Selector

1.1.5 Class

A class describes objects that are similar; that is, objects containing the same type of data fields and responding to the same messages, as shown in Figure 1-5. Think of the class that describes an object as being a template

for the functionality of its objects. When an object is sent a message, the class that describes that object handles the message, not the object itself. Different objects of the same class can respond to messages in the same way; that is, they apply the same method in response to receiving the same message.

To create new objects, send a message to a class requesting that a new object be created. Classes respond to messages because they are also objects.

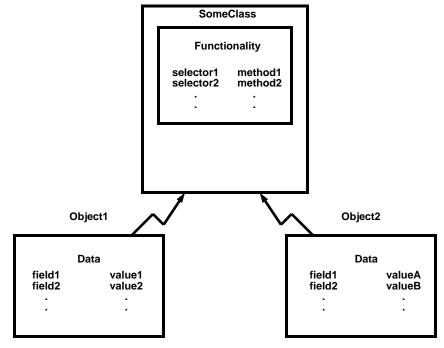

Figure 1-5. Class with Several Objects

1.1.6 Instance

An instance is an object described by a particular class. Every object within LOOPS is an instance of exactly one class.

1.2 Storage of Data in Objects

The data associated with an object is called an object's variables. Methods can change the values of these variables.

1.2.1 Class Variables and Instance Variables

LOOPS supports two kinds of variables:

Instance variables, often abbreviated IVs.

Instance variables contain the information specific to an instance.

· Class variables, often abbreviated CVs.

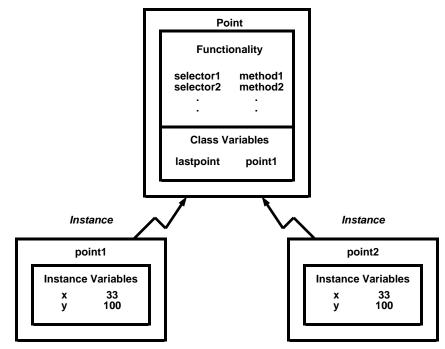

Class variables contain information shared by all instances of the class. A class variable is typically used for information about a class taken as a whole.

Both kinds of variables have names, values, and other properties. For example, the class for **Point** could specify two instance variables, **x** and **y**, and a class variable, **lastPoint**, used by methods associated with all points.

For any particular instance, you can access the values for the instance variables specific to that instance. You can also access the values for the class variables that are available to all instances of the same class.

Determining the value of a class variable requires a similar lookup procedure to that occurring when searching for a method to execute. Instance variable values are stored within the instances, and class variable values are stored within the class.

A class describes the structure of its instances by specifying the names and default values of instance variables, as shown in Figure 1-6. In this way, when a message is sent to a class to create a new instance, LOOPS can determine from the class description the number of instance variables for which it must allocate space the the initial values for those variables.

Class

Figure 1-6. Class Variables and Instance Variables

1.2.2 Properties

LOOPS provides extensible property lists for classes, their variables, and their methods. Property lists provide places for storing documentation and additional kinds of information. For example, in a knowledge engineering application, a property list for an instance variable could be used to store the following information:

- Support (reasons for believing a value)
- · Certainty factor (numeric assessments of degree of belief)
- Constraints on values
- Dependencies (relationships to other variables)
- Histories (previous values)

1.3 Metaclasses

Classes themselves are instances of some class. Metaclasses are classes whose instances are classes. When a class is sent a message, its metaclass determines the response. For example, instances of a class are created by sending the class the message **New**. This message is handled by the class that describes the class receiving the message. For most classes, this method is provided by the standard metaclass for classes **Class**.

To create a new class, send a message to the class **Class**. The class that handles this message is **MetaClass**. Instances of **MetaClass** are classes that describe objects which are classes. Instances of **Class** are classes whose instances are not classes. Figure 1-7 shows an instance of **MetaClass**, which is a class named **Class**, and instances of Class, which are named **Window** and **Point**.

Another class available in the system in **AbstractClass**. This is useful when creating classes that implement general functionality, which must then be specialized into instantiable classes. Instances of this class are classes that are impossible to instantiate. An example of an **AbstractClass** is **ActiveValue**, which is described in Chapter 5, Active Values.

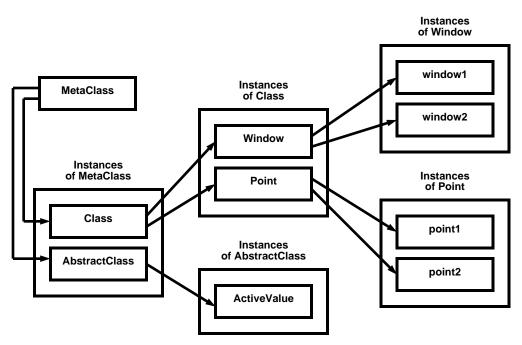

Figure 1-7. A Metaclass and its Instances

1.4 Introduction to Inheritance

Inheritance allows you to organize information in objects. With a few incremental changes, you can use inheritance to create objects that are almost like other objects. Inheritance allows you to avoid specifying redundant information and simplifies updating, since information that is common to several objects need be changed in only one place.

LOOPS objects exist in an inheritance network of classes. Figure 1-8 shows an example in which a class **3DPoint** is a subclass of another class **Point**. Instances of **3DPoint** contain instance variables that are defined in

Point as well as **3DPoint**. **Point** is referred to as a superclass of **3DPoint**. When an instance of **3DPoint** is created, the instance variables it contains and the messages to which it responds are not limited to those instance variables or methods as defined in the class **3DPoint**. For example, the object **pt2** contains three instance variables; two of them are inherited from the class **Point** and the other defined in the class **3DPoint**. This instance can also respond to three different messages containing one of the three different selectors: **selector1**, **selector2**, or **selector3**.

All descriptions in a class are inherited by a subclass unless overridden in the subclass. For methods and class variables, this is implemented by a runtime search for the information, looking first in the class, and then at the superclasses specified by its supers list. For instance variables, no search is made at run time. Default values are cached in the class, and are updated if any superclass is changed, thus maintaining the same semantics as the search. Each class can specify inheritance of structure and behavior from any number of superclasses.

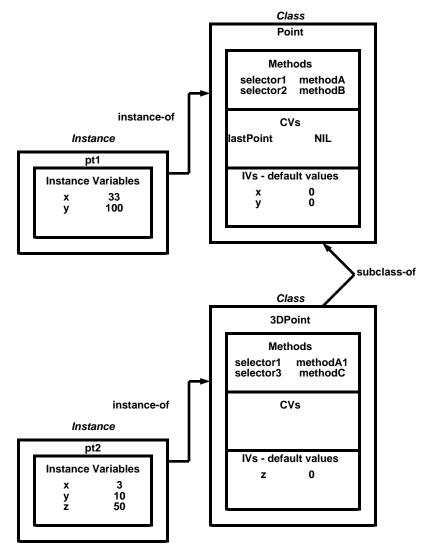

Figure 1-8. A Sample Inheritance Network

1.4.1 Single Superclasses

In the simplest case, each class specifies only one superclass. If the class **A** has the supers list **(B)**, which is a one-element list containing **B**, then all of the instance variables specified local to **A** are added to those specified for **B**, recursively. That is, **A** gets all those instance variables described in **B** and all of **B**'s supers. For example, in Figure 1-9, **A** has instance variables **x**, **z**, and **B1**.

Any conflict of variable names is resolved by using the description closer to **A** in traversing up the hierarchy to its top at the class **Object**. Method lookup uses the same conflict resolution. The method to respond to a message is obtained by first searching in **A**, and then searching recursively in **A**'s supers list. For example, in Figure 1-9, the method **selector2** uses **methodA2** instead of **methodB2**.

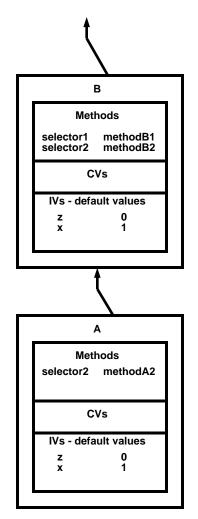

Figure 1-9. A Class with a Single Superclass

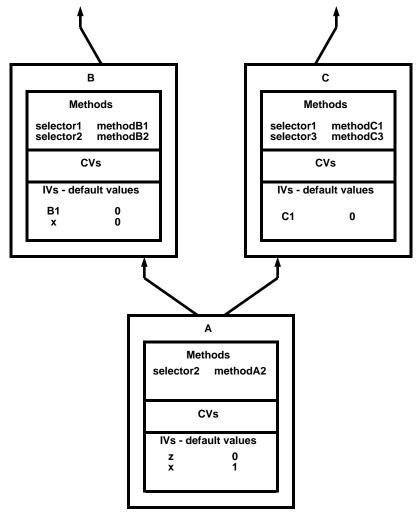

1.4.2 Multiple Superclasses

Classes in LOOPS can have more than one class specified on their supers list. Multiple superclasses permit a modular programming style where the following conditions hold:

- Methods and associated variables for implementing a particular feature are placed in a single class.
- Objects requiring combinations of independent features inherit them from multiple supers.

As in Figure 1-10, if **A** has the supers list (**B C**), first the description from **A** is used, then the description from **B** and its supers is inherited, and finally the description from **C** and its supers. In the simplest usage, the different features have unique variable names and selectors in each super. In case of a name conflict, LOOPS uses a depth first left-to-right precedence.

For example, if any super of **B** had a method for **selector3**, then it would be used instead of the method **methodC3** from **C**. In every case, inheritance from **Object** is only considered after all other classes on the recursively defined supers list. The general rule is left-to-right, depth first, up to where the separate branches of the hierarchy join together; that is, up to any class that is repeated. Alternatively, consider the list as generated by listing all the

superclasses in a depth first left-to-right order, eliminating all but the last occurrence of a class in the list.

Figure 1-10. A Class with Multiple Superclasses

1.5 Introduction to Access-Oriented Programming: Using Active Values

In access-oriented programming, you can specify a particular procedure to invoke for reqad or write access of any variable of an object. LOOPS checks every object variable access to determine whether the value is marked as an active value. An active value is a LOOPS object. If a variable is marked as an active value, then aa message is sent to the active value object whenever the variable is read or set. This mechanism is dual to the notion of sending messages. Messages are a way of telling objects to perform operations, which can change their variables as a side effect. Active values are a way of accessing variables, which can send messages as a side effect.

The messages sent to the active value object will depend on the type of access If you try to read a variable, the message **GettingWrapped Value** is sent to the active value object. If you try to set a variable, the message **Putting Wrapped Value** is sent. The object receiving the message may or may not trigger side effects as the result of receiving these messages. In this way, you have control over the side effects that may occur as a result of accessing data.

Active values enable one process to monitor another one. For example, LOOPS has debugging tools that use active values to trace and trap references to object variables. A graphics module updates views of particular objects on a display when their variables are changed. In both cases, the monitoring process is invisible to, and isolated from, the monitored process. No changes to the code of the monitored object are necessary to enable monitoring.

Active values can also be used to maintain constraints among data in a system. As one piece of data changes, the active value associated with that data can contain functionality that updates other data within the system. Examples of this are spreadsheets or electric circuit modeling.

A powerful feature of active values is that they can be nested to yield a natural composition of the access functions.

1.6 Introduction to the LOOPS User Interface

A key feature of LOOPS is its smooth integration with the Venue Medley environment. Many of the tools within Medley have been extended to provide the necessary functionality for manipulating objects. Among these tools are the following:

- SEdit
- The inspector
- Masterscope
- The File Manager
- The Library Module Grapher

This section describes how LOOPS interfaces with each of these Medley tools.

Another aspect of LOOPS is that objects have a name space that is separate from the Lisp name space. LOOPS names are Interlisp symbols. Applying a LOOPS function **\$** to a Medley symbol extracts a pointer to a LOOPS object. Objects can also be pointed to as a Lisp value.

1.6.1 SEdit

Class structures are Lisp data types. To change a class structure, LOOPS creates a list structure source for the class definition. This list can then be edited easily by SEdit. Upon exiting SEdit, the list structure is converted back to a data type. This process of converting to and from a list is hidden from view.

1.6.2 Inspector

Inspector macros have been defined within LOOPS that allow you to view the necessary class and instance data while hiding implementation details. Inspectors opened on classes or instances also provide functionality for changing the way one views an object. As an example, you can inspect a class and see or not see information inherited from its superclasses.

1.6.3 Masterscope

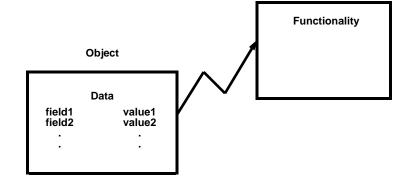

The Library Module Masterscope has been extended to a LOOPS Library Module so that message sending and the use of instance and class variables are understood. The functionality of CHECK has been extended to allow consistency checking of LOOPS methods.

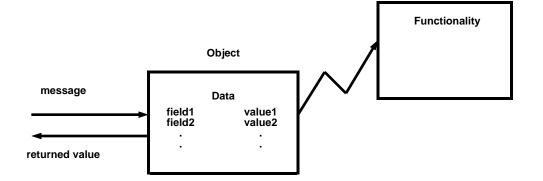

1.6.4 File Manager

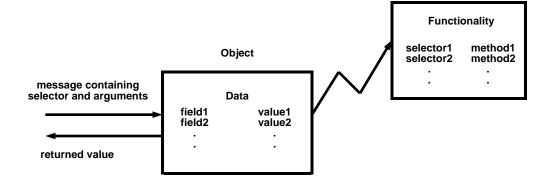

Additional File Manager commands have been added to allow you to save classes, instances, and methods on files.

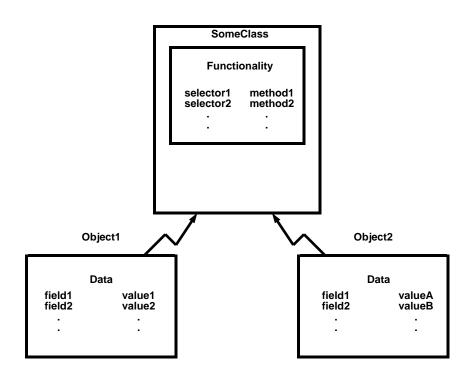

1.6.5 Grapher Module

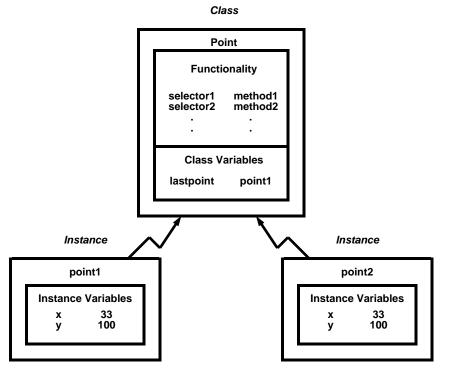

An important part of the LOOPS interface is its ability to show relationships between objects and to enable the programmer to easily manipulate those objects. Browsers of various kinds are in the system to allow you to understand the relationships between classes and how those classes are related to files. The browsers are built upon the Library module Grapher. You can easily extend the built-in browsers to create views onto any object relationship. An example of this is a decision tree where each node was an object representing a particular state of a system. [This page intentionally left blank]

20. SYSTEM VARIABLES AND FUNCTIONS

GLOSSARYGL	_OSSARY-1

Every object within the LOOPS system is an instance of some class. In this manual, however, the word instance generally refers to objects that are not themselves classes. Instances are a data type that contain local storage for instance variables, a pointer to the class that describes the instance, the Unique Identifier (UID), and other information.

This chapter describes naming and creating instances, accessing data stored within instances or pointed to by instances, and other related topics.

2.1 Instance Naming Conventions

	A separate name space for LOOPS objects is maintained by the LOOPS system within a separate object name table. Since Lisp structures and LOOPS objects are stored in separate name tables, you can use the same symbol to refer to both a Lisp structure and a LOOPS object.
	Note: The separate name space is not implemented by using the Common Lisp Package System.
	Instances are not created with names; therefore, it may be necessary to keep pointers to them. Two ways are available to create pointers:
	Use Lisp variables, as in:
	(SETQ window1 ((\$Window) New))
	This creates an instance of the class Window that can be referenced by the Lisp variable window1 .
	 Use a LOOPS name. This can be done in two ways:
	 Assign a name at the same time the instance is created. This can be done by using
	$(\leftarrow (\$ Window) New 'window2)$
	as described above. This creates an instance of the class Window that can be referenced by the LOOPS expression (\$ window2).
	 Use the message SetName if you have a pointer to an object and want to assign a LOOPS name to that object.
	The following table shows the items that manipulate LOOPS names.
Name	Type Description
\$	NLambda Distinguishes between the Lisp value of a symbol and the LOOPS value of the same symbol; does not evaluate its argument.

	\$!	Function	Distinguishes between the Lisp value of a symbol and the LOOPS value of the same symbol; evaluates its argument.
	SetName	Method	Assigns a LOOPS name to an object.
	UnSetName	Method	Removes a name pointer to an object.
	Rename	Method	Changes the name of an object.
	GetObjectNames	Function	Returns the names of an object, including its UID.
	ErrorOnNameConflict	Variable	Causes a break to occur when an attempting to name an object that already has a LOOPS name.
(\$ name)			[NLambda and Macro]
(+	Duma a a /Dahautiam	Determent	· · · · · · · · · · · · · · · · · · ·
	Purpose/Behavior:	no object exi	inter to a LOOPS object specified by the LOOPS name <i>name</i> . If sts for <i>name</i> , NIL is returned.
	Arguments:	name	A LOOPS name.
	Returns:	Pointer to a L	_OOPS object or NIL; see Behavior.
	Example:	Given that	
			Window) New 'window2) dow (NEW0.1Y%:.;h.eN6 . 495))
		then	
		25←(\$ win #,(\$& Wind	dow2) dow (NEW0.1Y%:.;h.eN6 . 495))
			value is a pointer to the new window instance. For a further see Chapter 18, Reading and Printing.
<u>(\$! name)</u>			[Function]
	Purpose/Behavior:	Returns a po given that the returned.	inter to an object specified by the value of the variable <i>name</i> , a value is a LOOPS name. If no object exists for <i>name</i> , NIL is
	Arguments:	name	Evaluates to a valid LOOPS name.
	Returns:	Pointer to a L	_OOPS object or NIL; see Behavior.
	Example:	Given that	
		26←(SETQ Window	foo 'Window)
		and Window	r is a LOOPS object, then
		27←(\$! fc #,(\$C Wind	

(← self SetName name)	[Method of Object]
Purpose:	Assigns a LOOPS name to an object.
Behavior:	If <i>name</i> is NIL, then a break occurs. If <i>name</i> is not a symbol, a break occurs. If <i>name</i> is already in use as a LOOPS name, and if the variable

ErrorOnNameConflict is non-NIL, then a break occurs, giving you the chance to OK "rebinding" *name*.

- Note: If an object has multiple names, (← *self* **SetName** *NewName*) results in both the old name and new name appearing when (FILES?) is executed. The instance is also printed twice on the file if both names are specified to be saved.
- Arguments: self An object.
 - name The LOOPS name to be given to the object; must be a symbol.

Returns: self

Categories: Object

Specializations: Class

Example: Given the commands

28←(SETQ window1 (← (\$ Window) New)) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 496))

29←(← window1 SetName 'window3) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 496))

the Lisp variable **window1** and the LOOPS expression

(\$ window3)

now point to the same object.

$(\leftarrow self UnSetName name)$

[Method of Object]

[Method of Object]

- Purpose: Removes a LOOPS name pointer to an object.
- Behavior: Removes the reference of *name* to *self* from the object name table maintained by the LOOPS system. If *name* is NIL, all names pointing to *self* in the object name table are removed from the files on **FILELST**. If *name* is non-NIL and the instance is associated with any files on **FILELST**, the instance is removed from those files. If *name* is not a valid LOOPS name for the object in question, an error occurs.
- Arguments: self An object.
 - name A LOOPS name.
 - Returns: Used for side effect only.

Categories: Object

(← self Rename newName oldNames)

Purpose:Changes the name of an object.Behavior:If oldNames is NIL, removes all old names when newName is installed as the
name for self; otherwise replaces only names specified in oldNames by
newName. If oldNames is not a valid LOOPS name for the object in question,
an error occurs.Arguments:selfEvaluates to a LOOPS name.
newNameThe LOOPS name to be given to the object; must be a symbol.

	oldNames	List of symbols whose names are to be removed; if NIL, all old names are removed when <i>newName</i> is installed as the name for <i>self</i> .
Returns:	self	
Categories:	Object	
Specializations:	Class	
Example:	Examine the	e following expressions to see the effects of Rename .
	30←(\$ wi: #,(\$& Win	ndow2) dow (NEW0.1Y%:.H53.G2A . 496))
		\$ window2) Rename 'MyWindow) dow (NEW0.1Y%:.H53.G2A . 496))
	32←(\$ wi: NIL	ndow2)
	33←(\$ My #,(\$& Win	Window) dow (NEW0.1Y%:.H53.G2A . 496))

(GetObjectNames object)

[Function]

Purpose/Behavior:	Returns the names of object, including its UID.		
Arguments:	object A LOOPS object.		
Returns:	The names of <i>object</i> , including its UID.		
Example:	The command		
	(PROGN (← (\$ Window) New 'w1) (← (\$ w1) SetName 'w1again) (GetObjectNames (\$ w1)))		
	returns		
	(wlagain wl (NEW0.1Y%:.H53.G2A . 497))		
ErrorOnNameConflict		[Variable	
Purpose/Behavior:	Behavior depends on the value.		
	• If NIL, the existing object is replaced by a new object.		
	 If non-NIL, a break occurs when an attempt is made to give a name that is already in use as a LOOPS name. 	an object a	

Initially, the value for ErrorOnNameConflict is NIL.

2.2 Creating Instances

When an instance is created by sending the **New** message to a class, the default behavior for **Class.New** is to send the message **NewInstance** to the newly created object. If you require that special or additional operations occur at instance creation time, specialize the method **NewInstance**.

Specializations of the **NewInstance** method should return *self*. You also have the capability to pass arguments to the **NewInstance** method when the **New** message is sent to create the instance. For example, the following defines a class **NamedClass** which adds the instance variable **name** and specializes **New** to set that instance variable to the name of the instance when created.

(DefineClass 'NamedClass) (←(\$ NamedClass) AddIV 'name) (DefineMethod (\$ NamedClass) 'New '(self name) '(←@ (←self NewIstance name) name name))

You can also indicate whether instances are to be saved on files using the File Manager, which is described in Chapter 14, File Manager.

The following table shows the methods in this section.

Name	Туре	Description
New	Method	Creates a new object of a particular class.
←New	Macro	Creates an object and sends a message to it.
NewInstance	Method	Allows initialization of newly created instances by class.
NewWithValues	Method	Creates an object with instance variables of assigned values.

(← class **New** name arg1 arg2 ...) [Method of Class] Purpose: Creates a new object, which is an instance of the class class. Creates a new instance name and then sends the message Behavior: (\leftarrow "the new instance" **NewInstance** name arg1arg2 ...) In the default case, the New method uses the default values for the instance variable values in the newly created instance. These default values are given in the instance variable descriptions of the given class. When that process is finished, the instance can be altered in various ways by sending it messages. Specializations of the New method should return the new instance, and can take more arguments after name. The internal data structure of an instance contains a pointer to the class of which it is an instance. Arguments: Pointer to a class. class name Name assigned to the instance; if NIL, object does not have a LOOPS name. Arguments passed to the **NewInstance** method. arg1arg2... Returns: Newly created instance of the class. Class Categories: Specializations: AbstractClass, MetaClass Example: The following command creates a new instance named **window1** of class Window. $20 \leftarrow (\leftarrow (\$ Window) New 'window1)$ #,(\$& Window (NEW0.1Y%:.;h.eN6 . 515)) The command

 $21 \leftarrow (INSPECT (\leftarrow (\$ Window) New))$

results in the following inspector window:

All Value:	s of Window (\$ window1).	
left	NIL	
bottom		
width		
height		
	<pre>#,(\$AV Lisp\indowAV</pre>	((YI
title	NIL	
menus	Т	

Some of the values assigned to the various instance variables are default values. These values are defined in the class **Window**.

(← New class selector args)		[Macro]
Purpose:	Creates a	n instance and sends a message to it within one form.
	← New is	pronounced "send new."
Behavior:	Is equivale	ent to the form
	(← (← cla	ss New) selector args)
Arguments:	class	Evaluates to a class.
	selector	Name of the message to be sent to the new instance.
	args	Arguments to be sent to the function invoked by the message.
Returns:	The new i	nstance.
Example:	The comm	hand
	23←(←N	ew (\$ Window) Open)
		new instance of the class Window and then sends the message ne newly created object.
(\leftarrow self NewInstance name arg1		
	arg2 arg3 a	arg4 arg5) [Method of Object]
Purpose:	Allows init	ialization of newly created instances by the class of the instance, as the metaclass. Subclasses of Object that specialize this method ve a \leftarrow Super form within the method to allow the execution of the

This allows you a the :initForm behavior by setting values for instance variables ecuting the ←Super form. See the discussion of :initForm in
Purpose:	Allows init opposed t should ha default be Not norma is as follow If name is Within sel have an :i to override before exe Section 2. Sends the	 ialization of newly created instances by the class of the instance, as o the metaclass. Subclasses of Object that specialize this method ve a ←Super form within the method to allow the execution of the havior. illy called directly, but is sent by method New. The default behavior vs. non-NIL, the message SetName is sent to self. f, instance variables that are bound to the value of NotSetValue and nitForm property in the class description are filled. This allows you a the :initForm behavior by setting values for instance variables ecuting the ←Super form. See the discussion of :initForm in 3, "Data Storage in Instances at Creation Time."

[Method of Class]

- LOOPS name given to a new instance. name
- Optional arguments referenced by user-written specialization arg1...arg5 code.
- Returns: LOOPS name of new object created.

Categories: Object

Specializations: IndexedObject

(← class NewWithValues valDescriptionList)		
Purpose:	Creates a new object and initializes the instan valDescriptionList.	nce variables specified in
Behavior:	Creates the object with no other initialization.	directly installs the value

ctly installs the values and property lists specified in valDescriptionList, and returns the created object. Variables that have no description in valDescriptionList are given no value in the instance and thus inherit the default value from the class.

> NewWithValues does not invoke the NewInstance method or the :initForm properties (see Section 2.3, "Data Storage in Instances at Creation Time"). This means that the instance is not recognized by the File Manager; to be recognized, the instance must be named.

- Arguments: class Pointer to a class.
 - valDescriptionList

Evaluates to a list of value descriptions, each of which is a list of variableNames and properties, for example,

((VarName1 value1 prop1a propVal1a prop1b propVal1b ...) (VarName2 value2 prop2a propVal2a prop2b propVal2b ...) ...)

- Returns: The created object.
- Categories: Class
- Specializations: MetaClass

Example: The command

22←(INSPECT (← (\$ Window) NewWithValues '((width 300)(height 200))))

results in the following inspector window:

All Value:	s of Window (<mark>\$ (M</mark> WX0.;F5.o28.Z;*
	NIL
bottom	
width	
height	200
window	#,(\$AV Lisp∀indowAV ((YI
title	NIL
menus	T

Contrast the values for the instance variables width and height with the inspector window for New, above.

2.3 Data Storage in Instances at Creation Time

		assigned to value of the Trying to acc	tance is first created, the value of the variable NotSetValue is its instance variables. NotSetValue is initialized to be an active class NotSetValue and should not be changed by the user. cess an instance variable triggers this active value which in turn method IVValueMissing .	
		Data is stored in instances on all Puts and on GetValues when the default value is an active value but not NotSetValue . Be aware that in reading the value of an instance variable that is not stored in the instance, changes in the default value of the instance variable in the class description are seen in accesses of the instance.		
		One exception to this method of data storage at creation time is if an instance variable has the property :initForm in the class description. In this case, data is stored in the instance at the time of creation.		
		Testing for whether data is stored locally in the instance can be done in two ways:		
		 Through the user interface, you can inspect an instance in the local mode. (See Chapter 18, User Input/Output Modules, for more information.) Values not locally stored appear as #,NotSetValue. 		
		 Programmed Programmed Programme	natically, through the function GetIVHere with the macro Ilue.	
		The following	g table describes the items in this section.	
	Name	Туре	Description	
	IVValueMissing	Method	Handles cases when an attempt is made to access the value of an instance variable that is not stored in an instance.	
	NotSetValue	Macro	Determines if its argument is equivalent to the value of NotSetValue .	
	NotSetValue :initForm	Macro IV Property	NotSetValue.	
			NotSetValue.	
(← self l		IV Property	NotSetValue. Signals a property value that can be evaluated.	
(← self ľ	:initForm	IV Property me propName Invoked by t an instance	NotSetValue. Signals a property value that can be evaluated.	
(← self ľ	:initForm VValueMissing varNai	IV Property me propName Invoked by t an instance the system o	NotSetValue. Signals a property value that can be evaluated. typeFlg newValue) [Method of Object] he system to handle the cases when you try to access the value of variable that is not stored in an instance. This is the mechanism	
<u>(← self ľ</u>	: initForm <u>VValueMissing</u> varNat Purpose:	IV Property me propName Invoked by t an instance the system of Varies accord	NotSetValue. Signals a property value that can be evaluated. typeFlg newValue) [Method of Object] he system to handle the cases when you try to access the value of variable that is not stored in an instance. This is the mechanism uses to access default values. rding to the functionality that invoked it. Only accesses return the default value of the instance variable	
<u>(← self ľ</u>	: initForm <u>VValueMissing</u> varNat Purpose:	IV Property me propName Invoked by t an instance the system u Varies accor • GetValue stored in the in the class a copy of	NotSetValue. Signals a property value that can be evaluated. typeFlg newValue) [Method of Object] he system to handle the cases when you try to access the value of variable that is not stored in an instance. This is the mechanism uses to access default values. rding to the functionality that invoked it. Only accesses return the default value of the instance variable	

• **PutValue** accesses store the new value in the instance unless the default value of the instance variable stored in the class is an active value. If this is the case, a copy of the active value is made, stored in the instance, and sent the **PutWrappedValue** message.

Arguments: *varName* Instance variable name.

	propName	Property name for instance variable varName.
	typeFlg	Used internally to indicate the type of access.
	newValue	If called by PutValueOnly or PutValue , this is the value to be placed into the instance variable or property name.
Returns:	Value deper	nds on the functionality that invoked this method; see Behavior.
Categories:	Object	

(NotSetValue arg)

[Macro]

(NotSetValue arg)	[Macro]
Purpose:	Determines if <i>arg</i> is EQ to the value of NotSetValue .
Arguments:	arg Any value.
Returns:	NIL or T.
Example:	Given that
	51←(← (\$ Window) New 'w) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 515))
	then
	52←(NotSetValue (GetIVHere (\$ w) 'title)) T
:initForm	[IV property]
Purpose:	This allows instance variables to be initialized at the time of the creation of an instance. The :initForm property and its value are in the class definition. Its value is a form that is evaluated when an instance is created. The result of the evaluation is stored as the value of the instance variable containing this property in the newly created instance.
	This behavior does not hold if the value of the instance variable is not NotSetValue . Refer to the method Object.NewInstance in Section 2.2, "Creating Instances," for more information.
Example:	Given the commands
	53←(DefineClass 'testclass) #,(\$C testclass)
	54←(AddCIV (\$ testclass) 'date NIL '(:initForm (DATE))) date
	then
	$55 \leftarrow (INSPECT (\leftarrow ($ testclass) New))$
	returns the following inspector window:
	All Values of testclass (\$ (MWX0.;F date "30-Mar-88 13:53:37"

2.4 Changing the Number of Instance Variables in an Instance

An instance can contain more instance variables than are defined in the class that describes it. It is not possible to remove an instance variable from an instance if the instance variable is defined in the class.

When you try to access the value of an instance variable that is not defined as an instance variable in the instance, the **IVMissing** method is invoked.

The following table shows the functions and methods in this section.

Name	Туре	Description
AddIV	Function	Adds an instance variable to an instance.
AddIV	Method	Adds an instance variable to self.
DeletelV	Function	Removes an instance variable or property from an instance.
DeletelV	Method	Removes an instance variable or property from self.
ConformToClass	Method	Makes self contain only those instance variables that are defined or inherited by the class of <i>self</i> .
IVMissing	Method	Is sent by the system when an attempt is made to access an instance variable that does not exist. It is used for recovery.

(AddIV self name value propNam	ne)	[Function]	
Purpose:	Adds an ins	tance variable to an instance.	
Behavior:	Varies according to the arguments.		
		me is non-NIL and if <i>name</i> already exists, it is added as a property tance variable <i>name</i> with the value <i>value</i> .	
		Iready exists, and if <i>propName</i> is NIL, the value of the instance name is changed to <i>value</i> .	
	name is a	loes not exist and if <i>propName</i> is non-NIL, the instance variable added to the instance and given the value of the variable alue . It is given the property <i>propName</i> with the value <i>value</i> .	
	 If name a changed 	nd <i>propName</i> already exist, the value of the property <i>prop</i> is to <i>value</i> .	
Arguments:	self	A pointer to the instance.	
	name	The name of the instance variable to be added.	
	value	The value the new instance variable will be assigned.	
	propName	Property name of instance variable name; may be NIL.	
Returns:	Used for sid	e effect only.	
Example:	Given that		
	55←(← (\$	S Window) New 'w)	
	the commar	nd	
	56←(AddI	V (\$ w) 'left 1234)	
	changes the	value of the instance variable left to 1234. The command	

57←(AddIV (\$ w) 'foo 1234)

adds the instance variable foo to (\$ w) and gives it the value 1234.

(self AddIV name value propName)

[Method of Object]

Purpose:	Adds an instance variable to <i>self</i> .
Behavior:	Method form of the function AddIV.
Arguments:	See the function AddIV.
Returns:	NIL
Categories:	Object
Specializations:	Class
Example:	Given that
	$58 \leftarrow (\leftarrow (\$ Window) New 'w)$
	the command
	$59 \leftarrow (\leftarrow (\$ w) AddIV 'left 1234)$
	changes the value of the instance variable left to 1234. The command
	$60 \leftarrow (\leftarrow (\$ w) \text{ AddIV 'foo 1234})$
	adds the instance variable foo to (\$ w) and gives it the value 1234.

(DeletelV self varName propName)

[Function]

Purpose:	Removes an instance variable or property from an instance.		
Behavior:	Varies according to the arguments.		
	• If self does not have varName, an error occurs.		
	• If varNam	ne is defined in the class or a super class of self, an error occurs.	
	 If the instance self has varName, and propName is NIL, the instance variable is deleted. 		
	 If propName is non-NIL, it is deleted only if it is a locally stored property, that is, not defined in a class. If propName is not a property of varName or is defined in a class, no error occurs. 		
Arguments:	self	A pointer to the instance from which the instance variable is to be deleted.	
	varName	The name of the instance variable to be deleted.	
	propName	If non-NIL, specifies that a property, not an instance variable, is to be deleted.	
Returns:	If no errors o	occur, this returns <i>self</i> .	
Example:	The following	g command deletes the instance variable foo from (\$ w):	
	62←(Delet	teIV (\$ w) 'foo)	

(← self DeletelV varName propl	Vame)	[Method of Object]
Purpose:	Deletes an instance variable or property from self.	
Behavior:	Method version of the function DeletelV .	
Arguments:	See the function DeleteIV .	
Returns:	If no errors occur, this returns self.	
Categories:	Object	
(← self ConformToClass)		[Method of Object
Purpose/Behavior:	Makes <i>self</i> contain only those instance variables inherited by the class of <i>self</i> .	that are defined in o
Returns:	NIL	
Categories:	Object	
Example:	This example adds an instance variable to an ins ConformToClass removes it.	stance and shows how
	63←(← (\$ Window) New 'w1) (#,(\$& Window (MXWO.:F5.G18.Z:? .18))	
	64←(← (\$ w1) AddIV 'NewIV 1234) 1234	
	$65 \leftarrow (INSPECT (\$ w1))$	
	This produces the following inspector window:	
	All Values of Window (\$ w1). left NIL bottom NIL width 12 height 12 window #,(\$AV LispWindowAV ((YI title NIL menus T NewIV 1234	
	66←(← (\$ w1) ConformToClass) NIL	
	67←(INSPECT (\$ w1))	
	This produces the following inspector window:	
	All Values of Window (\$ w1). left NIL bottom NIL width 12 height 12 window #,(\$AV LispWindowAV ((YI title NIL menus T	
(← self IVMissing varName pro	ppName typeFlg newValue)	[Method of Object

Purpose: This message is sent by the system when an attempt is made to access an instance variable that does not exist. It is used for recovery.

Behavior: Varies according to the arguments.

- If the instance variable *varName* is now defined in the class, copy it to *self*. This can happen if the class was changed after the instance was created.
- If there is a class variable with the name *varName*, use it. The method of use is determined by the **:allocation** class variable property:
 - dynamicCached

Copy the class variable to self on puts or gets.

- dynamic

Copy the class variable to *self* on puts. If the access is by **GetValue** or **GetValueOnly**, then get the value from the class. The value retrieved from the class is dependent on the value of *propName* and the class variable property :**initform**. If *propName* is NIL and there is a class variable property :**initform**, then retrieve the value returned from evaluating :**initform**. Otherwise, retrieve the value of the class variable *varName* if *propName* is NIL or the value of the property *propName* if it is non-NIL.

- class (the default if there is no :allocation property)

Do not copy the class variable *varName* to *self*. On puts, store the value in the class. With gets, do the same as the case when the **:allocation** property is dynamic. Essentially, this allows you to access class variables with the same syntax as instance variables.

An attempt is made to correct the spelling of *varName* and try the above steps again before breaking.

Arguments:	self	self A pointer to the instance.	
	varName	Instance variable name for self.	
	propName	Property name of instance variable varName.	
	typeFlg	One of PutValue, PutValueOnly, GetValue, GetValueOnly.	
	newValue	Value to be stored in <i>varName</i> .	
Returns:	If doing a pu instance var	it, this returns <i>NewValue</i> ; else this returns the value of the rable name.	
Categories:	Object		
Example:	If w1 is a Window, then the following command breaks under Object.IVMissing because windows do not have an instance variable named mumble.		
	(← (\$ w1) Get 'mumble)	

2.5 Moving Variables

	These functions allow you to move variables between classes.		
Name	Туре	Description	
RenameVariable	Function	Changes a variable name in a class.	
MoveVariable	Function	Moves an instance variable from one class to another.	

MoveClassVariable Function Moves an class variable from one class to another.

(RenameVariable	classivame	oldvarivame	newvarivame	classvar-iq)

[Function]

Purpose:	Changes oldVarName to newVarName in class className.		
Behavior:	Can cause inconsistency without warning; does not test for references to the variable in methods of <i>className</i> .		
Arguments:	className Class in which function is defined.		
	oldVarName Old name of variable.		
	newVarName New name of variable.		
	classVarFlg If not NIL, then oldVarName refers to a class variable.		
Returns:	If successful, returns newVarName; else NIL.		
Example:	The following command renames the class variable OldVar to NewVar .		
	27←(RenameVariable (\$ MyClass) 'OldVar 'NewVar T)		

(MoveVariable oldClassName newClassName varName)

Purpose:	Moves an instance variable from oldClassName to newClassName.		
Behavior:	Moves both the <i>varName</i> instance variable and its description to <i>newClassName</i> . Deletes <i>varName</i> from <i>oldClassName</i> .		
Arguments:	oldClassName Source class.		
	newClassName Destination class.		
	varName Variable to be moved.		
Returns:	Used for side effect only.		
(MoveClassVariable oldClassNa	ame newClassName varName) [Functi	ion]	
(MoveClassVariable oldClassNa Purpose:	ame newClassName varName) [Functi Moves a class variable from oldClassName to newClassName.	ion]	
		ion]	
Purpose:	Moves a class variable from <i>oldClassName</i> to <i>newClassName</i> . Moves the class variable <i>varName</i> and its properties to <i>newClassName</i> .	ion]	

varName Class variable to be moved.

Returns: Used for side effect only.

2.6 Destroying Instances

A protocol allows you to customize the behavior of the system at insta destruction time. The naming convention is somewhat asymmetrical creation time. To programmatically influence instance creation, spec method NewInstance . To programmatically influence instance destr specialize the method Destroy . Include a (\leftarrow Super) in specialization Destroy to guarantee normal system behavior. The following table describes the methods in this section.		time. The naming convention is somewhat asymmetrical to that of e. To programmatically influence instance creation, specialize the wInstance . To programmatically influence instance destruction, ne method Destroy . Include a (\leftarrow Super) in specializations of guarantee normal system behavior.	
Name	Туре	Description	
Destroy	Method	Removes an object from the environment.	
Destroy!	Method	Removes an object from the environment. If the object is a class, it also destoys all subclasses.	
DestroyInstance	Method	Modifies the data structure of an instance as described above.	
$(\leftarrow self \text{ Destroy})$		[Method of Object]	
Purpose:	Removes a	n object from the environment.	
Behavior:	Sends the I self. Unma of the File N	DestroyInstance message with <i>self</i> as an argument to the class of rkedAsChanged is called to remove the instance from the notice <i>l</i> anager.	
Arguments:	self	A pointer to the instance.	
Returns:	Used for sid	le effect only.	
Categories:	Object		
Specializations:	Class, Dest	royedClass, IndexedObject, Window	
Example:	The following command destroys an instance named window1.		
	70←(← (;	\$ window1) Destroy)	
(← self Destroy!)		[Method of Object]	
Purpose/Behavior:	Removes a destoys all	n object from the environment. If the object is a class, it also subclasses.	
Arguments:	self	A pointer to the instance.	
Returns:	Used for side effect only.		
Categories:	Object		

Specializations: Class, DestroyedClass, DestroyedObject

(*class* **DestroyInstance** *instance*)

[Method of Class]

Purpose/Behavior: Destroys *instance* by overwriting its contents. When an instance is destroyed, several things occur:

• The instance is removed from any files on **FILELST**. See the *Interlisp-D Reference Manual*.

	 The instance is deleted from system hash tables used for maintaining object identities. 		
	 The class of the instance is changed to DestroyedObject. 		
	Other fields of the internal instance data structure are set to NIL.		
	lf an instanc for garbage	e is only pointed to by a LOOPS name, its data structure is freed collection.	
Arguments:	class	Class of instance.	
	instance	The instance being destroyed.	
Returns:	Used for side effect only.		
Categories:	Class		
Specializations:	MetaClass, DestroyedClass		

2.7 Methods Concerning the Class of an Object

Given an instance, you often need to manipulate the class of an instance. This section describes how to perform this manipulation.

Name	Туре	Description
ChangeClass	Method	Changes the class of an instance.
Class	Macro	Determines the class of an object.
Class	Method	Determines the class of an object.
ClassName	Function	Returns the class name of an object.
ClassName	Method	Returns the class name of an object.
InstOf	Method	Determines if self is an instance of a class.
InstOf!	Method	Determines if <i>self</i> is an instance of a class or any of its subclasses.

You can also compute a class corresponding to a Lisp data type for Lisp objects by using **GetLispClass**, described in Chapter 4, Metaclasses.

$(\leftarrow$ self ChangeClass newClas	[Method of Object]	
Purpose:	Changes the	e class of an instance.
Behavior:	Creates a blank instance of the <i>newClass</i> . Any instance variables that are locally stored within <i>self</i> are added to the new instance.	
	If <i>newClass</i> occurs.	is not the name of a class or a pointer to the class, an error
Arguments:	self	A pointer to an instance.
	newClass	Either the name of a class or a pointer to the class.
Returns:	self	

Categories: O	oject
Jategories: O	Sject

Specializations: IndexedObject

Example: Create an instance of class **Window** and assign a local value to the instance variable **width** - all other instance variables of (\$ w) lack local values. Then, when the class of (\$ w) is changed to **IndirectVariable**, (\$ w) will have all of the instance variables of its new class, plus the one instance variable of its old class which had a local value, **width**.

71 ← (← (\$ Window) New 'w)
#,(\$& Window (NEW0.1Y%:.;h.eN6 . 501))
72 ← (←@ (\$ w) width 123)
123
73 ← (← (\$ w) ChangeClass 'IndirectVariable)
#,(\$& IndirectVariable (NEW0.1Y%:.;h.eN6 . 502))

 $74 \leftarrow (\leftarrow (\$ w) \text{ Inspect})$

This produces the following inspector window:

All Values o	f Indi
object	NIL
varName	NIL
propName	NIL
type	NIL
width	123

(Class self)

[Macro]

Purpose:	Determines the class of an object.		
Behavior:	If self is a LOOPS object, return its class.		
	If self is not a LOOPS object, evaluate (GetLispClass self)		
Arguments:	self A pointer to a LOOPS or Lisp object.		
Returns:	Value depends on the arguments; see Behavior.		
Example:	Given that		
	75←(← (\$ Window) New 'window1) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 503))		
	then		
	76←(Class (\$ window1)) #,(\$C Window)		
	Note: If <i>self</i> is an annotated value, the method Class and the macro Class return different values. See Chapter 8, Active Values, for more information on annotated values.		
$(\leftarrow \textit{ self Class})$	[Method of Object]		
Purpose/Behavior:	Method version of the macro Class.		

Purpose/Behavior:	Method version of the macro Class.	
Arguments:	self	A pointer to a LOOPS object or a Lisp data structure.
Returns:	Value depends on the arguments; see Behavior of the macro Class.	
Categories:	Object	

Example: Given that $77 \leftarrow (\leftarrow (\$ Window) New 'window1)$ #,(\$& Window (NEW0.1Y%:.;h.eN6 . 504)) then $78 \leftarrow (\leftarrow (\$ window1) Class)$ #,(\$C Window) (ClassName self) [Function] Purpose: Returns the class name of the class of the object. Behavior: Varies according to the argument. • If self is a class, this returns the name of that class. If self is an instance, this returns the name of the class that describes that . instance. • If self is neither of these, an attempt is made to get the class of self by applying the function GetLispClass to self. If this returns NIL, the function LoopsHelp is called with the arguments self and "has no class name." Arguments: Can have multiple values; see Behavior. self

Returns: Value depends on the argument; see Behavior.

Example: The command 80←(ClassName (\$ Window))

returns

Window

(self ClassName)

Purpose/Behavior:

Arguments:

Method version of the function **ClassName**. See the function **ClassName**.

Returns:	Value depends on the arguments; see Behavior of the function ClassName .
Categories:	Object

(~ self InstOf class)

[Method of Object]

Purpose/Behavior:	Determines if self is an instance of class.	
Arguments:	self	A pointer to an instance.
	class	A symbol name of a class or a pointer to a class.
Returns:	T or NIL	
Categories:	Object	
Example:	Given that	
	83←(← (\$ Window) New 'w1) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 505))	

then $84 \leftarrow (\leftarrow (\$ w1) \text{ InstOf 'Window})$ T $85 \leftarrow (\leftarrow (\$ w1) \text{ InstOf } (\$ Window))$ T

(*self* **InstOf!** *class*)

[Method of Object]

[Method of Object]

Purpose:	Determines if self is an instance of class or any of class's subclasses.		
Behavior:	Tests if class of <i>self</i> is a subclass of <i>class</i> .		
Arguments:	self	A pointer to an instance.	
	class	A symbol name of a class or a pointer to a class.	
Returns:	Object		
Categories:	Object		

8	Copying Instances		
		This section	on describes the methods for copying instances.
	Name	Туре	Description
	СоруDеер	Method	Copies all nested objects, annotated values, and lists.
	CopyShallow	Method	Creates a new instance of the same class as <i>oldInstance</i> . Fills the instance variables of the new instance with the data contained in the old instance.

(← oldInstance CopyDeep newObjAList)

Purpose: Copies all nested objects, annotated values, and lists. All other values are shared, not copied. This method is similar to the Interlisp function COPYALL. Behavior: Creates a new instance of the same class as *oldInstance*. Fills the instance variables of the new instance with copies of lists, active values, and instances pointed to by oldInstance. Arguments: oldInstance A pointer to an instance. newObjAList An association list of old copied objects with their associated copies; used to allow copying of circular structures. Users typically let this argument default to NIL. The value of the new instance. Returns: Categories: Object Example: Create the class **CopyTest** with the following structure:

SEdit CopyTest Package; INTERLISP	
((MetaClass Class Edited%:	; Edited 22-Mar-88 ; 11:07 by jrb:
) (Supers Object) (ClassVariables) (InstanceVariables (var NIL) (list NIL) (instance NIL)) (WethodFns))	

Create the instance **CopyTest1** and initialize it as shown in the following inspector:

All Values of CopyTest (\$ CopyTest1).		
var	123	
var list	(ABC)	
instance	¥, (\$ CopyTest2)	

Now create a copy and inspect it.

(INSPECT (SETQ DeepCopy (← (\$ CopyTest1) CopyDeep)))

All Values	of Copy	yTest (\$ (M	UX0.;F5.G18.?7C.517)).	
var	123			
list	(ABC)			
instance	#,(\$&	CopyTest	(NUX0.%:F5.618.?7C .	518))

The value of the instance variable instance is different. Also,

```
(EQ (@ ($ CopyTest1) list)(@ DeepCopy list))
```

returns NIL.

[Method of Object]

- Purpose/Behavior: Creates a new instance of the same class as *oldInstance*. Fills the instance variables of the new instance with the data contained in the old instance.
 - Arguments: *oldInstance* A pointer to an instance.
 - Returns: A copy filled with the values shared by the instances.
 - Categories: Object
 - Example: Compare this example to the **CopyDeep** example above. Use the same **CopyTest1** instance as above.
 - (INSPECT (SETQ ShallowCopy (\leftarrow (\$ CopyTest1) CopyShallow)))

All Values	of CopyTest (\$ CopyTest1).
var	123
	(ABC)
instance	¥, (\$´CopyTest2)

The value of the instance variable instance is the same. Also,

(EQ (@ (\$ CopyTest1) list)(@ ShallowCopy list))

returns T.

2.9 Querying Structure of Instances

At run time, user-written code may need to determine the structure of some object which has been passed into it. This section describes the methods to do this.

Name	Туре	Description
HasCV	Method	Determines if a class variable can be accessed via self.
HasIV	Method	Determines if an instance variable can be accessed via self.
Inspect	Method	Inspects self as a class or instance.
ListAttribute	Method	Determines instance variable or instance variable property names contained in an instance.
ListAttribute!	Method	Recursively determines instance variable or instance variable property names contained in an instance.
WhereIs	Method	Searches the supers hierarchy to find a class where a specified name is defined.

(← self **HasCV** cvName propName)

[Method of Object]

Purpose:	Returns T if the class variable <i>cvName</i> (or its property <i>propName</i> if it is non- NIL) can be accessed via <i>self</i> , otherwise NIL.		
Behavior:		Sends the message HasCV to the class of <i>self</i> passing the arguments <i>cvName</i> and <i>propName</i> .	
Arguments:	self	A pointer to an instance or a class.	
	cvName	Class variable name	
	propName	Property name for class variable cvName.	
Returns:	T or NIL; se	e Behavior.	
Categories:	Object		
Specializations:	Class		
Example:	The followin RightButto	g command checks if an instance window1 has the class variable nItems :	
	87←(← (\$ T	<pre>window1) HasCV 'RightButtonItems)</pre>	

(self HasIV ivName propName)

Purpose/Behavior:	Returns T if the instance variable <i>ivName</i> (or its property <i>propName</i> if it is non-NIL) can be accessed via <i>self</i> ; otherwise NIL.	
Arguments:	self A pointer to an instance or a class.	
	ivName	Instance variable name.
	propName	Property name for instance variable ivName.
Returns:	T or NIL; se	e Behavior.
Categories:	Object	

Specializations: Class

$(\leftarrow self lnspect INSPECTLOC)$	[Method of Object]
Purpose/Behavior:	Inspects <i>self</i> as a class or an instance. Uses <i>INSPECTLOC</i> as the region for the inspector window if it is given.
Arguments:	self A pointer to an instance.
	INSPECTLOC The region for the inspector window. If NIL, the system prompts you to place the window.
Returns:	The Lisp window used by the inspector.
Categories:	Object
Example:	The following command inspects an instance (\$ window1)
	$88 \leftarrow (\leftarrow (\$ window1) \text{ Inspect})$
	This results in the following inspector window:
	All Values of Window (\$ window1). left NIL bottom NIL width 12 height 12 window #,(\$AV LispWindowAV ((YI title NIL menus T

(self ListAttribute type name)

Purpose:	Determines instance variable or instance variable property names contained in an instance.		
Behavior:	Converts <i>type</i> into uppercase on entry. The remaining behavior varies according to the arguments.		
	• If <i>type</i> is one of IV, IVPROPS, or NIL, and <i>name</i> is the name of an instance variable of <i>self</i> , this returns a list of property names of <i>name</i> that have property values locally stored in the instance.		
	 If type is IVS, this returns a list of the instance variable names of self, whether or not the values for the instance variables are locally stored. 		
	• If <i>type</i> is none of the above, this evaluates (← (Class <i>self</i>) ListAttribut <i>type name</i>).		
	Note: Using a <i>type</i> of SUPERS or SUPERCLASSES returns a list of the names of the super classes.		
Arguments:	self A pointer to an instance.		
	type See Behavior.		
	<i>name</i> If <i>type</i> is one of IV, IVPROPS, or NIL, then <i>name</i> is an instance variable of <i>self</i> ; else it is NIL.		
Returns:	Value depends on the arguments; see Behavior.		
Categories:	Object		

(self ListAttribute! type name verboseFlg)

Purpose:	Provides a recursive form of ListAttribute . Omits inheritance from the classes Object and Tofu unless <i>verboseFlg</i> is T.		
Behavior:	Converts <i>type</i> into uppercase on entry. The remaining behavior varies according to the arguments.		
	• If type is I	VS, this is the same as ListAttribute.	
		one of IV, IVPROPS, or NIL, and <i>name</i> is the name of an instance of <i>self</i> , this returns a list of property names of <i>name</i> .	
	 If type is r type nam 	none of the above, this evaluates (\leftarrow (Class <i>self</i>) ListAttribute! e).	
		ng a <i>type</i> of SUPERS or SUPERCLASSES returns a list of the less of the super classes.	
Arguments:	self	A pointer to an instance.	
	type	See Behavior.	
name		If type is one of IV, PROPS, or NIL, then <i>name</i> is an instance variable of <i>self</i> , else it is NIL.	
	verboseFlg	T or NIL; if T, inheritance from object and Tofu are included. If NIL, they are omitted.	
Returns:	Value depends on the arguments; see Behavior.		
Categories:	Object		
Specializations:	Class		
Example:	Given that		
	95←(← (\$ Window) New 'w1) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 515))		
	then		
	96←(← (\$ w1) ListAttribute! 'IV 'menus) (RightButtonItems doc TitleItems)		

(← self Wherels name type pr	name type propName)		
Purpose:	Searches s	upers hierarchy to find class where <i>name</i> is defined.	
Behavior:	Performs the method Class.ListAttribute for <i>self</i> and for each super <i>self</i> , checking to see if <i>name</i> (or <i>propName</i> as appropriate) is a mem- list returned. The value returned is the class where <i>name</i> (or <i>propNa</i> first found.		
		gument is changed to uppercase and then coerced to a valued ent for ListAttribute .	
	 If type is WhereIs 	one of METHOD, METHODS, NIL, or T, it becomes METHODS. then looks for a method with the name <i>name</i> .	
		one of IVPROP or IVPROPS, it becomes IVPROPS. WhereIs is for an instance variable property with the name <i>name</i> .	
		one of IV or IVS, it becomes IVS. WhereIs then looks for an variable with the name <i>name</i> .	
	 If type is class var 	one of CV or CVS, it becomes CVS. WhereIs then looks for a iable with the name <i>name</i> .	
Arguments:	self	A pointer to an instance.	
	type	See Behavior.	
	name	The name of an object attribute being searched for.	
	propName	Property name for instance variable name.	
Returns:	The class w	where name or propName is first found.	
Categories:	Object		
Example:	The comma	and	
	97←(← (+	← (\$ LatticeBrowser) New) WhereIs 'left 'IV)	
	returns		
	#,(\$C Wir	ndow)	

2.10 Other Instance Items

This section describes other items involved with instances.

NoValueFound			[Variable]
Purpose/Beł	navior:		as a result of various accesses; initially set to NIL. When developing nd this to the symbol NoValueFound to assist in debugging.
(NoValueFound arg)			[Macro]
Purpose/Beł	navior:	Returns va	lue of (EQ NoValueFound <i>arg</i>).
Argur	nents:	arg	Any value.
Re	eturns:	T or NIL.	

[Macro]

Purpose/Behavior:	Returns value of (NEQ NoValueFound arg).		
Arguments:	arg	Any value.	
Returns:	T or NIL.

Classes provide a description of instances within the object domain. The following information is contained within a class:

- The metaclass for this class. See Chapter 4, Metaclasses, for a discussion of metaclasses.
- Class Properties. Examples of class properties are an edit stamp and documentation.
- The supers list for this class. Classes exist in a hierarchy and the supers list places the class within that hierarchy. Instances of the class contain data and respond to messages that are described within the class and superclasses of the class.
- Class variables, their values, and their properties and values.
- Instance variables, their default values, and their properties and values.

This chapter covers creating and destroying classes, editing, accessing data stored in classes, inheritance, and related topics. Other chapters that contain information relevant to this chapter are Chapter 4, Metaclasses, since a metaclass is a class of classes, and Chapter 10, Browsers, since the primary user interface for manipulating classes is the browser.

3.1 Creating Classes

Several ways are available to create a class:

- Use the browser interface.
- Use function calling or message sending.
- Use dynamic mixins to dynamically create classes.

The rules for naming classes are the same as those for naming instances. Simply stated, a class name must be a litatom. One exception to this rule is the naming of dynamic mixin classes, which is discussed later in this chapter.

A class is generally referred to with this form: (\$ className). See Chapter 2, Instances, for more details regarding LOOPS names.

As discussed in Chapter 2, Instances, the protocol that is followed when instances are created is for the LOOPS system to send the **NewInstance** message to the newly created instance. The **NewInstance** message can be specialized to incorporate behavior specific to the creation time of an instance. Similarly, the system follows a prototol when creating a class using the **New** message. After the class is created, it is sent the **NewClass** message.

3.1.1 Function Calling and Message Sending

The following table shows the items in this section.

Name	Туре	Description
DefineClass	Function	Creates a new class.
New	Method	Creates a new class.
CreateClass	Method	Creates a new class.
NewClass	Method	Provides a placeholder for modifying the class creation protocol.

(DefineClass name supers self)

Purpose: Creates a new class. Behavior: If name is not a litatom, a break occurs. If supers is non-NIL, it should be a list of classes or names of classes to be the supers for the newly created class. If the list contains multiple classes, this results in a class that has multiple super classes (see Section 3.3, "Inheritance"). The order of classes in the list specifies the order in which lookup will proceed. If one of the these classes is not a valid class, a break occurs. If supers is NIL and if self is (\$ MetaClass), then the supers list is (Class). If both supers is NIL and self is NIL, the supers list is (Object). If self is non-NIL, it is installed as the metaclass for the newly created class. See Chapter 4, Metaclasses. A class is then built with an **Edited:** property containing the date and time and the value of variable INITIALS. (See the Interlisp-D Reference Manual.) The newly created class has no class variables, instance variables, or methods. The variable **LASTWORD** is set to *name*, which is added to **USERWORDS** for spelling escape completion. (See the Interlisp-D Reference Manual for information on LASTWORD and USERWORDS.) Arguments: A LOOPS name to be given to the class. name A list of classes. supers self A metaclass. Returns: The class object. Examples: The following command defines a subclass of the class **Object**. (DefineClass 'ExampleClass) The following command defines a subclass of the class **Window**. (DefineClass 'MyClass '(Window)) The following command defines a class with multiple supers: ExampleClass and Window. (DefineClass 'AnotherClass '(ExampleClass Window))

[Function]

The following command defines a subclass of the class **Window** that has **AbstractClass** as its metaclass.

(DefineClass 'DontMakeMe '(Window) (\$ AbstractClass))

(← class **New** name supers init1 init2 init3)

[Method of Metaclass]

[Method of Metaclass]

[Method of Class]

Purpose:	Creates a new class.		
Behavior:	Sends the message CreateClass to <i>class</i> , passing the arguments <i>name</i> and <i>supers</i> . This returns a new class which is then sent the message NewClass passing the arguments <i>init1</i> , <i>init2</i> , and <i>init3</i> .		
Arguments:	class	A pointer to a class.	
	name	A LOOPS name to be given to the class.	
	supers	A list of classes.	
	init1, init2, ir	<i>nti3</i> See Behavior.	
Returns:	The new class.		
Categories:	Object		
Specializes:	Class		
Specializations:	AbstractClass		
Example:	The following command creates the class, AClass , which is a subclass of the class Window . The metaclass of AClass is Class .		
	$(\leftarrow$ (\$ Class) New 'AClass '(Window))		
	After AClass	s is created, the system sends the following message:	
	(← (\$ AC	lass) NewClass)	

(← self CreateClass name supers)

Purpose:	Creates a new class.			
Behavior:	Method vers	Method version of DefineClass .		
Arguments:	self	A metaclass.		
	name	The name of the newly created class.		
	supers	A list of classes.		
Returns:	The clsss o	bject.		
Categories:	MetaClass			

(← class NewClass init1 init2 init3)

Purpose:	Provides a hook into class initialization. If you want special actions to occur when creating a class, specialize this method.		
Arguments:	class	A pointer to a class.	
<i>init1, init2, init3</i> Dependent on u		<i>nit3</i> Dependent on user-defined functionality.	

Returns: class

Categories: Class

Example: Create a subclass of **Class** called **MyClass**:

(DefineClass 'MyClass '(Class))

Give it a method **NewClass**:

(DefineMethod (\$ MyClass) 'NewClass '(init1 init2 init3)
'(PROGN (PutClass self init1 'prop1) self))

This looks like the following display editor window:

SEdit MyClass.NewCl	lass Package: INTERLISP
(Method ((MyClass)	NewClass) self init1 init2 init3
;; This dem	onstrates the NewClass protocol
(PutClass s	self init1 'prop1) self)

Now send the class MyClass the following command:

(\leftarrow (\$ MyClass) New 'testclass NIL "this is a test")

This results in the creation of the class shown in the following display editor window:

SEdit #,(\$C testclass) Packa	ge: INTERLISP			
((MetaClass MyClass Edited%:	; Edited 2-Dec-87			
	; 15:24 by			
	; Martin.pasa			
prop1 "this is a test")				
(Supers Object) (ClassVariables)				
(InstanceVariables) (MethodFns))				

To display the class, enter

 $(\leftarrow$ (\$ testclass) Edit)

3.1.2 Dynamic Mixins

In some programming situations, you may develop sets of mixins that are designed to be used together. (Mixins are classes that are used only in conjunction with another class to create a subclass, or provide some functionality useful in more than one class.) For example, the class **NamedClass** adds one instance variable **name** and specializes the **New** message to ensure that the instance variable **name** contains the name of the object.

(DefineClass 'NamedClass) (← (\$ NamedClass) AddIV 'name) (DefineMethod (\$ NamedClass) 'New '(self name) '(←@ (←self NewInstance name) name name))

Other classes that want the names of their objects in an instance variable **name** can use **NamedClass** as a mixin.

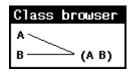

As another example, assume that you have one set consisting of A1, A2, A3, and A4 and another set containing B1, B2, and B3. Formerly, to allow creation of an instance taking properties from arbitrary combinations of an element from each set, you had to create in advance all 12 combinations of classes with a super from A and a super from B. This was even more cumbersome if the As and Bs can also combine with any of a set of 5 Cs.

What is desired is the ability to create combinations of these classes on the fly, without having to invent a name for each combination and without having each present in the system when only a few may be needed in any given application. To meet this need, LOOPS now provides the dynamic mixin class. The name of such a class is a list, in order, of the classes which are to be the supers of the class. Such a class is automatically created the first time it is referred to. Thus, the following sequence

(DefineClass 'A) (DefineClass 'B) (\leftarrow (\$ (A B)) New)

creates the class whose supers are **A** and **B** (if it did not already exist), and builds an instance of that class.

Dynamic mixins appear in browsers as shown in this sample window.

All of the browser operations still function on dynamic mixin classes.

These classes print as

#,(\$C (A B))

3.2 Destroying Classes

The following messages have been provided to destroy a class that has been created. Destroyed classes, if not being pointed to in some fashion, are eventually collected by the garbage collector.

The following table shows the methods in this section.

Name	Туре	Description
Destroy	Method	Removes a class from the LOOPS system.
Destroy!	Method	Destroys a class and its subclasses.
DestroyClass	Method	Destroys a class by deleting its contents.

(← class **Destroy**)

[Method of Class]

	Purpose:	Removes a class from the LOOPS system.			
	Behavior:	If <i>self</i> has any subclasses, a break occurs and you are prompted to determin if you want to use Destroy! .			
		Sends the message DestroyClass to the metaclass of <i>self</i> .			
		might have b If you specia	has of this method may be necessary to undo any actions that been performed by user specializations of the NewClass method. lize Destroy , be sure to include a \leftarrow Super to guarantee that the of the Destroy method is performed.		
A	Arguments:	class	Must be a class.		

Returns:	NIL
Categories:	Object
Specializes:	Object
Specializations:	DestroyedClass
Example:	The following command destroys the class Datum:
	(← (\$ Datum) Destroy)

(← class **Destroy!**)

[Method of Class]

[Method of Class]

Purpose:	Destroys a class and its subclasses.			
Behavior:	Recursively sends the Destroy message to <i>self</i> and its subclasses.			
Arguments:	<i>class</i> Must be a class.			
Returns:	NIL			
Categories:	Object			
Specializes:	Object			
Specializations:	DestroyedClass			

(< class DestroyClass classToDestroy)

Purpose:	Destroys <i>classToDestroy</i> by deleting its contents. This method is invoked the LOOPS system and should generally not be called directly by user co However, it can be specialized to change the way classes are destroyed.			
Behavior:	Performs the following actions:			
	 Removes classToDestroy from any files on FILELST. 			
	 Sends the Destroy! message to all methods locally associated with classToDestroy. 			
	 Removes classToDestroy from any subclass data contained in the supers of classToDestroy. 			
	 Changes the class name of classToDestroy to *aDestroyedClass*. 			
	 Changes the supers list of classToDestroy to DestroyedObject and Object. 			
	 Changes the metaclass of classToDestroy to DestroyedClass. 			
	Sets other fields of the internal class data structure to NIL.			
Arguments:	class Metaclass of classToDestroy.			
	classToDestroy Class to destroy.			
Returns:	NIL			
Categories:	Class			
Specializations:	DestroyedClass			

3.3 Inheritance

Classes exist in an ordered lattice or hierarchy. Information contained within a class - the supers list - defines where that class is located within the lattice. The supers list specifies the classes immediately above a given class. When an instance of a class is created, it contains not only the instance variables of the defining class, but also the instance variables of all of the classes above the defining class in the class hierarchy. When you try to determine the value of a class variable associated with an instance, all classes above the defining class may be searched. When you send a message to an instance, all classes above the defining class may be searched for the appropriate method.

There are two types of inheritance:

- Simple, in which a class has only one superclass.
- Multiple, in which a class has two or more classes on its supers list.

When an instance is created, it may contain an instance variable that is defined in more than one class. The default value for that instance variable depends on its inheritance. In the case of simple inheritance, the instance variable gets the value from the class that is lowest in the hierarchy. In multiple inheritance, the instance variable gets the value from the class that is lowest in an inheritance list. To create this list,

- 1. Put the first class that describes the instance.
- 2. Begin with the first class on its supers list and move up from it, making a list of classes which assume simple inheritance.
- 3. Build one of these lists for all successive super classes.
- 4. Append these lists together.
- 5. Remove all occurrences of any classes that appear in the list a multiple number of times except for the last entry.

Another way to think about this, which creates the same inheritance list, is the following:

- 1. Begin with the first super class and walk up the hierarchy until you reach a class where the inheritance paths merge.
- 2. Walk up each path leading from each successive super class to where paths merge.
- 3. Take the class where the paths merge and walk up from there.

As an example of simple inheritance, examine Figure 3-1 which shows some of the class variables and instance variables defined within each class.

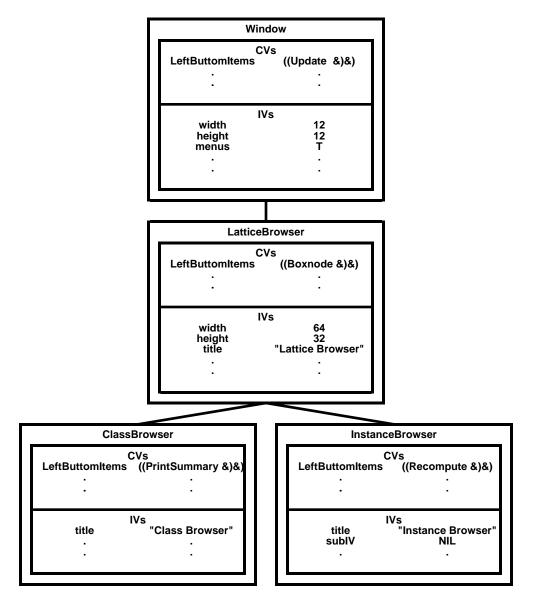

Figure 3-1. Simple Inheritance Lattice

An instance of the class ClassBrowser has this as an inheritance list:

ClassBrowser LatticeBrowser Window Object Tofu

The instance variable values of this instance are as follows:

IV	Value	From Class
title	"Class browser"	ClassBrowser
width	64	LatticeBrowser
height	32	LatticeBrowser
menus	Т	Window

Accessing the value of the class variable **LeftButtonItems** causes this value to come from the class **ClassBrowser**.

Figure 3-2 shows an example of multiple inheritance.

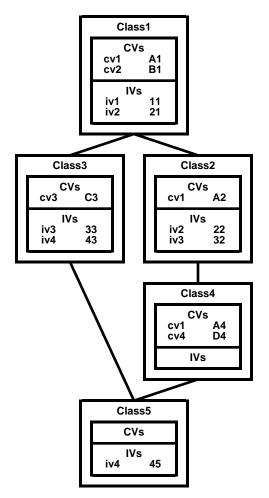

Figure 3-2. Multiple Inheritance Lattice

If the order of the supers for **Class5** is **Class3** and then **Class4** (that is, its supers list is (Class3 Class4)), then the inheritance list for an instance of **Class5** is as follows:

Class5
Class3
Class4
Class2
Class1

The instance variable and class variable values this instance are as follows:

IV	Value	From Class	CV	Value	From Class
iv1	11	Class1	cv1	A4	Class4
iv2	22	Class2	cv2	_	Class1
iv3	33	Class3	cv3	-	Class3
iv4	45	Class5	cv4	D4	Class4

3.4 Editing Classes

Changing the contents of a class typically involves using the display editor, although programmatical ways to make these changes are available. To edit a class structure, the LOOPS system first changes the structure to a list and then passes that list to the display editor. Upon exit from the display editor, the system translates the modified list back into the class structure.

The editor is most often called from the browser interface. (See Chapter 10, Browsers.) The following method provides a programmatical way to invoke the editor.

(•	<u></u>	class	Edit	commands

Purpose:	Edits a class definition.			
Behavior:	Calls EDITE (see the <i>Interlisp-D Reference Manual</i>) with the translated class structure passed as the EXPR argument and <i>commands</i> passed as the COMS argument.			
	This method binds the variable LASTCLASS to the class name of <i>self</i> .			
Arguments:	class Pointer to a class.			
	commands Commands passed to EDITE.			
Returns:	Name of the class.			
Categories:	Object			
Specializes:	Object			
Example:	The following command causes a display editor window to appear.			
	$(\leftarrow (\$ LoopsIcon) Edit)$			
	Calling the editor causes a structure to appear in a display editor window. At this time, you can change the structure of the class by using any of the following techniques:			
	 Changing the value of the class's metaclass. This is done by changing the class name after the word MetaClass. 			
	Changing the superclasses for the class. The form for this is:			
	(Supers class1 class2)			
	At least one class must be in the supers list. The order of this list determines the order of inheritance; the first class after the word Supers on this list is the first class to search for inherited data and methods.			
	 Adding or removing class properties. Class properties occur within the same list as MetaClass, after the metaclass class name. The form for this is 			
	(MetaClass metaclassName classProp1 propVal1 classProp2 propVal2)			
	 Adding or removing class variables or associated properties. The form for class variables is: 			
	(ClassVariables (cvName1 cvVal1 prop1a propVal1a prop1b propVal1b) (cvName2 cvVal2 prop2a propVal2a prop2b propVal2b))			

It is not necessary to have any properties for a class variable. If the length of each class variable list is not an even number, a break occurs under the editor. The message in the break window describes an odd length list the first time you try to exit from the editor.

 Adding or removing instance variables or associated properties. These have the same form as class variables with the distinction that the value listed for each instance variable is not its value, but only its default value for the purposes of instanciation.

For example, examine the display editor window in Figure 3-3.

Figure 3-3. Sample Display Editor Window

This figure shows the following information:

- The title bar of the display editor window indicates the class being edited.
- The metaclass of the class IndirectVariable in this example is the class Class. IndirectVariable has two class properties. The first is a doc property. The second is an Edited: property.
- This class has one super class: ActiveValue.
- This class has no class variables. It has four instance variables: object, varName, propName, and type. Each has a **doc** property.
- The MethodFns are listed in this structure as a convenience. It is not
 possible to add or delete elements of this list from the editor and have any
 changes actually occur. Selecting one of the method function names and
 then selecting Edit (Meta-O in SEdit) allows you to edit that method either
 as its method code (METHOD-FNS), its method object (METHODS), or its
 Interlisp code (FNS).

3.5 Modifying Classes

In addition to the editing technique for changing a class, you can use programmatic means to modify the structure of a class. This section describes the functions and methods for modifying classes.

Name	Туре	Description
Add	Method	Adds a component to a class.
Delete	Method	Deletes a component from a class.
DeleteClassProp	Function	Removes a class property from a class.

AddCV	Function	Adds a class variable to a class.
AddCV	Method	Adds a class variable to a class.
DeleteCV	Function	Deletes a class variable or one of its properties from a class.
AddCIV	Function	Adds an instance variable to a class; can also add properties to a class.
AddIV	Method	Adds an instance variable to a class.
DeleteCIV	Function	Removes an instance variable or property from a class.
ReplaceSupers	Method	Changes the super classes of a class.

(← class Add type name value prop)

[Method of Class]

[Method of Class)

Purpose/Behavior:	Adds a component to a class.		
Arguments:	class Pointer to a class.		
	type	One of IV, IVPROP, CV, CVPROP, METACLASS, or METHOD.	
	name The name of the item to be added.		
	value	The value, or default value if <i>type</i> is one of IV or IVPROP.	
	prop	The name of the property, if a property is to be added.	
Returns:	NIL		
Categories:	Class		
Example:	The following command adds a new instance variable color to class Datum :		
	(← (\$ Datum) Add 'IV 'color)		

(← class **Delete** type name prop)

Purpose:	Deletes a component from a class.		
Behavior:	Varies according to the arguments.		
	• If type is one of IV, IVPROP, or NIL, this calls (DeleteCIV class name prop)		
	• If type is	one of CV or CVPROP, this calls (DeleteCV class name prop).	
	 If <i>type</i> is META, METACLASS, or CLASS, and if <i>prop</i> is NIL, then the metaclass of <i>self</i> is changed to the class Class. If <i>type</i> is META, METACLASS, or CLASS, and if <i>prop</i> is non-NIL, then this calls (DeleteClassProp <i>class prop</i>). 		
	 If type is prop). 	METHOD or SELECTOR, this calls (DeleteMethod class name	
Arguments:	class	A pointer to a class.	
	type	See Behavior.	
	name	IV, CV, or selector name.	
	prop	A property name.	

Returns:	NIL
Categories:	Class
Example:	The following command deletes the instance variable color from the class Datum :
	(← (\$ Datum) Delete 'IV 'color)

(DeleteClassProp classRec propName)

[Function]

[Function]

Purpose:	Removes a class property from a class.	
Behavior:	Marks <i>classRec</i> as changed.	
Arguments:	classRec	Pointer to a class.
	propName	Property to be deleted.
Returns:	NIL is <i>propName</i> is not found; otherwise <i>propName</i> .	

(AddCV class varName newValue)

Purpose:	Adds a class variable to a class.		
Behavior:	Varies according to the arguments.		
	 If <i>varName</i> is NIL, you are prompted to enter a name. If <i>varName</i> is already a class variable, its value is changed to <i>newValue</i>. NIL is returned. If <i>varName</i> is not a class variable of <i>class</i>, it is added to <i>class</i> with the value <i>newValue</i>. Also, a doc property is added with the following value: (* CV added by , (USERNAME NIL T)) 		
	varName	e is returned in this case.	
Arguments:	class	A pointer to a class.	
	varName	Name of the new variable.	
	newValue	The new value.	
Returns:	Value depe	nds on the arguments; see Behavior.	
(← class AddCV varName new	Value)	[Method of Class]	
Purpose:	Adds a clas	s variable to a class.	

Purpose:	Adds a class variable to a class.
Behavior:	Provides a method version of the function AddCV.
Arguments:	See the function AddCV.
Returns:	NIL
Categories:	Class

(DeleteCV class varName prop)

Purpose: Deletes a class variable or one of its properties from a class.

[Function]

Behavior:	Marks class	as changed.
Arguments:	class	Pointer to a class.
	varName	Class variable name to be deleted.
	prop	Property to be deleted.
Returns:	NIL, if varName is not found, else varName.	

(AddCIV class varName defaultValue otherProps)

[Function]

[Method of Class]

- Purpose: Adds an instance variable, and perhaps properties, to a class.
 - Behavior: If the length of *otherProps* is odd, an error occurs.

The remaining behavior varies according to the arguments.

- If *varName* is NIL, you are prompted to enter a name.
- If *varName* is already an instance variable of *class*, then change its default value to *defaultValue*. Properties on *otherProps* are added or changed as necessary. NIL is returned.
- If *varName* is not an instance variable of *class*, it is added to *class* and its default value is *defaultValue*. Properties on *otherProps* are also added. If there is no **doc** property, it is added and given the following value:
 - `(* IV added by , (USERNAME NIL T))

varName is returned in this case.

Arguments:	class	Must be a pointer to a class.
	varName	New instance variable name.
	defaultValue	e New default value.
	otherProps	NIL or a list in property list format.
Returns:	Value deper	nds on the arguments; see Behavior.

(← class AddIV varName defaultValue otherProps)

Purpose: Adds an instance variable to a class. Provides a method version of the function AddCIV. Behavior: Arguments: See the function AddCIV. NIL Returns: Categories: Object Specializes: Object Example: Define a new class TestClass, add an instance variable testIV with two properties testProp1 and testProp2, all with initial values, and then prettyprint the class's variables. $64 \leftarrow (\text{DefineClass 'TestClass})$ #, (\$C TestClass) 65←(← (\$ TestClass) AddIV 'testIV 1234

Class Variables

(**DeleteCIV** class varName prop)

[Function]

Purpose:	Removes a	n instance variable or property from a class.	
Behavior:	If <i>class</i> doe	s not have <i>varName</i> , a break occurs.	
	Marks class	s as changed.	
Arguments:	class	Pointer to a class.	
	varName	Instance variable to be deleted.	
	prop	If non-NIL, property to be deleted.	
Returns:	Value depe	nds on the arguments.	
	• NIL for re	emoving an instance variable if successful.	
	• prop for	removing a property if successful.	
	• NIL if pro	op is not a property.	
(← class ReplaceSupers supe	rs)		[Method of Class]

Purpose:	Changes the super classes of a class.		
Behavior:	Checks that no circular lists can be made in the inheritance lattice.		
	 If the sup 	er class of <i>class</i> is Tofu, no change occurs.	
		is different from the current supers, the supers list of <i>class</i> is and <i>class</i> is marked as changed.	
Arguments:	class	Pointer to a class.	
	supers	A list of class names or classes.	
Returns:	NIL		
Categories:	Class		

3.6 Methods for Manipulating Class Names

LOOPS classes must have one and only one LOOPS name. The following functions and methods allow you to change and rename class names.

3.6 METHODS FOR MANIPULATING CLASS NAMES

Name	Туре	Description
Rename	Method	Changes the name of a class. Prompts for name if not provided, then calls SetName .
SetName	Method	Changes the name of a class.
UnSetName	Method	Unnames a class.
ClassName	Function	Finds the class name of an object.

(<-- class Rename newName)

[Method of Class]

[Method of Class]

Purpose:	Changes the name of a class. Prompts for name if not provided, then calls SetName .		
Behavior:	Varies according to the argument.		
	 If newName is NIL, this causes a break and prompts you for a name. Rename then sends the message SetName passing this name as an argument 		
	 If newName is non-NIL, Rename sends the message SetName passing newName as an argument. 		
Arguments:	class Pointer to a class.		
	newName A litatom.		
Returns:	NIL		
Categories:	Object		
Specializes:	Object		
Example:	The following command renames class Datum to Thing:		
	(← (\$ Datum) Rename 'Thing)		

(< class SetName newClassName)

	,		
Purpose:	Changes the name of a class.		
Behavior:	Removes the old name of self from ObjNameTable.		
	to the class succeed, fo printed that	ses the Interlisp-D function EDITCALLERS to rename references name or any file that contains the class. If EDITCALLERS cannot r example, when a file is not RANDACCESSP, a message is the class cannot be renamed on that file. For complete on EDITCALLERS , see the <i>Interlisp-D Reference Manual</i> .	
	The names newClassN	of the method functions of <i>class</i> are changed to use <i>ame</i> .	
Arguments:	class	Pointer to a class.	
	newClassN	ame A litatom.	
Returns:	NIL		
Categories:	Object		
Specializes:	Object		

a class name from being typed in. Behavior: Removes class from the LOOPS name hash table and from any files on FILELST. This method is intended to be used internally only; it is not recommended to create an unnamed class. Arguments: class Pointer to a class. Returns: NIL Categories: Object Specializes: Object [Fur Purpose: Finds the class name of an object. [Fur Behavior: Varies according to the arguments. • If self is a class, this returns the name of that class.	← <i>cla</i> ss UnSetName)	[Method of Class]
FILELST. This method is intended to be used internally only; it is not recommended to create an unnamed class. Arguments: class Pointer to a class. Example: Given that (← (\$ Window) New 'w1) the commands (ClassName (\$ w1)) (ClassName (\$ Window)) 	lassName self)	[Function]
 If self is a class, this returns the name of that class. If self is an instance, this returns the name of the class that describes instance. If self is neither a class or an instance, this returns Tofu. Arguments: self See Behavior. Returns: Value depends on the arguments; see Behavior. Example: Given that (← (\$ Window) New 'w1) the commands (ClassName (\$ w1)) (ClassName (\$ Window)) 	Purpose:	Finds the class name of an object.
 If self is an instance, this returns the name of the class that describes instance. If self is neither a class or an instance, this returns Tofu. Arguments: self See Behavior. Returns: Value depends on the arguments; see Behavior. Example: Given that (← (\$ Window) New 'w1) the commands (ClassName (\$ w1)) (ClassName (\$ Window)) 	Behavior:	Varies according to the arguments.
 instance. If self is neither a class or an instance, this returns Tofu. Arguments: self See Behavior. Returns: Value depends on the arguments; see Behavior. Example: Given that (← (\$ Window) New 'w1) the commands (ClassName (\$ w1)) (ClassName (\$ Window)) 		• If <i>self</i> is a class, this returns the name of that class.
Arguments: self See Behavior. Returns: Value depends on the arguments; see Behavior. Example: Given that (← (\$ Window) New 'w1) the commands (ClassName (\$ w1)) (ClassName (\$ Window))		
Returns: Value depends on the arguments; see Behavior. Example: Given that (← (\$ Window) New 'w1) the commands (ClassName (\$ w1)) (ClassName (\$ Window))		• If self is neither a class or an instance, this returns Tofu .
Example: Given that (← (\$ Window) New 'w1) the commands (ClassName (\$ w1)) (ClassName (\$ Window))	Arguments:	self See Behavior.
(← (\$ Window) New 'wl) the commands (ClassName (\$ wl)) (ClassName (\$ Window))	Returns:	Value depends on the arguments; see Behavior.
the commands (ClassName (\$ w1)) (ClassName (\$ Window))	Example:	Given that
(ClassName (\$ w1)) (ClassName (\$ Window))		(← (\$ Window) New 'wl)
(ClassName (\$ Window))		the commands
both return Window.		
		both return Window.

3.7 Querying the Structure of a Class

The following functions and methods allow you to query what is contained in a class.

Name	Туре	Description
GetClassProp	Method	Obtains a class's metaclass or properties.
HasAttribute	Method	Determines whether self has an attribute name.
HasAttribute!	Method	Recursive form of HasAttribute, but works only on classes.
HasCV	Method	Determines if a class has a class variable with a specified property.

3.7 QUERYING THE STRUCTURE OF A CLASS

HasItem	Method	Determines if a class has an item of a given type.
HasIV	Method	Determines if a class has an instance variable with a specified property.
HasIV!	Method	Same as HasIV , except that HasIV! also searches up the supers chain.
ListAttribute	Method	Lists the elements of a class that are local to the class.
ListAttribute!	Method	Lists all the items associated with a class.
WhoHas	Function	Determines what classes contains a specified item.

(<- class GetClassProp propname)

[Method of Class]

Purpose:	Obtains a class's metaclass or properties by following metaclass links.		
Behavior:	Varies accor	ding to the arguments.	
	• If propnar	ne is NIL, this returns the <i>class</i> 's metaclass.	
		ne is non-NIL, this looks first in <i>class</i> for that property. If it cannot e, it looks through <i>class</i> 's metaclass links.	
	If no prop	erty is found, the value of the variable NotSetValue is returned.	
Arguments:	class	A pointer to a class.	
	prop	Property name.	
Returns:	Value depen	ds on the arguments; see Behavior.	
Categories:	Class		
Example:	The following	g commands show the variety of responses.	
	51←(← (\$ Window) GetClassProp) #,(\$C Class)		
	52←(← (\$ Window) GetClassProp 'doc) "A LOOPS object which represents a window"		
	"An icon	IconWindow) GetClassProp 'doc) window that appears as an irregular shaped image reen See the ICONW Library utility"	

(self HasAttribute type name propname)

[Method of Class]

Purpose:	Determines whether <i>self</i> has an attribute name, with a property <i>propname</i> if supplied.
Behavior:	<i>self</i> can be an instance or a class. Remaining behavior depends on <i>type</i> , which is converted to uppercase on entry:
	 If type is IV, IVPROP, or NIL, this returns T if self has an instance variable of name, with a property called propname (if propname is non-NIL), otherwise it returns NIL.
	 If type is CV or CVPROP, this returns T if self has a CV called name, with a property of propname (if propname is non-NIL), otherwise it returns NIL.
	• If type is METHOD or SELECTOP, this returns NIL or the name of the

 If type is METHOD or SELECTOR, this returns NIL or the name of the method implementing name. **HasAttribute** applied to an instance reports on the actual state of the instance; it sees all instance variables and class variables whether local, inherited, or specially added to the instance. If only local attributes are required, use (\leftarrow (Class instance) HasAttribute ...).

Arguments:	self	Can be an instance or a class.
	type	See Behavior.
	name	A symbol which is looked up as the variable or method name.
	propname	A symbol which is looked up as the property name.
Returns:	See Behavio	or.
Categories:	Object	
Specializations:	Class	
Example:	The command	
	$(\leftarrow (\$ Lo$	opsIcon) HasAttribute 'IV 'icon)
	returns T.	

(class HasAttribute! type name propname)

Purpose:	Recursive form of HasAttribute; only works on classes		
Behavior:	Similar to HasAttribute, but will also search through <i>class</i> 's supers.		
Arguments:	class	A class.	
	type	See Behavior under HasAttribute.	
	name	A symbol which is looked up as the variable or method name.	
	propname	A symbol which is looked up as the property name.	
Returns:	See Behavior.		
Categories:	Object		
Specializations:	Class		
Example:	The command		
	$(\leftarrow$ (\$ Lo	opsIcon) HasAttribute 'IV 'left)	
	returns NIL, but		
	$(\leftarrow$ (\$ Lo	opsIcon) HasAttribute! 'IV 'left)	
	returns T.		
Categories: Specializations:	<pre>propname A symbol which is looked up as the property name. See Behavior. Object Class The command (← (\$ LoopsIcon) HasAttribute 'IV 'left) returns NIL, but (← (\$ LoopsIcon) HasAttribute! 'IV 'left)</pre>		

(class **HasCV** cvName prop)

[Method of Class]

[Method of Class]

Purpose:	Determines if a class has a class variable <i>cvName</i> with a property <i>prop</i> .		
	Note: The preferred form of this method is HasAttribute or HasAttribute !.		
Behavior:	Varies according to the arguments.		

- If *prop* is NIL, this returns T if *class* contains a class variable called *cvName*, else NIL.
- If *prop* is non-NIL, this returns T if *class* contains a class variable called *cvName* with the property *prop*, else NIL.
- Note: **HasCV** does not distinguish between locally defined class variables and inherited class variables. If you need to test a class to see if it has a class variable defined locally, you can use the **HasAttribute** method. For example, the form (←MyClass HasAttribute 'CV 'ABC) will return a non-NIL value if and only if the class **MyClass** has a local definition of the class variable ABC.

Arguments:	class	A pointer to a	class.
	cvName	A class variabl	le name.
	prop	Property name).
Returns:	NIL or T; se	e Behavior.	
Categories:	Object		
Specializes:	Object		
Example:	The command		
	(← (\$ Wi	ndow) HasCV	'TitleItems)
	returns T.		

(class HasItem itemName prop itemType)

,	1 21 7		
Purpose:	Determines if a class has an item of a given type.		
	Note: The p	preferred form of this method is HasAttribute or HasAttribute!.	
Behavior:	Varies according to the arguments.		
	 If itemTypic itemNam 	be is IV or IVS, this sends the message ($\leftarrow class HasIV$ e prop).	
	 If <i>itemType</i> is CV or CVS, this sends the message (← <i>class</i> HasCV <i>itemName prop</i>). 		
	 If <i>itemType</i> is SELECTOR, METHOD, SELECTORS, or METI finds the corresponding local method of <i>class</i>. 		
	• If itemTy	be is not one of the above, this returns NIL.	
Arguments:	class	Pointer to a class.	
	prop	Property name.	
	itemType	See Behavior.	
Returns:	Value deper	nds on the arguments; see Behavior.	
Categories:	Class		

(← class HasIV IVName prop)

[Method of Class]

[Method of Class]

Purpose: Determines if a class has an instance variable IVName with a property prop.

	Note: The p	referred form of this method is HasAttribute or HasAttribute!.
Behavior:	class should point to a class.	
	• If prop is	NIL, this returns T if IVName is contained in class.
		non-NIL, this returns T if <i>IVName</i> is contained in <i>class</i> , and <i>prop</i> is y of <i>IVName</i> in <i>class</i> or one of its supers.
Arguments:	class	Pointer to a class.
	IVName	Instance variable name.
	prop	Property name.
Returns:	Value deper	nds on the arguments; see Behavior.
Categories:	Object	
Specializes:	Object	
(← class HaslV! IVName prop)		[Method of Class]
Purpose/Behavior:	Same as Ha	ISIV, except that HasIV! also searches up the supers chain.
	Note: The p	referred form of this method is HasAttribute or HasAttribute!.

Arguments: See the method **HasIV**.

Returns: Value depends on the arguments; see Behavior.

Categories: Class

(← class ListAttribute type name)

Purpose:	Lists the elements of a class that are local to the class.		
Behavior:		verted to uppercase on entry. The remaining behavior varies of the arguments.	
		IVS, this returns the instance variable names (not values) local to ame is ignored.	
	variable	IV, IVPROPS, or NIL, <i>name</i> should be bound to an instance of <i>class</i> . This returns the property names (not values) of the variable <i>name</i> . If <i>name</i> is not an instance variable of <i>class</i> , this IIL.	
	 If type is CVS, this returns the class variables local to class. namignored. 		
	class. Tl	CV or CVPROPS, <i>name</i> should be bound to a class variable of his returns the property names of the class variable <i>name</i> . If <i>name</i> class variable of <i>class</i> , this returns NIL.	
		METHODS or SELECTORS, this returns the selectors for the ame is ignored.	
Arguments:	class	Pointer to a class.	
	type	See Behavior.	
	name	See Behavior.	
Returns:	Value depends on the arguments; see Behavior.		

Categories: Object
Specializes: Object
Example: The following commands show the variety of responses.
55←(← (\$ SupersBrowser) ListAttribute 'IVs)
(title)
56←(← (\$ Window) ListAttribute 'iv 'menus)
(DontSave Title LeftButtonItems MiddleButtonItems TitleItems doc)
57←(← (\$ IconWindow) ListAttribute 'METHODS)
(GetMenuItems)

(← class ListAttribute! type name verboseFlg)

[Method of Class]

[Function]

Purpose:	Lists all items associated with a class.		
Behavior:	Provides a recursive version of ListAttribute.		
	If <i>verboseFlg</i> is NIL, items that are inherited from Tofu, Object, or Class are omitted, unless <i>class</i> is one of Tofu, Object, or Class.		
	type is converted to uppercase on entry.		
	• If type is I	META or METACLASS, this returns the same as ListAttribute.	
	 If type is l would have 	VS or NIL, this returns the instance variables an instance of <i>class</i> ve.	
	 If type is SUPERS or SUPERCLASSES, this returns the ordered list of super classes of class. 		
	 If <i>type</i> is SUBS or SUBCLASSES, this returns all of the subclasse If <i>type</i> is any other option that can be passed to ListAttribute, this all local and inherited values. 		
Arguments:	class	Pointer to a class.	
	type	See Behavior.	
	name	A litatom.	
	verboseFlg	See Behavior.	
Returns:	Value deper	nds on the arguments; see Behavior.	
Categories:	Object		
Specializes:	Object		

(WhoHas name type files editFlg)

Purpose:Determines what classes contain a specified item.Behavior:Returns a list of classes on *files* that contain *name*. If *editFlg* is non-NIL, then
edit the methods (if *type* is METHOD), or the classes before returning.Arguments:nameThe item specified.
typetypeOne of IV, CV, METHOD, or Method. If type is NIL, it defaults to
METHOD.

- files A file or a list of files. If files is NIL, it defaults to FILELST.
- editFlg T or NIL.
- Returns: A list of classes on files that contain name.

3.8 Copying Classes and Their Contents

Inheritance lets classes be described in terms of other classes in a hierarchical manner. When it is preferable to duplicate a class description in different parts of a lattice these methods provide the capability.

The following table shows the methods in this section.

Name	Туре	Description
Сору	Method	Copies a class.
СоруСV	Method	Copies a class variable to another class.
СоруІV	Method	Copies an instance variable to another class.

(\leftarrow class **Copy** name)

[Method of Class]

Purpose:	Makes a copy of a class.		
Behavior:	If <i>name</i> is NIL, you are prompted to supply a name for the new class. This copies variables and properties and methods.		
Arguments:	class	The class being copied.	
	name	The name of the copy.	
Returns:	The new class.		
Categories:	Class		
Example:	Given that		
		lass 'Datum) tum) AddIV 'someThing)	
	the followin	g command makes a copy of class Datum and names it Thing :	
	(← (\$ Da	tum) Copy 'Thing)	

(← class CopyCV cvName toClass)

[Method of Class] Copies a class variable to another class. This also copies the properties of Purpose/Behavior: cvName to toClass. Arguments: class The source class. cvName The name of the class variable to copy. toClass The destination class. Returns: NIL

Categories: Class

(← class **CopyIV** ivName toClass) [Method of Class] Copies an instance variable to another class. This also copies the properties Purpose/Behavior: of *ivName* to toClass. The source class. Arguments: class ivName The name of the instance variable to copy. toClass The destination class. NIL Returns: Categories: Class

3.9 Enumerating Instances of Classes

New instances may be created without names, or without being tracked. These methods allow you to produce a list of instances according to their classes. **Prototype** instances are a convenience used where the methods defined for a class must be used, but there is no logical instance for the class.

The following table shows the items in this section.

Name	Туре	Description
AllInstances	Method	Finds all instances of a class.
AllInstances!	Method	Finds all instances of a class or its subclasses.
IndexedObject	Class	Keeps track of instances so that AllInstances searches can proceed more rapidly.
PrintOn	Method	Modifies how instances of IndexedObject that do not have LOOPS names will be printed.
Prototype	Method	Returns an instance of a class that is stored on the class's class variable Prototype .

(*← class* AllInstances)

,	
Purpose:	Finds all instances of a class.
Behavior:	Checks if <i>class</i> is a subclass of IndexedObject . If so, a faster search is used to find all of the instances of <i>class</i> . If not, this checks if each object is an instance of <i>class</i> . Instances that do not yet have a UID will not be found.
Arguments:	class A class.
Returns:	A list of the instances found.
Categories:	Class
Example:	The following command produces a list of all the LOOPS window instances:
	$61 \leftarrow (\leftarrow (\$ Window) AllInstances)$

(← class AllInstances!)	[Method of Class]
Purpose:	Finds all instances of a class or its subclasses.
Behavior:	Returns a list of instances that are instances of <i>class</i> or any of its subclasses. Instances that do not have the class IndexedObject as a super class, or that do not yet have a UID are not found. (See Chapter 18, Reading and Printing, for more information on UIDs.)
Arguments:	class A pointer to a class.
Returns:	A list of the instances found.
Categories:	Class
IndexedObject	[Class]
Purpose:	Keeps track of instances so that AllInstances searches can proceed more rapidly.
Behavior:	This class is to be used as a Mixin (an addition superclass), and should be the first class on a supers list for a class.
	IndexedObject provides NewInstance and Destroy protocols that cause instances to be added to or removed from a global list when they are created or destroyed. This global list allows the AllInstances protocols to search more quickly.
	IndexedObject also provides a PrintOn protocol that modifies how instances will be printed if they have no LOOPS name.
MetaClass:	Class
Supers:	Object
Class Variables:	IdentifierVar The name of an instance variable which will contain a string which could provide some identification to the user. Used in PrintOn if variable is in object and filled. shortName, the value of this class variable, is the default variable name which is used.
<u>(← self</u> PrintOn)	[Method of IndexedObject]
Purpose:	Modifies how instances of IndexedObject that do not have LOOPS names will be printed.
Behavior:	If self has a LOOPS name, or if self does not have an instance variable with a name aqual to $(@$ solf identifier)(or) then do a (Suppr). Otherwise, build a

- The self has a LOOPS name, or if self does not have an instance variable with a name equal to (@ self ::IdentifierVar), then do a (←Super). Otherwise, build a form that incorporates the value of the instance variableIV referenced by (@ self ::IdentifierVar).
- Arguments: *self* An instance.
- Returns: A list ; see example
- Categories: Object
- Specializes: Object
 - Example: Create a class, IndexedObjectTest, that has this structure.

62←(DefineClass 'IndexedObjectTest '(IndexedObject))
#,(\$C IndexedObjectTest)
63←(← (\$ IndexedObjectTest) AddIV 'shortName 'ioTest)
shortName
Create an instance.
64←(SETQ test (← (\$ IndexedObjectTest) New))
#,(\$& IndexedObjectTest (YMW0.0X%:.>T4.n18 . 36))
65←(←@ test shortName 'changeName)
changeName
66←(← test PrintOn)
("#," \$& IndexedObjectTest (changeName (YMW0.0X%:.>T4.n18 . 36)))

(*← class* **Prototype** *newProtoFlg*)

Purpose:	Returns a prototype instance of a class.
Behavior:	Varies according to the arguments.
	 If <i>class</i> has a class variable Prototype and the variable's value is an instance of <i>class</i>, return the value (assuming <i>newProtoFlg</i> is NIL).
	 If there is no class variable Prototype, or if there is a class variable Prototype but its value is not an instance of <i>class</i>, or if <i>newProtoFlg</i> is non- NIL, then create a new instance of <i>class</i>, store the instance on the class variable Prototype, and return the instance.
	See Proto in Chapter 7, Message Sending Forms, for more information.
Arguments:	class A class.
	newProtoFlg If non-NIL, create a new prototype instance.
Returns:	The prototype.
Categories:	Class
Example:	LOOPS defines an icon to make it easy to bring up class browsers and file browsers. The icon is the Prototype instance of the class LoopsIcon .
	To move the icon to the center of the bottom of the screen, enter
71←(←P (576 .	roto (\$ LoopsIcon) Move (QUOTIENT SCREENWIDTH 2) 0) 0)
	This places the left edge of the icon at the center of the screen. To move the icon to the center of the screen, enter
	C ((icon (← (\$ LoopsIcon) Prototype))) (← icon Move (QUOTIENT (DIFFERENCE SCREENWIDTH (@ icon width)) 2)
(544 .	0))

3.10 Dealing with Inheritance

The inheritance lattice for classes shows how methods and variables are shared (see Chapter 10, Browsers, for details on how to graph the lattice on the screen). To programmatically inspect and add to this lattice via **Specialize**, use the following functions and methods:

Name	Туре	Description
Fringe	Method	Finds the leaves of a branch of an inheritance tree.
Specialize	Method	Creates a subclass of a class.
SubClasses	Method	Returns a list of subclasses.
Subclass	Method	Determines if a class is a subclass of another class.
AllSubClasses	Function	Computes the subclasses of a class.
SubsTree	Function	Computes all the names of the subclasses of a class.

(~ class Fringe)

[Method of Class]

Purpose:	Finds the leaves of a branch of an inheritance tree.		
Behavior:	Returns a list of subclasses of <i>class</i> , whether close or distant, that have no subclasses.		
Arguments:	<i>class</i> A class, the root of the tree to explore.		
Returns:	Names of subclasses of <i>class</i> that have no subclasses.		
Categories:	Class		
Example:	The following commands show the variety of responses.		
	73←(← (\$ Window) Fringe) (InstanceBrowser MetaBrowser SupersBrowser FileBrowser LoopsIcon IconWindow)		
	74←(← (\$ ClassBrowser) Fringe) (MetaBrowser SupersBrowser FileBrowser)		

(*← class* **Specialize** *newName*)

Purpose:	Creates a subclass of a class.			
Behavior:	Creates a class with class as its only super.			
	• If newNa	• If <i>newName</i> is non-NIL, this is the name of the new class.		
	• If <i>newName</i> is NIL, this creates a name consisting of the name of <i>class</i> followed by an integer.			
Arguments:	class	Pointer to a class.		
	newName	Name of the new subclass.		
Returns:	The new class.			
Categories:	Class			
Example:	Given that			

(DefineClass 'Datum)

the following command creates a specialization of the class **Datum** called **DatumX**:

(← (\$ Datum) Specialize 'DatumX)

$(\leftarrow class SubClasses)$

[Method of Class]

[Method of Class]

Purpose:	Returns a list of subclasses.		
Behavior:	The classes returned by this are the immediate subclasses of <i>class</i> .		
Arguments:	class	A pointer to a class.	
Returns:	A list of subclasses.		
Categories:	Class		
Specializations:	DestroyedCl	ass	
Example:	The following	g command gets a list of the subclasses of the class Window :	
	$(\leftarrow$ (\$ Wir	ndow) SubClasses)	

(← class Subclass super)

1 /			
Purpose:	Determines if a class is a subclass of another class.		
Behavior:	If class is a subclass of super, super is returned, else NIL.		
Arguments:	class Pointer to a class.		
	<i>super</i> Either the LOOPS name of a class or a pointer to a class.		
Returns:	Value depends on the arguments; see Behavior.		
Categories:	Class		
Example:	The command		
	(\leftarrow (\$ DestroyedClass) Subclass 'Class)		
	returns		
	#,(\$C Class)		

(AllSubClasses class currentSubs)

[Function]

Purpose:	Computes the subclasses of a class.		
Behavior:	This is a recursive function that computes (without duplicates) all of the subclasses of <i>class</i> .		
Arguments:	class Must be a pointer to a class, f	or example, (\$ Window).	
	currentSubs Used by LOOPS; NIL when c	alled by the user.	
Returns:	A list of classes.		
Example:	The command		
	(AllSubClasses (\$ LatticeBrowser	·))	

returns

(#,(\$C FileBrowser) #,(\$C SupersBrowser) #,(\$C MetaBrowser) #,(\$C ClassBrowser) #,(\$C InstanceBrowser))

(SubsTree class currentList)

[Function]

Purpose:	Computes the names of the subclasses of a class.		
Behavior:	Provides a recursive function that computes (without duplicates) all of the names of the subclasses of <i>class</i> .		
Arguments:	class Can be a class name or a pointer to a class		
	currentList	Used internally by SubsTree ; it should be NIL when called by the user.	
Returns:	A list of class names.		
Example:	The command		
	(SubsTree 'LatticeBrowser)		
	returns		
	(InstanceBrowser ClassBrowser MetaBrowser SupersBrowser FileBrowser)		

[This page intentionally left blank]

Overview of the Manual

The *LOOPS Reference Manual* provides a detailed description of all the methods, functions, classes, and other items available in the Lisp Object-Oriented Programming System, LOOPS. This manual describes the Medley Release of LOOPS, which runs under Medley.

This manual is for people who are familiar with LOOPS programming principles, and is not intended to teach you LOOPS or how to use it. Please contact your LOOPS distributor for information about classes and training material.

Organization of the Manual and How to Use It

This manual is divided into chapters, with most chapters focusing on a particular aspect of LOOPS. The organization of this manual is similar to the *Interlisp-D Reference Manual*.

A Table of Contents is included at the beginning of the manual to help you find specific material. At the end of the manual, a Glossary is included to define terms within the context of LOOPS.

All readers should review Chapter 1, Introduction, before referring to specific material.

Conventions

This manual uses the following conventions:

- Case is significant in LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type. Optional arguments are indicated by a dash (-).
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a message sending form appears as follows:

 $(\leftarrow self$ **Selector** Arg1 Arg2 -)

• Examples appear in the following typeface:

 $89 \leftarrow (\leftarrow \text{LOGIN})$

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.

- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Method names often appear in the form ClassName.SelectorName.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the LOOPS items (functions, methods, etc.) by using the following template:

- Purpose: Gives a short statement of what the item does.
- Behavior: Provides the details of how the item operates.
- Arguments: Describes each argument in the following format:

argument Description

- Returns: States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.
- Categories: A way to group related methods. For example, all the methods releated to Masterscope on the class **FileBrowser** have the category Masterscope, not **FileBrowser**. This item appears only for methods.
- Specializes: The next higher class in the class hierarchy that contains a method with the same selector; only appear for methods. For example, **the manual entry for RectangularWindow.Open** would say that it specializes **Window.Open**, since **Window** is the first superclass of **RectangularWindow** that implements a method for **Open**.
- Specializations: The next lower class(es) in the class hierarchy that contains method(s) with the same selector; only appears for methods. For example, the manual entry for **Window.Open** would say that it has a specialization of **RectangularWindow.Open** since **RectangularWindow** is a subclass of **Window** and has its own version of **Open** method.
 - Example: An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See Chapter 18, Reading and Printing, for details.

[This page intentionally left blank]

In object-oriented programming, every object is described by a class. Instances are described by classes and classes are, in turn, described by metaclasses. The methods that an instance inherits are defined in the class definition of that instance and the methods that the class inherits are defined in the metaclass definition of that class's metaclass. Sending a message to an instance invokes method in class. Similarly, sending a message to class invokes method in metaclass.

The two classes **Class** and **MetaClass** are metaclasses of other classes. If **Class** or **MetaClass** refers to the metaclass, it appears in a bold typeface.

One method defined by a class's metaclass is **New**, which returns a new instance of a class. Different classes can initialize their instances in different ways. For example, one class may need to have certain values assigned to instance variables at creation, while another does not. The different forms of **New** are defined in separate metaclasses.

A class's metaclass is assigned when the class is created. A new class is created by sending a metaclass the message **New** or by specializing an already existing class. In the latter case, the metaclass defaults to the metaclass of the class's super class. The class's metaclass can be changed by directly editing the class definition.

This chapter discusses the metaclasses provided with LOOPS, describes pseudoclasses, explains how to define new metaclasses, and discusses the root class ${\bf Tofu}$.

4.1 Specific Metaclasses

This section describes the metaclasses provided by LOOPS: **Class**, **MetaClass, AbstractClass**, and **DestroyedClass**. These metaclasses are shown in Figure 4-1.

Class browser			
Class ———	— MetaClass —	AbstractClass	DestroyedClass

Figure 4-1. Class Browser Showing Metaclasses

4.1.1 Metaclass Class

Class is the default metaclass for LOOPS classes. When a class whose metaclass is **Class** receives the message **New**, it creates a new instance of itself and returns that instance. If this message is sent at the top level, the definition of the created instance is printed in the Executive window.

4.1.2 Metaclass MetaClass

MetaClass is the metaclass for all metaclasses and provides the message **New** to all metaclasses. For metaclasses, the result of sending the message **New** is the definition of a new metaclass. This is discussed in detail in Section 4.3, "Defining New Metaclasses."

4.1.3 Metaclass AbstractClass

If a class's metaclass is **AbstractClass**, then it cannot be instantiated. If an abstract class is sent the message **New**, the following message is printed to the TTY window.

#,(\$C className) Abstract Class cannot be instantiated

To make a class an **AbstractClass**, either send the metaclass **AbstractClass** the message **New** or change the metaclass of the class definition directly using the editor.

Use an abstract class to define a class which should not have any instances. For example, consider mixin classes. Mixins are always used in conjunction with another class to create a subclass. Instances are created from the new subclass that has the mixin as one of its parents. Because mixins never have instances, they have **AbstractClass** as their metaclass.

As an example, consider a circuit simulation module that contains various classes such as **Resistors, Inductors, Batteries,** and **Wires**. A possibility is to define a super class for these classes called **AnalogDevice** to contain all the information common to all such classes: current, impedance, voltage drop, etc. This super class also holds all the methods common to the classes, such as **ApplyOhmsLaw**. Since **AnalogDevice** is not itself intended to be instantiated (only its subclasses are), its metaclass can be **AbstractClass** so that an error occurs if it is accidentally instantiated.

Note: Whenever **AnalogDevice** is specialized to create a new subclass, be sure to change its metaclass.

4.1.4 Metaclass DestroyedClass

DestroyedClass is the metaclass for classes that have been sent the message **Destroy** or **Destroy!** Trying to instantiate a **DestroyedClass** causes an error. Attempts to destroy a **DestroyedClass** have no effect.

4.2 **Pseudoclasses**

Pseudoclasses provide an object interface to Lisp data types, which are also known as Lisp objects. Pseudoclasses associate a class with the type name of a Lisp object. When messages are sent to Lisp objects of the named type, the messages are actually sent to the pseudoclass. Lisp objects which have pseudoclasses are considered pseudoinstances.

Pseudoclasses provide two special cases in the message-sending mechanism: for lists whose first element is a class, or for ordinary Lisp data types.

In the first case, the list's first element is used as the class to look up the method to be used.

In the second case, the class of the data type is found by using the **GetLispClass** function, which looks in an internal table based on the type name of the data type. If none is found, it is assumed to be **Tofu**. If found, the data type is considered a pseudoclass and instances of it pseudoinstances.

Pseudoclasses also provide special cases in the behavior of **GetValue** and **PutValue**, to allow simulation of variable or property access, as described below.

(GetValue pseudoinstance varName propName)

[Function]

[Function]

Purpose:	A variation on the behavior of GetValue to simulate retrieving variable or property values on pseudoinstances.		
Behavior:	If GetValue is called with <i>self</i> bound to a pseudoinstance, then the method associated with the selector GetValue in the pseudoclass is called with the arguments:		
	pseudoir	nstance varName propName	
Arguments:	pseudoinsta	ance A Lisp object which has a pseudoclass.	
	varName	The simulated variable name.	

- propName The simulated property name, or NIL.
- Returns: The result of the call to the **GetValue** method in the pseudoclass.

(PutValue pseudoinstance varName propName newValue)

Purpose:	A variation on the behavior of PutValue to simulate setting of variable or property values on pseudoinstances.
Behavior:	If PutValue is called with <i>self</i> bound to a pseudoinstance, then the method associated with the selector PutValue in the pseudoclass is called with the arguments:
	instance varName newValue propName
Arguments:	<i>pseudoinstance</i> A Lisp object which has a pseudoclass.
	varName The simulated variable name.
	propName The simulated property name, or NIL.
	<i>newValue</i> The new value to be placed in the simulated slot.
Returns:	The result of the call to the PutValue method in the pseudoclass.
(GetLispClass <i>obj</i>)	[Function]
Purpose:	Used by the system to compute a class corresponding to a Lisp data type.
Behavior:	Gets the hash value for the key (TYPENAME <i>obj</i>) from an internal hash array.

- If this hash value is NIL, (\$ Tofu) is returned.
- If the hash value is not NIL and it is a class, it is returned.
- In all other cases, the hash value, which should be a function, is applied to *obj* and the result is returned.

Arguments: *obj* A Lisp object.

	Returns:	Value depends on the hash value; see Behavior.
	Example:	The command
		$79 \leftarrow (GetLispClass (create annotatedValue))$
		returns
		#,(\$C AnnotatedValue)
LispClassTable		[Global Variable]
	Purpose:	Used by GetLispClass to map type names of Lisp objects to pseudoclasses.
	Format:	This hash table has EQ hashing. It contains pairs of symbol keys (a type name) and either classes, NIL, or a function object to be applied (see GetLispClass).

4.2.1 Example

This example creates a pseudoclass from the Lisp data type STRINGP.

1. Define a class **String** that receives its messages:

```
37←(DefineClass 'String)
#,($C String)
```

2. Place an entry in the LispClass hash table to link the Lisp data type STRING to the **String** class.

```
38←(PUTHASH 'STRINGP ($ String) LispClassTable)
#,($C String)
```

3. Add methods to **String** which will operate on Lisp STRINGPs, for example:

This allows messages like the following:

 $40 \leftarrow (\leftarrow "abc" UpCase)$ "ABC"

 Specialize GetValue and PutValue to allow element access in strings, for example:

```
41← (DefineMethod ($ String) 'GetValue '(index)
        '(NTHCHAR self index))
String.GetValue
42← (DefineMethod ($ String) 'PutValue '(index value)
        '(RPLSTRING self index value))
String.PutValue
```

This allows messages to access characters in strings, for example:

```
43←(← "abc" GetValue 2)
b
44←(← "abc" PutValue 2 'p)
"apc"
```

4.3 Defining New Metaclasses

A new metaclass must be defined if you want to create several classes for which a class message, such as **Destroy**, needs to be specialized. To create a new metaclass, an object of the class **MetaClass** must be instantiated. This is done by sending **MetaClass** the message **New**.

$(\leftarrow (\$ MetaClass) New metaClass)$	lassName supers)	[Method of Metaclass]
Purpose:	Instantiates a new metaclass with Meta <i>metaClassName</i> as its name, and <i>supe</i>	I Class as its metaclass, ars as a list of its super classes.
Behavior:	Evaluates <i>metaClassName</i> , which mus <i>supers</i> is (Class) . If used, <i>supers</i> mu message returns the new metaclass.	t evaluate to a symbol. The default for ust evaluate to a list of classes. The
Arguments:	<i>metaClassName</i> Name of the new metacla	ss; must evaluate to a symbol.
	supers List of classes.	
Categories:	MetaClass	
Specializes:	Class.New	
Specializations:	AbstractClass.New	
Example :	Assume the following MetaClass definition	tion:
	42←(←(\$ MetaClass) New 'List #,(\$C ListMetaClass)	:MetaClass '(Class))
	The message New can then be defined this example, it saves all the instances ListMetaClass . The instances are stor AllInstances . Define the message Ne	created of a class with the metaclass red as the value of the class property
	DefineMethod (\$ ListMetaClass arg4 arg5) ′((* * Create an instance list in class) (LET ((newObj (←Super)))	
		e instance returned by New message provided by SS.)
	(PutClass self (CONS newObj (LIS s 'AllInstances)	TP (GetClassHere self 'AllInstances)))

(* * LISTP returns list or NIL if not a list) (* * GetClassHere returns the value of a property of a class.) newObj] Now a new class can be defined by sending #,(\$C ListMetaClass) the message New. The result is a new class with ListMetaClass as the metaclass. 43←(←(\$ ListMetaClass) New 'Book) #,(\$C Book) [New class called Book] 44←(←(\$ Book) New 'Book1) #,(\$C Book1)

#, (\$C Book2)
46←(GetClass (\$ Book) 'AllInstances)
#, (\$C Book2) #, (\$C Book1) [List of all instances created so far]

4.4 Tofu

The highest class in the LOOPS hierarchy is **Tofu**, which is an acronym for Top of the Universe. It is the simplest class, having no instance variables and only three defined messages:

MessageNotUnderstood

 $45 \leftarrow (\leftarrow (\$ Book) New 'Book2)$

- MethodNotFound
- SuperMethodNotFound

Figure 4-2 shows specializations of **Tofu**. The most familiar specialization of **Tofu** is the class **Object**, which is the root of the most of the other classes. Another specialization of **Tofu** is **AnnotatedValue**. **AnnotatedValue** is used with active values (see Chapter 8, Active Values).

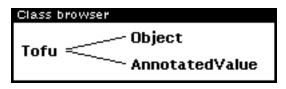

Figure 4-2. Specializations of Tofu

If another evaluation protocol or scheme for catching error conditions is needed, specialize **Tofu** and define all the methods required for handling data, usually some subset of the methods of **Object**. Specializing Tofu should only be necessary on very rare occasions.

The following table shows the methods in this section.

Functionality	Туре	Description
MessageNotUnderstood	Method	Provides the error handling mechanism for when a message is sent to an object that cannot respond to that message.

[Method of Tofu]

[Method of Tofu]

MethodNotFound	Method	Provides some intermediate checking before sending the message MessageNotUnderstood.
SuperMethodNotFound	Method	Provides some intermediate checking before sending the message MessageNotUnderstood .

(← self MessageNotUnderstood selector messageArguments superFlg)

Provides the error handling mechanism for when a message is sent to an object that cannot respond to that message. Purpose/Behavior: Calls ERROR with a list which includes self, selector, and "not understood." Arguments: self An object receiving a message with the selector selector. selector A selector. messageArguments A list of the arguments to the message. superFlg Used internally. Returns: See Behavior. Categories: Tofu Specializations: Object

(← self **MethodNotFound** selector)

Purpose/Behavior:		ome intermediate checking before sending the message lotUnderstood.
Arguments:	self	An object receiving a message with the selector selector.
	selector	A selector.
Returns:	Used for si	de effect only.
Categories:	Tofu	
(← self SuperMethodNotFound	selector clas	sOfSendingMethod) [Method of Tofu
Purpose/Behavior:		ome intermediate checking before sending the message lotUnderstood.
Arguments:	self	An object receiving a message with the selector selector.
	selector	A selector.
	classOfSei	ndingMethod The class with the method that contains a \leftarrow Super.

- Returns: Used for side effect only.
- Categories: Tofu

[This page intentionally left blank]

This chapter discusses the various ways to access data:

- · Generalized Get and Put functions
- Accessing data in instances
- · Accessing data in classes

5.1 Generalized Get and Put Functions

5.

These functions support generalized instance variable and property access for LOOPS objects. They can be very useful for implementing methods that support new types of conditional accessing; they have been used to simplify code in the active values system, for example.

This section deals with the following functions:

Name	Туре	Description
Getlt	Function	Retrieves values from instance variables and properties.
GetItOnly	Function	Like GetIt , but returns active values on a variable/property without triggering them.
GetltHere	Function	Like GetIt , but returns active values on a variable/property without triggering them; does not observe NotSetValue as GetItOnly does.
Putlt	Function	Stores values into instance variables and properties.
PutItOnly	Function	Like Putlt , but stores by smashing active values on a variable/property without triggering them.

(GetIt self varOrSelector propName type)

[Function]

Purpose:	Retrieves values from instance variables and properties.	
Behavior:	Varies according to the arguments.	
	• If type is 'IV or NIL	
	 If self is an instance, this is equivalent to (GetValue self varOrSelector propName) 	
	 If self is a class, this is equivalent to (GetClassIV self varOrSelector propName) 	
	 If type is 'CV, this is equivalent to 	

(GetClassValue self varOrSelector propName)

A

- If type is 'CLASS, this is equivalent to (GetClass self (OR varOrSelector propName))
- If type is 'METHOD, this is equivalent to (GetMethod self varOrSelector propName)

Arguments:	self	A class or an instance.
	varOrSelect	or An instance variable name or the name of a method.
	propName	Property name.
	type	Specifies the type of the object self.
Returns:	Value deper	nds on the arguments; see Behavior.
Example:	The command	
	(GetIt (\$	Window) 'doc NIL 'CLASS)
	returns	
	"A Loops	object that represents a window"

(GetItOnly self varOrSelector propName type)

Purpose: Retrieves values from instance variables and properties without triggering active values. Behavior: Varies according to the arguments. If type is 'IV or NIL If self is an instance, this is equivalent to (GetValueOnly self varOrSelector propName) If self is a class, this is equivalent to -(GetClassIV self varOrSelector propName) • If type is 'CV, this is equivalent to (GetClassValueOnly self varOrSelector propName) If type is 'CLASS, this is equivalent to (GetClassOnly self (OR varOrSelector propName)) If type is 'METHOD, this is equivalent to ٠ (GetMethodOnly self varOrSelector propName) Arguments: A class or an instance. self varOrSelector An instance variable name or the name of a method. propName Property name. Specifies the type of the object self. type Returns: Value depends on the arguments; see Behavior. Example: The command (GetItOnly (GetClassValue (\$ LoopsIcon) 'Prototype) 'window)

returns the LoopsWindowAV that holds the image of the LOOPS icon. Calling **GetIt** with similar arguments returns the Lisp window object held by that LoopsWindowAV.

[Function]

(GetItHere self varOrSelector propName type)

[Function]

Purpose:	Retrieves values from instance variables and properties without triggering active values; does not observe NotSetValue like GetItOnly .
Behavior:	Varies according to the arguments.
	• If type is 'IV or NIL
	 If self is an instance, this is equivalent to (GetIVHere self varOrSelector propName)
	 If self is a class, this is equivalent to (GetClassIVHere self varOrSelector propName)
	 If type is 'CV, this is equivalent to (GetCVHere self varOrSelector propName)
	 If type is'CLASS, this is equivalent to (GetClassHere self (OR varOrSelector propName))
	 If type is 'METHOD, this is equivalent to (GetMethodHere self varOrSelector propName)
Arguments:	self A class or an instance.
	<i>varOrSelector</i> An instance variable name or the name of a method.
	propName Property name.
	<i>type</i> Specifies the type of the object <i>self</i> .
Returns:	Value depends on the arguments; see Behavior.
Example:	The command
(GetItHere	(GetClassValue (\$ LoopsIcon) 'Prototype) 'title)
	returns the value of NotSetValue . Calling GetIt with similar arguments return the default value for this instance variable, NIL.

(PutIt self varOrSelector newValue propName type)

lector newVall	ue propNan	ne type)	[Function]	
Purpose:	Stores values into instance variables and properties.			
Behavior:	Varies ad	Varies according to the arguments.		
	• If type	is 'IV or NIL		
		is an instance, this is equivalent to alue self varName newValue propName)		
		is a class, this is equivalent to lassIV self varName newValue propName)		
		is 'CV,this is equivalent to lassValue self varName newValue propName)		
		is 'CLASS,this is equivalent to lass self newValue (OR varName propName))		
Arguments:	self	A class or an instance.		

5.1 GENERALIZED GET AND F		15	
	varName	An instance variable name.	
	propName	Property name.	
	type	Specifies the type of the object self.	
Returns:	Value deper	nds on the arguments; see Behavior.	
Example:	The comma	nd	
(PutIt (Get	ClassValue	(\$ LoopsIcon) 'Prototype) 'title "foo")	
	sets the insta be verified b examining th	ance variable title of the LOOPS icon prototype to "foo" y inspecting (GetClassValue (\$ LoopsIcon) 'Prototype) he title slot.	. This can and
(PutitOnly self varOrSelector new	wValue propNa	ame type)	[Function]
Purpose:	Stores value values it find	es into instance variables and properties and smashes a ls in its way without triggering them.	ny active
Behavior:	Varies accor	ding to the arguments.	
	• If type is '	IV or NIL	
		n instance, this is equivalent to eOnly self varName newValue propName)	
		class, this is equivalent to sIV self varName newValue propName)	
	 If type is ' (PutClass) 	CV,this is equivalent to sValueOnly s <i>elf varName newValue propName</i>)	
	 If type is ' (PutClass) 	CLASS,this is equivalent to sOnly <i>self newValue</i> (OR <i>varName propName</i>))	
Arguments:	self	A class or an instance.	
	varName	An instance variable name.	
	propName	Property name.	
	type	Specifies the type of the object self.	
Returns:	Value deper	nds on the arguments; see Behavior.	
Example:	If the inspec instance var	tor from the PutIt example is used to set a break on the iable title of the LOOPS icon prototype, then doing	the
(PutItOnly (GetClas	sValue (\$	LoopsIcon) 'Prototype) 'title "mumble")	
	will set the ir value.	nstance variable title to "mumble" while smashing the tr	ace active

5.2 Accessing Data in Instances

Two kinds of variables are associated with an instance:

• Its local instance variables, also referred to as IVs.

 The class variables, also referred to as CVs, that it shares with all instances of the class.

The data contained within instances are the values of instance variables and associated properties as well as a pointer to the class that describes the instance. Details of the LOOPS implementation determine exactly when the values of instance variables are stored within an instance. In some cases, the system must look to the class to find the values of instance variables. In general, you do not need to be concerned with this distinction; however, the details of it are covered in Chapter 2, Instances.

The types of data that an instance may contain is not limited. The values for an instance variable or a class variable can be any Lisp or LOOPS data structure.

The active value is a special case of data. When you try to access a variable with an active value as its value, the active value may be returned, depending upon the type of access. Normally, however, data computed by the active value is returned, not the active value. The details of how this computation is performed is described in Chapter 8, Active Values.

Instance variable names and class variable names are symbols and are not necessarily unique to each class. Although it is possible to use the same symbol for both a class variable name and an instance variable name, it is advisable not to do this since some of the LOOPS functionality examines both the instance variables and class variables in the search for data. See the method **IVMissing** in the class **Object**.

This section deals with the following functions and methods. See the *LOOPS Library Modules Manual* for information on how these interact with Masterscope.

Name	Туре	Description
GetValue	Function	Finds the value of an instance variable.
Get	Method	Finds the value of an instance variable.
PutValue	Function	Writes the value of an instance variable.
Put	Method	Writes the value of an instance variable.
GetValueOnly	Function	Finds the value of an instance variable without triggering active values.
PutValueOnly	Function	Writes the value of an instance variable without triggering active values.
GetClassValue	Function	Returns the value of a class variable.
PutClassValue	Function	Changes the value of a class variable. The change occurs within the class and therefore causes all instances to access the new value of the variable.
GetClassValueOnly	Function	Returns the value of a class variable; does not trigger active values.
PutClassValueOnly	Function	Changes the value of a class variable. The change occurs within the class and therefore causes all instances to access the new value of the variable. Does not trigger active values.
GetIVHere	Function	Gets the value stored in an instance variable without invoking active values.

(GetValue self varName propName)

[Function]

- Purpose: Finds the value of an instance variable when *varName* and *propName* are to be computed.
- Behavior: Varies according to the arguments.
 - If *self* is an instance and *propName* is NIL, this returns the value of the instance variable *varName*. If there is no instance variable of the name *varName* and there is a class variable of that name, this returns the value of the class variable. See the **IVMissing** message for a complete discussion of this behavior. If there is neither an instance variable or class variable of that name, a break occurs.
 - If self is an instance and propName is non-NIL, this returns the value of the property propName of the instance variable or class variable varName. If there is no property of the name, propName, this returns the value of the variable NoValueFound.
 - If the value of *varName* (or *propName* if it is non-NIL) is an active value, the active value is activated.
 - If self is not an instance, this calls (GetIt self varName propName 'IV)

See the LOOPS Library Modules Manual about interaction with Masterscope.

Arguments: *self* A class or an instance.

varName Instance or class variable name.

- propName Property name.
- Returns: Value depends on the arguments; see Behavior.
- Example: Given that

32←(← (\$ window1) Shape '(100 200 300 400)) (100 200 300 400)

then

33←(GetValue (\$ window1) 'width)
300
34←(GetValue (\$ window1) 'LeftButtonItems)
((Update ...))

(← self Get varName propName)

[Method of Object]

[Function]

Purpose/Behavior:	Method version of GetValue.
Arguments:	See GetValue.
Categories:	Object

(PutValue self varName newValue propName)

Purpose: Writes the value of an instance variable when *varName* and *propName* are to be computed.

- Behavior: Varies according to the arguments.
 - If *self* is an instance and *propName* is NIL, this changes the value of the instance variable *varName to newValue*. This returns *newValue*. If *varName* is not an instance variable of *self*, this causes a break.

	 If self is an instance and propName is non-NIL, this changes the value of the property propName of the instance variable varName to newValue. If propName is not already a property of varName, it is added. This returns newValue. 		
		e of <i>varName</i> (or <i>propName</i> if it is non-NIL) is an active value, the ue is activated.	
		class, this calls alf varName newValue propName (IV)	
	See the LOC	DPS Library Modules Manual about interaction with Masterscope.	
Arguments:	self	A class or an instance.	
	varName	Instance name or class name.	
	newValue	The new value for varName or propName.	
	propName	Property name.	
Returns:	Value depen	ds on the arguments; see Behavior.	
Example:	(PutValue	(\$ window1) 'width 120)	

(self **Put** varName newValue propName)

[Method of Object]

[Function]

[Function]

Purpose/Behavior:	Method version of the function PutValue .
Arguments:	See PutValue.
Categories:	Object
Specializations:	Class

(GetValueOnly self varName propName)

Purpose:	Similar to GetValue, except that it overrides the active value mechanism.
Behavior:	See GetValue . If the value found is an active value, it is returned without triggering its side effects.
Arguments:	See GetValue.
Returns:	See Behavior.
Example:	The following expressions compare GetValue and GetValueOnly
	35←(GetValue (\$ window1) 'window) {WINDOW}#nn,mmmm
	36←(GetValueOnly (\$ window1) 'window) #,(\$AV LispWindowAV)

(PutValueOnly self varName newValue propName)

Purpose:	Similar to PutValue , except that it overrides the active value mechanism.
Behavior:	See PutValue . The argument <i>newValue</i> overwrites any active value on the slot without triggering it.
Arguments:	See PutValue.
Returns:	Used for side effect only.

(GetClassValue self varName propName)

Purpose:	Returns the value of a class variable.			
Behavior:	Varies according to the arguments.			
Denavior.	varies accor	ulig to the arguments.		
	 If <i>propName</i> is NIL, this returns the value of the class variable <i>varName</i>. <i>varName</i> is not a class variable, a break occurs. If <i>propName</i> is non-NIL, this returns the value of the property, <i>prop</i>, of the class variable <i>varName</i>. If <i>varName</i> has no property of that name, the value of the variable NoValueFound is returned. 			
	See the LOOPS Library Modules Manual about interaction with Masterscop			
Arguments:	self	An instance or a class.		
	varName	Class variable name of <i>self</i> .		
	propName	Property name for class variable varName; may be NIL.		
Returns:	Value depends on the arguments; see Behavior.			
Example:	The following commands show a variety of retuned values.			
	37←(GetClassValue (\$ window1) 'window) This breaks, since window is not a class variable of Window .			
	38←(GetC ((Update	<pre>lassValue (\$ window1) 'LeftButtonItems)))</pre>		
	39←(GetC] NIL	lassValue (\$ window1) 'LeftButtonItems 'qwerty)		

(PutClassValue self varName newValue propName)

[Function]

Purpose:	Changes the value of a class variable. The change occurs within a class and therefore causes a class variable lookup by other instances to find the new value.		
Behavior:	Varies according to the arguments.		
	 If <i>propName</i> is NIL, this changes the value of the class variable <i>varName</i> to <i>newValue</i>. If <i>varName</i> is not a class variable, this breaks. If <i>prop</i>Name is non-NIL, this changes the value of the property, <i>prop</i>Name of the class variable <i>varName</i> to <i>newValue</i>. If <i>varName</i> has no property of that name, the property is added. See the <i>LOOPS Library Modules Manual</i> about interaction with Masterscope. 		
Arguments:	self	An instance or a class.	
	varName	Class variable name of self.	
	newValue	Value to be assigned to class variable or property name.	
	propName	Property name for class variable <i>varName</i> ; may be NIL.	
Returns:	newValue		
Example:	The following command breaks since left is not a class variable name of Window .		

40←(PutClassValue (\$ window1) 'left 1234) The command 41←(PutClassValue (\$ window1) 'TitleItems 1234) changes the value of TitleItems. The command 42←(PutClassValue (\$ window1) 'TitleItems 123 'asdf) adds the property asdf with the value 123 to TitleItems.

(GetClassValueOnly self varName propName)

[Function]

Purpose:	Gets the value of a class variable without triggering active values.		
Behavior:	Varies according to the arguments.		
	 If <i>propName</i> is NIL, this returns the value of the class variable <i>varName</i> without triggering active values. If <i>varName</i> is not a class variable, this breaks. If <i>propName</i> is non-NIL, this returns the value of the property, <i>propName</i>, of the class variable <i>varName</i> without triggering active values. If <i>varName</i> has no property of that name, the value of the variable NotSetValue is returned. 		
	See the LO	OPS Library Modules Manual about interaction with Masterscope.	
Arguments:	self	An instance or a class.	
	varName	Class variable name for self.	
	propName	Property name of class variable varName; may be NIL.	
Returns:	Value deper	nds on the arguments; see Behavior.	
Example:	The followin LeftButtonl	g command returns the value of the variable NotSetValue since tems has no property of the name qwerty .	
	-(GetClass NotSetValue	ValueOnly (\$ window1) 'LeftButtonItems 'qwerty)	
(PutClassValueOnly self varNal	me newValue	propName) [Function]	
Purpose:	change occ	e value of a class variable without triggering active values. The urs within a class and therefore causes a class variable lookup by ces to find the new value.	
Behavior:		or is the same as PutClassValue except that the value stored does n active value, but overwrites it instead.	
Arguments:	self	An instance or a class.	
	varName	Class variable name of self.	
	newValue	Value to be assigned to class variable or property name.	
	propName	Property name for class variable varName; may be NIL.	
Returns:	newValue		

(GetIVHere self varName propName)

[Function]

Purpose:	Gets the value stored in an instance without invoking active values.			
Behavior:	Returns the value of <i>varName</i> (or the property, <i>propName</i> , if it is non-NIL) without triggering active values. If the value of <i>varName</i> (or <i>propName</i>) is not yet stored in <i>self</i> , the value of the variable NotSetValue is returned.			
	See the LOC	OPS Library Modules Manual about interaction with Masterscope.		
Arguments:	self	Must be an instance.		
	varName	Instance variable of self.		
	propName	Property name for variable varName; may be NIL.		
Returns:	Value depends on the arguments; see Behavior.			
Example:	Given that			
	44←(← (\$ Window) New 'w2) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 496))			
	then			
	45←(GetIVHere (\$ w2) 'left) #,NotSetValue			
	After entering the command			
	46←(PutValue (\$ w2) 'left 123) 123			
	then			
	47←(GetIV	/Here (\$ w2) 'left)		

123

5.2.1 Compact Accessing Forms

When you write methods for classes that you have defined, there are a number of accesses to the data contained in the object bound to the method argument *self*. The following forms have been created to allow a more concise notation for these accesses.

Name	Туре	Description
@	Macro	Provides compact GetValue and GetClassValue forms.
@*	Macro	Provides compact GetValue forms.
@ →	Macro	Provides compact PutValue and PutClassValue forms and assigns a new value.

(@ accessF	Path)
------------	-------

[Macro]

Purpose:	Provides compact GetValue or GetClassValue forms.
Behavior:	The accessPath can be one, two, or three arguments.
	• If the <i>accessPath</i> is one argument, <i>self</i> is assumed to be the object and the argument points to an instance variable. This is the most common usage in methods in which you need to get the value of an instance variable contained in <i>self</i> . For example,

(@ iv1)

translates to

(GetValue self 'iv1).

• If the *accessPath* is two arguments, the first argument is an object and the second argument is an instance variable. For example,

(@ (\$ w) left)

translates to

(GetValue (\$ w) 'left).

 If the accessPath is three arguments, the first argument is an object, the second argument is an instance variable, and the third argument is a property. For example,

(@ (\$ w) menus DontSave)

translates to

(GetValue (\$ w) 'menus 'DontSave).

When programming using objects, one object often points to another object. For example, the value of an instance variable is another object. Using different *accessPath* forms allows you to write accesses into objects that are nested inside of other objects. As an example, assume an object (\$ pipe) has an instance variable named output with a value (\$ tank), which has an instance variable named **level**. The command

(@ (\$ pipe) output:level)

which is equivalent to

(@ (@ (\$ pipe) output) level)

gets the value of the instance variable level of (\$ tank).

The ":" is a delimiter that indicates instance variable access. The following table shows all the delimiters.

Delimiter	Description	
:	Indicates instance variable access.	
::	Accesses the value of a class variable whose name follows the double colon.	
:,	Accesses the value of a property whose name follows the colon- comma.	
	Sends a message to the object with the selector following the period.	
!	Evaluates the next expression.	
١	States that the next symbol refers to a Lisp symbol. This is often used in conjunction with the exclamation mark, above.	
\$	States that the next expression is a LOOPS object.	
You can test forms using these delimiters by evaluating		

(Parse@ (LIST accessPath) 'IV).

Arguments: accessPath One, two, or three arguments; refer to Behavior.

Returns: See Behavior.

Example: The following examples show the (@ accessPath) form, the Parse@ test, and the translation.

- 1. (@ foo)
 (Parse@ (LIST 'foo) 'IV)
 (GetValue self 'foo)
- 2. (@ ::fie:foe)
 (Parse@ (LIST '::fie:foe) 'IV)
 (GetValue (GetClassValue self 'fie) 'foe)

The following three examples are rarely seen in code, but they are additional examples of the expressions that can be interpreted by the system.

- 3. (@ foo::!::fum)
 (Parse@ (LIST 'foo::!::fum) 'IV)
 (GetClassValue (GetValue self 'foo) (GetClassValue self 'fum))
- 4. (@ (\$ w) fie:,foe.fum)
 (Parse@ (LIST '(\$ w) 'fie:,foe.fum) 'IV)
 (← (GetValue (\$ w) 'fie 'foe) fum)
- 5. (@ \$fie.foe:!\fum.!foo)
 (Parse@ (LIST '\$fie.foe:!\fum.!foo) 'IV)
 (←! (GetValue (← (GetObjectRec 'fie) foe) fum)(GetValue self 'foo))

(@* accessPath)

Provides a concise form for writing embedded GetValue forms.			
bllowed by an arbitrary number of instance variable			
The value of a nested instance variable.			
The command			
(@* (\$ foo) a b c)			
e (GetValue (\$ foo) 'a) 'b) 'c)			

(←@ accessPath newValue)

[Macro]

- Purpose/Behavior:
 Similar to the @ macro, but used to assign a new value instead of reading a value. Evaluates newValue.

 Arguments:
 accessPath
 See Behavior in the @ macro.

 NewValue
 Value to be assigned to variable indicated by accessPath.

 Returns:
 newValue

 Example:
 The following examples show the (←@ accessPath) form, the Parse@ test, and the translation.
 - 1. (←@ foo 1234)
 (ParsePut@ (LIST 'foo 1234) 'IV)
 (PutValue self 'foo 1234)

```
2. (←@ ($ w) ::left 1234)
  (ParsePut@ (LIST ($ w) '::left 1234) 'IV)
  (PutClassValue #.($ w) 'left 1234)
```

3. (←@ (\$ w) menus DontSave 'Any)
 (ParsePut@ (LIST (\$ w) 'menus 'DontSave '(QUOTE Any)) 'IV)
 (PutValue #.(\$ w) 'menus 'Any 'DontSave)

5.2.2 Support for Changetran

Interlisp uses Changetran to provide an extensive set of facilities for expressing changes to structures, such as push, pushnew, pop, add, change, by using access expressions. You can use any LOOPS access expression in a Changetran context, so that you can now write expressions such as:

```
(push (@ v1) newTop)
(change (@ x) newValue)
(pushnew (@ colors:,truck) 'red)
(pop (@ ::cv17))
(add (@ x:y:z) 37)
```

The first two are equivalent to:

```
(PushValue self 'v1 (CONS newTop(@ V1)))
(_@ x newValue)
```

This uniform interface allows simpler expressions for changes, and arbitrary extensions through Changetran. See the *Interlisp-D Reference Manual* for more information on Changetran.

5.3 Accessing Data in Classes

A number of functions and methods are available for reading and storing data within classes. Some of these change existing data, and others change the structure of the class by adding variables or properties.

When reading or storing data, some of these functions trigger any active values that are associated with that data. See Chapter 8, Active Values, for a discussion of their behavior.

5.3.1 Metaclass and Property Access

Associated with a class are a metaclass and properties. This section describes the following functions to manipulate their values.

Name	Туре	Description
GetClass	Function	Obtains a class's metaclass or properties.
PutClass	Function	Changes the metaclass or class properties of a class.
GetClassOnly	Function	Obtains a class's metaclasses or properties without triggering active values.
PutClassOnly	Function	Changes the metaclass or class properties of a class without triggering active values.

GetClassHere		Function	Obtains a property local to the class.	
(GetClass	classRec propName)			[Function]
	Purpose:	Obtains a cl	ass's metaclass or properties by following metaclass linl	<s.< td=""></s.<>
	Behavior:	Sends the message GetClassProp to <i>classRec</i> and passes <i>propName</i> as an argument.		
Varies according to the arguments.If <i>propName</i> is NIL, this returns the <i>class</i>'s metaclass.		Varies accor	rding to the arguments.	
		me is NIL, this returns the <i>class</i> 's metaclass.		
			me is non-NIL, this looks first in <i>cla</i> ss for that property. re, it looks through <i>class</i> 's metaclass links.	lf it cannot
		If no prop	perty is found, the value of the variable NotSetValue is re	eturned.
	Arguments:	classRec	Pointer to a class.	
		propName	Property name.	
	Returns:	See Behavio	or.	
	Example:	The followin	g commands show the variety of returned values.	
		31←(GetC #,(\$C Cla	lass (\$ Window)) ass)	
			lass (\$ Window) 'doc) 6 object which represents a window"	
		"An icon	lass (\$ IconWindow) 'doc) window that appears as an irregular shape reen See the ICONW Library utility"	d image

(PutClass classRec newValue propName)

Purpose:	Changes the metaclass or class properties of a class.		
Behavior:	Varies according to the arguments.		
	• If propName is NIL, this changes the metaclass of classRec to newValue. It newValue is not a class or the name of a class, this causes a break.		
	• If <i>propName</i> is non-NIL and <i>classRec</i> already has this property, this triggers an active value on <i>propName</i> if it exists and changes the value of <i>propName</i> to <i>newValue</i> .		
	 If propName is non-NIL and classRec does not have this property, the property is added with the value newValue. 		
	Marks the cl	ass <i>classRec</i> as changed.	
Arguments:	classRec	Pointer to a class.	
	newValue	See Behavior.	
	propName	Property name.	
Returns:	Newly create	ed class object.	
Example:	The followin	g command changes the doc property of class Datum :	

```
66←(DefineClass 'Datum)
#,($C Datum)
67←(PutClass ($ Datum) '(* this is the updated doc for class Datum) 'doc)
(* this is the updated doc for class Datum)
```

[Function]

[Function]

Purpose:	Obtains a class's metaclass or properties by following superclass links, without triggering active values.		
Behavior:	Varies according to the arguments.		
	• If propName is NIL, this returns the classRec's metaclass.		
	 If propName is non-NIL, this looks first in classRec for that property. If it cannot find it there, it looks through classRec's supers links. This returns the value of the property found without triggering active values. 		
	• If no property is found, the value of the variable NotSetValue is returned.		
Arguments:	classRec Pointer to a class.		
	propName Property name.		
Returns:	Value depends on the arguments; see Behavior.		
Example:	The command		
	(GetClassOnly (\$ IconWindow) 'doc)		
	returns		
	"An icon window that appears as an irregular shaped image on the screen See the ICONW Library utility"		

(PutClassOnly classRec newValue propName)

Purpose:	Changes the metaclass or class properties without triggering active values.		
Behavior:	Varies according to the arguments:		
	 If propName is NIL, this changes the metaclass of classRec to newVa newValue is not a class or the name of a class this causes a break. 		
	 If propName is non-NIL and classRec already has this property, this changes the value of propName to newValue. Any active values are replaced. 		
	 If propName is non-NIL ar property is added with the 	nd <i>classRec</i> does not have this property, the value <i>newValue</i> .	
	The class <i>classRec</i> is marke	d as changed.	
Arguments:	classRec Pointer to a cla	ss.	
	newValue A class or the r	name of a class.	
	propName NIL or the nam	e of a class property.	
Returns:	newValue		

(GetClassHere classRec propNa	me) [Function]
Purpose:	Obtains property local to class.
Behavior:	Gets the class property without triggering active values or inheritance. If there is no local property the value of NotSetValue is returned.
Arguments:	classRec Pointer to a class.
	propName NIL or the name of a class property.
Returns:	newValue
Example:	The command
	(GetClassHere (\$ ActiveValue) 'doc)
	returns
	#,NotSetValue

5.3.2 Class Variable Access

A class variable can be thought of as being shared by all instances of that class and by all instances of any of its subclasses. This section describes how to access class variables with the functions shown in the following table.

Name	Туре	Description
GetClassValue	Function	Returns the value of a class variable or property.
PutClassValue	Function	Stores a value in a class variable or property.
GetClassValueOnly	Function	Returns the value of a class variable or property, without triggering active values.
PutClassValueOnly	Function	Stores a value in a class variable or property, without triggering active values.
GetCVHere	Function	Returns the value of a class variable in a particular class without looking for inherited values.
PutCVHere	Function	Stores a class variable locally with a value if it is not local.

(GetClassValue self varName prop)

Purpose:	Returns the value of a class variable or property.
Behavior:	Varies according to the arguments.
	If <i>self</i> is an instance, the lookup begins at the class of the instance, since instances do not have class variables stored locally. If <i>self</i> is a class, the lookup is in that class.
	 If prop is NIL, GetClassValue returns the value of the class variable varName. If varName is not found, this breaks.
	 If prop is non-NIL, GetClassValue returns the value of the property prop, associated with the class variable varName. If the value is an active value, it is activated. If varName has no property prop, this returns the value of the variable NoValueFound.

If the class does not have a class variable *varName*, **GetClassValue** searches through the super classes of the class until it finds *varName*. Since this is rare, class variables are stored only in the class in which they are defined, and the runtime search is necessary.

Arguments:	self	An instance or a class.		
	varName	A class variable name.		
	prop	Property name.		
Returns:	Value deper	Value depends on the arguments; see Behavior.		
Example:	Given that			
	(← (\$ Window) New 'window1)			
then the command		nmand		
	(GetClassValue (\$ window1) 'LeftButtonItems) returns the same value as the command			
(GetClassValue (\$ Window) 'LeftButtonItems)		Value (\$ Window) 'LeftButtonItems)		
	The comma	nd		
	(GetClass	Walue (\$ Window) 'abcde)		
	breaks. The	e command		
	(GetClass	Walue (\$ Window) 'LeftButtonItems 'wxyz)		
	returns the	value of NoValueFound .		

(PutClassValue self varName newValue propName)

		, ,	
Purpose:	Stores a val	ue in a class variable or property.	
Behavior:	Varies according to the arguments.		
	If <i>self</i> is an instance, the lookup begins at the class of the instance, since instances do not have class variables stored locally. If <i>self</i> is a class, the lookup is in that class.		
	 If prop is NIL, PutClassValue changes the value of the class variable varName. 		
		non-NIL, PutClassValue stores <i>newValue</i> as the value of the <i>prop</i> . If an active value is the current value, it is triggered.	
	If <i>varName</i> i inheritance I occurs.	s not local to the class, the value is put in the first class in the ist in which <i>varName</i> is found. If <i>varName</i> is not found, a break	
Arguments:	self	An instance or a class.	
	varName	A class variable name.	
	newValue	A new value.	
	propName	Property name.	
Returns:	newValue		
Example:	Given that		

 $(\leftarrow (\$ Window) New 'window1)$

then the command

(PutClassValue (\$ window1) 'LeftButtonItems 2 'number)

adds the property number with the value 2 to the class variable **LeftButtonItems** of the class **Window.** The following command performs the same action.

(PutClassValue (\$ Window) 'LeftButtonItems 2 'number)

(GetClassValueOnly classRec varName prop)

[Function]

Purpose:	Returns the value of a class variable or property, without triggering active values.
Behavior:	Similar to GetClassValue, with the following exceptions:
	 If GetClassValueOnly finds that the value is an active value, the active value is returned without being triggered.
	 If prop is non-NIL and is not found, GetClassValueOnly returns the value of the variable NotSetValue.
Arguments:	See GetClassValue.
Returns:	Value depends on the arguments; see Behavior.
Example:	The command
	(GetClassValueOnly (\$ Window) 'abcde)
	breaks. The command
	(GetClassValueOnly (\$ Window) 'LeftButtonItems 'wxyz)
	returns the value of NotSetValue.

(PutClassValueOnly self varName newValue propName)

[Function]

Purpose:	Stores the value of a class variable or property, without triggering active values.
Behavior:	Similar to PutClassValue , except that PutClassValueOnly does not trigger an active value, but replaces it with <i>newValue</i> .
Arguments:	See PutClassValue .
Returns:	Used for side effect only.

(GetCVHere classRec varName propName)

Purpose:	Returns the value of a class variable in a particular class without looking for inherited values.
Behavior:	Returns the value of the class variable <i>varName</i> , or the <i>propName</i> property if <i>propName</i> is non-NIL.
	If the value is an active value, it is returned without being triggered.
	If there is no <i>varName</i> (or <i>propName</i>), this returns the value of the variable NotSetValue .

Arguments: classRec Must be a class. A class variable name. varName propName Property name. Returns: Value depends on the arguments; see Behavior. Example: The command (GetCVHere (\$ NonRectangularWindow) 'LeftButtonItems) returns #,NotSetValue The command (GetCVHere (\$ Window) 'LeftButtonItems) returns ((Update (QUOTE Update)...)

(PutCVHere self varName value)

[Function]

Purpose:	Puts a class variable locally with a value if it is not local.	
Behavior:	Calls (AddCV self varName value).	
Arguments:	self	An instance or a class.
	varName	A class variable name.
	value	Value for the class variable.
Returns:	value	

5.3.3 Instance Variable Access

An instance variable can be thought of as being local to each instance of a class. The class defines what instance variables and their default values will be in an instance. This section describes the functions that manipulate the default values in the class.

See the LOOPS Library Modules Manual for interaction with Masterscope.

Name	Туре	Description
GetClassIV	Function	Gets the default value of an instance variable or associated property as defined in a class or one of its supers.
GetClassIVHere	Function	Gets the default value of an instance variable or associated property as defined in a class.
PutClassIV	Function	Changes the default value for an instance variable in a class.

(GetClassIV self varName prop)

[Function]

Purpose:

Gets the default value of an instance variable or associated property as defined in a class or one of its supers.

Behavior:	If self is not bound to a class, an error occurs. Searches through the supers of <i>self</i> to find <i>varName</i> or <i>prop</i> .		
	• If prop is	NIL, this returns the default value for varName.	
	• If <i>prop</i> is non-NIL, this returns its default value.		
	If the default	t value is an active value, it is returned without being triggered.	
Arguments:	self	Must be bound to a class.	
	varName	The name of an instance variable.	
	prop	Name of a property associated with varName.	
Returns:	Value deper	nds on the arguments; see Behavior.	
Example:	The commands		
		IV (\$ Window) 'window) IV (\$ NonRectangularWindow) 'window)	
	both return		
	#,(\$AV Li	ispWindowAV)	

(GetClassIVHere self varName prop)

[Function]

Purpose:	Gets the default value of an instance variable or associated property as defined in a class.	
Behavior:	Similar to GetClassIV . This does not search the super classes of <i>self</i> for <i>varName</i> . If <i>varName</i> or <i>prop</i> is not local to <i>self</i> , this returns the value of NotSetValue .	
Arguments:	self	Pointer to a class.
	varName	Name of an instance variable.
	prop	Name of a property associated with varName.
Returns:	The default	value of varName or prop or NotSetValue.
Example:	The comma	nd
	(GetClass	IVHere (\$ Window) 'window)
	returns	
	#,(\$AV Li	spWindowAV)
	the commar	nd
	(GetClass	IVHere (\$ NonRectangularWindow) 'window)
	returns	
	#,NotSetV	alue

(PutClassIV self varName newValue propName)

[Function]

Purpose: Changes the default value for an IV in a class.

- Behavior: If *self* is not a class that contains the instance variable *varName*, an error occurs.
 - If *propName* is NIL, the default value for the instance variable *varName* is changed to *newValue*.
 - If propName is non-NIL, the default value for it is changed to newValue.

Arguments:	self	Must be a class that contains the instance variable varName.
	varName	An instance variable name.
	newValue	The new default value.
	propName	Property name.
Returns:	newValue (u	used for side effect only).
Example:	After the commands 68←(DefineClass 'Datum) #,(\$C Datum)	
	69←(← (\$ id#	S Datum) AddIV 'id# NIL)
		command changes the default value of the instance variable id# new instances of the class Datum :
	70←(PutC (7)	lassIV (\$ Datum) 'id# '(7))

[This page intentionally left blank]

abstract class	A class which cannot be instantiated, for example, ActiveValue.
active value	The mechanism that carries out access-oriented programming for variables in LOOPS. Active values send messages as a side effect of having an object's variable referenced.
activeValue	The previous implementation of the active value concept.
ActiveValue	An abstract class that defines the general protocol followed by all active value objects.
annotatedValue	A special Interlisp-D data type that wraps each ActiveValue instance.
AnnotatedValue	An abstract class that allows an annotatedValue to be treated as an object.
browser	A window that allows you to examine and change items in a data structure.
class	A description of one or more similar objects; that is, objects containing the sames types of data fields and responding to the same messages.
class inheritance	The means by which a class inherits variables, values, and methods from its super class(es).
class lattice	A network showing the inheritance relationship among classes.
class variable (CV)	A variable that contains information shared by all instances of the class. A class variable is typically used for information about a class taken as a whole.
inheritance	The means by which you can organize information in objects, create objects that are similar to other objects, and update objects in a simplified way.
Inspector	A Lisp display program that has been modified to allow you to view classes, objects, and active values.
instance	An object described by a particular class. Every object within LOOPS is an instance of exactly one class.
instance variable (IV)	A variable that contains information specific to an instance.
instantiate	To make a new instance of a class.
lattice	An arrangement of nodes in a hierarchical network, which allows for multiple parents of each node.
Masterscope	A Lisp Library Module program analysis tool that has been modified to allow analysis of LOOPS files.
message	A command sent to an object that activates a method defined in the object's class. The object responds by computing a value that is returned to the sender of the message.
metaclass	Classes whose instances are classes or abstract classes.
method	What an object applies to the arguments of a message it receives. This is similar to a procedure in procedure-oriented programming, except that here, you determine the message to send and the object receiving the message determines the method to apply, instead of the calling routine determining which procedure to apply.

mixin	A class that is used in conjunction with another class to create a subclass. Mixins never have instances, and hence have AbstractClass as their metaclass.
object	A data structure that contains data and a pointer to functionality that can manipulate the data.
property list	A place for storing additional information on classes, their variables, and their methods.
selector	Part of a message that is sent to an object. The object uses the selector to determine which method is appropriate to apply to the message arguments.
self	A method argument that represents the receiver of the message.
specialization	The process of creating a subclass from a class, or the result of that process.
subclass	A class that is a specialization of another class.
super class	A class from which a given class inherits variables, values, and methods.
Tofu	An acronym for Top of the universe, which is the highest class in the LOOPS hierarchy.
Unique Identifier (UID)	An alphanumeric identifier that LOOPS uses to store and retrieve objects. Objects do not have UIDs unless they are named, are instances of indexed objects, or are instances printed to a file.
wrap	Objects have fields that can contain data. Some ActiveValue can be added so this data is stored within it. When this occurs, the ActiveValue wraps the data.

Methods are the expressions that evaluate when a message is sent to an instance or a class. Methods are analogous to Interlisp-D functions, except that they are defined by a LOOPS class and invoked by sending a message to an instance of that class.

This chapter presents the basic constructs used to create and implement methods. Also included are important methods and functions relevant to the definition and maintenance of methods.

6.1 Categories	6
	LOOPS methods can be divided into categories. This section contains a brief description of each method category. These categories serve as additional documentation only; they do not imply differences in implementation.
	Any symbol can be used as a category. Categories can be used as a tool for the organization of methods. Methods may belong to more than one category.
Class	[Category]
	Messages associated with a class method can only be sent to an object of type class. Methods associated with the class Class have this category. See Chapter 3, Classes, for more information on classes.
Object	[Category]
	The message associated with an object method can only be sent to an object of type object. Methods associated with the class Object have this category.
Internal	[Category]
	Internal methods are low-level system methods, and should not be specialized by users.
Public	[Category]
	Public methods are defined by the user or the system. These methods can be specialized by users.
Any	[Category]
	Methods that have not been categorized belong to this category by default.
Masterscope	[Category]

Masterscope is an interactive program analysis tool. Methods that are predefined for Masterscope are local only to Masterscope and can be used only when Masterscope has been invoked. Refer to the *Lisp Library Modules Manual* for more information on Masterscope.

(<i>elf</i> AllMethodCategories)	[Method of Class]
Purpose/Behavior:	Extracts and lists the categories of all methods defined by the class self.
Arguments:	self Pointer to a class.
Returns:	The categories of the methods defined by the class of self.
Categories:	Class
Example:	Line 98 shows the categories of all methods defined in the class self.
	98←(← (\$ Class) AllMethodCategories) (Class Object Masterscope)

(<- self CategorizeMethods categorization)

[Method of Class]

Purpose:	Allows you to change how methods are categorized.		
Behavior:	Varies according to the arguments.		
	 If categorization is NIL, this opens a display editor window with a form that represents the current categorizations. After you have exited from the editor, these new categorizations are installed. 		
	• If categorization is non-NIL, it must be of the following form:		
	(category1 (selector1 selectorN)) (category2 (selector)).		
	A categorization specified by CategorizeMethods deletes any previous categorization; i.e., if method Print for class Thing was in categories Internal and I/O, after doing		
	(← (\$ Thing) CategorizeMethods ′((Output (Print))(Printing (Print))))		
	Print will be only in categories Output and Printing.		
Arguments:	self Pointer to a class.		
	<i>categorization</i> A list in the form as described in Behavior, or NIL.		
Categories:	Class		
Example:	This example shows how to use CategorizeMethods with categorization NIL.		
	$1 \leftarrow (\leftarrow (\$ MetaClass) CategorizeMethods)$		
	The following display editor window appears:		

SEdit Package; INTERLISP

((Any (CreateClass DestroyInstance New NewWithValues)) (Public (CreateClass DestroyInstance New NewWithValues)) (Internal NIL) (MetaClass (CreateClass)) (Class (DestroyInstance New NewWithValues)))

(*c* self **ChangeMethodCategory** selector newCategory)

[Method of Class]

Purpose: Changes the category of a selected method. Behavior: Varies according to the arguments. • If selector is NIL, a menu appears showing the selectors for the class of self. This is done using the message PickSelector to determine the selector that is to have its category changed. • If selector is supplied, but not associated with self, this message returns NIL. • If newCategory is an atom, adds selector to the category. If newCategor a list of atoms, removes selector from all its current categories, then add to the categories in the list. If newCategory is NIL, pops up a menu showing all of the known categories and an additional item, *other*. If *other* is selected, you are prompted to enter a new category name. Arguments: self Pointer to a class. selector Method selector for class of self or NIL. newCategory An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated of Shape1. 2 (<((§ Window) ChangeMethodCategory 'Shape1 ' (Window Internal)) (Window Internal) (Window Internal)				
 If selector is NIL, a menu appears showing the selectors for the class of self. This is done using the message PickSelector to determine the selector that is to have its category changed. If selector is supplied, but not associated with self, this message returns NIL. If newCategory is an atom, adds selector to the category. If newCategor a list of atoms, removes selector from all its current categories, then add to the categories in the list. If newCategory is NIL, pops up a menu showing all of the known categories and an additional item, *other*. If *other* is selected, you are prompted to enter a new category name. Arguments: self Pointer to a class. selector Method selector for class of self or NIL. newCategory An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated with Shape1. 2← (← (\$ Window) ChangeMethodCategory 'Shape1 ' (Window Internal)) 	Purpose:	Changes the category of a selected method.		
self. This is done using the message PickSelector to determine the selector that is to have its category changed. • If selector is supplied, but not associated with self, this message returns NIL. • If newCategory is an atom, adds selector to the category. If newCategor a list of atoms, removes selector from all its current categories, then add to the categories in the list. If newCategory is NIL, pops up a menu showing all of the known categories and an additional item, *other*. If *other* is selected, you are prompted to enter a new category name. Arguments: self Pointer to a class. selector Method selector for class of self or NIL. newCategory An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated v Shape1. 2← (← (\$ Window) ChangeMethodCategory 'Shape1 ' (Window Internal))	Behavior:	Varies acco	ording to the arguments.	
NIL. • If newCategory is an atom, adds selector to the category. If newCategor a list of atoms, removes selector from all its current categories, then add to the categories in the list. If newCategory is NIL, pops up a menu showing all of the known categories and an additional item, *other*. If *other* is selected, you are prompted to enter a new category name. Arguments: self Pointer to a class. selector Method selector for class of self or NIL. newCategory An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated v Shape1. 2← (← (\$ Window) ChangeMethodCategory 'Shape1 ' (Window Internal))		 If selector is NIL, a menu appears showing the selectors for the class of self. This is done using the message PickSelector to determine the selector that is to have its category changed. 		
a list of atoms, removes selector from all its current categories, then add to the categories in the list. If newCategory is NIL, pops up a menu showing all of the known categories and an additional item, *other*. If *other* is selected, you are prompted to enter a new category name. Arguments: self Pointer to a class. selector Method selector for class of self or NIL. newCategory An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated with the following command changes the category 'Shape1. 2← (← (\$ Window) ChangeMethodCategory 'Shape1 '(Window Internal))				
selector Method selector for class of self or NIL. newCategory An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated w Shape1. 2← (← (\$ Window) ChangeMethodCategory 'Shape1 ' (Window Internal))		a list of a to the ca showing	toms, removes <i>selector</i> from all its current categories, then adds it tegories in the list. If <i>newCategory</i> is NIL, pops up a menu all of the known categories and an additional item, *other* . If	
newCategory An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated w Shape1. 2←(← (\$ Window) ChangeMethodCategory 'Shape1 ' (Window Internal))	Arguments:	self	Pointer to a class.	
An atom, a list of atoms, or NIL. Returns: The new category if there was a change made; else NIL. Categories: Class Example: The following command changes the categories of the method associated with the state of the		selector	Method selector for class of self or NIL.	
Categories: Class Example: The following command changes the categories of the method associated w Shape1. 2←(← (\$ Window) ChangeMethodCategory 'Shape1 '(Window Internal))		newCatego	ry An atom, a list of atoms, or NIL.	
Example: The following command changes the categories of the method associated v Shape1. 2←(← (\$ Window) ChangeMethodCategory 'Shape1 '(Window Internal))	Returns:	The new category if there was a change made; else NIL.		
Shape1. 2←(← (\$ Window) ChangeMethodCategory 'Shape1 '(Window Internal))	Categories:	Class		
'Shape1 '(Window Internal))	Example:		ng command changes the categories of the method associated with	
		'Shape1	(Window Internal))	

6.2 Structure of Method Functions

This section discusses the structure of a LOOPS method.

(**Method** :FUNCTION-TYPE type ((class selector) self args ...) body...)

[Definer]

Purpose: Similar to **DefineMethod**, but gives more control over the argument list and body syntax. Allows use of Common Lisp lambda argument lists, and Common Lisp syntax in the body of the method. This is the form you will see when editing methods.

Behavior: Defines a method whose argument list is either Interlisp (default) or Common Lisp style. The body of the method may likewise contain either Common Lisp

or Interlisp syntax. Common Lisp syntax is distinguished by lexical scoping, etc. (see the *Common Lisp Implementation Notes* for more information).

Arguments:

	type	The :FUNCTION-TYPE type clause is optional and defaults to :IL.				
		:IL - The body of the method uses Interlisp syntax, allows CLISP expressions, etc.				
		:CL - The body of the method uses Common Lisp syntax (is lexically scoped).				
	class	The class to which the method will be attached.				
	selector	The new method's selector.				
	self	This argument must be present and first.				
	args	If type was given as :CL this argument list may contain Common Lisp keys like &OPTIONAL, &KEY and &REST.				
	body	The body of the method. If the type was given as :CL it will be treated as the body of a Common Lisp lambda is, e.g. scoping will be lexical.				
Returns:	The name of the method function.					
Example:	<pre>12← (Method :FUNCTION-TYPE :CL ((Window Foo) self bar &OPTIONAL baz &REST glorp)</pre>					

6.3 Creating, Editing, and Destroying Methods

This section describes the methods and functions which are used to create, rename, delete, and edit LOOPS methods.

Name	Туре	Description
DefineMethod	Function	Defines a new method on a class.
DeleteMethod	Function	Deletes a method from a class.
EditMethod	Method	Invokes the editor on a method of a class.
SubclassResponsibil	ity	Macro Appears in the template when you create a new method.

(DefineMethod class selector args expr file -)

Purpose:	Defines a new method on a class.		
Behavior:	Varies according to the arguments.		
	as the n appropr Also, <i>ar</i>	a non-NIL symbol and <i>expr</i> is NIL, its function definition is installed nethod for (class selector). This definition must accept an late number of arguments and otherwise work as a LOOPS method. <i>gs</i> must be a symbol of the form Name1.Name2 for many of the internal routines to handle it properly.	
		a list of arguments and <i>expr</i> is a function, its body will be installed efinition of class.selector .	
Arguments:	class	Class in which method is defined.	
	selector	Method selector (message).	
	args	List of arguments.	
	expr	Function definition or NIL.	
	file	Place where method is stored.	
Example:		ng expression shows how to add a method called Increment to a d Documentation .	
(DefineMethod	(\$ Documen	tation) 'Increment '(Number) '(PLUS number 1]	
(DefineMethod		tation) 'Increment '(Number) '(PLUS number 1] [Function]	
	prop)		
(DeleteMethod class selector p	prop) Deletes a r	[Function]	
(DeleteMethod class selector p Purpose:	prop) Deletes a r Varies acc	[Function] nethod from a class.	
(DeleteMethod class selector p Purpose:	Deletes a r Deletes a r Varies acc • If <i>prop</i> is	[Function] nethod from a class. ording to the arguments.	
(DeleteMethod class selector p Purpose:	Deletes a r Deletes a r Varies acc If <i>prop</i> is If <i>prop</i> is Note: Yo Br mi	[Function] method from a class. ording to the arguments. s NIL or T, the method is deleted from the class.	
(DeleteMethod class selector p Purpose:	Deletes a r Deletes a r Varies acc If <i>prop</i> is If <i>prop</i> is Note: Yo Br mi	[Function] nethod from a class. ording to the arguments. s NIL or T, the method is deleted from the class. s T, the function definition is also deleted. u may also delete methods by using the ClassInheritance owser. Position the mouse on the appropriate class, press the ddle mouse button, and select DeleteMethod from the resulting	
(DeleteMethod class selector p Purpose: Behavior:	Deletes a r Varies acc If <i>prop</i> is If <i>prop</i> is Note: Yo Br mi	[Function] method from a class. ording to the arguments. s NIL or T, the method is deleted from the class. s T, the function definition is also deleted. u may also delete methods by using the ClassInheritance owser. Position the mouse on the appropriate class, press the ddle mouse button, and select DeleteMethod from the resulting enu.	

Example: The following command deletes the method associated with '**MyOpen** from **LatticeBrowser**.

(DeleteMethod (\$ LatticeBrowser) 'MyOpen)

(← self EditMethod selector commands okCategories)

[Method of Class]

Purpose: Invokes the display editor on a method of a class.

- Behavior: Varies according to the arguments.
 - If *selector* is NIL, a menu of selectors is presented using the message **PickSelector** in *okCategories*. This can be a list or a symbol.
 - If *selector* is non-NIL, and if it corresponds to a method that is in not *self's* class, you are asked whether the method should be created.

	local sele inherited determin	br cannot be found, the spelling corrector is invoked to find a correct ector. If it can be corrected, the local method is used, or an method that is made local is used. When the method is finally ed, EDITF (refer to the <i>Lisp Release Notes</i> and the <i>Interlisp-D</i> <i>ce Manual</i>) is invoked with <i>commands</i> passed as the second it.
	Pos	a may also edit methods by using the ClassInheritance Browser . sition the mouse on the appropriate class, press the middle mouse ton, and select EditMethod from the resulting menu.
Arguments:	self	Class name.
	selector	Refers to the method.
	commands	List of EDITF commands.
	okCategorie	Atom or list specifying valid categories.
Categories:	Class	
(SubclassResponsibility)		[Macro]
Purpose/Behavior:		the template when you create a new method. It is used to make ecialize a method.

6.4 Escaping from Message Syntax

The methods described in the previous section manipulate methods in a specific order. Sometimes it may be necessary to invoke multiple inherited methods in some other order. The more general functions in this section have been provided to do this.

CAUTION

These functions do not conform to the conventions of method inheritance and should be used as a last resort and with extreme caution.

The following table shows the items in this section.

Name	Туре	Description
DoMethod	Function	Computes the action which should be a method associated with a class and applies it to an object and arguments.
ApplyMethod	Function	Computes the action which should be a method associated with a class and applies it to an object and argument list.
DoFringeMethod	Function	Invokes a method in the class of an object or in each of the super classes for that class.

(DoMethod object selector class arg1 ... argn)

	Purpose:	Computes the applies it to	ne action which should be a method associated with <i>clas</i>	s and
	Behavior:	All of the arguments are evaluated. If <i>class</i> is NIL, DoMethod uses the class of <i>object</i> . If no method from <i>class</i> can be computed from <i>selector</i> , an error is generated.		
	Arguments:	object	Instance to which action is applied.	
		selector	Evaluates to a method selector.	
		class	NIL or class in which method name resides.	
		arg1argn	The arguments for the method.	
(ApplyMethod	object selector ar	gList class)		[Function]

Purpose:	Same as Do	Method.	
Behavior:	Applies the selected method to the already evaluated arguments in <i>argList</i> ; otherwise, this is the same as DoMethod.		
Arguments:	object	Instance to which action is applied.	
	selector	Evaluates to a method name.	
	arglist	The arguments for the method.	
	class	Class in which method name resides.	
Example:	ApplyMetho MessageNo selector. (Se	e illustrates the MessageNotUnderstood protocol, the function od, and the macro _Super . This is a specialization of the default otUnderstood message that tries to correct the spelling of the ee Chapter 11, Errors and Breaks, for more information on otUnderstood .)	
(LET ((correctSelector	r mesageAr (FixSelect or (ApplyM)	guments superFlg)	
(DoFringeMethods object selector			
Purpose:		hod for <i>selector</i> in the class of <i>object</i> or in each of the super	
Behavior:	Evaluates all of the arguments. If the method for <i>selector</i> in the class of <i>object</i> is defined in that class (not through inheritance), DoFringeMethods invokes the local method. If there is no local method, DoFringeMethods goes down the class of <i>object</i> , and for each super invokes its method for selector if one exists. If the supers share supers this can result in the same method being called more than once.		
Arguments:	object	Class instance.	
	selector	Method selector.	
	arg1argn	Arguments to selector.	
Returns:	NIL		

6.5 Movement between Classes

This section describes functions and methods that are used in moving methods between classes, as well as stack method macros.

6.5.1 Movement of Methods

The following functions and methods are used to move methods, instance variables, and class variables between classes.

Name	Туре	Description
RenameMethod	Function	Renames a function used as a method.
MoveMethod	Function	Moves a method from one class to another.
MoveMethod	Method	Moves a method from one class to another.
MoveMethodToFile	Function	Moves a method to this file if it has the same name as a function on a specified file.
CalledFns	Function	Finds names of all functions called from a set of classes.

(RenameMethod classOrName oldSelector newSelector)

Purpose: Renames a function used as a method in classOrName. Behavior: This changes the selector for a method. If no method is associated with oldSelector or newSelector, this generates an error. Explicit references to oldSelector such as (←Super self oldSelector)) will not be fixed by RenameMethod. Arguments: classOrName Class in which function is defined. oldSelector Old name of method; invokes method before this function is called. newSelector New name of method; invokes method after this function is called. Returns: If successful, returns *newSelector* in the form **ClassName.Selector**. Example: The following command renames a method named **Foo** to **Fie** in the class MyClass. 24←(RenameMethod (\$ MyClass) 'Foo 'Fie) (MoveMethod oldClassName newClassName selector newSelector files) [Function] Moves a method from oldClassName to newClassName. The method is Purpose:

- deleted from *oldClassName*.
- Behavior: If *newSelector* is a different name than *selector*, **MoveMethod** renames the method. Explicit references to *oldSelector* such as

	(←Supe	r self oldSelector))		
	will not be fixed by RenameMethod .			
	E r	You may also move methods by using the ClassInheritance Browser. Position the mouse on the appropriate class, press the niddle mouse button, and select MoveMethod from the resulting nenu.		
Arguments:	oldClass	Name Source class.		
	newClas	sName Destination class.		
	selector	Method selector to be moved.		
	newSele	<i>ctor</i> New name; if NIL, the existing <i>selector</i> is preserved.		
	files	Files in which the change is to occur.		
Example:		wing command moves the method Buy from class Car to class Boat mes the method to Purchase .		
	25←(Mc Boat.Pı	veMethod (\$ Car) (\$ Boat) 'Buy 'Purchase) urchase		
(← self MoveMethod newClassN	ame selec	tor) [Method of Class]		
Purpose:	Moves a	method from the class associated with self to newClassName.		
Behavior:	Same as	the function MoveMethod , except that you cannot rename selector.		
Arguments:	self	Pointer to a class from which the method is taken.		
	newClas	sName Destination class; must be a class, not a class name.		
	selector	Method selector to be moved.		

Returns: NewsClass.Selector

(MoveMethodsToFile file)

Purpose/Behavior:	Moves a method to this file if it has the same name as a function on file.		
Arguments:	file	Name of a file to which methods are moved.	
Returns:	Normally T; file.	NIL if a method does not have the same name as a function on	

definedFlg)	[Function]
Purpose:	Finds names of all functions called from a set of <i>classes</i> .
Behavior:	Varies according to the arguments.
	• If <i>definedFlg</i> is NIL, all the functions associated with <i>classes</i> are returned.
	• If <i>definedFlg</i> is T, the defined functions are returned.

• If *definedFlg* is 1, the undefined functions are returned.

Arguments:	classes List of classes to search.		
	definedFlg	NIL, 1, or T.	
Returns:	NIL or the list of functions.		
Example:	The following command finds all functions called from the class Method.		
	(CalledFn	s '(Method))	

6.5.2 Stack Method Macros

This section describes macros that access methods on the stack.

(ClassNameOfMethodOwner)	[Macro]	
Purpose:	Uses the stack to perform a help check. Returns the name of the class to which the method on top of the stack belongs.	
(SelectorOfMethodBeingCompiled)		
Purpose:	Uses the stack to perform a help check. Returns the name of the method being compiled.	
(ArgsOfMethodBeingCompiled) [Macro]	
Purpose:	Uses the stack to perform a help check. Returns all arguments associated with the method being compiled.

Objects in LOOPS communicate with each other by sending messages. This chapter describes the standard message sending forms used in LOOPS.

	The following table shows the macros in this section.		
Name	Туре	Description	
\leftarrow	Macro and Function	Sends a message to an object.	
SEND	Macro and Function	Sends a message to an object.	
-1	Macro and Function	Evaluates the selector and sends a message to an object.	
−VI→	Macro	Invokes the function stored in an instance variable of the object.	
←Try	Macro	Sends a message to an object only if it has a corresponding method.	
←Proto	Macro	Sends a message to the prototype instance of a class.	
←Super	Macro and Function	Combines an inherited method with local code; must appear in the body of a method.	
←Super?	Macro	Combines an inherited method with local code; must appear in the body of a method. This does not cause an error if there is no inherited method.	
←SuperFringe	Macro and Function	Invokes general methods for objects with more than one super class from which to inherit methods; must appear in the body of a method.	
←New	NLambda NoSpread Macro	Creates an instance of a class and then sends a message to that instance.	
FetchMethod	Macro	Finds the function name which implements the method invoked by a selector.	
	In addition, Chapter 8, Active Values, contains a description of $\leftarrow AV$, and		

The following table shows the macros in this section.

7.

In addition, Chapter 8, Active Values, contains a description of \leftarrow **AV**, and Chapter 15, Performance Issues, contains a description of \leftarrow **Process** and \leftarrow **Process!**.

$(\leftarrow$ self sel arg1 argn)	[Macro and Function]	
Purpose:	Sends the message with the selector <i>sel</i> to an object <i>self</i> . This is the standard way to send a message.	
Behavior:	Evaluates all arguments except sel.	
	When an object receives a message, it tries to match the selector <i>sel</i> with the names of its methods. If the object or the message does not recognize the message, a Not Understood error occurs.	

The function version does more error checking than the macro and also attempts to convert unbound symbols into names for classes and instances.

Arguments:	self Pointer to an object.		
	sel Selector; not evaluated.		
	arg1argn Arguments associated with sel		
Returns:	The value returned by the method associate	d with <i>sel</i> .	
Example:	In this example, the message New is sent to the class Window . This returns the newly created instance.		
	76←(← (\$ Window) New 'Window1) #,(\$& Window (OZW0.1Y:.;h.Qm: .	495))	
(SEND self sel arg1 argn)		[Macro and Function]	
Purpose:	Same as ←, above.		
Example:	The expression		
	(SEND (\$ Window) 'New 'Window1)		
	is equivalent to		
	(\leftarrow (\$ Window) New 'Window1)		
(←! self sel arg1 argn)		[Macro and Function]	
Purpose/Behavior:	Sends a message with the selector <i>sel</i> to an that it evaluates all of its arguments, including		
Arguments:	self Pointer to an object.		
	sel Selector, which is evaluated.		
	arg1argn Arguments associated with sel		
Example:	This example illustrates the fact that \leftarrow ! eva	luates the sel argument.	
	The code		
	(for sel in '(Shape Invert) do (←! (\$ Window1) sel))		
	is equivalent to		
	$(\leftarrow Window1 Shape) (\leftarrow Window1 Invert$	=)	
(← IV self IVName arg1argn)		Magral	
	Involves the function stored in the instance v	[Macro]	
Purpose:	Invokes the function stored in the instance v		
Behavior:			
	Gets a function from <i>IVName</i> of self and app arguments <i>args</i> . Returns the value of the fur	action or breaks.	

arg1...argn Arguments associated with *sel*; bound to arguments specified in the call.

(← Try self sel arg1 argn)		[Macro]
Purpose:	Sends the m correspondi	nessage with the selector <i>sel</i> to <i>self</i> , but only if there is a ng method.
Behavior:		act a selector of <i>self</i> , the method is applied and the appropriate rned. If the method is not a selector of <i>self</i> , the symbol NotSent is
Arguments:	self	Pointer to an object.
	sel	Selector; not evaluated.
	arg1argn	Arguments associated with sel.
Example:	The express	ion (\leftarrow (\$ Window1) abcd) normally causes a break.
	79←(←Try NIL	v (\$ Window1) Update)
	80←(←Try NotSent	v (\$ Window1) abcd)
(← Proto class sel arg1 argn)		[Macro]
Purpose:	Sends a me	ssage to the prototype instance of a class.
Behavior:	class variab instance is r	nstance of a class, if necessary, and puts that instance on the le Prototype of <i>class</i> , marking the class as changed. This eferred to as the prototype instance. Proto then sends the <i>l</i> to that instance.
Arguments:	class	Pointer to a class.
	sel	Selector; not evaluated.
	arg1argn	Arguments associated with sel.
Example:		one instance of LoopsIcon is needed at a time, so the class keeps one in its class variable Prototype .
	81←(←Prc	oto (\$ LoopsIcon) Open)
(← Super self sel arg1 argn)		[Macro and Function]
Purpose:		an inherited method within a method. ← Super must appear in the ethod; it cannot be invoked directly.
Behavior:	the same na returns the v when the ar	the class hierarchy and invokes the next more general method of time, even if a specialized method is inherited over a distance. It value from that super method. You can use the form (\leftarrow Super) guments are not changed. If no arguments are provided, \leftarrow Super guments of the method from which it was called.
	illegal to call	d the other similar functions are now lexically scoped; that is, it is \leftarrow Super anywhere but within a method body, and any selector be the same as the selector for that method.

Arguments:selfPointer to an object.selSelector; not evaluated. Must be the same as the selector of the
method in which the ← Super appears.

arg1...argn Arguments associated with sel.

Example: Two examples of \leftarrow **Super** are included:

- One example shows where the arguments are not changed.
- to call ple shows where the arguments are changed.

Example 1: A use of \leftarrow **Super** where the arguments are not changed.

Define a subclass of **Window** that will call **RINGBELLS** before a window is shaped.

(DefineClass 'RingingWindow '(Window))

Through the browser interface, specialize the method **Shape**, to create the following method.

Executing the following command calls **RINGBELLS** before the new window is shaped.

(←New (\$ RingingWindow) Shape)

In the method above, if the positions of **RINGBELLS** and (\leftarrow **Super**) were reversed, **RINGBELLS** would be called after the window was shaped.

Example 2: A use of \leftarrow **Super** where the arguments are changed.

Define a subclass of **Window** that will be square.

(DefineClass 'SquareWindow '(Window))

Through the browser interface, specialize the method **Shape**, to create the following method.

Executing the following command creates a square window:

(←New (\$ SquareWindow) Shape)

(←Super? self sel arg1 argn)		[Macro]
Purpose:	Invokes the method. Th	single next most general method; must appear in the body of a is does not cause an error if no inherited method matches.
Behavior:	that ← Supe	o ← Super . The difference between ← Super ? and ← Super is r? does not break if the <i>sel</i> does not have a more general method, Super generates a break if there is not a more general method.
Arguments:	self	Pointer to an object.
	sel	Selector; not evaluated. Must be the same as the selector of the method in which the \leftarrow Super? appears.
	arg1argn	Arguments associated with sel.
(←SuperFringe self sel arg1	argn)	[Macro and Function]
Purpose:		eral methods for objects with more that one super class from rish to inherit methods; must appear in the body of a method.
Behavior:	each of the analogous to arguments a	Ind executes the next more general method of the same name from classes on the super's list <i>object's</i> class. Calling \leftarrow SuperFringe is o sending \leftarrow Super up through each item on the super's list. If no are provided \leftarrow SuperFringe uses the arguments of the method t was called.
Arguments:	self	Pointer to an object.
	sel	Selector; not evaluated. Must be the same as the selector of the method in which the \leftarrow SuperFringe appears.
	arg1argn	Arguments associated with sel.
(← New class selector arg1 arg	ın)	[NLambda NoSpread Macro]
Purpose:	Creates an i instance.	instance of class and then sends sel and arguments to that
Behavior:	returns the by invoking	ew instance of a class and sends a message to that instance. It instance as a value and discards any value that may be returned the method specified by selector. \leftarrow New is equivalent to (\leftarrow (\leftarrow New) selector arg1 argn).
Arguments:	class	Pointer to a class.
	sel	Selector; not evaluated.
	arg1argn	Arguments associated with sel.
Returns:	The new ins	tance.
Example:		e shows an example of \leftarrow New that creates a new instance of the bw and asks you to shape it.
		ndow) Shape) W0.1Y:.;h.Qm: . 497))
(← class FetchMethod sel)		[Method of Class]
Purpose:	message wi	nction name which implements the method invoked by sending a th the selector <i>sel</i> to an instance of <i>class</i> . The function can be her <i>class</i> or its supers.

Behavior:	Calls the function FetchMethod.		
Arguments:	class	Pointer to a class.	
	sel	Selector; evaluated.	
Returns:	The function for <i>sel</i> or NIL.		
Example:	Line 100 shows that the class Window implements the method Update .		
	<pre>100←(← (\$ Window) FetchMethod 'Update) Window.Update Line 1 shows that neither the class Window nor any of its supers implements the method abcd. 1←(← (\$ Window) FetchMethod 'abcd) NIL</pre>		
	Line 2 shows that the class Object implements the method PP which will be triggered when instances of the class Window receive the PP message.		
	2←(← (\$ Object.PI	Window) FetchMethod 'PP)	

[This page intentionally left blank]

Active values are used in LOOPS to transpose the access of data within an object to a message being sent to a different object. Typical uses include:

- · Causing side effects to occur when data is accessed
- Debugging

Χ.

- Initializing variables
- · Maintaining constraints between variables

An **ActiveValue** is an instance of a subclass of the LOOPS class **ActiveValue**. When an **ActiveValue** instance is installed in the value of a variable, further references to that variable cause messages to be sent to the instance.

LOOPS provides several kinds of active values which are described in this chapter. You can obtain new behavior by specializing one of the existing LOOPS **ActiveValue** subclasses.

When **GetValue** notices that an **ActiveValue** is installed on the variable, it sends the **GetWrappedValue** message to the **ActiveValue**. Similarly, when **PutValue** notices that an **ActiveValue** is installed on the variable, it sends the **PutWrappedValue** message to the **ActiveValue**. The value returned from the get or put is the value returned from the message send. Each specialization of **ActiveValue** either inherits these methods from its superclasses or specializes them to call user code. The messages are received and processed by the **ActiveValue** instances.

For example, assume that you are modeling a simulation that requires the value of an instance variable called windSpeed to be a random value. You can make the value of windSpeed into an active value called (\$ RandomWindSpeedAV1). Now, if you try to determine the value of windSpeed by entering

(@ (\$ SomeAirport) windSpeed)

the value returned from this expression is the value returned from

(< (\$ RandomWindSpeedAV1) GetWrappedValue . otherArgs)

This returns the required random value.

The variable containing the **ActiveValue** may still have a current value. Most system **ActiveValue** subclasses are specializations of **LocalStateActiveValue**, which uses an instance variable **localState** in the **ActiveValue** to hold the value.

For efficient implementation, LOOPS uses a special Interlisp data type, the annotatedValue data type, to "wrap" each **ActiveValue** instance when it is installed as a value within an object; the **annotatedValue** contains the **ActiveValue** instance. That is, if the value of an instance variable is said to be an active value, in actuality, the value of the instance variable is an annotatedValue which contains the active value. This allows every **GetValue** or **PutValue** to use Interlisp's microcoded type checking mechanism to see if it should be processed normally or via the **ActiveValue** mechanism. This extra layer is largely invisible in application programs. LOOPS also contains a class **AnnotatedValue** to handle the occasional accident when a user forgets about

the distinction between annotatedValue and **ActiveValue**, and attempts to treat an annotatedValue as a LOOPS object.

The class **ActiveValue** defines the general protocol followed by all active value objects. Methods setting up the basic functionality of **ActiveValues** are defined in this class and inherited by all its specializations. Methods defined in this class include **AVPrintSource** to specify how annotatedValues print, **AddActiveValue** to install an **ActiveValues**, and **DeleteActiveValue** to delete an installed **ActiveValue**.

The class **ActiveValue** itself is an abstract class; that is, it is a placeholder in the class hierarchy that is not intended to be instantiated. When this documentation refers to an active value object, it is referring to an instantiation of a specialization of the class **ActiveValue**.

Note: The current **ActiveValue** is different from the **activeValue** implementation in the Buttress version of LOOPS. See Appendix A, Active Values in Buttress LOOPS, for more information.

8.1 Using Active Values

A general template is available when using active values. As with all templates, you should not blindly follow it. A good understanding of the active value mechanism is necessary to avoid errors in more complicated situations.

- Determine the functionality that you want the active value to provide. For example, will it cause a side effect to occur on access of data? Will it maintain constraints between two pieces of data? The required functionality will give an indication of which active value class you should use.
- Specialize one of the active value classes to satisfy your specific requirements, if necessary.
- Create an instance of the active value class that you have chosen or created.
- Initialize the contents of that instance, if necessary.
- Install that active value instance on the data that you want to become active. This is accomplished by using the AddActiveValue message.

In a number of situations, you may want to install an active value on an instance variable for every instance of a class. One technique for doing this is discussed in Section 8.5, "Active Values in Class Structures."

8.2 Specializations of the Class ActiveValue

The class **ActiveValue** is an abstract class, and therefore cannot be instantiated. This class contains a number of methods, described in Section 8.3, "ActiveValue Methods," that are necessary for the active value mechanism to function. As a user, you will be making active values which are instances of some subclass of **ActiveValue**, either one of those already provided or one that you created. Figure 8-1 shows the class **ActiveValue** and its specializations. This section describes the subclasses of **ActiveValue** in order of their appearance in this figure. Also included is information on specializing active values.

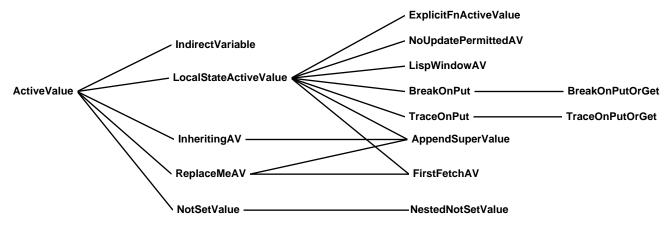

Figure 8-1. The Class ActiveValue and its Specializations

8.2.1 IndirectVariable

This specialization sets up the functionality of an **ActiveValue** to return the value of another variable as its value. It is analogous to the concept of indirect addressing in other computer languages.

Note: Indirect variables must be the innermost of nested active values. Wrapping precedence (see Section 8.3, "Active Value Methods") insures this.

IndirectVariable

Purpose:	simulates tw	able values to be accessed indirectly from other variables. This o variables sharing the same memory location. This is a useful r implementing simulations and enforcing constraints.	
Behavior:	When a Fetch is made on the variable containing the IndirectVariable instance, this active value retrieves and returns the value of the tracked variable. If a Store is made with the variable containing the IndirectVariable instance, this active value stores the new value in the tracked variable. Essentially, this forces the two variables to share the same data.		
Instance Variables:	object	Object instance containing the tracked value.	
	varName	The name of the variable being tracked.	
	propName	If non-NIL, the name of the variable property being tracked.	
	type	Type of variable being tracked. Value can be CV, IV or NIL, which defaults to IV.	
Examples:	Several exar	mples are included to show the use of IndirectVariable .	
Example 1: Consider a chemical reactor simulation where you have a tank draining into a pipe. The output pressure of the tank needs to equal the input pressure of the pipe. The following demonstrates this.			
First, build the appropriate pipe and tank classes and make instances of them.			
78← (DefineClass 'Tank) #,(\$C Tank)			
79← (Define #,(\$C Pipe)	79← (DefineClass 'Pipe) #,(\$C Pipe)		
80← (← (\$	Tank) AddI	V 'outputPressure)	

outputPressure

[Class]

81← (← (\$ Pipe) AddIV 'inputPressure)
inputPressure
82← (← (\$ Tank) New 'tank1)
#,(\$& Tank (NYW0.0X%:.aF4.6R8 . 5))
83← (← (\$ Pipe) New 'pipe1)
#,(\$& Pipe (NYW0.0X%:.aF4.6R8 . 6))

Create an instance of **IndirectVariable** and initialize its contents to point to the tank's output pressure.

```
84← (← ($ IndirectVariable) New 'indVar1)
#,($& IndirectVariable (NYW0.0X%:.aF4.6R8 . 7))
85← (←@ ($ indVar1) object ($ tank1))
#,($& Tank (NYW0.0X%:.aF4.6R8 . 5))
```

86← (←@ (\$ indVar1) varName 'outputPressure) outputPressure

Install the active value instance as the value of the pipe's input pressure.

```
87← (← ($ indVar1) AddActiveValue ($ pipe1) 'inputPressure)
#,($AV IndirectVariable (indVar1 (NYW0.0X%:.aF4.6R8 . 7)) (object
#,($& Tank (NYW0.0X%:.aF4.6R8 . 5))) (varName outputPressure))
```

Accesses to either the pipe's input pressure or the tank's output pressure produce the same result.

```
90← (@ ($ pipe1) inputPressure)
NIL
92← (←@ ($ pipe1) inputPressure 100)
100
94← (@ ($ tank1) outputPressure)
100
95← (←@ ($ tank1) outputPressure 200)
200
96← (@ ($ pipe1) inputPressure)
200
```

An inspector window of (\$ pipe1) appears as follows:

```
All Values of Pipe ($ pipe1).
inputPressure #,($AV IndirectVariable (indVar1 (
```

Example 2: Consider a conveyor that must be three feet above a bin. Assume both have an instance variable named height.

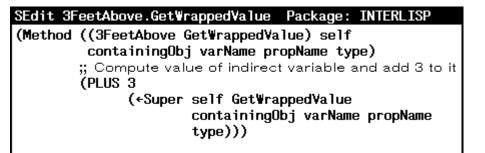

First, create the classes and instances.

```
53← (DefineClass 'Bin)
#,($C Bin)
54← (DefineClass 'Conveyor)
#,($C Conveyor)
55← (← ($ Bin) AddIV 'height 0)
height
56← (← ($ Conveyor) AddIV 'height 0)
height
```

```
57← (← ($ Bin) New 'bin1)
#,($& Bin (|DAW0.1Y:.H53.]99| . 506))
58← (← ($ Conveyor) New 'conveyor1)
#,($& Conveyor (|DAW0.1Y:.H53.]99| . 507))
```

Create a specialization of **IndirectVariable** and specialize the methods **GetWrappedValue** and **PutWrappedValue**. You need to specialize **IndirectVariable** because you do not want to maintain equality between the two variables, but instead want to maintain a different mathematical relationship. The **_Supers** are used to use the default behavior of **IndirectVariable** which takes care of retrieving or storing the data into the tracked variable.

```
59← (DefineClass '3FeetAbove
'(IndirectVariable))
#,($C 3FeetAbove)
```

SEdit 3FeetAbove.PutWrappedValue Package: INTERLISP (Method ((3FeetAbove PutWrappedValue) self containingObj varName newValue propName type) ;; Instead of placing newValue here, substract 3 ;; from it and put it in the indirect variable (←Super self PutWrappedValue containingObj varName (DIFFERENCE newValue 3) propName type) ;; return newValue newValue)

Create an instance of **3FeetAbove** and initialize its contents to point to the bin's height.

65← (← (\$ 3FeetAbove) New '3fal)
#,(\$& 3FeetAbove (|DAW0.1Y:.H53.]99| . 505))
66← (←@ (\$ 3fal) object (\$ bin1))
#,(\$& Bin (|DAW0.1Y:.H53.]99| . 506))
67← (←@ (\$ 3fal) varName 'height)
height

Install this instance of **3FeetAbove** as the value of the conveyor's height.

The height of **bin1** defaults to 0, what is the height of **conveyor1**?

69← (@ (\$ bin1) height) 0 70← (@ (\$ conveyor1) height) 3 Set either **bin1's** height or **conveyor1's** height and notice how they track each other.

71← (←@ (\$ bin1) height 15)
15
72← (@ (\$ conveyor1) height)
18
73← (←@ (\$ conveyor1) height 21)
21
74← (@ (\$ bin1) height)
18

8.2.2 LocalStateActiveValue

This specialization sets up a class of **ActiveValue** that contains the instance variable **localState**, which is used primarily for storing the value of the referenced variable.

If you need an active value that will produce your own specific side-effect, you will most likely use your own specialization of **LocalStateActiveValue**. The data that would have been accessed, had an active value not been installed, is stored in the **localState** instance variable.

LocalStateActiveValue	[Class]
Purpose:	Creates a subclass of ActiveValue with an instance variable to hold the current value of the referenced variable.
Behavior:	Holds the data that normally is stored in the variable where it is installed. At installation time, the current variable value is placed in the localState instance variable of the ActiveValue . Subclasses of LocalStateActiveValues are the most common ActiveValue instances.
	The class LocalStateActiveValue is commonly specialized. In particular, it is usually desirable to specialize the methods GetWrappedValue and PutWrappedValue associated with new subclasses of LocalStateActiveValue. These methods implement the active value messages sent when the variable is accessed.
Instance Variable:	localState Stores the value of the referenced variable.
Examples:	Several examples are included to show the use of LocalStateActiveValue.
	this example, an active value will print a message if an attempt is made to range value in an instance variable.
Define a subcla the values of th	e limits.
99← (Define #,(\$C Warni	eClass 'WarningAV '(LocalStateActiveValue)) ngAV)
100← (← (\$ lowTrigger	WarningAV) AddIV 'lowTrigger 0)
101← (← (\$ highTrigger	WarningAV) AddIV 'highTrigger 100)
Specialize Loc . WarningAV .	alStateActiveValue's PutWrappedValue method to create one for

SEdit WarningAV.PutWrappedValue Package: INTERLISP
(Method ((WarningAV PutWrappedValue) self containingObj
varName newValue propName type)
;; If newValue is greater than highTrigger or lower
;; than lowTrigger, then print a message, but store
;; the data anyway
(if (OR (< newValue (@ lowTrigger))
(> newValue (@ highTrigger)))
then (PRINTOUT T "The value " newValue
" is out of range." T))
(+Super self Put\rappedValue containingObj
varName newValue propName type))

Create an instance of a Bin and attach an instance of a WarningAV to its height.

```
4← (← ($ Bin) New 'bin3)
#,($& Bin (|DAW0.1Y:.H53.]99| . 513))
5← (←New ($ WarningAV) AddActiveValue ($ bin3) 'height)
#,($& WarningAV (|DAW0.1Y:.H53.]99| . 514))
```

Attempt to store various values into the bin's height.

```
7← (←@ ($ bin3) height 10)
10
8← (←@ ($ bin3) height -10)
The value -10 is out of range.
-10
9← (←@ ($ bin3) height 110)
The value 110 is out of range.
110
10← (@ ($ bin3) height)
110
```

Example 2: In this example, an active value will return a random number when it is read from. Puts to it will change the range of the random value returned on gets. This will use **localState** for something other than storing the data for active values that provide only pure side-effect behavior.

```
99← (DefineClass 'RandomAV '(LocalStateActiveValue))
#,($C RandomAV)
```

100
 \leftarrow (\$ RandomAV) AddIV 'localState '(0 100)) localState

Specialize LocalStateActiveValue's PutWrappedValue and GetWrappedValue methods to create them for RandomAV.

SEdit Ra	andomAV.Get¥rappedValue	Package:	INTERLISP
(Method	((RandomAV GetWrappedVa varName propName type)	-	containing0bj
	;; Get the value of the loc	alState,	
	<pre>;; We'll assume for this e: ;; is a list of two numbers (APPLY #'RAND (@ localS)</pre>	, If it is no	

SEdit RandomAV.PutWrappedValue Package: INTERLISP

(Method ((RandomAV PutWrappedValue) self containingObj varName newValue propName type)

;; We'll assume that the new value is a list of two

- ;; numbers,
- (+@ localState newValue))

Now, try to test this.

```
36← (DefineClass 'RandomTest)
#,($C RandomTest)
39 \leftarrow (\leftarrow \text{IT AddIV 'randomIV})
randomIV
40 \leftarrow (\leftarrow (\$ RandomTest) New 'rt1)
#,($& RandomTest (DCW0.0X%:.aF4.5S; . 518))
41← (←New ($ RandomAV) AddActiveValue ($ rt1) 'randomIV)
#,($& RandomAV (DCW0.0X%:.aF4.5S; . 519))
42 \leftarrow (@ (\$ rt1) randomIV)
24
43← redo
32
44 \leftarrow redo
9
45← redo
49
46 \leftarrow (\leftarrow @ (\$ rt1) randomIV '(4.0 5.0))
(4.0 5.0)
47 \leftarrow (@ (\$ rt1) randomIV)
4.190201
48← REDO
4.1129
49← REDO
4.380234
50← REDO
4.397278
```

8.2.2.1 ExplicitFnActiveValue

ExplicitFnActiveValue emulates the activeValue implementation from the Butttress version of LOOPS. Users are discouraged from using this particular form of active values within new projects.

See the *LOOPS Users' Modules* for details on LOOPSBACKWARDS, which describes **ExplicitFnActiveValue**. See Appendix A, Active Values in Buttress LOOPS, for details on the compatibility of **ActiveValue** with activeValue.

8.2.2.2 NoUpdatePermittedAV

This specialization sets up a class of **ActiveValue** that prevents the value of a variable from being replaced.

NoUpdatePermi	ttedAV	[Class]
	Purpose:	Prevents the value of a variable from being replaced using the PutValue method.
	Behavior:	Stores the current value of the variable in localState , then prevents it from being updated. GetWrappedValue requests return the value found in localState , but PutWrappedValue requests cause a break with the break message NoUpdatePermitted! , or a message if sent from the Exec.
	Example:	Suppose an identification number for a piece of data should never be changed. Installing a NoUpdatePermittedAV in the data's ID number will cause a break if a replacement attempt is made.
		Start with a user-defined class named Datum . Make a Datum instance named Datum1 . Set the instance variable named idNumber to the value 999. Look at the instance. Make a new instance of NoUpdatePermittedAV , and name it NumberGuard . Install the ActiveValue in the instance variable idNumber of the instance Datum1 . Look at the ActiveValue instance; the localState instance variable contains the previous value of idNumber . To test this ActiveValue , attempt to replace the idNumber of Datum1 with a new value.
	67← (Defin #,(\$C Datum	eClass 'Datum) N
	68← (← (\$ idNumber	Datum) AddIV 'idNumber 0)
		Datum) New 'Datum1) u (DAW0.1Y:.H53.]99 . 524))
	70← (←@ (\$ 999	S Datum1) idNumber 999)
	(DEFINST Da	Datum1) PP) utum (Datum1 (DAW0.1Y:.H53.]99 . 524)) (idNumber 999)) u (DAW0.1Y:.H53.]99 . 524))
		NoUpdatePermittedAV) New 'NumberGuard) latePermittedAV (DAW0.1Y:.H53.]99 . 525))
	#,(\$AV NoUp	NumberGuard) AddActiveValue (\$ Datum1) 'idNumber) odatePermittedAV (NumberGuard (DAW0.1Y:.H53.]99 . 525)) alState 999))
	(DEFINST Da (i	Datum1) PP) htum (Datum1 (DAW0.1Y:.H53.]99 . 524)) .dNumber #,(\$AV NoUpdatePermittedAV (NumberGuard (DAW0.1Y:.H53.]99 . 525)) (localState 999)))) n (DAW0.1Y:.H53.]99 . 524))
	77← (←@ (\$ No update p NIL	5 Datum1) idNumber 888) permitted!

8.2.2.3 LispWindowAV

This specialization sets up a class of **ActiveValue** used by the system to guarantee that the **window** instance variable within a LOOPS **Window** instance contains an Interlisp window. This class provides functionality required by the LOOPS system, and should not generally used by LOOPS users.

LispWindowAV

[Class]

Purpose: Guarantees that a variable contains a window which has been made into a LOOPS window.
 Behavior: Meant to be installed only in the instance variable window of instances of class Window. A specialization of LocalStateActiveValue. Checks to see if its localState is a window, and assures that other instance variables of the window instance are set correctly. See Chapter 19, Windows, for further details.

8.2.2.4 Breaking and Tracing Active Values

		The following active values are all specializations of LocalStateActiveValue and are used for debugging, as described in Chapter 12, Breaking and Tracing. This chapter also describes UnbreakIt , which unbreaks or untraces a method of a class. These classes provide functionality required by the LOOPS system, and are not generally used by LOOPS users.
		Note: All breaks and traces occur before the variable is read or modified.
BreakOnPut		[Class]
	Purpose:	Breaks when a replacement attempt is made.
	Behavior:	Breaks when a replacement attempt is made. Local variables bound at the time of the break are containingObj , varName , and propName .
BreakOnPutOrGet		[Class]
	Purpose:	Breaks when a retrieval or replacement of a variable is made. This is a specialization of BreakOnPut .
	Behavior:	Break occurs before any access to the variable where it is installed. Local variables bound at the time of the break are containingObj , varName , and propName .
TraceOnPut		[Class]
	Purpose:	Traces replacements of a variable.
	Behavior:	Has a specialized PutWrappedValue method that causes the values of the arguments containingObj , varName , and propName to print in the trace window when the variable is about to be modified.
TraceOnPutOrGet		[Class]
	Purpose:	Traces retrievals and replacements of a variable. This is a specialization of TraceOnPut .

Behavior: The **GetWrappedValue** method is also specialized so that the variable is traced before any access of the variable where it is installed.

8.2.2.5 AppendSuperValue

This specialization allows the value of a variable to reside only partially in the local instance or class. This is a specialization of the **ReplaceMeAV**, **InheritingAV**, and **LocalStateActiveValue** classes.

AppendSuperValue

[Class]

Purpose:	Allows the value of a variable to be defined by both a local value and an inherited value.

Behavior: When an instance of **AppendSuperValue** is installed in a variable, Getreferences return its **localState** appended to the end of the inherited value the variable would have if it had no local value. Any **PutValue** to the variable replaces the active value, not just the **localState**; **InheritingAV** and its specializations are designed for use more in class variables where replacement is infrequent.

Examples: Several examples are included to show the use of **AppendSuperValue**.

Example 1: Append the **localState** of the instance variable **idNumber** to the default value specified in the class description.

23←(DefineClass 'Datum) #, (\$C Datum) $24 \leftarrow (\leftarrow (\$ \text{ Datum}) \text{ AddIV 'idNumber '(5)})$ idNumber $25 \leftarrow (\leftarrow (\$ \text{ Datum}) \text{ New 'Datum1})$ #,(\$ Datum1) $26 \leftarrow (@ ($ Datum1) idNumber)$ (5) $27 \leftarrow (\leftarrow @ (\$ Datum1) idNumber '(9))$ (9) 28←(@ (\$ Datum1) idNumber) (9) 29←(←New (\$ AppendSuperValue) AddActiveValue (\$ Datum1) 'idNumber) #, (\$& AppendSuperValue (45 . 54648)) $30 \leftarrow (@ (\$ Datum1) idNumber)$ (5 9)

Example 2: In this example, there are two classes of cars; the **Two-tone-Car** class is a subclass of the class **Car**. Each **Car** class has the instance variable color. The default value for color in the class **Car** is (white).

```
89← (DefineClass 'Car)
#,($C Car)
90← (DefineClass 'Two-tone-Car '(Car))
#,($C Two-tone-Car)
91← (← ($ Car) AddIV 'color '(white))
color
```

```
92<br/>\leftarrow ($ Two-tone-Car) AddIV 'color) color
```

The default value for color in the class **Two-tone-Car** is an instance of **AppendSuperValue** with its localState set to (blue). The technique for adding active values as default values in a class is discussed in Section 8.3.1, "Adding and Deleting Active Values.".

When an instance of a **Two-tone-Car** is created the default value for its instance variable color is the combination of the values in both the classes **Car** and **Two-tone-Car**. The first inspector shows the existence of the active value that provides this behavior. As soon as one puts a value for color in this instance, the **AppendSuperValue** active value is replaced by the new value as shown in the second inspector.

```
12← (@ ($ ttcar1) color)
(white blue)
```

13← (INSPECT (\$ ttcar1)) {WINDOW}#50,5000

All Values of Two-tone-Car (\$ ttcar1). color #,(\$AV AppendSuperValue (asv1 ([[

14 \leftarrow (\leftarrow @ (\$ ttcar1) color '(tan brown)) (tan brown)

All Values of Two-tone-Car (\$ ttcar1). color (tan brown)

For another example, see the **TitleItems** class variable of the class **ClassBrowser**, where **AppendSuperValue** is used to add menu items to an inherited menu.

8.2.2.6 FirstFetchAV

This specialization has instances that have an expression as the value of the instance variable **localState**. These active values allow a form to be evaluated the first time that they are read.

FirstFetchAV

[Class]

Purpose: This is a specialization of the **ReplaceMeAV** mixin and **LocalStateActiveValue**. Instances of this class have an expression as the value of the instance variable **localState**.

Behavior: On the first get access, the expression in **localState** is evaluated. The resulting value replaces the **FirstFetchAV** so the variable is no longer an active value. On the first put access, the put value replaces the **FirstFetchAV** so the variable is no longer an active value. A **FirstFetchAV** is often used as the default value for a variable. This class also specializes the method **AVPrintSource** so that instances print as follows when wrapped in an annotatedValue:

#,(Defer contentsOfLocalState)

CAUTION

FirstFetchAVs cannot be shared. Unlike lists, SEdit does not make copies of active values. Hence, if active values are copied in SEdit, they will share structure, and if one is modified, all will be changed.

Workaround: Use **CopyActiveValue** to copy the active value instance and the local state into each instance which uses the **FirstFetchAV**. See Section 8.3.4, "Shared ActiveValues in Variable Inheritance," for information on **CopyActiveValue**.

Example: An example application of **FirstFetchAV** is an instance variable that stores a font descriptor. A font descriptor in a class definition does not save correctly;only the pointer to the descriptor is saved. A **FirstFetchAV** stores the expression used to create the descriptor. So, for example the expression held in the **localState** of the **FirstFetchAV** is

(FONTCREATE 'HELVETICA 12 'BOLD)

On the first access of the instance variable, the font descriptor produced by calling **FONTCREATE** replaces the **FirstFetchAV**.

The complete example follows.

SEdit #,(\$C TextObject) Package:	INTERLISP	
((MetaClass Class Edited%:	; Edited 4-Dec-87	
	; 14:22 by RBGMartin

36← (INSPECT (\$ to1)) {WINDOW}#47,125470

All Values of TextObject (\$ to1). font #,(Defer (FONTCREATE (QUOTE

37← (@ (\$ to1) font) {FONTDESCRIPTOR}#74,167334

All Values of TextObject (\$ to1). font {FONTDESCRIPTOR}#74,167334

8.2.3 InheritingAV

This specialization of **ActiveValue** is used as a mixin to add the **InheritedValue** method.

InheritingAV		[Class]
Purpose:	Used as a m	nixin to add the InheritedValue method.
Behavior:	value a varia	class, adds a method InheritedValue which allows looking at the able would have if it had no local value, as NotSetValue would as a mixin to add this capability to other specializations of e .
Example:		per class of AppendSuperValue to provide incremental menus in s of LOOPS.
(← self InheritedValue containing	gObj varName	e propName type) [Method of InheritingAV]
Purpose/Behavior:	yet assigned	ing the value a variable would have inherited if it had no local value d. Similar to the way NotSetValue works, it is removed by an to the variable.
Arguments:	self	InheritingAV instance.
	containingO	<i>bj</i> The instance or class that contains the variable to be viewed.
	varName	In the <i>containingObj</i> the variable to be viewed.
	propName	Name of an instance variable or class variable property to be looked at. If <i>propName</i> is NIL, the variable itself is viewed.

		<i>type</i> One of IV, CV, or NIL: a <i>type</i> of IV or NIL indicates that the variable is an instance variable or an instance variable property of <i>containingObj</i> ; a <i>type</i> of CV indicates a class variable or class variable property of <i>containingObj</i> .
	Returns:	The value which would have been inherited if the variable had no local value.
8.2.4 ReplaceM	eAV	
		This specialization of the class ActiveValue sets up the functionality to replace itself on the first Put- access.
ReplaceMeAV		[Class]
	Purpose:	Specializes the method PutWrappedValue to simply replace itself on the first Put- request.
	Behavior:	No variables are defined in this class. It is an abstract class not intended for instantiation. It is a mixin (see Chapter 3, Classes) to be combined in specialization with another class to add its functionality to the subclass.
	Example:	FirstFetchAV combines LocalStateActiveValue and ReplaceMeAV to get an ActiveValue that replaces itself with the value of an expression stored in the instance variable localState.
8.2.5 NotSetVal	ue	
		This section describes where and when instances of this class appear in user- defined objects.
		CAUTION
		Do not specialize the classes NotSetValue and NestedNotSetValue . The documentation is provided here only to explain the functionality that these classes provide to the LOOPS system.
NotSetValue		[Class]

Purpose:	This specialization of the class ActiveValue is unique in that it was created primarily for implementing instance variable inheritance. It has no instance variable to hold a local value and is replaced after the first Put- variable access.
Behavior	When an instance of any LOOPS object is created, its instance variables are initialized to contain the value of the variable NotSetValue . NotSetValue is an annotatedValue whose ActiveValue is the only instance of the class NotSetValue . The value of NotSetValue stored in an instance variable may be replaced within other initialization procedures of new instances that are invoked by the methods NewWithValues and NewInstance and the instance variable property :initForm.
	The class NotSetValue specializes the default ActiveValue protocol to trigger instance variable inheritance. An annotatedValue check is always done by GetValue and PutValue . LOOPS speeds up instance generation by always initializing instance variables to the value NotSetValue . If a retrieval attempt is made on the variable, NotSetValue finds the inherited value and returns that value. If no requests are made for the value of the variable, there is no overhead for the instance variable.

The term local value refers to the values LOOPS has actually written into that instance's instance variables. The local value is always equal to **NotSetValue** before the first Put- access, and to a new value after the first Put- access.

The annotatedValue **#,NotSetValue** is bound to the Lisp variable **NotSetValue**. It must always be on the inside of any sequence of nested **ActiveValues**. Its **WrappingPrecedence** method returns NIL, ensuring this functionality. **NotSetValue** has no **localState** instance variable to hold any nested **ActiveValues**.

See Section 8.3.4, "Shared ActiveValues in Variable Inheritance," for information on **ActiveValues** as default values.

Example: Consider the class **Datum** with the instance variable **idNumber**. Create a new instance named **Datum2**. A standard **GetValue** or @ call returns the default value of **idNumber**, since nothing else has yet been assigned. The call **GetIVHere** shows that the value is not stored in the instance, but is actually returned by **NotSetValue**.

91←(← (\$ Datum) New 'Datum2)
#,(\$ Datum2)
92←(@ (\$ Datum2) idNumber)
NIL
93←(GetIVHere (\$ Datum2) 'idNumber)
#,NotSetValue

8.2.5.1 NestedNotSetValue

This subclass of the class **NotSetValue** is used by the internal of LOOPS to solve the problem of using active values as default values.

8.2.6 User Specializations of Active Values

	If new specializations of the class ActiveValue are defined, the methods GetWrappedValueOnly and PutWrappedValueOnly might need to be specialized (LOOPS-defined specializations of ActiveValue , such as LocalStateActiveValue , have already done this). You may also want to specialize the following methods:
AVPrintSource	Prints an ActiveValue instance.
GetWrappedValue	Method associated with getting an ActiveValue.
PutWrappedValue	Method associated with putting an ActiveValue.
WrappingPrecedence	Returns T, NIL, or a number to specify order of ActiveValue nesting.
CopyActiveValue	Copies an annotatedValue and its wrapped ActiveValue.

8.3 Active Value Methods

Methods defined in the class ActiveValue describe how active values work.

8.3.1 Adding and Deleting Active Values

This section describes the methods to install, delete, and replace active values.

Name	Туре	Description
AddActiveValue	Method	Makes a variable or property an active value.
WrappingPrecedence	Method	Returns a value which determines how to nest the active value.
DeleteActiveValue	Method	Deletes an active value.
ReplaceActiveValue	Method	Replaces an active value.
(← self AddActiveValue containin	ngObj varNam	e propName type annotatedValue) [Method of ActiveValue]
Purpose:	active value.	es two tasks fundamental in making a variable or property an First, the ActiveValue is wrapped inside an annotatedValue. <i>annotatedValue</i> is placed as the value of the variable.
Behavior:	the argumen new annotate current value WrappingPr	(alue associates the annotatedValue with the variable specified by ts. If the argument <i>annotatedValue</i> is not specified or is NIL, a edValue is created containing the ActiveValue <i>self</i> . When the e of the variable is already an annotatedValue, the recedence message determines if it should be nested in the for wrapped around it.
Arguments:	self	ActiveValue instance.
	containingOl	<i>bj</i> The instance or class that contains the variable where the ActiveValue is to be added.
	varName	In the <i>containingObj</i> the variable to be made into an ActiveValue .
	propName	Name of an instance variable or class variable property to be made into an ActiveValue . If <i>propName</i> is NIL, the ActiveValue is associated with the variable itself.
	type	One of IV, CV, CLASS, METHOD, or NIL.
		 A type of IV or NIL indicates that varName is an instance variable or an instance variable property of containingObj.
		 A type of CV indicates a class variable or class variable property of containingObj.
		 A type of CLASS indicates access to a class object's instance variables and properties.
		 A type of METHOD indicates access to a method object 's instance variables and properties.
	annotatedVa	alue AnnotatedValue object used to contain this ActiveValue. If NIL, a new annotatedValue is created.
Returns:	annotatedVa	lue
Example:		tiveValue instance named (\$ ActiveValueInstance) to the object _oopsWindowInstance) in the instance variable width.

 $71 \leftarrow (\leftarrow (\$ ActiveValueInstance) AddActiveValue (\$ ExampleLoopsWindowInstance) 'width)$

#,(\$AV IndirectVariable (ActiveValueInstance (NCV0.0X:.SD7.KR . 8))
(object #,(\$ ExampleLoopsWIndowInstance))(varName width))

(← self WrappingPrecedence)	[Method of ActiveValue]
Purpose:	Returns a value which determines how to nest the ActiveValue associated with <i>self</i> .
Behavior:	Varies according to the value returned.
	• T
	The ActiveValue associated with <i>self</i> goes on the outside of any other active values.
	• NIL
	This ActiveValue goes on the inside.
	If two ActiveValues return either T or NIL, a break occurs.
	Number
	Specifies precedence: ActiveValues with larger WrappingPrecedence values go outside ones with smaller WrappingPrecedence values.
	CAUTION
	It is potentially dangerous to have more than one class with a T or NIL precedence.
	ActiveValues that have the instance variable localState nest in the following way. When a new ActiveValue is added to an existing one with equal WrappingPrecedence, the original ActiveValue is held in the localState of the new one. ActiveValues not having an instance variable localState must nest inside of ones that do. To set the WrappingPrecedence for a user specialization of ActiveValue, specialize this method to return the proper value.
Arguments:	self ActiveValue instance.
Returns:	The default method defined in the class ActiveValue returns 100. WrappingPrecedence for the class NotSetValue returns NIL. WrappingPrecedence for IndirectVariable returns 50.
(← self DeleteActiveValue conta	niningObj varName propName type) [Method of ActiveValue]
Purpose:	Deletes an ActiveValue from <i>containingObj</i> .
Behavior:	If the variable defined by the arguments is an ActiveValue , it is deleted. If it contains a nested ActiveValue , the one matching <i>self</i> is deleted; otherwise, nothing happens. No ActiveValue messages are triggered. If the deleted ActiveValue had a localState , it becomes the current value.
Arguments:	self ActiveValue instance.

	containingOl	<i>bj</i> The instance or class that contains the variable where the ActiveValue is found.
	varName	In the <i>containingObj</i> the variable that contains the ActiveValue .
	propName	Name of an instance variable or class variable property where the ActiveValue resides. If <i>propName</i> is NIL, the ActiveValue is associated with the variable itself.
	type	One of IV, CV, CLASS, METHOD, or NIL.
		 A type of IV or NIL indicates that varName is an instance variable or an instance variable property of containingObj.
		 A type of CV indicates a class variable or class variable property of containingObj.
		 A type of CLASS indicates access to a class object's instance variables and properties.
		 A type of METHOD indicates access to a method object's instance variables and properties.
Returns:	The deleted	annotatedValue if a match was found, NIL otherwise.
(← self ReplaceActiveValue new)	Val containing	<i>GObj varName propName type</i>) [Method of ActiveValue]

Purpose:	Replaces an ActiveValue.		
Behavior:	Replaces the ActiveValue <i>self</i> with <i>newVal</i> . The location of the old ActiveValue is described by the arguments. No ActiveValue messages are triggered.		
Arguments:	self	ActiveValue instance.	
	newVal	The new value used to replace self.	
	containingO	<i>bj</i> The instance or class that contains the variable where the ActiveValue is found.	
	varName	In the <i>containingObj</i> the variable that holds the ActiveValue .	
	propName	Name of an instance variable or class variable property where the ActiveValue resides. If <i>propName</i> is NIL, the ActiveValue is associated with the variable itself.	
	type	<i>type</i> is one of IV, CV, or NIL: a <i>type</i> of IV or NIL indicates that the variable is an instance variable or an instance variable property of <i>containingObj</i> ; a <i>type</i> of CV indicates a class variable or class variable property of <i>containingObj</i> .	
Deturne		f now//al	

Returns: The value of *newVal*.

8.3.2 Fetching and Replacing Wrapped Values

The value of a variable is wrapped in an ActiveValue, usually by keeping it in the instance variable localState. Specify the behavior of new ActiveValue specializations by specializing the methods GetWrappedValue and PutWrappedValue. For example, IndirectVariable.GetWrappedValue just does a GetValue on the slot specified by its object, varName, propName, and type instance variables. These methods may perform arbitrary work before returning a value, usually that of localState. The methods GetWrappedValueOnly and PutWrappedValueOnly are available for accessing localState and bypassing the ActiveValue mechanism. The following table shows the items in this section.

Name	Туре	Description
GetWrappedValue	Method	Contains the code to be triggered by a Get- reference to the variable which has been made an ActiveValue .
GetWrappedValueOnly	Method	Provides a mechanism to assist in handling nested ActiveValues .
PutWrappedValue	Method	Contains the code to be triggered by a Put- reference to the variable which has been made an ActiveValue .
PutWrappedValueOnly	Method	Provides a mechanism to assist in handling nested ActiveValues.

(self **GetWrappedValue** containingObj varName propName type)

[Method of ActiveValue]

- Purpose: Contains the code to be triggered by a Get- reference to the variable which has been made an **ActiveValue**.
- Behavior: Performs arbitrary actions, but when finished, it must return a value which will be returned as the value of the **Get** to the original variable.

This method is fundamental for **ActiveValues**. When **GetValue** or **GetClassValue** finds an annotatedValue in an instance, it does not return that as the value. Instead, it sends the contained **ActiveValue** the **GetWrappedValue** message. This method is not usually called explicitly by users, but is triggered when the **GetValue** function retrieves the value of a variable that contains an **ActiveValue**. It should be specialized when a new subclass of **ActiveValue** is defined.

- Arguments: *self* **ActiveValue** instance.
 - containingObjThe instance or class that contains the variable where the
ActiveValue is found.varNameIn the containingObj the variable that holds the ActiveValue.propNameName of an instance variable or class variable property where
the ActiveValue resides. If propName is NIL, the ActiveValue
is associated with the variable itself.typeOne of IV, CV, or NIL: a type of IV or NIL indicates that the
variable is an instance variable or an instance variable property
of containingObj; a type of CV indicates a class variable or class
variable property of containingObj.
 - Returns: The value returned from the actions performed by **GetWrappedValue** message.

(← self GetWrappedValueOnly) [Method of ActiveValue] Purpose: Enables the ActiveValue mechanism to deal with different problems of nested ActiveValues. You will generally not need to specialize this method, as most uses of ActiveValues will specialize a subclass of ActiveValue. Behavior: Specializations of the class ActiveValue may need to specialize this method. (LocalStateActiveValue, IndirectVariable, and NotSetValue all have specialized versions of this method.) The class LocalStateActiveValue specialization simply returns the value of

The class **LocalStateActiveValue** specialization simply returns the value of *self*'s **localState** without triggering the active value mechanism.

The class **IndirectVariable** specialization simply returns the value of tracked variable without triggering the active value mechanism.

The class **NotSetValue** specialization simply returns the value of **NotSetValue**.

Arguments: *self* **ActiveValue** instance.

Returns: See Behavior.

(<- self **PutWrappedValue** containingObj varName newValue propName type)

[Method of ActiveValue]

- Purpose: Contains the code to be triggered by a Put- reference to the variable which has been made an **ActiveValue**.
- Behavior: The **PutWrappedValue** message is similar to **GetWrappedValue** except that it is triggered when the local state of the value is to be replaced. When **PutValue** or **PutClassValue** attempts to replace an **ActiveValue**, it instead sends the contained **ActiveValue** the **PutWrappedValue** message.

The default method found in the class **ActiveValue** checks for nested **ActiveValues** by sending the **GetWrappedValueOnly** message to *self*. If the result is an **AnnotatedValue**, **PutWrappedValue** forwards the message on the nested **ActiveValue**; otherwise it sends the message **PutWrappedValueOnly** to *self* and returns the result.

- Arguments: self ActiveValue instance.
 - containingObj

The instance or class that contains the variable where the **ActiveValue** is found.

- *varName* In the *containingObj* the variable that holds the **ActiveValue**.
- newValue The value used to replace the ActiveValue containing self.
- *propName* Name of an instance variable or class variable property where the **ActiveValue** resides. If *propName* is NIL, the **ActiveValue** is associated with the variable itself.
- *type* One of IV, CV, or NIL: a *type* of IV or NIL indicates that the variable is an instance variable or an instance variable property of *containingObj*; a *type* of CV indicates a class variable or class variable property of *containingObj*.
- Returns: The value of *newValue*.

(← self PutWrappedValueOnly /	newValue)	[Method of ActiveValue]
Purpose:	Enables the ActiveValue mechanism to de ActiveValues. You will generally not nee uses of ActiveValues will specialize a sub	d to specialize this method, as most
Behavior:	Specializations of the class ActiveValue m (LocalStateActiveValue , IndirectVariable specialized versions of this method.)	
	The class LocalStateActiveValue speciali self's localState without triggering the activ	
	The class IndirectVariable specialization s variable without triggering the active value	
	The class NotSetValue specialization cause	ses a break.

Arguments:	self	ActiveValue instance.
	newValue	The new value for localState.
Returns:	See Behavi	or.

8.3.3 Get and Put Functions Bypassing the ActiveValue Mechanism

ActiveValues normally convert GetValue, GetClassValue, PutValue, and PutClassValue accesses into messages which invoke methods to return a value, usually from the localState instance variable of the ActiveValue. The following functions allow access to class variables and instance variables without triggering any installed ActiveValue. See Chapter 2, Instances, for details.

Name	Туре	Description
GetValueOnly	Function	Finds the value of an instance variable without triggering active values.
PutValueOnly	Function	Writes the value of an instance variable without triggering active values.
GetClassValueOnly	Function	Returns the value of a class variable; does not trigger active values.
PutClassValueOnly	Function	Changes the value of a class variable and changes the value of a class variable. The change occurs within the class and therefore causes all instances to access the new value of the variable. Does not trigger active values.

8.3.4 Shared ActiveValues in Variable Inheritance

When a **LocalStateActiveValue** is used as the default value for an instance variable in a class, it must be copied into each instance or else all of the instances try to share a single **localState**. This copying is done automatically by LOOPS when the instance variable is first accessed, which means that all instances will share the same ActiveValue until that first access. Copying an **ActiveValue** implies creating a new annotatedValue, so it must be done with the specialized method **CopyActiveValue**.

ActiveValues with no local state may be shared by several variables. In the most extreme case, one instance of **NotSetValue** is the default for the instance variables of all new instances of all classes.

(<- self CopyActiveValue annotatedValue)

[Method of ActiveValue]

Purpose: Makes a copy of an **ActiveValue** instance.

Behavior: Copies the *AnnotatedValue* and the wrapped **ActiveValue** handling instance variables as follows:

- Instance variables that contain **AnnotatedValues** are copied using the **CopyActiveValue** method.
- The instance variable **localState** is copied so that each copy has its own unique local state.
- All other instance variables are considered shared, and are not copied.

Arguments: *self* ActiveValue instance.

annotatedValue The annotatedValue that surrounds self.

Returns: A new annotatedValue wrapped around a copy of the ActiveValue self.

8.3.5 Creating Your Own Active Value

This example defines a new kind of active value, a **BlippingActiveValue**, which prints out a "blip" of some kind whenever the variable it wraps is read or written.

First, define the new class as a specialization of **LocalStateActiveValue**, then specialize the **PutWrappedValue** and **GetWrappedValue** methods. This is done with the display editor, so in the example they are printed out via the **PPMethod** method. In each case, a **PRINTOUT** function was added before the call to \leftarrow **Super**.

Create an instance of **Window** for a location to install a **BlippingActiveValue** for the example. Line 38 is required to set the value of **height** locally to instance **Window1**; if this is not done, its initial value is the active value **#,NotSetValue**, which would remove any active value as soon as it was accessed.

The last few statements in the example show how read and write accesses to height cause a blip character to be printed before **height** is either read or written, with a "!" character representing a write access triggering **PutWrappedValue**, and a "." character representing a read access triggering **GetWrappedValue**.

32 (DefineClass 'BlippingActiveValue '(LocalStateActiveValue]
#,(\$ BlippingActiveValue)

33←(← (\$ BlippingActiveValue) SpecializeMethod 'PutWrappedValue] BlippingActiveValue.PutWrappedValue

34←(← (\$ BlippingActiveValue) SpecializeMethod 'GetWrappedValue] BlippingActiveValue.GetWrappedValue

35←(← (\$ BlippingActiveValue) PPMethod 'PutWrappedValue]

(BlippingActiveValue.PutWrappedValue

 $36 \leftarrow (\leftarrow (\$ BlippingActiveValue) PPMethod 'GetWrappedValue]$

(BlippingActiveValue.GetWrappedValue

#, (\$ Window1)

 $38 \leftarrow (\leftarrow @ (\$ Window1) height 9876]$

8.4 Annotated Values

AnnotatedValue is a LOOPS pseudoclass, and instances of it, called pseudoinstances, are Interlisp data type instances.

The structure of the data type is simple. Each annotatedValue contains one field named annotatedValue. This field contains an **ActiveValue** object. The Interlisp record package macros discussed below let you create and work with instances of the data type annotateValue.

There is also a LOOPS class named **AnnotatedValue**. It is an abstract class so it cannot be instantiated, but paradoxically there are objects which consider it their class. (Actually, it is not paradoxical, but this behavior is implemented at a low level within the LOOPS system.) These are the Lisp data type annotatedValue. In normal use this class can be ignored.

AnnotatedValue

[Class]

Purpose: LOOPS class equivalent of Lisp data type annotatedValue.

Behavior: This is a LOOPS class, but not a subclass of **Object**. Its super is the LOOPS class **Tofu**. (See Chapter 4, Metaclasses, for a description of **Tofu**.) **AnnotatedValue** is a LOOPS abstract class, and instances are Interlisp data type instances. LOOPS fields messages sent to the annotatedValue data type instances by using the class definition **AnnotatedValue**.

8.4.1 Explicit Control over Annotated Values

This section describes the macros and methods that allow explicit control over annotated values.

Name	Туре	Description
type?	Macro	Performs a type check for an instance of the Lisp data type annotatedValue.
create	Macro	Creates a new instance of the data type annotatedValue.

fetch	Macro	Retrieves the contents of the annotatedValue field of an annotatedValue instance.
replace	Macro	Replaces contents of the annotatedValue field of the annotatedValue instance.
_AV	Macro	Sends a message to the ActiveValue object wrapped in an annotatedValue.
MessageNotUndersto	ood Method	Forwards messages intended for the wrapped ActiveValue to that object.
(type? annotatedValue value)		[Macro]
Purpose:	Performs a	type check for an instance of the Lisp data type annotatedValue.
Arguments:	value	The value to type check.
Returns:	T if value is	an instance of the data type annotatedValue, NIL otherwise.
(, , , , , , , , , , , , , , , , , , ,		
(create annotatedValue annotat	edValue ←	object) [Macro]
Purpose:	Creates a n	ew instance of the data type annotatedValue.
Arguments:	object	An ActiveValue object to initialize the field annotatedValue of the new annotatedValue instance. This must be an object that has a method AVPrintSource (a method of ActiveValue) or this form breaks on evaluation. No type checking of object will be performed by the macro.
Returns:	An instance	e of annotatedValue.
(fetch annotatedValue of value))	[Macro]
Purpose:	Retrieves th instance.	ne contents of the annotatedValue field of an annotatedValue
Arguments:	value	An annotatedValue instance.
Returns:	Contents of	field annotatedValue.
/aanlaas ann state Nielse of wel		
(replace annotatedValue of valu		
Purpose:	Replaces co with <i>object</i> .	ontents of the annotatedValue field of annotatedValue instance
Arguments:	value	An annotatedValue instance.
	object	ActiveValue object to be stored in the field. No type checking is done on <i>object</i> .
Returns:		ot an annotatedValue, generates an error; otherwise the previous the field is returned.
(_AV av selector . args)		[Macro]
Purpose:	Sends a me	essage to the ActiveValue object wrapped in an annotatedValue.

Behavior: Equivalent to

	(_ (fetch annotatedValue of av) selector .args)	
Arguments:	av	Instance of an annotatedValue.
	selector	Selector for message to send to the ActiveValue object.
	args	Arguments to be passed when the message is sent.
Returns:	Result of message.	

(*self* MessageNotUnderstood)

[Method of AnnotatedValue]

Purpose:	Forwards messages intended for the wrapped ActiveValue to that object.
Behavior:	Messages sent to an annotatedValue are forwarded to its wrapped ActiveValue . Users should not explicitly send this message.

8.4.2 Saving and Restoring Annotated Values

The following are methods of the class ActiveValue that handle annotated values.

(← self AVPrintSource)		[Method of ActiveValue]
Purpose:	Prints Activ	eValues.
Behavior:		dValue determines how it prints out by sending the irce message to its wrapped ActiveValue.
	The default	method in ActiveValue returns a list of the form:
("#," \$AV className	avNames(i	vName value propName value)(ivName))
	which cause	s the annotatedValue to print out as
#,(\$AV className av	Names(ivNa	me value propName value)(ivName))
Arguments:	self	ActiveValue instance.
	className	Name of the class of the ActiveValue.
	avNames	List of names of <i>self</i> ; the last element being the unique identifier (UID) of <i>self</i>
	variables of print form er different ann	ame value propName value) describes the state of the instance the ActiveValue. Including the UID of the ActiveValue in the hables recovery of the identity of the ActiveValue. This enables notatedValues to share the same ActiveValue, and maintain this ss saving to a file and reloading into Lisp.
Returns:	a pair of the will be printe	ble for use by the Interlisp function DEFPRINT . Result should be form (item1 . item2); item1 will be printed using PRIN1 , and item2 d using PRIN2 (see <i>Lisp Release Notes</i> and the <i>Interlisp-D Manual</i> description of DEFPRINT).
Example:	. 8))	directVariable (HeightFromWidth (NCV0.0X:.SD7.KR .(\$ SquareWindow)) (varName width) (propName NIL))

(\$AV className avNames . ivForms)

Purpose:	Reconstructs an annotatedValue that has been saved to a file.	
Arguments:	className	Name of the class of ActiveValue.
	avNames	A list of the LOOPS names of ActiveValue instances.
	ivForms	A list describing the state of the instance variables of the ActiveValue .
Returns:	A new annotatedValue whose ActiveValue is reconstructed from the <i>avNames</i> and <i>ivForms</i> .	

8.5 Active Values in Class Structures

It is possible to have an active value as the default value of an instance variable or the value of a class variable in a class. For example, the following class has an active value installed in the class variable **dontChange** and one installed in the instance variable **firstRead**.

SEdit #,(\$C test) Package: INTERL	ISP	
((MetaClass Class Edited%:	; Edited 2-Dec-87 12:59	
)		
(Supers Object)		
(ClassVariables		
(dontChange		
#,(\$AV NoUpdatePermittedAV (([DAW0.1Y:.H53.]99] . 540)) (localState 100))))		
(InstanceVariables (firstRead #,(Defer (DATE)))) (MethodFns))		

LocalStateActiveValue active values as default IV values are copied down into the instance when their localState is smashed, instead of being shared by all instances; this is different from normal default behavior. It is also possible to create a LocalStateActiveValue which inherits its localState value by giving it a localState value of the value of NotSetValue). These copy the inherited value down from the superclass when the LocalStateActiveValue is created; if the value in the superclass is changed after the LocalStateActiveValue is created, that change will not be reflected in the LocalStateActiveValue. Normally inherited values are always tracked by instances that inherit them.

There are two ways to enter active values into the structure of a class: with the editor or programmatically.

It is possible to create active values by typing in a form such as:

(\$AV activeValueClassName NIL (ivname value propName value ...)(ivname value propName value ...) ...). None of the arguments are evaluated.

To add an active value through the editor, you can type in the above form, select it, and mutate it with the function **EVAL**.

Programmatically, you can use the functions **PutClassIV**, **PutClassValue**, **PutClassValueOnly**, **AddCIV**, **AddCV**, etc. or different methods, such as **Add**, to modify or add class variables and instance variables.

For example, given the above class, test:

(← (\$ test) Add 'CV 'randomJustOnce (\$AV FirstFetchAV NIL (localState (RAND 0 1000))))

and

(AddCIV (\$ test) 'newIV (\$AV LocalStateActiveValue NIL (localState (1 2 3))))

will result in the following:

SEdit #,(\$C test) Package: INTERLISP	
((MetaClass Class Edited%:	; Edited 2-Dec-87 13:20
)	
(Supers Object)	
(ClassVariables	
(dontChange	
#,(\$AV NoUpdatePermittedAV ((DAW0.1	Y:.H53.]99 . 540)) (localState 100)))
(randomJustOnce #,(Defer (RAND 0 1000)))))
(InstanceVariables (firstRead #,(Defer	(DATE)))
(newIV	
#,(\$AV LocalStateActiveValue ((DAW0.1	Y:.H53.]99 . 541)) (localState (1 2 3))
(MethodFns))	

An even more general programmatic method that more easily allows customization of an active value uses the annotatedValue data type explicitly. First, you must create an instance of an **ActiveValue** class.

```
(\leftarrow ($ MyActiveValue) New 'MyAV1)
```

Then the contents of the instance **MyAV1** are initialized. Finally, it is added as the value of a variable in a class structure.

(AddCIV (\$ test) 'myNewIV (create annotatedValue annotatedValue ← (\$ MyAV1))) [This page intentionally left blank]

DATA TYPE PREDICATES AND ITERATIVE OPERATORS

This chapter describes data type predicates and an operator for iterative statements.

9.1 Data Type Predicates

9.

Data type predicates test the Lisp data type of some datum. For example, some predicates test whether a datum is an object, instance, or class.

LOOPS defines three Lisp data types: annotatedValue, class, and instance. LOOPS provides predicates that enable testing aspects of these types.

Name	Туре	Description
Object?	Macro	Determines if a particular datum is a LOOPS object.
Class?	Macro	Determines if a particular datum is a class.
Instance?	Macro	Determines if a particular datum is an instance of a class.
AnnotatedValue?	Macro	Determines if a particular datum is an instance of the annotatedValue Lisp data type.
Understands	Method	Determines if an object will respond to a message.

To determine if a particular datum has an instance variable, class variable, or a property, use **HasIV**, **HasIV**!, or **HasCV** (see Chapter 2, Instances, and Chapter 3, Classes). To determine if a particular datum is an instance of a class or its superclasses, use **InstOf** or **InstOf**! (see Chapter 2, Instances).

(Object? X)

[Macro]

Purpose/Behavior:	Determines if X is a LOOPS object. Object? returns T for both instances and classes.
Arguments:	X Possible object.
Returns:	Returns T if a name is a pointer to a LOOPS object, and returns NIL otherwise.
Example:	This example demonstrates the use of Object? .
	3←(← (\$ Window) New 'Window1) #,(\$& Window (OZW0.1Y:.;h.Qm: . 495))
	4←(Object? (\$ Window1)) T
	5←(Object? (\$ Window))

T 6←(Object? (\$ NotAnObject)) NIL 7←(Object? 'NotAnObject) NIL

(Class? X)

[Macro]

Purpose/Behavior:	Determines if X is a class.	
Arguments:	X	Possible class.
Returns:	Returns T if	X is a class; returns NIL otherwise.
Example:	Window) is a	e demonstrates the use of the predicate Class? Since ($\$$ a class, the function returns T. Since Window1 and NotClass names, NIL is returned. (Class? X) is equivalent to (type?
	8←(Class? T	? (\$ Window))
	9←(Class? NIL	? (\$ NotClass))
	10←(Class NIL	3? (\$ Window1))

(Instance? X)

[Macro]

Purpose/Behavior:	Determines if X is an instance of some class.	
Arguments:	X Possible instance.	
Returns:	Returns T if X is an instance; returns NIL otherwise.	
Example:	This example shows the use of Instance? (Instance? X) is equivalent to (type? instance X).	
	11←(Instance? (\$ Window1)) T	
	12←(Instance? 'Unbound) NIL	
	13←(Instance? (\$ Window)) NIL	
(AnnotatedValue? X)	[Macro]	
Purpose/Behavior:	Determines if X is an instance of the annotatedValue data type. For a complete explanation of annotated values, see Chapter 8, Active Values.	
Arguments:	X Possible annotatedValue.	
Returns:	Returns T if X is an annotated value; returns NIL otherwise.	
Example:	Instances of class Window are created with an active value in the window instance variable. AnnotatedValue returns T for the annotatedValue which "wraps" an active value, not for the active value itself.	

 $100 \leftarrow (\leftarrow (\$ Window) New 'Window3]$

	#,(\$& Window (OZW0.1Y:.;h.Qm: . 495))
	1←(GetValue (\$ Window3) ′window) {WINDOW}#51,140000
	2←(GetValueOnly (\$ Window3) 'window) #,(\$AV LispWindowAV ((OZW0.1Y:.;h.Qm: . 495)) (localState {WINDOW}#51,140000))
	3←(AnnotatedValue? (GetValueOnly (\$ Window3) 'window)) T
	4←(AnnotatedValue? (GetValue (\$ Window3) 'window)) NIL
	5←(AnnotatedValue? (_ (\$ LispWindowAV) New 'LWAV4] NIL
(← self Understands selector)	[Method of Object]
<u>. </u>	
Purpose/Behavior:	Determines if the object self will respond to a message with selector.
Arguments:	self Instance or class in question.
	selector Selector in question.
Returns:	T if <i>self</i> is a class or an instance of a class that understands message selector; NIL otherwise.
	Note: If <i>self</i> is not a LOOPS object, you get NIL and not an error.
Categories:	Object
Example:	Given that Window is a class, MyWindow is an instance, and SpinAround is a method of MyWindow , Window returns NIL, and MyWindow returns T. Since Shape is a method of Window , this also returns T.
	90←(← (\$ Window) Understands 'SpinAround) NIL
	91←(← (\$ MyWindow) Understands 'SpinAround) T
	91←(← (\$ MyWindow) Understands 'Shape) T

9.2 Iterative Operators

LOOPS provides an iterative operator to be used with Interlisp-D iterative statements.

in-supers-of X	[Iterative Statement Operator]
Purpose / Behavior:	Allows iteration up the supers chain of the object <i>X</i> . Used in an Interlisp-D iterative statement. (See the <i>Interlisp-D Reference Manual</i> for more information on iterative statements.)
Arguments:	X A LOOPS class or an instance.
Example:	This example shows one way to use this operator.

```
55←(FOR I in-supers-of ($ ClassBrowser) DO (PRINT (← I ClassName]
ClassBrowser
IndexedObject
LatticeBrowser
Window
Object
Tofu
NIL
```

[This page intentionally left blank]

As described in Chapter 1, Introduction, one of the key components in the LOOPS system is inheritance, in which structures have well-defined relationships to other structures. Class inheritance is a typical example of this relationship.

Since inheritance can be described by a two-dimensional graph, it is natural to create a user interface for LOOPS built on the Lisp Library Module, Grapher. This user interface is called a browser. Browsers are tools to assist in the development cycle of a product or vehicles for building user interfaces within a final product.

Much development time is spent building, examining, and modifying the relationships between classes. These tasks include specifying the contents of various classes: class variables, instance variables, properties, and methods. The location of the class within the inheritance structure must also be determined. After a number of classes have been built, the relationships between the classes may need to be reviewed. Often, the initial design is flawed and requires the following changes:

- Moving parts of one class to another class.
- Adding, substracting, or changing data or functionality within classes.
- Adding new classes, or merging different classes.

Browsers are the facility within LOOPS which support these types of operations. This chapter describes how to use browsers both interactively with the mouse, and programmatically.

Browsers are most commonly used on the classes defined for an application. Many of the examples here browse objects which LOOPS uses internally; the functionality is exactly the same.

10.1 Types of Built-in Browsers

A number of different types of browsers are already built into LOOPS:

- Lattice browsers
- Class browsers
- File browsers
- Supers browsers
- Metaclass browsers

This section describes these browsers in detail.

10.1.1 Lattice Browsers

The most general class is called **LatticeBrowser**. Figure 10-1 shows a class inheritance lattice with the subclasses of **LatticeBrowser**.

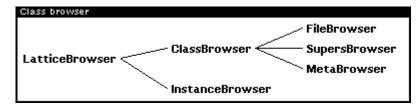

Figure 10-1. Sample Lattice Browser

10.1.2 Class Browsers

A class browser shows the linkages between a class or classes and their subclasses. Super classes are shown on the left (or top) side of the browser window. Subclasses of these are connected by links moving to the right (or down). An example of a class browser is shown in the previous section. The class LatticeBrowser is the root object of this example. Subclasses of LatticeBrowser are ClassBrowser and InstanceBrowser. Subclasses of ClassBrowser are FileBrowser, SupersBrowser, and MetaBrowser.

10.1.3 File Browsers

A file browser is a class browser containing all classes defined within a file. Additionally, file browsers contain a menu interface to common operations on files.

10.1.4 Supers Browers

A supers browser is an inverted class browser. A class browser is built by following subclass links from a class. A supers browser is built by following superclass links from a class. An example of a supers browser is shown in Figure 10-2.

Supers browser		
ClassBrowser <	LatticeBrowser ` IndexedObject	— Window Object ——— Tofu

10.1.5 Metaclass Browsers

A metaclass browser is like a supers browsers, but is built by following metaclass links. Figure 10-3 shows two root classes: **ActiveValue** and **ClassBrowser.**

MetaClass browser
ActiveValue ——— AbstractClass
ClassBrowser ————————————————————————————————————

Figure 10-3. Sample Metaclass Browser

10.1.6 Instance Browsers

An instance browser shows the relationships between instances. These relationships may be more dynamic than the inheritance relationships shown by the class browsers. Typically, the relationships are not defined until runtime, and may be changed often. By specializing the instance browser, you can show several relationships between a fixed set of objects.

10.2 Opening Browsers

A browser can be opened in several ways:

- Selecting a menu option from the Background Menu.
- Selecting a menu option from the LOOPS icon.
- Sending a **Browse** message to an instance of a browser.
- Calling either of the functions **Browse** or **FileBrowse**.

10.2.1 Using Menu Options to Open Browsers

Since browsers are an important part of LOOPS, you can use menus in several ways to create standard browsers. Once opened, via menu or program, any browser can be operated from both the appropriate menus and programmatic commands.

10.2.1.1 Overview of Background Menu and LOOPS Icon

When LOOPS is loaded, the option **Loops Icon** is added to the background menu, as shown in this window:

The Loops Icon option has two suboptions:

- Browse Class
- Browse File

These suboptions are shown in the following windows:

		Browse File
Loops Icon	Browse Glass	Edit FiloCome
ldle	🔉 Browse File	Cleanup File

Selecting **Loops Icon** puts a LOOPS icon on the screen; you are prompted to place the icon after it is created. The other commands are discussed in Section 10.2.1.2, "Command Summary."

The LOOPS icon, which appears in Figure 10-4, is a prototype instance of the class **Loopsicon**. It is provided to give you another convenient menu interface to typical programming operations.

Figure 10-4. LOOPS Icon

Pressing the left button while the mouse is on the icon causes the following menu to appear with options appropriate for class browsers:

Pressing the middle button while the mouse is on the icon causes the following menu to appear with choices appropriate for file browsers:

Pressing the right button while the mouse is on the icon causes the following menu to appear with two options for operations on the icon itself:

Close removes the icon from the screen. It can be restored at any time from the background menu. **Move** lets the icon be moved to another location on the screen, just as any icon is moved in Lisp.

10.2.1.2 Command Summary

The background menu and the LOOPS icon provide the same functionalities. This section describes the commands available.

Browse Class, Browse Supers

Selecting either of these options causes the following prompt to appear in the prompt window.

Please tell me the name of the root object >

Enter the name of a class without using the "\$" notation. The system builds the appropriate type of browser and prompts you to move the window containing the browser.

Browse File

	Selecting this option causes the following menu to appear:
	newFile *loadFile* *newFile* ARFDIT
	The top option on this menu is *newFile * which has three suboptions; the remaining options are the names of the files that are on FILELST (Lisp remembers what files are loaded and how they were loaded; FILELST files were loaded normally. See the <i>Interlisp-D Reference Manual</i> for a full explanation). Selecting one of the filenames will open a file browser on that file.
newFile	Prompts you in the prompt window with the following prompt :
	Please type in file name: >.
	Enter the name of a file to create. The system checks to determine if a filecoms exists for that file name. If one exists, the system asks for confirmation before destroying the value of that filecoms and opening up an empty browser window. If no filecoms exists for that filename, an empty file browser window is opened.
loadFile	Prompts you with:
	Please type in file name to load: >
	The system loads that file and opens a browser on it.
hiddenFile	Causes a menu to appear with files that have been loaded but not SYSLOAD ed and are not on FILELST ; that is, the files are on LOADEDFILELST , but not on FILELST . The LOOPS files, for example, the .LCOMs that add LOOPS to Lisp, are on this list.
Edit Filecoms	
	Selecting this option brings up the same menu as the option Browse File . Instead of opening a browser on the file, a display editor window is opened on the filecoms of that file. If *newFile * is selected, you are prompted to enter a file name and an SEdit window is opened with a template containing the File Manager commands CLASSES , METHODS , FNS , VARS , and INSTANCES .
CleanUp File	
	Selecting this option first calls FILES? and then builds a menu of files in FILELST that have changed. From this menu, select a file to be cleaned up;

10.2.2 Using Commands to Open Browsers

this calls CLEANUP.

You can use the following methods and functions for opening browsers programmatically and from the Lisp Executive window.

Name	Туре	Description
Browse	Method	Opens a browser showing the relationships between classes.

BrowseFile	Method	Opens a browser showing the relationships between classes on a file.
Browse	Function	Provides a short way to create a class browser.
FileBrowse	Function	Provides a short way to create a file browser.

(← self **Browse** browseList windowOrTitle goodList position)

Purpose/Behavior: Opens a browser showing inheritance relationships between classes. Arguments: self An instance of ClassBrowser, MetaBrowser, or SupersBrowser. browseList A LOOPS class name, a LOOPS pointer to a class name, or a list of those. windowOrTitle A title to appear on the browser or a window to use (but which will be reshaped to fit the browser.) Title defaults to "Class browser." goodList A goodList other than the *browselist*. (See Section 10.5.1, "Instance Variables of Class LatticeBrowser," for more information on goodList.) position Lower left corner of browser. If NIL, position the window with the mouse. Pointer to the browser object. Returns: Examples: The following command opens a class browser on Window. (←New (\$ ClassBrowser) Browse 'Window) The following command opens a supers browser on InstanceBrowser and ClassBrowser.

(←New (\$ SupersBrowser) Browse (LIST 'InstanceBrowser (\$ ClassBrowser)))

(← self BrowseFile fileName)		[Method of FileBrowser]
Purpose:	Opens a bro	owser showing relationships between classes on a file.
Behavior:	Classes defined within <i>fileName</i> are displayed within the browser. If <i>fileName</i> is NIL, a menu of files on FILELST opens. The selected file has a file browser opened on it.	
Arguments:	self	An instance of the class FileBrowser
	fileName	File to browse; should not be a list.
Returns:	self	
Categories:	FileBrowser	·
Example:	The followir	ng command opens a file browser on the file LoopsWindow.
	(←New (\$	FileBrowser) BrowseFile 'LoopsWindow)

(Browse classes title goodClasses position)

[Function]

[Method of LatticeBrowser]

Provides a s	hort way to create a class browser.
classes, title	wse message to a new instance of a ClassBrowser passing , <i>goodClasses</i> , and <i>position</i> as arguments. If <i>goodClasses</i> is T, it o the value of <i>classes</i> before the message is sent.
classes	A LOOPS class name, a LOOPS pointer to a class name, or a list of those.
title	A title to appear on the browser. Title defaults to "Class browser."
goodClassse	A goodList other than <i>classes</i> . (See Section 10.5.1, "Instance Variables of Class LatticeBrowser," for more information on goodList .)
position	Lower left corner of browser. If NIL, position the window with the mouse.
A new instar	nce of ClassBrowser.
The following and all its su	g command creates a class browser on the class ActiveValue bclasses.
11←(Brows	se 'ActiveValue)
	[Function]
Provides a s	hort way to create a file browser.
	wseFile message to a new instance of a FileBrowser passing the argument.
filename	File to browse.
New instance	e of FileBrowser.
	Sends a Bro classes, title is rebound to classes title goodClassse position A new instan The following and all its su $11 \leftarrow (Brows)$ Provides a s Sends a Bro filename as to filename

Example: The following command creates a file browser on the file **LoopsWindow**.

12←(FileBrowse 'LoopsWindow)

10.3 Using Class Browsers, Meta Browsers, and Supers Browsers

Instances of **ClassBrowser, SupersBrowser, MetaBrowser** all have the same menu interface. This section shows examples of the various menus followed by descriptions of the actions performed after selecting particular options.

Three pop-up menus are associated with browsers:

- One menu appears by positioning the mouse on the title bar of the browser window and pressing either the left or the middle mouse button. This menu contains options that control the appearance of the browser.
- A second menu appears by positioning the mouse on one of the nodes in a browser and pressing the left mouse button. This menu contains informational options.
- A third menu appears by positioning the mouse on one of the nodes in a browser and pressing the middle mouse button. This menu contains editing options.

(FileBrowse file

These menus differ depending on the browser type. The following sections describe the menus associated with class browsers, supers browsers, and metaclass (or, more simple, meta) browsers. Sections then describe the additional functionality associated with file browser menus.

10.3.1 Selecting Options in the Title Bar Menu

The following menu appears when you position the mouse on the title bar of the browser menu and press either the left or the middle mouse button:

This section describes each menu option.

10.3.1.1 Recompute and its Suboptions

Selecting the **Recompute** option and dragging the mouse to the right causes the following submenu to appear:

	the following subment to appear.
	SaveValue Recompute RecomputeLabels InPlace ShapeToHold ChangeFontSize Lattice/Tree AddRoot
	Most of the Recompute suboptions change the appearance of a browser but not its contents. For example, SaveValue provides a pointer to the browser without changing anything in it.
SaveValue	The browser instance is stored in the instance variable savedValue of the prototype instance of LoopsIcon and in the value of IT (see the <i>Interlisp-D Reference Manual</i>). This value is returned from the function call SavedValue .
Recompute	Recomputes the entire browser structure from the starting objects. It does not recompute the labels for each item if those labels have been cached in the property objectLabels of the instance variable menus.
RecomputeLabels	Recomputes the entire browser structure from the starting objects and recomputes the labels for each item.
InPlace	Recomputes the browser without affecting the scrolled location of the lattice within the window. This may be necessary for a browser containing a large lattice structure.
ShapeToHold	Makes the window for the browser just large enough to hold all of the nodes in the browser, up to a maximum size. Browser windows may also be changed interactively or programmatically with SHAPEW .
ChangeFontSize	Causes a menu to appear containing 8, 10, 12, and 16. Selecting one changes the font size used to display the nodes to that value. The font family is
	(@ self browseFont:,FontFamily)
	The fort face is

The font face is

(@ self browseFont:,FontFace)

Note: An alternative way to change the font of a browser is to enter:

[PROGN (\leftarrow @ (\$ InstanceOfBrowser) browseFont (FONTCREATE))(\leftarrow (\$ InstanceOfBrowser) RecomputeLabels)]

Lattice/Tree Causes the following menu to appear:

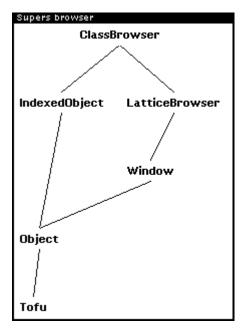

Using the example of a supers browser for the class **ClassBrowser**, this browser is drawn for each of the formatting options. A tree does not show branches recombining; a lattice does. A boxed node in a tree indicates the node shows up in more than one location in a tree. When a browser is constructed by the system the default formatting style is HORIZONTAL/LATTICE.

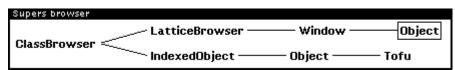

HORIZONTAL/LATTICE

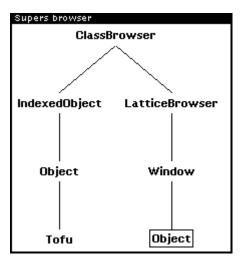

VERTICAL/LATTICE

HORIZONTAL/TREE

VERTICAL/TREE

10.3.1.2 AddRoot and its Suboptions

The AddRoot options add items or subtrees to the browser.

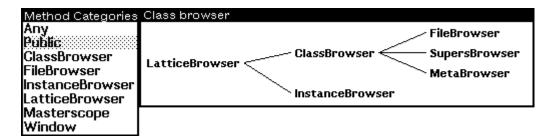

Selecting the **AddRoot** option and dragging the mouse to the right causes the following submenu to appear:

Recompute	AddBoot
AddRoot	RemoveFromBadList
Add Category Menu	

- AddRoot A prompt appears in an attached window to enter the name of a class to be added to the browser. If the entered item is not an object, a message that nothing was added to the browser is printed. If the entered item is already in the browser, nothing occurs. If the entered name does not correspond to a class, nothing occurs.
- RemoveFromBadList Objects within a browser can be put on the instance variable badList. This can be done by positioning the mouse on the node in a browser, pressing the left mouse button, and selecting an option from the menu that appears. Items on the badList are not displayed in the browser. If you select the option RemoveFromBadList, a menu appears showing any objects on the badList. Selecting one of those objects removes it from the badList and causes it to be redisplayed in the browser.

10.3.1.3 Add Category Menu

The system searches all methods in all classes shown in the browser and computes the categories for these. These categories are made into a sorted menu with the categories **Any** and **Public** included at the top. This menu is attached to the left side of the browser. Selecting options in this menu acts as a toggle, either highlighting them or returning them to their normal display.

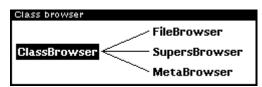

Selected options are stored on the browser instance variable **viewingCategories.** Options on this menu interact with the browser interface for editing methods as described in Section 10.3.2, "Selecting Options in the Left Menu."

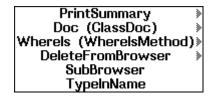

Note: Very often when using a browser, you ask to see what items a class inherits from classes above it in the inheritance lattice. To keep this inherited information more manageable, information inherited from the classes **Tofu**, **Object**, and **Class** are filtered out from the information presented to you. As an example, see the description of **PP** in the following section.

10.3.2 Selecting Options in the Left Menu

When the mouse is inside a browser and you hold down the left mouse button, nodes within the browser become inverted when the cursor moves over them, as shown in the following window:

If you release the left mouse button while the cursor is over a node, the following menu appears:

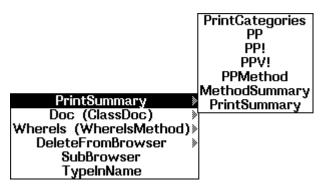

The options shown on the menu operate on the node (class) selected. Several of these options have associated submenus. Common options are in the main menu, and less common ones are menu suboptions. The actions that occur as a result of selecting one of these options are described in the following subsections. An additional subsection describes extended functionality available with the left mouse button.

10.3.2.1 PrintSummary and its Suboptions

PrintSummary provides a quick way to see object and method definitions. For all printing that occurs as a result of selecting this option or one of its suboptions, the output is sent to the value of the variable **PPDefault**, which is by default the Common Lisp Executive Window.

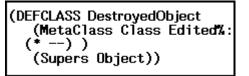

Selecting the **PrintSummary** option and dragging the mouse to the right causes the following submenu to appear:

PrintCategories Prints the categories and associated methods for the selected class, as shown in the following window:

#,(\$ DestroyedObject)
)bject Destroy!

PP Produces a standard PrettyPrint of class, as shown in the following window:

PP! Produces a formatted Print of class, as shown in the following window:

Information that is defined locally within the class is printed in the bold font. Inherited information is printed in the regular font. Inherited information from the classes **Object** and **Tofu** is not printed.

PPV! Same as **PP!**, but does not include **Methods**, as shown in the following window:

	<pre>#,(\$ DestroyedObject) MetaClass and its Properties Class Edited; (* TheCollaborators; 15-Oct-84 16;23) Supers (Object Tofu) Instance Variable Descriptions Class Variables</pre>
PPMethod	Brings up a menu of the methods for this class followed by a list of the known categories. The menu is influenced by the shaded options on the Method Categories menu (see Section 10.3.1.3, "Add Category Menu"), whether or not it is opened. Selecting a category will include any methods under that category in the menu. After selecting one of the methods, the Lisp function for that method is prettyprinted.
	For example, selecting PPMethod from the node ClassBrowser with the Method Categories menu as shown results in the following menu of methods:
	Method Categories Class t Any Any Public ClassBrowser GlassBrowser ClassB FileBrowser ClassB LatticeBrowser MewItem Masterscope ** Any category ** ** ClassBrowser category **
MethodSummary	Prints a summary of the methods defined for the class, as shown in the following window:
	((Destroy! DestroyedObject.Destroy! args NIL doc NIL))
PrintSummary	Similar to PP , but default values or properties associated with variables and methods are not printed, as shown in the following window:
	#,(\$ DestroyedObject) Supers Object IVs
	GVs
	Methods Destroy!

10.3.2.2 Doc (ClassDoc) and its Suboptions

Each part of an object's definition has a **doc** property containing strings. This menu option is a quick way to see the string for a specific part of a definition. For all printing that occurs as a result of selecting this option or one of its

suboptions, the output is sent to the value of the variable **PPDefault**, which is by default the Common Lisp Executive Window.

Selecting the **Doc (ClassDoc)** option and dragging the mouse to the right causes the following submenu to appear:

	ClassDoc
	MethodDoc
PrintSummary >	IVDoc
Doc (ClassDoc) >>	CVDoc
WhereIs (WhereIsMethod)»	0.000
DeleteFromBrowser >>	
SubBrowser	
TypeInName	

ClassDoc Prints documentation for class, that is, the **doc** property.

MethodDoc Causes a menu to appear in the same manner as **PPMethod** described in Section 10.3.2.1, "PrintSummary and its Suboptions." After selecting a method, information about that method is printed, as shown in the following window:

class: ClassBrowser selector: BoxNode args: NIL doc: NIL

The menu of methods reappears until a selection is made from outside the menu.

IVDoc Causes a menu to appear showing instance variables associated with the class. After selecting one, its documentation is printed, as shown in the following window:

ClassBrowser:menus: Cache For Saved Menus. Will Cache Menus only if value is T

The menu of instance variables reappears until a selection is made from outside the menu.

CVDoc Causes a menu to appear showing class variables associated with the class. After selecting one, its documentation is printed, as shown in the following window:

> ClassBrowser::RightButtonItems: Items to be done if Right button is selected

The menu of class variables reappears until no selection is made from the menu.

10.3.2.3 WhereIs and its Suboptions

WhereIs describes where each part of the object comes from. For all printing that occurs as a result of selecting this option or one of its suboptions, the output is sent to the value of the variable **PPDefault**, which is by default the Common Lisp Executive Window.

Selecting the **Wherels** option and dragging the mouse to the right causes the following submenu to appear:

PrintSummary Doc (ClassDoc) Wherels (WherelsMethod) DeleteFromBrowser SubBrowser TypelnName	WherelsIV WherelsCV WherelsMethod
--	---

WhereIsIV Causes a menu to appear at the current cursor position, showing the local and inherited instance variables. A sample menu appears here:

Finding IVS: ClassBrowser LabelMaxCharsWidth LabelMaxLines badList
bottom
boxedNode
browseFont
goodList
graphFormat
height
lastSelectedObject
left
menus
showGraphFn startingList
startingList
title
topAlign uiswingCategories
viewingCategories width
window

When you select an instance variable from this menu, these actions occur, as shown in the following window:

- A search starts with the selected class and then proceeds upwards through its supers. The first class that contains the selected instance variable flashes three times.
- All other classes in the browser that contain, that is, specialize, the instance variable are shaded.
- The name of the topmost class name is printed across the top of the window.

IV width is in #,(\$C LatticeBrowser)	
Class browser	
LatticeBrowser ClassBrowser Supe	rowser. FrsBrowser aBrowser

WhereIsCV Same as above, but for class variables.

WhereIsMethod Same as above, but for **Methods**. The menu of methods is not filtered by any category information.

10.3.2.4 DeleteFromBrowser and its Suboptions

Browsers show all of the lattice or tree from the root to the leaves. The **DeleteFromBrowser** option and its suboptions, shown here, allow you to prune the tree.

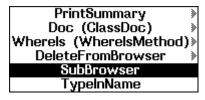

PrintSummary >> Doc (ClassDoc) >> Wherels (WherelsMethod)>> DeleteFromBrowser SubBrowser	DeleteFromBrowser DeleteSubtreeFromBrowser
SubBrowser	
TypeInName	

DeleteFromBrowser Deleting a class from a browser adds it to that browser's instance variable **badList**. Items listed in a browser's **badList** are not displayed by the browser. If a class on the **badList** has subclasses, these are made into roots. To redisplay a class once it has been deleted, refer to the command **RemoveFromBadList** in Section 10.3.1.2, "AddRoot and its Suboptions."

DeleteSubtreeFromBrowser Deleting a class with this command places this class on the browser's **badList**. Additionally, any subclasses of the deleted class are also placed on the **badList**. If one uses the command **RemoveFromBadList** to redisplay the deleted class, only that class is redisplayed. Its subclasses remain on the **badList** until they are explicitly removed from it.

10.3.2.5 SubBrowser

The following window shows the selection of this option:

For class and supers browsers, the SubBrowser option opens a new browser of the same type (for example, a **SubBrowser** of a supers browser is a supers browser) with the class selected becoming the root object of the browser. For file browsers, the **SubBrowser** becomes a class browser.

10.3.2.6 TypeInName

The following window shows the selection of this option:

PrintSummary	>
Doc (ClassDoc)	≥
WhereIs (WhereIsMethod	d)≽
DeleteFromBrowser	`>
SubBrowser	
TypeInName	

This option puts the class name in the type-in buffer.

10.3.2.7 Extending Functionality with the Left Mouse Button

Using various keys in conjunction with the left mouse button extends the available options.

• SHIFT key

Pressing the **SHIFT** key while selecting a node with the left button causes the name of the class to be typed into the current type-in point. If a node is not selected, but the cursor is in the background of the browser, the entire graph is copied. This can be used to insert browser images into TEdit documents, for example. See the Lisp Library documentation on Grapher for more details.

• Control (CTRL) key

Pressing the **key** node with the left button causes the node to track movement by the cursor. This allows you to temporarily change the layout of the nodes in the graph. The next update of the browser recomputes the node positions.

• META key

Pressing the **META** key while selecting a node with the left button is the same as a **PrintSummary** selection.

10.3.3 Selecting Options in the Middle Menu

When you position the cursor on a browser node and press the middle mouse button, the following menu appears:

Box/UnBoxNode	
Methods (EditMethod)	≽
Add (AddMethod)	≽
Delete (DeleteMethod)	≽
Move (MoveMethodTo)	≽
Copy (CopyMethodTo)	≽
Rename (RenameMethod)))
Edit (EditClass)	≽

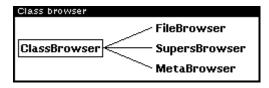

This section describes the actions that occur when you select an option from this menu.

Except for **BoxNode**, all options are followed by a parenthetical suboption. This suboption appears in the option's submenu and performs the same operation as the option itself. For example, selecting **Methods (EditMethod)** performs the same operation as selecting **EditMethod** from its submenu.

The prompt for these options usually appears in a small window at the top of the browser, unless otherwise stated.

10.3.3.1 Box/UnBoxNode

Draws a box around the node, as shown here:

This also selects the node as a target for **Move** and **Copy** options. If a node is already boxed, **Box/UnBoxNode** unboxes it. Only one node in a class browser can be boxed at a time with this menu option.

10.3.3.2 Methods (EditMethod) and its Suboptions

Selecting the **Methods (EditMethod)** option and dragging the mouse to the right causes the following submenu to appear:

	EditMethod EditMethod! EditMethodObject MethodMenu
Box/UnBoxNode	EditCategory >
Methods (EditMethod) >>	BreakMethod >
Add (AddMethod)	[]
Delete (DeleteMethod) >	
Move (MoveMethodTo) >	
Copy (CopyMethodTo)	
Rename (RenameMethod)»	
Edit (EditGlass)	

EditMethod Edits a method of class, selected from a menu of local methods. The menu that appears contains some or all of the methods of the class and some category choices. The menu options that appear depend on the shaded options on the **Method Categories** menu (see Section 10.3.1.3, "Add Category Menu").

For example, assume the following actions occur:

- A class browser is opened on the class LatticeBrowser.
- A category menu is added and the category LatticeBrowser is selected.
- FileBrowser under the class ClassBrowser is selected.
- The EditMethod suboption is selecte.

The following menu appears:

Method Categories	Class browser	EditMethod; FileBrowser Browse CareAbout? IconTitle
Any Public ClassBrowser FileBrowser InstanceBrowser LatticeBrowser Masterscope Window		Newitem Recompute SubBrowser ** Any category **

If you select one of the method names, an edit window appears containing the source code for the method (assuming the source code was loaded). If you select one of the categories, a similar menu appears showing the changed methods and categories. The method/category menu continues to appear until you select a method or press a mouse button outside of the menu. This operation is provided by the method **PickSelector**.

EditMethod! Edits a method selected from a menu of all the inherited methods, making the method local if necessary.

EditMethodObject Edits the object representing the method, as shown in this display editor window:

SEdit # ,(\$& Method (NEW0.1Y).;h.eN6 . 453
((className FileBrowser)
(selector Recompute)
(method FileBrowser.Recompute)
(args NIL)
(doc NIL)
(category (LatticeBrowser)))

This suboption uses the method **PickSelector** to provide the same menu interface for choosing a selector that **EditMethod** uses. Within this edit window, the only items you should change are the **doc** and **category** properties.

MethodMenu Creates a permanent menu of methods of this class, for example,

Edit methods for DestroyedObje	ect
Destroy!	

After you have placed the menu, pressing the left mouse when the cursor is over a menu option will cause the method to be printed; pressing the middle button will cause the method to be edited.

EditCategory This option has three suboptions:

• EditCategory

Opens a menu of available categories, similar to the following menu example:

After you select a category, another menu appears containing the methods of that category and a list of categories not chosen (using the method **PickSelector**). When a method is selected, it appears in an edit window.

ChangeMethodCategory

Using the method **PickSelector**, this prompts you for a method. When one is selected, another menu appears containing the option ***other*** with all of the categories of the selected class.

If one of the categories is chosen, the category for the method is changed to this value.

If ***other*** is chosen, this prompts you in the **PROMPTWINDOW** for a symbol or a list of symbols that will become the new category or categories for the method.

See the method Class.ChangeMethodCategory.

• CategorizeMethods

Edits an association list of categories and the local methods they contain via the editor.

This is an example of the edit window that appears:

SEdit Package; INTERLISP

((Any (CreateClass DestroyInstance New NewWithValues))
 (Public (CreateClass DestroyInstance New NewWithValues))
 (Internal NIL)
 (MetaClass (CreateClass))
 (Class (DestroyInstance New NewWithValues)))

BreakMethod This option has three suboptions:

BreakMethod

Places a break on a method of class, selected from a menu of local methods, by sending the message **BreakMethod**.

TraceMethod

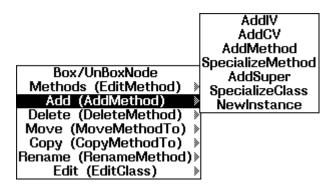

Places a trace on a method of class, selected from a menu of local methods, by sending the message **TraceMethod**.

UnbreakMethod

Brings up a menu of methods local to class that have been broken, and removes any breaks or traces on the one selected by sending the message **UnbreakMethod**.

10.3.3.3 Add (AddMethod) and its Suboptions

Selecting the **Add (AddMethod)** option and dragging the mouse to the right causes the following submenu to appear:

AddIV Prompts you for the name of a new instance variable to be added to a class, and opens an editor as shown here:

* SEdit DestroyedObject Package; INTERLISP

(newIV **DefaultValue doc (* IV added by MCGILL))

From here, change the default value of the instance variable to the desired value, and change the documentation to add any other properties and values if necessary. When you exit from the editor, the instance variable is added to the class.

AddCV Same as AddIV, except that you add a class variable.

AddMethod Allows you to create and edit a new method for this class. You are prompted to type a selector for the new method. Next, an edit window appears with the following template: SEdit DestroyedObject.newMethod Package; INTERLISP (Method ((DestroyedObject newMethod) self) "Method documentation" (SubclassResponsibility)) Replace the form (SubclassResponsibility) with the functionality you want. SubclassResponsibility is a macro that causes a call to HELPCHECK, so if you forget to remove it, or want to leave it in for debugging, it will break when the new method is invoked. SpecializeMethod Causes a menu to appear, containing the selectors of inherited methods, the option ** Generic Methods **, and available categories. If one of the selectors is chosen, a display editor window appears with a template that contains a _Super and the same comment as the specialized method. An example of this window appears here: SEdit DestroyedObject.Destroy! Package; INTERLISP (Method ((DestroyedObject Destroy!) self) "Specialization" (+Super self Destroy!)) If ** Generic methods ** is chosen this causes a menu to appear, listing the methods inherited from Object, Class, or Tofu. AddSuper Prompts you for a class name to be added to the beginning of the **Supers** list. **SpecializeClass** Defines a subclass of this class. This subclass is initialized with no locally defined instance variables, class variables, or methods. You are prompted to give a name for the new class. The new class is added to the browser. Creates a new instance of this class, calls **PutSavedValue** with the new NewInstance instance as an argument, and prints the instance.

10.3.3.4 Delete (DeleteMethod) and its Suboptions

Selecting the **Delete (DeleteMethod)** option and dragging the mouse to the right causes the following submenu to appear:

Box/UnBoxNode Methods (EditMethod) > Add (AddMethod) > Delete (DeleteMethod) > Move (MoveMethodTo) > Copy (CopyMethodTo) > Rename (RenameMethod) Edit (EditClass) >	
--	--

- **DeletelV** Opens a menu containing the local instance variables, that is, those defined in the class. Selecting one removes it from the class.
- **DeleteCV** Same as **DeleteIV**, but for class variables.

DeleteMethod Opens a menu containing the local selectors. Choosing one opens the following menu for confirmation:

Destroy!Confirm method deletion Delete Method and Function Abort

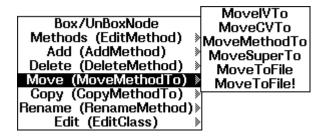

DeleteClass Deletes this class. Opens a menu similar to the following for confirmation:

Confirm Destroy DestroyedObject

If the class has no subclasses it will be deleted. If it does have subclasses a **HELPCHECK** break occurs; you can then abort or type OK to destroy the class and all of its subclasses.

10.3.3.5 Move (MoveMethodTo) and its Suboptions

Selecting the **Move (MoveMethodTo)** option and dragging the mouse to the right causes the following submenu to appear:

Moving methods and variables requires that you first have used **BoxNode** (see Section 10.3.3.1, "BoxNode") on the class which is to receive whatever is moved.

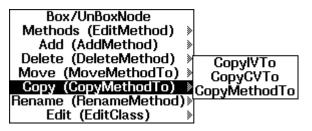

CAUTION

Moving methods and variables can have profound effects on the classes that inherit them.

MovelVTo	Opens a menu with the instance variables for the class. Choosing one causes it to be moved to the class that is boxed in the browser. When this operation is completed, the menu opens again prompting you for another instance variable to move, if desired.
MoveCVTo	Similar to MovelVTo , but for class variables.
MoveMethodTo	Similar to MovelVTo , but for methods.
MoveSuperTo	Opens a menu of the Supers for the class. Choosing one of these will cause it to be removed as a super class, and the boxed class to be added to the Supers list.
MoveToFile	Opens a menu of files on FILELST along with *newFile* . (See Section 10.2.1.2, "Command Summary," for more information on *newFile* .) The class and its methods are moved to the chosen file.
MoveToFile!	Same as MoveToFile , but includes subclasses and their methods of the classes.

10.3.3.6 Copy (CopyMethodTo) and its Suboptions

Selecting the **Copy (CopyMethodTo)** option and dragging the mouse to the right causes the following submenu to appear:

Copy options operates similarly to Move options, but leave the original method or variable in its place while adding it to the destination. You can then specialize the original or copy.

- **CopyIVTo** Similar to **MoveIVTo**, but copies the instance variables instead of moving them.
- **CopyCVTo** Similar to **MoveCVTo**, but copies the class variables instead of moving them.
- **CopyMethodTo** Similar to **MoveMethodTo**, but copies the methods instead of moving them.

10.3.3.7 Rename (RenameMethod) and its Suboptions

Selecting the **Rename (RenameMethod)** option and dragging the mouse to the right causes the following submenu to appear:

Methods (EditMethod) Add (AddMethod) Delete (DeleteMethod) Move (MoveMethodTo) Copy (CopyMethodTo) Rename (RenameMethod) Edit (EditClass)	RenamelV RenameCV RenameMethod BetireMethod
---	--

- **RenamelV** A menu appears, showing the instance variables of the class. After selecting one of these, you are prompted to give a new name for that instance variable.
- **RenameCV** Similar to **RenameIV**, but for class variables.
- **RenameMethod** Similar to **RenameIV**, but for methods. You are prompted to give a new name for the selector of the method. The method function name is changed to reflect the change in the name of the selector.
 - **RetireMethod** A menu appears, showing the selectors of the class. After selecting one of these, the selector is changed by adding the prefix "Old" to it. The method function is also renamed appropriately.
 - **RenameClass** You are prompted for a new name for the class. After the new name is entered, the browser is updated to reflect the change. In addition, the method functions associated with the class are also renamed. For example, given a class **Foo** with selector **Fie**, when the class is renamed to **Fum**, the method function is automatically renamed from **Foo.Fie** to **Fum.Fie**.

10.3.3.8 Edit (EditClass) and its Suboptions

Selecting the **Edit (EditClass)** option and dragging the mouse to the right causes the following submenu to appear:

Box/UnBoxNode]	
Methods (EditMethod)		
Add (AddMethod)		
Delete (DeleteMethod) >		
Move (MoveMethodTo) >		
Copy (CopyMethodTo)	EditClass	
Rename (RenameMethod))	EditClass!	
Edit (EditClass)	InspectClass	

Editing options allow you to make quick, massive changes to object descriptions, and are sometimes the only menu-driven way to change certain items. See Chapter 13, Editing, for more details.

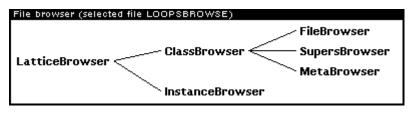

- **EditClass** Edits the class definition of the class showing only the locally defined class variables, instance variables, and methods.
- **EditClass!** Edits the class definition of the class showing both the locally defined and inherited class variables, instance variables, and methods. Changes to the inherited information that are done during the edit have no effect. The inherited information is included for informational purposes only. For example, you may want to copy the definition of an instance variable from the list of inherited instance variables to the list of local instance variables.
- **InspectClass** Opens an inspector window on the class. See Chapter 18, User Input/Output Modules, for more details.

10.4 Using File Browsers

File browsers are a specialization of class browsers. In addition to the capabilities of class browsers, file browsers allow you to manipulate files. This section explains the file browser menu options not available from class browser menus, or those that have been modified from the class browser menu options. This section lists all file browser menu options; references are made to class browser menus where appropriate.

Multiple files can be associated with a file browser. Thus, one of those files can be designated as the "selected" file. There are various options as to which classes should be displayed in a file browser. See Section 10.4.1.4, "Change display mode and its Suboptions," for more information.

When a file browser is opened, the window title displays the selected file:

The icon for a shrunken file browser contains the name of the selected file, as shown here:

10.4.1 Selecting Options in the Title Bar Menu

The title bar menu in a **FileBrowser**, shown here, is like the title bar menu in a **ClassBrowser**, but has additional entries for file system and Masterscope functions.

Recompute	~
AddRoot	≽
Add Gategory Menu	
Change display mode	≽
Uses IV?	≽
Edit File Coms	≽
GLEANUP file	

10.4.1.1 Recompute and its Suboptions

Operates identically to the class browser. See Section 10.3.1.1, "Recompute and its Suboptions," for more information.

10.4.1.2 AddRoot and its Suboptions

Prompts you for the name of a class to add. If the class already exists, it is added to the browser and shaded. If the class is not contained on the file, it will appear shaded in the browser. If the class does not exist, it is created and added to the selected file.

10.4.1.3 Add Category Menu

Operates identically to the class browser. See Section 10.3.1.3, "Add Category Menu and its Suboptions," for more information.

10.4.1.4 Change display mode and its Suboptions

Selecting the **Change display mode** option and dragging the mouse to the right causes the following submenu to appear:

Recompute >>	>
AddRoot >	Change display mode
Add Gategory Menu	Add file to browser
Change display mode	Select File
Uses IV? >>	
Edit File Coms	>
GLEANUP file	>

A **FileBrowser** logically includes more display options than a **ClassBrowser**. A **FileBrowser** can display a class hierarchy as it is stored in the file, or as it exists in combination with other files and the system as a whole.

Change display mode Selecting this option causes a sub-submenu to appear showing three options:

selectedFile

Displays only the classes contained within the selected file or classes that have been added to the browser by **AddRoot** or **AddSubs** (by setting the browser's instance variable **goodList** to the appropriate value). See Section 10.5.3, "Methods for the Class LatticeBrowser," for an explanation of **AddSubs**.

associatedFiles

Same as **selectedFile**, but the browser also includes any classes defined in files associated with the browser. The instance variable **goodList** is bound to this list, slightly differently than the use of **goodList** in a class browser.

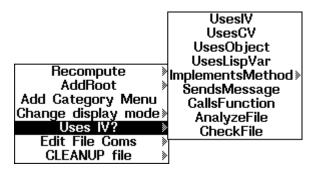

all

Same as **associatedFiles**, but any subclasses, even if not defined in the files, are also displayed because the instance variable **goodList** is bound to NIL.

- Add file to browser Prompts you with a menu that is similar to the menu that is displayed when you select **Browse File** from the LOOPS Icon or the background menu, except that files already associated with the browser are not displayed on the menu.
 - Select file Causes a menu to appear, showing the files associated with the browser. Selecting one causes that file to become the "selected file" of the browser. It clears the browser of any classes added to the browser by the AddRoot and AddSubs menu commands. That is, it resets the starting list of the browser to be only those classes contained within the selected file. The instance variable badList of the browser is set to NIL.

10.4.1.5 Uses IV? and its Suboptions

Selecting the **Uses IV?** option and dragging the mouse to the right causes the following submenu to appear:

These menu options trigger various Masterscope operations. Most of these operations prompt you for information that is used in a Masterscope query. The results of this query are used to build a second menu. If the situation occurs that the second menu is empty, a message is printed in the prompt window of the browser similar to "someCV not used as a CV."

CAUTION

Source files being displayed in the file browser must be available or these functions cannot work. In addition, the LOOPS Library Module LOOPSMS must also be loaded (see the *LOOPS Library Modules Manual* for details).

Additionally, the first time one of these options is selected there may be a pause while Masterscope analyzes the file. A window will open, and fill with "blips" as the analysis proceeds, until the file is analyzed and the original question is answered.

- **UsesIV** This first opens a menu of instance variables defined in classes contained in the selected file of the browser. Two additional options are placed at the top of the menu:
 - *other*

Selecting ***other*** causes a prompt to enter the name of an instance variable.

any

Selecting ***any*** creates a menu with all methods that reference any instance variable.

After an instance variable has been chosen, you are prompted to place a menu that contains the following options:

- · A list of methods on the selected file that use that instance variable
- A list of classes on the selected file that contain that instance variable.
- *EditAll*

If one of the methods or classes is selected, it is edited. Suboptions from the methods or classes include:

• Edit

Edits the method.

Substitute

Prompts for a new name for the instance variable. Changes the instance variable name to the new name in the method and then brings up the display editor for you to edit the method.

Check

Executes the Masterscope command CHECK <file> on the file associated with the LOOPS FileBrowser. See the *Lisp Library Modules Manual* for details.

EditAll has the following two suboptions:

EditAll
SubstituteAll

• *EditAll*

Edits each method and class in succession.

• *SubstituteAll*

Prompts you for a new name for the instance variable. Substitutes this new name for the old name in all methods and classes listed in the menu.

UsesCV Same as **UsesIV**, but for class variables.

UsesObject Opens a menu of classes or instances defined on the selected file that are used by any of the methods or functions on the selected file. After you choose one of the objects, a menu similar to the one created for **UsesIV** is created, but contains the methods and functions that use the chosen objects.

UsesLispVar Same as **UsesIV**, but the initial menu displays Lisp variables instead of objects.

ImplementsMethod This option has three suboptions:

ImplementsMethod

Opens a menu of all of the selectors in the selected file. When one is chosen, a menu is created showing the methods that use that selector and the classes that are associated with those methods.

OverridesMethod

Generates a menu of methods and classes that override (that is, does not invoke **_Super**) the selected method.

• SpecializesMethod

Generates a menu of methods and classes that specialize (that is, invoke **_Super**) the selected method.

SendsMessage Opens a menu of all of the selectors in the selected file. When one is chosen, a menu is created that lists the methods and functions that send messages using that selector. The following window shows a sample of this menu.

Sends message Browse	
EditAll	≫
Browse	≫
FileBrowser.SubBrowser	≫
LatticeBrowser.SubBrowse	:r≫

- **CallsFunction** Opens a menu of all of the functions that are called by functions or methods in the selected file. After one is chosen, a menu is opened that contains the methods and/or functions that call the chosen function; the last option on the menu is the chosen function.
 - **AnalyzeFile** Begins a separate process analyzing the selected file. When the analysis is completed, "Done analyzing" is printed in the browser's prompt window.
 - **CheckFile** Begins a separate process checking the selected file. When the checking is completed, "Done checking" is printed in the browser's prompt window.

10.4.1.6 Edit FileComs and its Suboptions

Selecting the **Edit FileComs** option and dragging the mouse to the right causes the following submenu to appear:

Recompute AddRoot Add Gategory Menu Change display mode Uses IV? Edit File Coms CI FAIUP file	Edit Functions» EditComs EditMacros EditRecords EditVars EditInstances
---	---

The filecoms are variables that describe the contents of a file, for example, methods, classes, and Lisp functions and variables. LOOPS extends the File Manager to handle object oriented code and data, and the **FileBrowser** gives users a menu driven interface to deal with this extended file functionality.

- **Edit Functions** Opens a sub-submenu giving options dealing with filecoms and with some of the items listed (functions in particular). This sub-submenu contains five suboptions:
 - EditFns

Opens a menu of the functions contained within the selected file (those listed under FNS in the filecoms) and the option ***NewFunction***. Selecting one of the functions calls the editor on that function.

Selecting ***NewFunction*** causes a prompt for a name for the new function. An edit window then opens containing a template for a lambda expression. This newly defined function is added to the FNS list of the selected file's filecoms.

MakeFunctionMenu

Does an **ADDMENU** (the Interlisp function which adds a permanent menu to the screen) of a menu containing functions on the selected file. Selecting one of the functions opens an editor on it.

BreakFunction

Opens a menu containing functions on the selected file that are not on **BROKENFNS** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*). Selecting one of the functions causes it to break next time it is invoked.

• TraceFunction

Same as **BreakFunction**, except that the selected function is traced.

UnbreakFunction

Creates a menu of functions that are members of **BROKENFNS** and are contained in the selected file. The selected file is unbroken.

- EditComs Edits the filecoms of the selected file.
- EditMacros Creates a menu of macros contained in the selected file. Selecting one of them opens an editor on it.
- EditRecords Same as EditMacros, but for records.
 - EditVars Same as EditMacros, but for variables.
- EditInstances Same as EditMacros, but for instances.

10.4.1.7 CLEANUP file and its Suboptions

This option invokes some or all of **CLEANUP**, which is the automatic file maintenance utility of Medley.

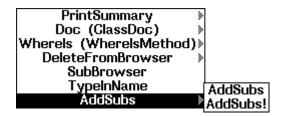

Selecting the **CLEANUP file** option and dragging the mouse to the right causes the following submenu to appear:

Recompute »	
AddRoot >	
Add Category Menu	
Change display mode	
Uses IV? >	CLEANUP file
Edit File Coms 🛛 🗎	Hardcopy file
GLEANUP file >	Hardcopy file Load PROP file

- CLEANUP file Calls FILES? and then calls CLEANUP on the selected file.
- Hardcopy file Sends the selected file to the DEFAULTPRINTINGHOST.
- Load PROP file Loads the selected file with LDFLG set to PROP, making sources available to Masterscope, but leaving any compiled code in place to execute.

10.4.2 Selecting Options in the Left Menu

When the cursor is inside of a file browser and you press the left mouse button, nodes within the browser are inverted when the cursor moves over them. If you release the left mouse button while the cursor is over a node, the following menu appears:

These options include those in a class browser and add **AddSubs**, an option that expands the lattice of a file browser to look more like that of a class browser by showing related classes not stored in the browsed file.

10.4.2.1 PrintSummary and its Suboptions

Operates identically to the class browser. See Section 10.3.2.1, "PrintSummary and its Suboptions," for more information.

10.4.2.2 Doc (ClassDoc) and Its Suboptions

Operates identically to the class browser. See Section 10.3.2.2, "Doc (ClassDoc) and its Suboptions," for more information.

10.4.2.3 WhereIs (WhereIsMethod) and Its Suboptions

Operates identically to the class browser. See Section 10.3.2.3, "WhereIs (WhereIsMethod) and its Suboptions", for more information.

10.4.2.4 DeleteFromBrowser and Its Suboptions

Operates identically to the class browser. See Section 10.3.2.4, "DeleteFromBrowser and its Suboptions," for more information.

10.4.2.5 SubBrowser

Creates an instance of a class browser with the selected class as the root node, not a file browser. See Section 10.3.2.5, "SubBrowser," for more information.

10.4.2.6 TypeInName

Operates identically to the class browser. See Section 10.3.2.6, "TypeInName," for more information.

10.4.2.7 AddSubs and its Suboptions

AddSubs fills out the class lattice in a file browser window. This shows classes, the file they are from (if any) and the inherited methods and variables from classes which are in the file.

AddSubs Adds the immediate subclasses of the class to the browser and shades the new subclasses, as shown here:

	File browser (selected file LOOPSWINDOW) Window Undow Loopslcon LatticeBrowser
	LispWindowAV
AddSubs!	Adds all subclasses of the class to the browser and shades the new

10.4.3 Selecting Options in the Middle Menu

subclasses.

When the cursor is over a node and you press the middle mouse button, the following menu appears:

BoxNode	
Methods (EditMethod)	≽
Add (AddMethod)	≽
	≫
Move (MoveMethodTo)	≫
Copy (CopyMethodTo)	≽
Rename (RenameMethod)	≽
Edit (EditClass)	≽
Uses IV	≫

The middle button commands are the same as those on a **ClassBrowser**, with some new functionality for **Add (AddMethod)**, and with Masterscope options added under the option **UsesIV**.

10.4.3.1 BoxNode

Operates identically to the class browser. See Section 10.3.3.1, "BoxNode/UnBoxNode," for more information.

10.4.3.2 Methods (EditMethod) and its Suboptions

Operates identically to the class browser. See Section 10.3.3.2, "Methods (EditMethod) and its Suboptions," for more information.

Operates identically to the class browser, but with additional functionality to

10.4.3.3 Add (AddMethod) and its Suboptions

	keep the added items associated with the file being browsed in the following suboptions.
SpecializedClass	Prompts you to enter a name for the new subclass for the chosen class. If the chosen class is on the selected file, the new subclass is added to that file. If the chosen class is on another file, choose a file from a menu of files to which the new subclass is added.
NewInstance	Creates a new instance of the class and calls PutSavedValue with the new instance as an argument. You are prompted to give the new instance a name, and the new instance is added to the selected file.

10.4.3.4 Delete (DeleteMethod) and its Suboptions

Operates identically to the class browser. See Section 10.3.3.4, "Delete (DeleteMethod) and its Suboptions," for more information.

10.4.3.5 Move (MoveMethodTo) and its Suboptions

Operates identically to the class browser. See Section 10.3.3.5, "Move (MoveMethodTo) and its Suboptions," for more information.

10.4.3.6 Copy (CopyMethodTo) and its Suboptions

Operates identically to the class browser. See Section 10.3.3.6, "Copy (CopyMethodTo) and its Suboptions," for more information.

10.4.3.7 Rename (RenameMethod) and its Suboptions

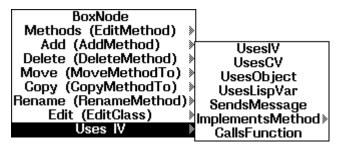

Operates identically to the class browser. See Section 10.3.3.7, "Rename (RenameMethod) and its Suboptions," for more information.

10.4.3.8 Edit (EditClass) and its Suboptions

Operates identically to the class browser. See Section 10.3.3.8, "Edit (EditClass) and its Suboptions," for more information.

10.4.3.9 UsesIV and its Suboptions

Selecting the **UsesIV** option and dragging the mouse to the right causes the following submenu to appear:

These commands operate similarly to the **Uses IV?** commands in the title bar menu. See Section 10.4.1.5, "UsesIV? and its Suboptions," for more information. Here, however, the Masterscope queries are limited to the class in question instead of the entire file.

10.5 Programmer's Interface to Lattice Browsers

LOOPS browsers are standard LOOPS objects, so their functionality can be exercised programmatically by messages which invoke their methods. Many browser functions are based on the Lisp Library Module, Grapher, but browsers apply only to dealing with LOOPS objects. All of the functionality in the menu-driven interface to the browsers is available programmatically.

Note: Data not a part of LOOPS data can be graphed with LOOPS calls to the Lisp Library Module, Grapher.

ClassBrowsers show the inheritance structure of object classes, a relationship defined at application design time. Browsers can also be used to show dynamic information, not computed until runtime. The LOOPS class **InstanceBrowser** does this, showing links between instances defined at runtime.

InstanceBrowser is derived from **LatticeBrowser** by specializing just two methods, **GetSubs** and **NewPath**. In general, you can specialize browsers to your own purposes by specializing these methods and **GetLabel**. An example is given in Section 10.7, "Class Instance Browser Example," producing a class browser which also shows instances, connected with dashed lines.

10.5.1 Instance Variables for the Class LatticeBrowser

Instance variables appear in alphabetical order.

badList	A list of objects that are not displayed in the browser window.	

boxedNode The last object boxed, if any.

browseFont The font used for labels. This has two properties: **FontFamily** and **FontFace** which are referenced in the method **ChangeFontSize**.

- lastSelectedObject The last object selected.
 - **goodList** A list of objects that are displayed in the browser window; if NIL, no objects are displayed.
 - graphFormat A list indicating the style of layout for the graph. See the method ChangeFormat and the Lisp Library Module, Grapher.

- LabelMaxCharsWidth Affects the way labels are generated. This limits the width of a label to LabelMaxCharsWidth times the width of the character "A". See the method ChangeMaxLabelSize. Default value is NIL, which puts no restrictions on label size.
 - LabelMaxLines Affects the way labels are generated. This limits the number of lines in a label to LabelMaxLines. Refer to the method ChangeMaxLabelSize. Default value is NIL which puts no restrictions on label size.
 - startingList List of objects used to compute this browser.
 - title Title passed to Grapher module.
 - **topAlign** This flag is used to indicate whether the graph should be aligned with the top or bottom of the window. If **topAlign** = T (the default), then the Grapher module aligns the graph to the top of the window.

10.5.2 Class Variables for the Class LatticeBrowser

Except for **BoxLineWidth**, the following class variables determine the menus that appear when a mouse is positioned over a node within a browser and the left or middle button is pressed. The default behavior is to send a message to the object represented by the node with the selector returned from the menu selection. The form for the values that these class variables can have is described in Chapter 20, Windows.

Class variables appear in alphabetical order.

- **BoxLineWidth** The width of line that is drawn around a node when it is boxed. See the method **BoxNode** in Section 10.5.3, "Methods for the Class LatticeBrowser."
- LeftButtonItems Items for the menu that appears when the mouse is on a node in the browser and the left button is pressed. When an item is selected from a menu, the returned value is sent as a message to an object represented by the node. See LocalCommands, below.
- **LocalCommands** When the cursor is positioned over a node in a browser and you press the left or middle mouse button, the default behavior is to bring up a menu from which you select an item. The value returned from that item specifies the selector of a message that is sent to the object which is represented by the node in the browser.

The class variable **LocalCommands** provides a way to override that behavior. If the value returned from the menu selection is on the list that is the value of **LocalCommands**, the message is not sent to the object, but is sent to the browser instead. The object is passed as an argument in that message.

- **MiddleButtonItems** Options for the menu that appears when the mouse is on one of the nodes in a browser and the middle button is pressed. When an option is selected from a menu, the returned value is sent as a message to the object represented by the node. See **LocalCommands**, above.
 - **TitleItems** Options for the menu that appears when the mouse is on the title bar in a browser and the left or middle button is pressed. When an option is selected from the menu, the returned value is sent as message to the browser.

The following selectors are associated with this menu:

- SaveInIT
- Recompute
- RecomputeInPlace
- ShapeToHold
- ChangeFontSize

- ChangeFormat
- AddRoot
- RemoveFromBadList

Examine the class LatticeBrowser for more information.

10.5.3 Methods for the Class LatticeBrowser

	The following table shows the methods and variables for the class LatticeBrowser .		
Name	Туре	Description	
AddRoot	Method	Adds a LOOPS name or an object to the starting list of the browser.	
BoxNode	Method	Puts a box around the node representing the object.	
Browse	Method	Uses a lattice or tree graph to display the relationship between a number of objects.	
BrowserObjects	Method	Returns the list of objects currently in the graph.	
ChangeFontSize	Method	Changes the size of the characters in the labels.	
ChangeFormat	Method	Changes between lattice and tree graphs.	
ChangeMaxLabelSize	Method	Changes how labels are printed.	
ClearLabelCache	Method	Recomputes labels.	
DeleteFromBrowser	Method	Prunes branches in a graph.	
DeleteSubtreeFromBr	owser Method	Prunes branches in a graph.	
FlashNode	Method	Changes the label of a node from black-on-white to white-on- black several times.	
FlipNode	Method	Changes the label of a node that represents an object from black-on-white to white-on-black.	
GetDisplayLabel	Method	Finds the label for a node.	
GetLabel	Method	Computes a label for an object.	
GetSubs	Method	Computes a list of subnodes of an object.	
GraphFlts	Method	Determines if the graph in the browser can be contained within the browser window.	
HasObject	Method	Returns T if an object is in the graph.	
HighlightNode	Method	Changes the way a node is displayed.	
IconTitle	Method	Computes the title to write in the icon.	
LeftSelection	Method	Controls the effect of using the left mouse button.	
LeftShiftSelect	Method	Sends the message PP! to an object.	
MiddleSelection	Method	Controls the effect of using the middle mouse button.	

MiddleShiftSelect	Method	Invoked by the mouse operations to edit an object in the TTY process context.
NewItem	Method	Gets an object.
NodeRegion	Method	Returns the region occupied in an object in the browser.
ObjectFromLabel	Method	Returns the object in the graph that has a specified label.
PositionNode	Method	Places a node at a particular position in the browser window.
Recompute	Method	Recomputes the browser graph in the same window.
RecomputeInPlace	Method	Recomputes the browser graph in the same window, trying to maintain the same scroll position in the window.
RecomputeLabels	Method	Recomputes the labels in a browser.
RemoveHighlights	Method	Removes all highlights in any node in the graph.
RemoveShading	Method	Removes all shading in any node in the graph.
SaveInIt	Method	Places a pointer in a browser where it can be accessed.
ShadeNode	Method	Adds shading to a node.
ShapeToHold	Method	Reshapes the window to all items.
MaxLatticeWidth	Variable	Restricts the maximum width of a browser window.
MaxLatticeHeight	Variable	Restricts the maximum height of a browser window.
Show	Method	Displays items and their subitems in a browser window.
Shrink	Method	Shrinks a browser window.
SubBrowser	Method	Creates a browser that is an instance of the same class as <i>self</i> with a specified object as the root.
TitleSelection	Method	Invokes an action when the mouse is in the title bar on a browser window and the left or middle button is pressed.
UnmarkNodes	Method	Sends the messages RemoveHighlights and RemoveShading to <i>self</i> .

(self AddRoot newltem)

[Method of LatticeBrowser]

Purpose:	Adds <i>newItem</i> , which is a LOOPS name, to the starting list of the browser.		
Behavior:	First determines if the name <i>newItem</i> points to a LOOPS object. If it does not, a message is printed that nothing has been added to the browser. If <i>newItem</i> is NIL, you are prompted to enter a name through the method NewItem . If the object pointed to by <i>newItem</i> is on the browser's instance variable badList , it is removed from badList . If the instance variable goodList has a value, <i>newItem</i> is added to it.		
Arguments:	newItem LOOPS name.		
Returns:	Class object or NIL.		
Categories:	LatticeBrowser		
Example:	The following command adds class Datum to a class browser instance named CB1 :		

 $55 \leftarrow (\leftarrow (\$ CB1) AddRoot (\$ Datum))$

(← self BoxNode object objNar	ne unboxPrev	ious) [Method of LatticeBrowser]	
Purpose:	Puts a box a	around the node in the graph representing the object.	
Behavior:	First checks to make sure <i>object</i> points to a LOOPS object. If not, nothing happens. The previous value of the instance variable boxedNode is returned		
	 If the instance variable boxedNode is NIL, then a box is drawn around the node with a line width equal to the value of the class variable BoxLineWidth. The instance variable boxedNode is assigned the value o object, and object is returned. 		
	• If <i>object</i> is EQ to the instance variable boxedNode , then the box is erased. That is, calling BoxNode twice in succession will draw and then erase the box. The instance variable boxedNode is assigned the value NIL, and NIL is returned.		
	 If none of the above conditions hold, the flag unboxPrevious is checked. If it is non-NIL, the previously boxed node is unboxed, and the node represented by <i>object</i> is boxed. The instance variable boxedNode is assigned the value of <i>object</i>, and <i>object</i> is returned. 		
	It is possible that <i>object</i> is not a node in <i>self</i> .		
Arguments:	object	LOOPS name or object.	
	objName	Used internally; can be NIL.	
	unboxPrevie	ous Can be NIL or T.	
Returns:	The object in boxed.	n the browser that is currently boxed, or NIL if nothing is currently	
Categories:	LatticeBrow	ser	
Specializations:	ClassBrows	er	
(← self Browse browseList wir	ndowOrTitle go	oodList position) [Method of LatticeBrowser]	
Purpose:		e or tree graph to display the relationships between a number of bwse is the proper message to use for initializing browsers.	
Behavior:	windowOrTi	nessage Show to self passing the arguments browseList, tle, and goodList. It next sends ShapeToHold to self. Finally it to self with the argument position.	
Arguments:	browseList	A list, elements of which can be a LOOPS name or an object, or a single item which can be a LOOPS name or an object. Used as the starting node(s) of a browser. See the Show message later in this section for details.	
	windowOrTi	tle If a window, the browser is displayed in this window. If not a window, this becomes the title of the browser window.	
	goodList	A list, elements of which can be a LOOPS name or an object. See the Show message later in this section for details.	
	position	A position to which the lower left corner of the browser is moved. Can be NIL.	
		<i></i>	

Returns: Used for side effect only.

Categories:	LatticeBrowser
Example:	The following command gets the class browser instance CB1 to browse class Datum and its subclasses:
	$57 \leftarrow (\leftarrow (\$ CB1) Browse 'Datum)$
(← self BrowserObjects)	[Method of LatticeBrowser]
· · · · · · · · · · · · · · · · · · ·	Returns the list of objects currently in the graph of the browser.
Purpose/Behavior:	
Categories:	LatticeBrowser
(← self ChangeFontSize size)	[Method of LatticeBrowser]
Purpose:	Changes the size of the characters of the labels.
Behavior:	Changes the font used to display labels in a browser. The browser is redrawn and the window shaped to fit. If no size is given, this lets you select the size from a menu. This menu is bound to the top level binding of the variable MenuSize (the first time it is called). The font family used is the value of the FontFamily property of the instance variable browseFont . The font face used is the value of the FontFace property of the instance variable browseFont .
	This sends the message RecomputeLabels to <i>self</i> .
Arguments:	size Integer size of font for node labels.
Returns:	Used for side effect only.
Categories:	LatticeBrowser
(← self ChangeFormat format)	[Method of LatticeBrowser]
Purpose:	Changes between lattice and tree graphs.
Behavior:	If <i>format</i> is NIL, then select a format from a menu that appears. The items in this menu are determined by the value of the choices property of the instance variable graphFormat . Changes the value of the instance variable graphFormat to <i>format</i> or the value selected from the menu.
Arguments:	<i>format</i> Describes the format layout. The argument <i>format</i> is an unordered list of atoms or lists. The following options control the structure of the graph:
	 COMPACT, the default, which lays out the graph as a forest (that is, a set of disjoint trees) using the minimal amount of screen space.
	 FAST, which lays out the graph as a forest, sacrificing screen space for speed.
	 LATTICE, which lays out the graph as a directed acyclic graph, that is, a lattice.
	In addition, the following options control the direction of the graph:
	 HORIZONTAL, the default, has roots at the left and links that run left-to-right.

• VERTICAL has roots at the top and links that run top-tobottom.

See the function **LAYOUTGRAPH** in the Grapher library module documentation for more information.

Returns: Used for side effect only.

Categories: LatticeBrowser

Example: The commands:

58 (SETQ b1 (~New (\$ SupersBrowser) Browse 'ClassBrowser))
#,(\$& SupersBrowser (NEW0.1Y%:.;h.eN6 . 506))

 $59 \leftarrow (\leftarrow b1 \text{ ChangeFormat '(HORIZONTAL REVERSE (MARK BORDER 3 LABELSHADE 1)))} #,($& SupersBrowser (NEW0.1Y%:.;h.eN6 . 506))$

results in:

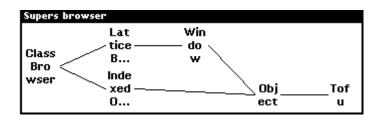

Supers brows	er		
Object	— Window —	—— LatticeBrowser	
Tofu —	Object	——— IndexedObject	Glassbruwser

(self ChangeMaxLabelSize newMaxWidth newMaxLines)

[Method of LatticeBrowser]

Purpose:	Changes how labels are printed.
Behavior:	Sets the maximum width of a node label. An argument value of zero means no maximum size, and NIL means no change.
	By setting both <i>newMaxWidth</i> and <i>newMaxLines</i> , you get an abbreviation facility. This binds the values of the instance variables LabelMaxCharsWidth and LabelMaxLines . The default values for LabelMaxCharsWidth and LabelMaxLines are both 0, so to return a browser b1 to default performance, send
	$(\leftarrow (\$ b1) ChangeMaxLabelSize 0 0).$
	The resulting labels may be bitmaps or strings. The width of the bitmap is a product of <i>newMaxWidth</i> and the width of the character "A" in the current value of the instance variable browsefont .
	Sends the message RecomputeLabels to <i>self</i> .
Arguments:	<i>newMaxWidth</i> Maximum number of characters per line; default is 0.
	<i>newMaxLines</i> Maximum number of lines; default is 0.
Returns:	Used for side effect only.
Categories:	LatticeBrowser
Example:	The commands:
	(\$ SupersBrowser) Browse 'ClassBrowser)) (NEW0.1Y%:.;h.eN6 . 506))
$61 \leftarrow (\leftarrow b1 ChangeMax #,($& SupersBrowser$	LabelSize 3 3) (NEW0.1Y%:.;h.eN6 . 506))

results in:

(self ClearLabelCache objects)

[Method of LatticeBrowser]

Purpose:	Forgets cac	hed labels in the browser.
Behavior:	this clears th	abel cache for item(s) in <i>objects</i> . If <i>objects</i> is the symbol T, then he entire label cache. The cache for the labels is on the Is property of the instance variable menus .
Arguments:	objects	An object or a list of objects.

- Returns: Used for side effect only.
- Categories: LatticeBrowser

(self DeleteFromBrowser object objname)

[Method of LatticeBrowser]

Purpose:	Prunes brar	iches in a graph.
Behavior:	badList and	<i>bject</i> from the browser by putting it on the instance variable then sending the Recompute message to <i>self</i> . The object and are deleted from the browser.
Arguments:	object	An object in the browser.
	objname	Used internally; can be NIL.
Returns:	Used for sid	e effect only.
Categories:	LatticeBrow	ser

(self DeleteSubtreeFromBrowser object)

[Method of LatticeBrowser]

Purpose:	Prunes branches in a graph	
----------	----------------------------	--

Behavior: Similar to **DeleteFromBrowser**, but the subnodes of *object* are also added to the instance variable **badList**.

- Arguments: *object* An object in the browser.
- Returns: Used for side effect only.

Categories: LatticeBrowser

$(\leftarrow \text{ self FlashNode node } N \text{ flas})$	hTime leaveF	ipped?) [Method of LatticeBrowser]
Purpose/Behavior:	Changes th times.	e label of a node from black-on-white to white-on-black several
Arguments:	node	LOOPS name or object.
	Ν	Number of times node will be flipped.
	flashTime	The amount of time in milliseconds that the node is held between transitions. If <i>flashTime</i> is NIL, this time defaults to 300 milliseconds.
	leaveFlippe	d? Can be NIL or T. If T, <i>node</i> is left inverted from its original state.
Returns:	Used for sid	le effect only.
Categories:	LatticeBrow	vser
(← self FlipNode object)		[Method of LatticeBrowser]
Purpose:	Inverts the I	abel of a node.
Behavior:	If the node i conversely.	s black-on-white then it is changed to white-on-black, and
Arguments:	object	LOOPS name or object.
Returns:	Used for sid	le effect only.

(*self* HighlightNode *object width shade*)

ntNode object v	vidth shade)		[Method of LatticeBrowser]
Purpose:	Changes th	e way a node is displayed.	
Behavior:	lines of the	x around a node for <i>object</i> using a giv box. A shade is a 16-bit number repr E in the <i>Interlisp-D Reference Manua</i>	esenting a 4x4 bitmap. See
Arguments:	object	LOOPS name or object.	
	width	Integer width of box.	
	shade	16-bit number representing a 4x4 b	itmap.
Returns:	Used for sid	de effect only.	
Categories:	LatticeBrow	vser	
Example:	The comma	and	

 $64 \leftarrow (\leftarrow b1 HighlightNode 'IndexedObject 10 123)$

results in the following window:

	Supers browser
	ClassProwson LatticeBrowser Window
	ClassBrowserObject
	IndexedObject
(← self lconTitle)	[Method of LatticeBrowser]
Purpose/Behavior:	Computes the title to write in the icon.
Returns:	The label of the first root entry in the lattice, that is, the CAR of the instance variable startingList . If this is NIL, then use "Browser". If AddRoot is called, the new root becomes the first entry on startingList .
Categories:	LatticeBrowser
Specializations:	FileBrowser
(self LeftSelection)	[Method of LatticeBrowser]
Purpose:	Controls the effect of using the left mouse button. LatticeBrowser provides defaults, but allows these methods to be overwritten or specialized.
Behavior:	The instance variable lastSelectedObject is bound to the object of the node that the left button selected.
	The remaining behavior varies according to the key pressed.
	 If the Move key or the Control key is down, this allows you to move the node the mouse is over when you press the left mouse button.
	 If the left shift key or Copy key is down while the cursor is over a node, the label of the node is copied to the system buffer. If the cursor is not over a node, the entire graph is copied. This allows you to copy browsers into TEdit documents.
	 If the Meta key is pressed, the message LeftShiftSelect is sent to self passing as an argument the object the cursor is over.
	 If none of the above keys are down, a menu pops up. This may trigger additional functionality to be evaluted in the TTY process context.
	This method is generally not called directly by the user, but is invoked by mouse operations.
Returns:	Used for side effect only.
Categories:	Window
Specializes:	Window
(← self LeftShiftSelect object o	objectName) [Method of LatticeBrowser]

(← self LeftShiftSelect object objectName)

[Method of LatticeBrowser]

Purpose/Behavior: Sends the message **PP!** to *object*. LatticeBrowser provides defaults, but allows these methods to be overwritten or specialized.

This is generally not called directly by the user, but is invoked by mouse operations.

Arguments:	object	An object.
	objectName	Used internally; can be NIL.
Returns:	Used for side	e effect only.
Categories:	LatticeBrows	ser
Specializations:	ClassBrowse	er

$(\leftarrow self MiddleSelection)$

Method	of I		Proweorl
method		Lauiter	JUWSEII

Purpose:	Controls the effect of using the middle mouse button. LatticeBrowser provides defaults, but allows these methods to be overwritten or specialized.
Behavior:	If no node is selected, then returns NIL.
	The instance variable lastSelectedObject is bound to the object of the node that the middle button selected.
	If the Meta key is down, the message MiddleShiftSelect is sent to self.
	If the Meta key is not down, a menu pops up. This may trigger additional functionality to be evaluated in the TTY process context.
	This is generally not called directly by the user, but is invoked by mouse operations.
Returns:	Used for side effect only.
Categories:	Window
Specializes:	Window
(← self MiddleShiftSelect object	objname) [Method of LatticeBrowser]

Purpose/Behavior:	Edits <i>object</i> in the TTY process context. LatticeBrowser provides defaults, but allows these methods to be overwritten or specialized.		
	This is generally not called directly by the user, but is invoked by mouse operations.		
Arguments:	object	LOOPS object.	
	objname	Used internally; can be NIL.	
Returns:	Used for sid	de effect only.	

Categories: LatticeBrowser

$(\leftarrow self Newltem newltem)$

[Method of LatticeBrowser]

Purpose:	Gets an object.		
Behavior:	If <i>newItem</i> is NIL, a prompt appears in an attached prompt window for the name of the item to be added.		
Arguments:	newItem LOOPS name or object.		
Returns:	An object pointed to by <i>newItem</i> or the name entered by the user at the prompt.		

Categories:	LatticeBrowser
Specializes:	None.
Specializations:	ClassBrowser, FileBrowser

(\leftarrow self **NodeRegion** object)

[Method of LatticeBrowser]

Purpose/Behavior:	Returns the region occupied by object in the browser.		
Arguments:	object LOOPS name or object.		
Returns:	A region defined in terms of the coordinates of the browser's window.		
Categories:	LatticeBrowser		

(*self* **ObjectFromLabel** *label*)

[Method of LatticeBrowser]

Purpose/Behavior:	Returns the object displayed in the browser that has the given <i>label</i> , or NIL if no object labelled with <i>label</i> is visible in the browser.		
Arguments:	<i>label</i> Symbol or bitmap as it appears in the <i>objectLabels</i> property of the instance variable <i>menus</i> .		
Returns:	The object in the graph that has the given <i>label</i> , or NIL if there is no such object.		
Categories:	LatticeBrowser		
Example:	The following command gets the object which is being displayed in browser CB1 as Datum:		
$65 \leftarrow (\leftarrow (\$ CB1) ObjectFromLabel 'Datum)$			

(← self **PositionNode** object windowX windowY)

[Method of LatticeBrowser]

- Purpose: Places a node at a particular position in a scrollable browser window.
- Behavior: When the browser is too large for its window and has become scrollable, **PositionNode** scrolls the graph so that the node for the given object is at the position (*windowX*. *windowY*) within the restrictions of the window property **SCROLLEXTENTUSE** (see the *Interlisp-D Reference Manual*). As in the **ScrollWindow** method of the class **Window**, if either of the arguments *windowX* or *windowY* is a **FLOATP**, it is taken to be a proportional position. For example,
 - (0.0, 0.0) is the lower left corner.
 - (1.0, 1.0) is the upper right corner.
 - (0.5, 0.5) is the center of the window.

If either is a **FIXP**, it is a position in the displayStream coordinate system. Any null argument is taken to be 0. **PositionNode** may only be sent to browsers which are scrollable.

Arguments:	object	LOOPS name or object represented by a node.	

- *windowX* X-coordinate for new node position. If type **FLOATP**, then a relative position; if type **FIXP**, then absolute position.
- *windowY* Y-coordinate for new node position. If type **FLOATP**, then a relative position; if type **FIXP**, then absolute position.

Returns: Position of **CLIPPINGREGION** of window after scrolling.

Categories: LatticeBrowser

(self Recompute dontReshapeFlg)

[Method of LatticeBrowser]

- Purpose: Recomputes the browser graph in the same window. Typically used after adding or deleting from the lattice.
 Behavior: Sends the Show message with the value of the instance variable startingList to self. If dontReshapeFlg is NIL or if the graph does not fit the window(as determined by GraphFits with snugly flag set to T), then send self the message ShapeToHold.
- Arguments: *dontReshapeFlg* If non-NIL, do not reshape browser.

Returns: self

Categories: LatticeBrowser

Specializations: FileBrowser

(self RecomputeInPlace)

[Method of LatticeBrowser]

Purpose/Behavior: Recomputes the graph, trying to maintain the same scroll position in the window. Returns: Used for side effect only. Categories: LatticeBrowser

(*self* **RecomputeLabels**)

[Method of LatticeBrowser]

Purpose:	Recomputes the labels in a browser.		
Behavior:	Performs the following sequence of expressions:		
	(← self ClearLabelCache T) (← self Recompute)		
Returns:	Used for side effect only.		
Categories:	LatticeBrowser		

(self RemoveHighlights)

[Method of LatticeBrowser]

Purpose/Behavior:Removes all highlights on any node in the graph, including nodes that are
boxed (see the method HighlightNode, which is described earlier in this
section). The method Recompute maintains shading and boxing and does
not do a RemoveHighlights. RemoveHighlights does not do a Recompute
automatically.Sets the value of the instance variable boxedNode to NIL.Returns:Used for side effect only. RemoveHighlights does not do a Recompute
automatically.Categories:LatticeBrowser

(← self RemoveShading)	[Method of LatticeBrowser]		
Purpose/Behavior:	Removes all shading on any node in the graph (see the method ShadeNode , which is described later in this section). Does not automatically do a Recompute.		
Returns:	Used for side effect only.		
Categories:	LatticeBrowser		
(← self SaveInIT)	[Method of LatticeBrowser]		
Purpose:	Places the pointer to self where it can be accessed by (SavedValue).		
Behavior:	Calls (PutSavedValue self).		
Returns:	Used for side effect only.		
Categories:	LatticeBrowser		
(← self ShadeNode object sha	de) [Method of LatticeBrowser]		
Purpose:	Adds shading to a node.		
Behavior:	Shades the inside of node with a given <i>shade</i> if the node is defined with a string nodeLabel , which is the usual case in lattice browsers. Six shades are available by name and are shown in Figure 10-5.		
	• WHITESHADE		
	• GRAYSHADE1		
	• GRAYSHADE2		
	• GRAYSHADE3		
	• GRAYSHADE4		
	• BLACKSHADE		
	Class browser White Gravit Black Gravit Gravit Gravit		
	Figure 10-5. Shading Available for a Node		
	If the label displayed for <i>object</i> is a bitmap, ShadeNode will destructively shade that bitmap.		
Arguments:	object LOOPS name or object.		
	shade A texture (See the Interlisp-D Reference Manual).		
Returns:	Used for side effect only.		
Categories:	LatticeBrowser		

Example: The following command shades the node for **Gray1** with GRAYSHADE1:

 $66 \leftarrow (\leftarrow (\$ CB1) ShadeNode 'Gray1 GRAYSHADE1)$

(← self ShapeToHold)				[Method of LatticeBrowser]
Purpose/Beha	vior:	Reshapes thup the scree	ne window to hold all the items comforent or more.	tably, unless they would fill

Beha		Initialized to	C C	
$(\leftarrow self Show browseList$	t window	/OrTitle good	List)	[Method of LatticeBrowser]
Purp	ose:	Displays iter method Bro	ms and their subitems in a browser wi wies which calls Show.	ndow. In general, uses the
Beha	ivior:	The instance variable startingList is assigned the value of objects referred to in <i>browseList</i> . If the argument <i>goodList</i> is provided, the instance variable goodList is assigned the value of objects referred to in it.		
Argume	ents:	browseList	A list, elements of which can be a LC a single item which can be a LOOPS as the starting node(s) of a browser.	
		windowOrTi	tle If a window, the browser is displayed window, this becomes the title of the	
		goodList	Optional. If provided, it is a list of LC names which are the only items the l nodes. As opposed to <i>badList</i> , which display, <i>goodList</i> gives a population members of to be displayed.	browser will display as h excludes nodes from
Retu	urns:	Used for sid	e effect only.	
Catego	ories:	LatticeBrows	ser	
(← self Shrink)				[Method of LatticeBrowser]
Purp	oose:	Shrinks a br	owser window to its icon.	
Beha	ivior:	example bel	w already has an icon, this is used. Of low) that has (_ <i>self</i> IconTitle) as a title he browser uses a RecomputeInPlac	e. When the icon is
		When the m	ouse is positioned on an icon and the	left or middle button is

The browser icon bitmap template is stored on the variable **BrowserIconBM**.

Returns: The icon for self.

Categories: Window

Specializes: Window

Example: All browser classes use the same icon:

(self SubBrowser obj objName)

[Method of LatticeBrowser]

	,		
Purpose/Behavior:	Creates a browser that is an instance of the same class as <i>self</i> with <i>object</i> as the root node.		
Arguments:	obj	LOOPS name or object .	
	objName	Used internally; can be NIL.	
Returns:	The new br	owser.	
Categories:	LatticeBrow	vser	
Specializations:	FileBrowse	r	
Example:	The following command creates a new browser on just the ClassBrowser subtree of a browser CB1 showing the entire LatticeBrowser lattice:		
	67←(← (\$ CB1) SubBrowser 'ClassBrowser)	
(← self TitleSelection)		[Method of LatticeBrowser]	
Purpose:		ge is sent to a browser when the mouse is positioned on its title her the left or middle mouse buttons are pressed. It should not be y by users.	
Behavior:	Opens a menu, created from the class variable <i>TitleItems</i> , from which you pick an entry. The resulting action that this causes is evaluated in the context of the TTY process.		
Returns:	Used for sid	de effect only.	
Categories:	Window		
Specializes:	Window		
TitleItems		[Class Variable]	
Purpose:	Holds the m	nenu list used by the TitleSelection method.	
(← <i>self</i> UnmarkNodes)		[Method of LatticeBrowser]	

Purpose/Behavior:	Sends the messages RemoveHighlights and RemoveShading to self.
Returns:	Used for side effect only.
Categories:	LatticeBrowser

10.6 Instance Browsers

Instance browsers show linkages between instances. That is, each node in an instance browser represents an instance. The links are determined by the value of a particular instance variable in each instance; the value should point to the subitems of an instance.

This section includes the instance variables, methods, and an example of instance browsers.

10.6.1 Instance Variables for the Class InstanceBrowsers

sublV N

Nodes within an instance browser have subitems determined by the value of a particular instance variable within each instance. The value of **subIV** is the name of that particular instance variable. Initialized to NIL.

10.6.2 Methods for the Class InstanceBrowsers

The **GetSubs** and **NewPath** methods are available for the class **InstanceBrowsers**.

$(\leftarrow \textit{self GetSubs object})$	[Method of InstanceBrowser]		
Purpose:	Computes the subitems for a node in a browser.		
Behavior:	If <i>self</i> has a value for the instance variable <i>subIV</i> , which should be a symbol, and <i>object</i> has an instance variable named with that symbol, then return the value of that instance variable in <i>object</i> .		
Arguments:	object An object in the browser.		
Returns:	The subitems of <i>object,</i> which should be a list.		
Categories:	LatticeBrowser		
Specializes:	LatticeBrowser		
Example:	The following commands perform these actions:		
	Create an instance of InstanceBrowser and call it IB1.		
	• Give the value of its instance variable subIV the symbol nextWindow .		
	Create a LOOPS window and call it W1 .		
	 Add the instance variable nextWindow to it and give it the value of another LOOPS window, instance W2. 		
	 Send the Browse message to IB1 with W1 as the root node. 		

68←(← (\$ InstanceBrowser) New 'IB1) #,(\$& InstanceBrowser (NEW0.1Y%:.;h.eN6 . 515))

69←(←@ (\$ IB1) subIV 'nextWindow) nextWindow
70←(← (\$ Window) New 'W1) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 516))
71←(← (\$ W1) AddIV 'nextWindow (LIST (← (\$ Window) New 'W2))) (#,(\$& Window))
72←(← (\$ IB1) Browse 'W1) (407 . 623)
Instance browser

W 1 ------ W 2

(\leftarrow self **NewPath** subName)

[Method of InstanceBrowser]

Purpose:	Specifies which of the instance variables in objects point to subitems.				
Behavior:	If subName is NIL, display a prompt for a value in an attached window.				
	If <i>subName</i> or the value entered is non-NIL, change the value of the instance variable subIV of <i>self</i> to that value.				
	Changes the instance variable title of the browser window to (CONCAT <i>subName</i> " instance browser").				
	If the browser is open, send the Recompute message to it.				
Arguments:	<i>subName</i> A symbol that should be an instance variable within each object of the browser.				
Returns:	Used for side effect only.				
Categories:	InstanceBrowser				
Example:	The following command causes an instance browser IB1 to look in W1 's instance variable nextPointer instead of in nextWindow to get its subnodes:				
	73_(_ (\$ IB1) NewPath 'nextPointer)				

10.6.3 Selecting Options in the Title Bar Menu

The title bar menu for instance browsers is a subset of that for class browsers, as shown here:

See Section 10.3.1, "Selecting Options in the Title Bar Menu," for details.

10.6.4 Selecting Options in the Left Menu

When you position the cursor on a node of an instance browser and press the left mouse button, the following menu appears:

BoxNode is the same as in the class browsers (see Section 10.3.3.1, "BoxNode"). **PP** prints out the instance class, name, and UID.

10.6.5 Selecting Options in the Middle Menu

When you position the cursor on a node of an instance browser and press the middle mouse button, the following menu appears:

Inspect
Édit
DeleteFromBrowser

This menu is a small subset of that for class browsers (see Section 10.3.3, "Selecting Options in the Middle Menu").

- Inspect opens an inspector window on the instance.
- Edit calls the instance into the editor.
- **DeleteFromBrowser** removes a node from display via the **badList** mechanism.

10.7 Automatic Updates of Class Browsers

LOOPS advises the File Manager **LOAD** function to guarantee that all class browsers are updated whenever a file is loaded. The updating is performed by the function **UpdateClassBrowsers** and controlled by the setting of the variable **UpdateClassBrowsers**?.

((U	pdateClassBrowser	s newLabels?)
		paalcolassbionsci	S now Laboros j

Purpose:	Updates instances of ClassBrowser and its subclasses.
Behavior:	Called whenever a new class is defined (including loading from a file) or destroyed. If the variable UpdateClassBrowsers? is NIL, then do nothing.
	For browsers that have been marked as needing updating and having windows that are opened, this sends the message Recompute or RecomputeLabels if <i>newLabels</i> ? is non-NIL.
Arguments:	newLabels?Can be NIL or T.
Returns:	Used for side effect only.

UpdateClassBrowsers?

Behavior:	See the function UpdateClassBrowsers, above. Initialized to T.		
Values:	NIL	Do not update browsers.	
	Т	Update browsers with each change.	
	SHADE Shade browsers that need to change.		

[Function]

[Variable]

[This page intentionally left blank]

LOOPS provides an interface to the Medley error system. This allows appropriate detection and recovery from errors that are LOOPS errors rather than Lisp errors. The full power of the Medley error system is available to help you determine and repair the causes of errors. In addition, under certain circumstances, LOOPS will attempt to repair an error and continue if you agree.

This chapter describes the functions and methods LOOPS uses to handle error conditions. It also describes the error messages generated by LOOPS.

11.1 Error Handling Functions and Methods

LOOPS provides several ways to trap and process many common errors. A default processing is available for most errors, and this processing can be specialized for actions you may require.

The following table shows the items in this section.

Name	Туре	Description
HELPCHECK	Function	Provides an interface to the Common Lisp error system.
LoopsHelp	NoSpread Function	d Generates an error if LoopsDebugFlg =NIL, else calls HELP .
LoopsDebugFlg	Variable	Controls the behavior of LoopsHelp.
ErrorOnNameConflict	Variable	Calls HELPCHECK when you attempt to give an object the same name as an existing object.
CVMissing	Method	Sent by access functions when you attempt to access a class variable that does not exist.
CVValueMissing	Method	Sent by access functions when you attempt to access a class variable that has no value.
IVMissing	Method	Sent by access functions when you attempt to access an instance variable that does not exist.
IVValueMissing	Method	Sent by access functions when you attempt to access an instance variable that has no value.
MessageNotUnderstood	Method	Sent when a message has no corresponding selector.

(HELPCHECK mess1 ... messN)

[Function]

Purpose/Behavior: HELPCHECK is the LOOPS interface with the Common Lisp error system. When LOOPS detects an error, it generally calls this function with up to four argument messages describing what is wrong and possibly what to do about it. HELPCHECK calls BREAK1 to put you into a break window and returns whatever the call to BREAK1 returns. For example, if you type OK, it returns

	T. If you type "RETURN 'someValue", it returns that value. In some instances, LOOPS uses such returned values to repair errors and continue execution.		
Arguments:	: <i>mess1 messN</i> Messages to print at the break.		
Returns:	Value depends on what you type in the break window; see Behavior.		
Example:	The following code causes a break window with the message "Are you certain?". If you type "OK" in the break window, the message "He said OK" will print.		
	(IF (HELPCHECK "Are you certain?") THEN (PRINT "He said OK"))		
(LoopsHelp mess1 messN)	[NoSpread Function	<u>ו</u>	
Purpose/Behavior:	Generates an error. Calls HELP if LoopsDebugFlg is T, otherwise calls ERROR . Use LoopsHelp whenever you want to give the user a way to recover from errors when LoopsDebugFlg is T. For example, have LoopsHelp print messages like "FOO is not the name of a class. Type RETURN ' <classname> to continue using <classname>."</classname></classname>		
Arguments:	mess1 messN Messages to print at the break.		
Returns:	Value depends on what you type in the break window; see HELPCHECK , above.		
LoopsDebugFlg	[Variable	<u>)</u>	
Purpose/Behavior:	Controls the behavior of LoopsHelp . If it is T, all calls to LoopsHelp generate a break. If it is NIL, such calls that occur near the top of the stack or after a short computation cause a message to be printed and a return to the next level. The default value is T. See BREAKCHK in the <i>Interlisp-D Reference</i> <i>Manual</i> for more information.	е	
ErrorOnNameConflict	[Variable	<u>)</u>	
Purpose/Behavior:	If T, an attempt to give an object the same name as an existing object causes a call to HELPCHECK . If you type "OK" in the resulting break window, the process continues and the original object is unnamed. The default value is NIL.		
(← self CVMissing object varNar	ne propName typeFlg newValue) [Method of Class	<u>\$]</u>	
Purpose:	Sent by access functions when there is an attempt to access a class variable that does not exist.		
Behavior:	Calls LoopsHelp with the message		
	varName not a CV of self		
	This method can be specialized to take more sophisticated action by using the other arguments which are provided.	÷	
	When, in an instance, an attempt is made to access a class variable that does not exist, the message CVMissing is sent to the instance's class with the instance in question as <i>object</i> .	;	
	Note: This method can be invoked if an instance variable is missing.		

Arguments:	object	The object upon which the access was attempted.	
	typeFlg	The name of the access function (GetValue , GetValueOnly , PutValue , PutValueOnly) which caused this message to be sent. The function name allows the type of access to be determined.	
	varName	The name of the variable on which access was attempted.	
	propName	The name of the property on which access was attempted. If NIL, the value of the class variable <i>varName</i> was accessed.	
	newValue	The value to which the class variable was to be set.	
Categories:	Class		
Example:		his method to automatically add the class variable which is missing described by <i>self</i> . Assuming the class of <i>self</i> is SomeClass , the nition is	
	(Method ((SomeClass CVMissing) self object varName propName typeFlg	
	(/ ~_lf	newValue)	
	(← sell.	AddCV varName newValue))	
(arName prop	Name typeFlg) [Method of Class]	
Purpose:	Sent by access functions when there is an attempt to access a class variable that has no value. This method can also be invoked if an instance variable is missing and you attempt to access it.		
Behavior:	If <i>propName</i> is NIL it returns the value of NotSetValue , otherwise it returns the value of NoValueFound .		
	The default setting for NoValueFound is NIL. The default setting NotSetValue is an annotatedValue. See Chapter 8, Active Values, for an explanation of NotSetValue .		
		d can be specialized to take more sophisticated action by using the nents which are provided. See the example for CVMissing , above.	
Arguments:	object	The object on which the access was attempted.	
	typeFlg	The name of the access function (GetValue , GetValueOnly , PutValue , PutValueOnly) which caused this message to be sent. The function name allows the type of access to be determined.	
	varName	The name of the variable on which access was attempted.	
	propName	The name of the property on which access was attempted. If NIL, the value of the class variable <i>varName</i> was accessed.	
Returns:	Value deper	nds on the arguments; see Behavior.	
Categories:	Class		
(← self IVMissing varName prop	Name typeFlg	newValue) [Method of Object]

11.2 Error Messages

This section contains the LOOPS error messages along with their explanations. Atoms which are in *italics* are replaced with specific values when the messages are generated. Messages generated by calls to **SHOULDNT** indicate problems in LOOPS system code. Messages generated by direct calls to **ERROR**, that is not via calls to the LOOPS function **LoopsHelp**, may indicate problems with the system or with user code.

Errors appear in their respective categories:

- Errors that occur when accessing classes and instances in LOOPS.
- Errors that occur when sending messages to LOOPS objects.

- Errors dealing with naming objects.
- Errors encountered when using annotated values and active values.
- Other error messages that may be encountered when using LOOPS.

11.2.1 Classes and Instances

This section describes errors that occur when accessing classes and instances.

<i>type</i> not recoani	zed part of class
Explanation:	The <i>type</i> argument to the method ListAttribute does not correspond to one of the parts of a class.
name not a CV	of self
Explanation:	A reference has been made to a class value that does not exist.
Error in Put or G	GetValue
Explanation:	An attempt has been made to access an instance variable that has no value in an object or in any of its supers.
varName not an	IV of self
Explanation:	An attempt has been made to access an instance variable and it does not exist in the object or its supers, and a class variable of the same name does not exist either.
varName is not	a local instance variable of class name. Type OK to ignore error and go on.
Explanation:	An attempt has been made to delete an instance variable which is not in the class.
<i>newValue</i> is not	a class. Type OK to replace metaclass of <i>classRec</i> with \$Class
Explanation:	A call has been made to PutClass or PutClassOnly with either <i>propName</i> erroneously set to NIL or left out, or the new metaclass set to something that is not a valid class.
varName is not	a CV of Class so cannot be moved from there
Explanation:	An attempt has been made to move a class variable from a class where it does not exist. Possible causes include wrong source class or misspelled class variable name.
<i>class</i> has subcla Type OK to use	asses. You cannot Destroy classes that have subclasses. Destroy! if that is what you want.
Explanation:	Sending the message Destroy to a class with subclasses will leave the subclasses referring to nonexistent superclasses. Destroy! destroys all of the subclasses as well. Be sure this is what you want before you type "OK".

11.2.2 Methods and Messages

This section describes errors that occur when sending messages to LOOPS objects.

GetValue, PutValue, GetValueOnly, PutValueOnly or GetIVHere self args not possible

- Explanation: An attempt has been made to access a value in an abstract class, which cannot have any values.
- \leftarrow or \leftarrow **Super** self selector -- not understood
- Explanation: Neither the object to which the message was sent nor any of its ancestors has such a method selector.
- (← NIL selector --) not understood
- Explanation: An attempt has been made to send a message to NIL. One way to do this is to execute (_(\$ foo) ...), where foo does not name a LOOPS object.

class does not contain the selector selector. Type RETURN 'selectorName to try again

Explanation: An attempt has been made to delete a nonexistent method. If the problem is that the wrong method selector was typed or the selector was misspelled, typing "RETURN 'correctName" will fix the problem.

selector is not local for self To copy anyway, type OK

Explanation: The object to which **CopyMethod** was sent does not contain *selector*, but one of its supers does. This is not necessarily an error.

selector is not a selector for self

Explanation: Neither the object to which **CopyMethod** was sent nor any or its supers contains *selector*.

newClass is not a class. Type OK to use oldClass

Explanation: Something may be missing from the argument to **HELPCHECK**, since nothing is printed after oldClass. Alternatively, the destination class specified in **CopyMethod** is neither a class nor a valid class name.

Typing "OK" causes the method to be copied to the class to which the message was sent. The net result can be to copy a method down from one of the class's supers or to make a copy within the class with a new selector.

name is not a defined function

Explanation: The selector named in **CopyMethod** exists but it does not have a function defined for it. It is possible the class has been loaded but the method has not or that the function definition for the method was somehow erroneously destroyed.

name not a currently defined class. Cannot add method to class. Type OK to create class and go on.

Explanation: An attempt has been made to add a method to a nonexistent class.

If the class should exist, but has not been created yet, type "OK" to let LOOPS create it automatically. If the class has yet to be loaded, abort and load it first.

Can't find source for fn

Explanation: The source file containing a method of a class that is being moved via **MoveToFile** cannot be found. **WHEREIS** is used to try to find it. Either add the necessary file to **FILELST** or use **LOADFNS** to load the function(s).

11.2.3 Naming Objects

This section describes errors that occur when naming objects.

name is already used as a name for an object

Explanation: **ErrorOnNameConflict** has been set to T and an object with the given name already exists. Typing "OK" will cause the new object to be created anyway.

Can't name object NIL

Explanation: The name argument to the method SetName has been left out.

name should be a symbol to be a name

Explanation: The method **SetName** has been given a non-symbolic name.

name cannot be a class name. Type OK to ignore

Explanation: A non-symbolic class name has somehow gotten into the CLASSES of a file.

Typing "OK" will continue writing the file, but will not remove the offending name.

Can't rename a class without specifying name. Type RETURN <newName> to continue and rename class: *self*

Explanation: The *newName* argument has been left out of **Rename**. Classes can not be named NIL.

Typing "RETURN 'aNewName" renames the class.

name not defined as a class or an instance. Type OK to ignore and go on.

Explanation: A name which refers to a nonexistent class or instance is in the **CLASSES** or **INSTANCES** file command of a file.

Typing "OK" continues writing out the file, but does not remove the offending name.

name not the name of an instance! Type OK to proceed.

Explanation: A name that refers to a nonexistent instance is in the **THESE-INSTANCES** file command of a file.

Typing "OK" continues writing out the file, but does not do anything to correct the source of the problem; that is, it does not remove the name from the filecoms or find out why it does not exist.

name is a defined object, but is not a class.

Explanation: The name of some LOOPS object that is not a class has been used as an argument where a class name should have been used.

11.2.4 Annotated and Active Values

This section describes errors that occur when using annotated values and active values.

Active value not found, so can't replace it.

Explanation: The old active value specified in **ReplaceActiveValue** does not exist or has been specified incorrectly.

Unknown access type type

Explanation: An improper *type* has been given to the message **AddActiveValue** or **DeleteActiveValue**.

Invalid type type

Explanation: An active value has an incorrect type specifier.

Conflicting active value wrapping precedence self active Value other Precedence

Explanation: An attempt has been made to add an annotated value with wrapping precedence T or NIL to an existing annotated value with the same wrapping precedence.

Unknown access type type

Explanation: GetWrappedValue or PutWrappedValue has been given an incorrect type.

Can't set the local state of #.NotSetValue

Explanation: **PutWrappedValueOnly** has been erroneously sent to a #.NotSetValue.

11.2.5 Miscellaneous

This section describes other errors that can occur when using LOOPS.

Use one of METHODS IVS CVS for type. RETURN one of these symbols to go on.

Explanation: An incorrect type has been specified to the method WhereIs.

To continue, enter the type into the break window. For example, enter "RETURN 'METHODS".

Name not installed because of error in source

Explanation: The source specification of a class has been corrupted in some way. It may be necessary to manually redefine the class or edit the file.

Time is not set! Call (SETTIME dd-mmm-yy hh:mm:ss) and then type in OK

Explanation: LOOPS uses the date and time to create unique internal names for objects; thus, the time must be set before any objects are created. Call **SETTIME** and then type "OK". For example, (**SETTIME** "15-APR-87 12:00:00") sets time at noon on April 15, 1987.

self varName propName not broken. Type OK to go on

Explanation: Either an attempt has been made to unbreak a value which was not broken or the value was specified incorrectly.

[This page intentionally left blank]

A number a functions and methods are available in the LOOPS environment to facilitate the process of finding and correcting bugs in user-written LOOPS code. These give you the capability to interrupt or trace methods so that you can examine the state of the computations by using the Interlisp-D Break package; see the *Interlisp-D Reference Manual*.

In addition to being able to break and trace methods, you can break and trace accesses to data within objects. For example, you can determine when a process is attempting to change a class variable or is trying to read the value of an instance variable. This feature gives you a powerful tool to assist in the understanding of the behavior of a piece of code from both a functional view and a data view.

12.1 Breaking and Tracing Methods

The Interlisp-D environment provides a number of features for breaking and tracing functions. LOOPS methods are implemented as Lisp functions, so the breaking and tracing of method invocation is similar to Interlisp-D.

The following table describes the methods in this section.

Name	Туре	Description
BreakMethod	Method	Breaks a method of a class.
TraceMethod	Method	Traces a method of a class.
UnbreakMethod	Method	Unbreaks or untraces a method of a class.
SelectorsWithBreak	Method	Returns a list of selectors whose implementations have a break.

(*elf* **BreakMethod** *selector*)

[Method of Class]

Purpose:	Breaks a m	ethod of a class.		
Behavior:	Varies acco	Varies according to the argument.		
	the class	r is NIL, a menu appears showing the selectors associated with <i>self</i> that have not already been broken. If you do not make a om the menu, this method returns the symbol NothingBroken .		
		r is non-NIL and is not associated with self, an error occurs stating ctor was not found in self.		
	method fund	is broken, this fact is printed in the Prompt Window. The broken ction is added to the list BROKENFNS . (See the <i>Interlisp-D</i> Manual for more information on BROKENFNS .)		
Arguments:	self	Must be bound to a class.		
	selector	Must be a selector associated with self or NIL.		

Returns:	The symbol NothingBroken or NIL.			
Categories:	Class			
Example:	The following command causes a break when the message Open is sent to any window:			
	$12 \leftarrow (\leftarrow (\$ Window) BreakMethod 'Open)$			
(← self TraceMethod selector)	[Method of Class]			
Purpose:	Traces a method of a class.			
Behavior:	Varies according to the argument.			
	 If selector is NIL, a menu appears showing the selectors associated with the class self that have not already been broken. If you do not make a choice from the menu, this method returns the symbol NothingTraced. 			
	 If selector is non-NIL and is not associated with self, an error occurs stating that selector was not found in self. 			
	If a method is traced, this fact is printed in the Prompt Window. The traced method function is added to the list BROKENFNS . (See the <i>Interlisp-D Reference Manual</i> for more information on BROKENFNS .) Whenever the function is called a message will be printed to a trace window, when it is exited a message will be printed with the returned value.			
Arguments:	self Must be bound to a class.			
	selector Must be a selector associated with self or NIL.			
Returns:	The symbol NothingTraced or NIL.			
Categories:	Class			

(<-- self UnbreakMethod selector)

Method selector)			[Method of Class]
Purpose:	Unbreaks o	r untraces a method of a class.	
Behavior:	Varies acco	ording to the argument.	
	the class	or is NIL, a menu appears showing the sele self that have been broken. If you do no is method returns the symbol NothingUnl	t make a choice from the
		or is non-NIL and is not associated with sector was not found in <i>self</i> .	lf, an error occurs stating
	(See the Int	is unbroken, its method function is remove terlisp-D Reference Manual for more inforr NS.) The value return is a list containing t ction.	nation on
Arguments:	self	Must be bound to a class.	
	selector	Must be a selector associated with self	or NIL.
Returns:	The symbol method fund	NothingUnbroken or a list containing the ction.	e name of the unbroken
Categories:	Class		
sWithBrook)			[Method of Class]

(<- self SelectorsWithBreak)

Purpose: Return a list of selectors whose implementations have a break.

Behavior: Searches through the list **BROKENFNS** collecting all selectors of method functions that begin with the class name of *self*. (See the *Interlisp-D Reference Manual* for more information on **BROKENFNS**.)

Arguments: self Must be bound to a class.

Returns: A list of selectors of *self*.

Categories: Class

12.2 Breaking and Tracing Data

Breaking or tracing functions or methods cause interruptions to occur in a computation when a function or method is entered. Breaks or traces on data can be made to occur when either the data is to be read or changed. Only data that is contained within objects can be broken; this feature is not available to arbitrary Lisp data. Breaks and traces on data are implemented through the mechanism of active values. The following **ActiveValue** classes contain this mechanism:

- BreakOnPut
- BreakOnPutOrGet
- TraceOnPut
- TraceOnPutOrGet

You can use the methods and functions in this section to place or remove breaks on data. You can also add and remove traces and breaks through the inspector interface. See Chapter 18, User Input/Output Modules, for more information on the inspector.

Note: Breaking or tracing a variable effectively breaks or traces any IndirectVariable that points to it.

The following table describes the items in this section.

Name	Туре	Description
Breaklt	Method	Puts a break on data within an object.
BreakIt	Function	Sends the message BreakIt to <i>self</i> .
Tracelt	Method	Puts a trace on data within an object.
Tracelt	Function	Sends the message Tracelt to self.
UnBreaklt	Function	Unbreaks broken data; untraces traced data.
BrokenVariables	Global Variable	Contains a list of broken or traced variables.

(← self **BreakIt** varName propName &OPTIONAL (type 'IV) breakOnGetAlsoFlg)

[Method of Object]

Purpose: Puts a break on data within an object.

Behavior: Adds an entry to the list **BrokenVariables**.

- If *breakOnGetAlsoFlg* is T, creates an instance of the class **BreakOnPutOrGet** and adds the active value to the data specified by *self*, *varName*, *propName*, and *type*.
- If *breakOnGetAlsoFlg* is NIL, the active value instance is of the class **BreakOnPut**.

When a break occurs, the break window shows the nature of the break and which object and what variable is broken. See examples below.

Arguments:	self	Points to the object that contains the data to be broken.	
	varName	The name of the variable.	
	propName	If a property access is to be broken, this is the name of the property.	
	type	The type of the data. This can be IV, CV, or METHOD; the default is IV.	
	breakOnGet	AlsoFlg If this is non-NIL, breaks will occur when data is read. If this is NIL, breaks will occur only on attempts to write the data.	

- Returns: self
- Categories: Object
 - Example: The following commands check if a window's width and height are going to change.

Trying to change the width causes this break:

Setting IV	
Setting IV width of #,(\$ ω)	
)1d value: #,NestedNotSetValue	
/alue: 100	
284;	

Trying to read the height causes this break:

Fetching				
Fetching IV Value: 12	height a	of #,(\$	ω)	
29+;				

(**BreakIt** self varName propName type breakOnGetAlsoFlg)

[Function]

Behavior: Sends the message **BreakIt** to *self* passing the remainder of the arguments. See the method **BreakIt**, above, for details.

(← self **Tracelt** varName propName &OPTIONAL (type 'IV) traceGetAlsoFlg)

[Method of Object]

Purpose: Puts a trace on data within an object. Behavior: Adds an entry to the list BrokenVariables. If traceGetAlsoFlg is T, creates an instance of the class TraceOnPutOrGet and adds the active value to the data specified by self, varName, propName, and type. • If traceGetAlsoFlg is NIL, the active value instance is of the class TraceOnPut. When a trace occurs, a trace window appears if necessary, with the traced information printed in it. See examples below. Arguments: self Points to the object that contains the data to be traced. The name of the variable. varName If a property access is to be traced, this is the name of the propName property. The type of the data. This can be IV, CV, or METHOD; the type default is IV. traceOnGetAlsoFlq If this is non-NIL, trace messages will occur when data is read. If this is NIL, trace messages will occur only on attempts to write the data. Returns: self Categories: Object Examples: To monitor if a window's width and height are going to change, enter $97 \leftarrow (\leftarrow (\$ Window) New 'w)$ #,(\$& Window (NEW0.1Y%:.;h.eN6 . 495)) $98 \leftarrow (\leftarrow (\$ w) TraceIt 'width)$ #, (\$& Window (NEW0.1Y%:.;h.eN6 . 495)) $99 \leftarrow (\leftarrow (\$ w) \text{ TraceIt 'height NIL NIL T})$ #, (\$& Window (NEW0.1Y%:.;h.eN6 . 495)) Trying to change the width or the height causes a trace.

 $100 \leftarrow (change (@ ($ w) width) 100)$

Trace-Output

Setting IV width of #,(\$ w) Old value: #,NestedNotSetValue Value: 100

100

101←(@ (\$ w) height)

Trace-Output

Fetching IV height of #,(\$ w) Value: 12 12

(Tracelt self varName propName	type breakOr	oGetAlsoFlg)	[Function]
Purpose/Behavior:	Sends the n See the met	nessage Tracelt to <i>self</i> passing the remainder of the argument of the argum	juments.
(UnBreaklt self varName propNa	nme type)		[Function]
Purpose:	Unbreaks b	roken data; untraces traced data.	
Behavior:	Varies acco	rding to the argument self.	
	 If self is N active val 	IIL, iterates through the list BrokenVariables and remo ues from the objects on that list. BrokenVariables is s	ves the et to NIL.
	varName BrokenV	ot NIL, removes the active value from the data describe, <i>propName</i> , and <i>type</i> . The corresponding entry is rem ariables. If there is no active value on the specified da aying that the specified data is not broken and type OK	oved from ta, a break
Arguments:	self	Points to the object that contains the data to be traced	ł.
	varName	The name of the variable.	
	propName	If a property access is to be traced, this is the name o property.	f the
	type	The type of the data. This can be IV, CV, or METHOI default is IV.); the
Returns:	Value deper	nds on the arguments.	
	 If self is N returned. 	IIL, the value of BrokenVariables before it was bound	to NIL is
		on-NIL and there were no errors, the list containing <i>sel</i> Name is returned.	f, varName,
Example:	The followin instance na	g command removes a break from the instance variable med Datum12 :	e id# in the
	(UnBreakI	t (\$ Datum12) 'id#)	
BrokenVariables		[Glob	al Variable]
Purpose/Behavior:	added to thi	lized to NIL. As data within objects is traced or broken, s list. Each entry contains the object, the variable name of to implement the break, the property name, and the t	e, the active

[This page intentionally left blank]

LOOPS has an interface to the display-based editor, SEdit. This editor is most often used for modifying classes, functions, and methods, but it can also be invoked to modify instances. Instances are typically modified through the inspector interface (see Chapter 18, User Input/Output Modules).

The technique for editing methods is exactly the same as that for editing functions. LOOPS uses Method, an extension of the lambda form that is documented in Chapter 6, Methods, which also gives details about the form of methods and how to invoke the editor upon them.

The process of editing classes and instances is different from editing methods in that you are not editing structure directly. The data structures representing the objects are translated into list structures, those list structures are then edited, and, finally, on exiting from the editor, the list structure is translated back into LOOPS objects. Because of this process, changes in objects do not take effect until you have exited from the editor.

13.1 Editing Classes

The **Edit** and **Edit!** methods provide a screen-based way to modify class structure. You can quickly add and delete local class and instance variables, make inherited variables local, and change initial values. The other methods listed are used to interface LOOPS to the display editor.

Name	Туре	Description
Edit	Method	Edits the structure of a class.
Edit!	Method	Edits a class in a form that includes inherited information.
InstallEditSource	Method	Makes a class conform to a description.
MakeEditSource	Method	Makes a list structure for editing a class.
MakeFullEditSource	Method	Makes a list structure, including inherited information, for editing a class.

(\leftarrow self Edit commands)

[Method of Class]

Purpose: Edits the structure of a class.

Behavior: Translates *self* from a data type to a list structure that is then passed to the editor through **EDITE** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*). If *commands* is non-NIL, this is passed as the second argument to **EDITE**.

The variable LASTCLASS is bound to the class name of self.

Generally, *commands* is NIL, which causes you to enter the editor interactively. From this point, you can perform the following actions:

- Change the metaclass of self
- Add or delete class properties
- · Add or delete class variables, instance variables, and their properties.

Also, as a user convenience, the edited form has a list of methods that you can select and edit, although you cannot delete items from this **MethodFns** list and have that action disassociate the methods from the class.

- Arguments: *commands* A list of editing commands to be passed to EDITE.
 - Returns: The class name of self.
- Categories: Object
- Specializes: Object

Example: The following editing window is generated as a result of

(← (\$ IndirectVariable) Edit)

SEdit # ,(\$C IndirectVariable) Package; INTERLISP		
((MetaClass Class doc		
(* Active Value for redirecting references to		
another variable)		
Edited%: (* smL " 9-May-86 09:52"))		
(Supers ActiveValue) (ClassVariables)		
(InstanceVariables		
(object NIL doc		
(* The object with the "real" variable))		
<pre>(varName NIL doc (* The name of the "real" variable))</pre>		
(propName NIL doc		
(* The prop name of the "real" variable))		
(type NIL doc (* The type of the "real" variable)))		
(MethodFns IndirectVariable.GetWrappedValueOnly		
IndirectVariable.PutWrappedValueOnly))		

The following information describes this window:

- The title of the window contains the name of the class being edited and package it uses for displaying symbols. This package should be INTERLISP when using LOOPS.
- It has the metaclass Class.
- It has the two class properties doc and Edited%:.
- It has one super class, the class ActiveValue.
- It has no class variables.
- It has four instance variables: **object**, **varName**, **propName**, and **type**. Each instance variable has a **doc** property.
- It has two local methods: GetWrappedValueOnly and PutWrappedValueOnly.

(\leftarrow self Edit! commands)

- Purpose: Edits a class in a form that includes inherited information.
- Behavior: This is similar is behavior to the method **Class.Edit**.

The form you are editing includes not only items local to *self* but also class variables and instance variables that are inherited. This allows you to easily move inherited information into *self*. Editing operations that modify the inherited values have no effect.

- Arguments: *commands* A list of editing commands to be passed to **EDITE**.
 - Returns: The class name of self.
- Categories: Class
 - Example: The following command puts you into the display editor. Compare this display with the previous one.
 - (← (\$ IndirectVariable) Edit!)

SEdit # ,(\$C IndirectVariable) Package; INTERLISP
((MetaClass Class doc
(* Active Value for redirecting references to
another variable)
Edited%: (* smL " 9-May-86 09:52"))
(Supers ActiveValue) (ClassVariables) (CVsInherited)
(InstanceVariables
(object NIL doc
(* The object with the "real" variable))
(varName NIL doc (* The name of the "real" variable))
(propName NIL doc
(* The prop name of the "real" variable))
(type NIL doc (* The type of the "real" variable)))
(IVsInherited))

(<- self InstallEditSource editedDescription)

[Method of Class]

Purpose:	Makes a class conform to a description.
Behavior:	Called by the system to change a class data structure to correspond to a list structure you have edited. If there are errors in the structure, the editor is activated again. If there are errors in the edited structure, an error message is printed in the prompt window and you are returned to the editor to fix it.
	If there are no errors in the structure, this successfully translates the structure into the class data type structure. In addition, a class property Edited: is added to <i>self</i> with the value returned by (EDITDATE NIL INITIALS).
Arguments:	editedDescription A list structure similar to that returned by the message MakeEditSource.
Returns:	Used for side effect only.
Categories:	Object
Specializes:	Object

(self MakeEditSource)

Purpose:	Makes a list structure for editing a class.		
Behavior:	This builds a list structure containing metaclass, super, class variable and instance variable information. In addition, the method function names are included in this list.		
Returns:	List expression of class structure.		
Categories:	Object		
Specializes:	Object		
Example:	The command		
	(\leftarrow (\$ BreakOnPutOrGet) MakeEditSource)		
	returns		
doc "This is (Supers Brea (ClassVariab (InstanceVar	les)		

(self MakeFullEditSource)

[Method of Class]

Purpose:	Makes a list structure, including inherited information, for editing a class.		
Behavior:	This is similar to MakeEditSource . The constructed list also includes instance variables and class variables that are inherited.		
	The list does not contain the method functions associated with self that MakeEditSource includes.		
Returns:	List expression of class structure.		
Categories:	Class		
Example:	The command		
	(\leftarrow (\$ BreakOnPutOrGet) MakeFullEditSource)		
	returns:		
doc "This is (Supers Brea (ClassVariab (CVsInherite (InstanceVar (IVsInherite	les) d) iables)		

13.2 Editing Instances

LOOPS instances can also be edited by the standard Medley code editor. From this editor, you can change the values of instance variables and properties, and add new instance variables. Instances follow the same basic editing protocol that classes do.

The following table shows the methods in this section.

Name	Туре	Description
Edit	Method	Allows you to change the values contained in an instance.
InstallEditSource	Method	Makes an instance conform to a description.
MakeEdit	Method	Makes a list structure for editing an instance.

$(\leftarrow self Edit commands)$

[Method of Object]

Purpose:	Allows you to change the values contained in an instance.		
Behavior:	Changes the data structure of <i>self</i> to a list and passes that list to EDITE (see the <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference Manual.</i>) If <i>commands</i> is non-NIL, this is passed as the second argument to EDITE .		
	Deleting a variable does not delete it from the instance.		
Arguments:	commands A list of editing commands to be passed to EDITE.		
Returns:	self		
Categories:	Object		
Specializations:	Class		
Example:	The following commands create the edit window shown.		
	71←(← (\$ Window) New 'w1) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 495))		
	72←(←@ (\$ w1) width 123) 123		
	$73 \leftarrow (\leftarrow (\$ w1) Edit)$		
	SEdit # (\$& Win ((left) (bottom) (width 123) (height) (window) (title) (menus))		

(*eself* MakeEditSource)

[Method of Object]

Purpose: Makes a list structure for editing an instance.

Behavior: Returns a list showing all instance variables, values, and properties. Returns: A list showing all instance variables, values, and properties. Categories: Object Specializations: Class Example: The following shows MakeEditSource results as values are assigned to the instance variables of (\$ w1). $38 \leftarrow (\leftarrow (\$ Window) New 'w1)$ #, (\$& Window (NEW0.1Y%:.;h.eN6 . 495)) $39 \leftarrow (\leftarrow (\$ w1) MakeEditSource)$ ((left) (bottom) (width) (height) (window) (title) (menus)) $40 \leftarrow (\leftarrow @ (\$ w1) width 123)$ 123 $41 \leftarrow (\leftarrow (\$ w1) MakeEditSource)$ ((left) (bottom) (width 123) (height) (window) (title) (menus)) $42 \leftarrow (\leftarrow @ (\$ w1) menus Title T)$ Т $43 \leftarrow (\leftarrow (\$ w1) MakeEditSource)$ ((left) (bottom) (width 123) (height) (window) (title) (menus #,NotSetValue Title T)) $44 \leftarrow (@ (\$ w1) window)$ {WINDOW}#74,25554 $45 \leftarrow (\leftarrow (\$ w1) MakeEditSource)$ ((left 31) (bottom 407) (width 123) (height 12) (window #,(\$AV LispWindowAV ((NEW0.1Y%:.;h.eN6 . 495)) (localState {WINDOW}#74,25554)))

(<- self InstallEditSource editedDescription)

(title) (menus #,NotSetValue Title T))

[Method of Object]

Purpose:	Makes an instance conform to a description.
Behavior:	This is called by the system to change an instance data structure to correspond to a list structure you have edited.
Arguments:	<i>editedDescription</i> A list structure similar to that returned by the message MakeEditSource .
Returns:	Used for side effect only.
Categories:	Object

[This page intentionally left blank]

LOOPS data structures are fully integrated into Medley. This includes the definition of new File Manager commands so that any LOOPS object or method can be saved on files and loaded into the environment in exactly the same way that normal Medley data types are saved and loaded.

In addition, the LOOPS file browser provides a menu-driven interface to the File Manager. When using a LOOPS file browser, newly created objects are associated with files automatically. If you are not familiar with LOOPS file browsers see Chapter 10, Browsers.

This chapter describes the functions, methods, and variables used to load and store files containing LOOPS objects. It describes the File Manager commands related to LOOPS objects. It also describes how to add objects to files, delete them from files, and move them from file to file. These are primarily of interest when customizing either the File Manager or LOOPS file browser.

14.1 Manipulating Files

LOOPS takes advantage of the ability to create user-defined File Manager commands to fully integrate LOOPS into the Medley environment. As a result, the same steps used to manipulate files containing Medley data structures are used to manipulate files containing LOOPS data structures. Furthermore, both LOOPS and Medley data structures can be saved together in the same file. This section contains a brief review of the three basic functions used to manipulate files. For a more detailed description which includes additional functions, see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*.

In addition, there is a LOOPS file browser which provides a convenient way of loading files and guaranteeing that newly created classes and methods are associated with files during the development of LOOPS programs. The LOOPS file browser is different from the Lisp Library Module **FILEBROWSER**. Files can be loaded and put into new or existing file browsers by a series of menu selections.

You can manipulate files with these basic steps:

- Assign data structures to a specific file using FILES?.
- Write data structures to a file using **MAKEFILE**.
- Enter data structures stored in a file into the environment using LOAD.

The following example shows these steps.

 $30 \leftarrow (FILES?)$ PIPEANDTANK, LOOPSPRINT, LOOPSUTILITY...to be dumped. plus the instances: FFAV1,Datum1,TestW plus the class definitions: Datum want to say where the above go ? Yes (instances) FFAV1 File name: LOOPSFILE create new file LOOPSFILE ? Yes File name: LOOPSFILE File name: LOOPSFILE Datum1 Test₩ (class definitions) Datum File name: LOOPSFILE NIL $31 \leftarrow (MAKEFILE 'LOOPSFILE)$ Copyright owner for file LOOPSFILE: XEROX {DSK}<LISPFILES>LOOPSFILE.;1 $32 \leftarrow (LOAD 'LOOPSFILE)$ {DSK}<LISPFILES>LOOPSFILE.;1 FILE CREATED 7-Jan-87 16:25:24 LOOPSFILECOMS {DSK}<LISPFILES>LOOPSFILE.;1

See the *Lisp Release Notes* and the *Interlisp-D Reference Manual* for more information on **FILES**? and **MAKEFILE**. See the following section for details on **LOAD**.

14.2	Loading Files		
		The followin section.	ng table shows the functions and commands described in this
	Name	Туре	Description
	LOAD	Function	Loads Medley symbolic files which includes LOOPS objects and methods.
	LOADFNS	Function	Allows selective loading from Medley symbolic files.
	UNDO	Prog. Asst.	Undoes previous entries into the Medley Executive which are stored on a history list, including calls to LOAD .
(LOAD F	FILE LDFLG)		[Function]
(LOAD F	FILE LDFLG) Purpose/Behavior:		[Function] ley symbolic files which includes all LOOPS objects and methods; p Release Notes and the Interlisp-D Reference Manual.
(LOAD F	,		ley symbolic files which includes all LOOPS objects and methods;
(LOAD F	Purpose/Behavior:	see the Lis	ley symbolic files which includes all LOOPS objects and methods; p Release Notes and the Interlisp-D Reference Manual.
(LOAD F	Purpose/Behavior:	see the <i>Lis</i> , <i>FILE</i>	ley symbolic files which includes all LOOPS objects and methods; p Release Notes and the Interlisp-D Reference Manual. File to be loaded.

	Returns:	Full file nam	ne.	
(LOADFNS	FNS FILE)			[Function]
	Purpose/Behavior:	The most lik functions w	ctive loading from Medley symbolic files including LOOPS kely use for this facility is to load the source code for meth hen the compiled versions are already loaded. The meth d by their explicit function names in the form ClassName .	nod ods must
(LOADFNS	'(SomeClass.AMet	hod Other	Class.AMethod) '{DSK} <lispfiles>SOMEFILE '1</lispfiles>	PROP)
		VARS (see because it i	ommended that LOOPS objects be selectively loaded by the <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference M</i> . s not possible to guarantee that all necessary related obje sses or methods of a class, are also loaded.	anuaľ),
	Arguments:	FNS	Selected functions to be loaded.	
		FILE	File from which functions specified in FNS are to be loa	ided.
	Returns:	List of funct	ions that have been loaded	
UNDO			[Program Assistant C	Command]
	Purpose/Behavior:	loading a fil destroyed a	ves enough information about objects that are created as e to allow the call to LOAD to be undone. The objects are and any preexisting objects that were deleted by the load ee the <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference</i>	e are

14.3 LOOPS File Manager Commands

Four File Manager types are defined to allow LOOPS objects to be stored in Medley files:

- CLASSES
- METHODS
- INSTANCES
- THESE-INSTANCES

These types and the functions and methods used by LOOPS to process these types are described in this section.

Note: The order of items in the filecoms is important. In particular, class definitions must appear in the file before any methods on that class or any instances of that class. Similarly, methods on a class must appear before any instances of that class.

Name	Туре	Description
CLASSES	File Mgr Command	Writes the appropriate DEFCLASSES and DEFCLASS expressions for the named classes.
DEFCLASSES	NLambda NoSpread	Creates a series of empty classes in preparation for reading their definitions via DEFCLASS .
DEFCLASS	NLambda NoSpread	Takes a source specification of a class from a file and causes the appropriate internal representation to be constructed.
METHODS	File Mgr Command	Writes the appropriate METH and DEFINEQ expressions for each method object and its associated function.

METH	NLambda NoSpread	Creates a method object and attaches it to the appropriate class.
INSTANCES	File Mgr Command	Writes the appropriate DEFINST expressions for each instance in the list.
THESE-INSTANCES	File Mgr Command	Appears as a sublist in a filecoms.
DEFINSTANCES	NLambda NoSpread	Creates empty structures for each instance name in a list.
DEFINST	NLambda NoSpread	Creates internal representations for source specifications of an instance.
FileIn	Method	Creates internal representations for source specifications of an instance.
(CLASSES ClassName1ClassN	lameN)	[File Manager Command]
Purpose/Behavior:	Manager to	a sublist in a filecoms. The keyword CLASSES tells the File use the appropriate DEFCLASSES and DEFCLASS expressions ed classes when writing to a file.
Arguments:	ClassName	Accepts any symbol, but only gives meaningful result when you use DEFCLASS to actually create the class.
Example:	(CLASSES	Myclass)
(DEFCLASSES CLASSES)		[NLambda NoSpread Function]
Purpose/Behavior:	their definition	e to create a series of empty classes in preparation for reading in ons via DEFCLASS . This allows the classes to be read in any rwise, superclasses would have to be read in before their
Arguments:	CLASSES	Accepts any symbol, but only gives meaningful result when you use DEFCLASS to actually create the class.
Returns:	NIL	
Example:	The comma	nd
	(DEFCLASS	ES MyClass)
	returns NII	
(DEFCLASS FORM)		[NLambda NoSpread Function]
Purpose/Behavior:	MakeFileSc	urce specification of a class, such as produced by the method purce , from a file and causes the appropriate internal on to be constructed.
Arguments:	FORM	The source specification of a class.
Returns:	NIL	
Example:	(DEFCLASS (MetaClas (Supers C	s Class doc (* Something for my project) Edited: (* nbm "18-Oct-87 13:20"))

(* Initial value for my instances)]

(METHODS ClassName.Message	e1ClassName.MessageN) [File Manager Command]		
Purpose/Behavior:	Appears as a sublist in a filecoms. The keyword METHODS tells the File Manager to use the appropriate METH and DEFINEQ expressions for each method object and its associated function.		
Arguments:	<i>ClassName.Message</i> The source specification of a class.		
Example:	(METHODS MyClass.Method1)		
(METH methDescr)	[NLambda NoSpread Function]		
Purpose/Behavior:	Creates a method object and attaches it to the appropriate class.		
Arguments:	methDescr Method object to create.		
Returns:	NIL		
Example:	(METH MyClass MyClass.Method1 NIL (category (Datum)))		

(INSTANCES InstName1...InstNameN)

[File Manager Command]

[File Manager Command]

Purpose/Behavior: Appears as a sublist in a filecoms. The keyword **INSTANCES** tells the File Manager to use the appropriate **DEFINST** expressions for each instance in the list and also for any other instances that are referenced inside any instances in the list. This assures that there are no references to nonexistent instances when read back in. The method **SaveInstance?** can be specialized to prevent instances from being saved in more than one file when they are referred to by instances in different files.

Example: (INSTANCES TestW)

(THESE-INSTANCES InstName1...InstNameN)

Purpose/Behavior: Appears as a sublist in a filecoms. The keyword **THESE-INSTANCES** tells the File Manager to use the appropriate **DEFINST** expressions for each instance in the list. Unlike the **INSTANCES** File Manager command, **THESE-INSTANCES** does not recursively dump instances that are pointed by *InstName1...InstNameN*.

(DEFINSTANCES Instances)	[NLambda NoSpread Function]
Purpose/Behavior:	Takes a list of instance names and creates empty structures for them in preparation for reading in their structures from a file.
Arguments:	Instances Accepts any symbol but result is useless unless you use DEFINST to actually create the <i>Instance</i> .
Returns:	NIL
Example:	(DEFINSTANCES TestW)
(DEFINST DEFINST% FORM)	[NLambda NoSpread Function]
Purpose/Behavior:	Takes a source specification of an instance and causes the appropriate internal representation to be created. It does this by sending the message FileIn to the instance's class. It creates the class if it does not exist.
Arguments:	DEFINST% FORM The source specification of an instance.
Returns:	NIL
Example:	[DEFINST Window (TestW (JEW0.0X:.H<4.NZ9 . 532)) (left 179) (bottom 446) (width 12) (height 12)]
(← self FileIn fileSource)	[Method of Class]
Purpose/Behavior:	Takes a source specification for an instance as it appears in a file and causes the appropriate internal representation to be constructed.
Arguments:	self Class of the instance to be created.
	fileSource Loadable form of an instance as stored in a file.
Returns:	self
Categories:	Class

14.4 Saving LOOPS Objects on Files

Adding LOOPS classes, methods and instances to files can be done in the same way that functions and variables are saved in Medley. In addition, the LOOPS browser allows newly created objects to be automatically associated with files. LOOPS also provides the means for moving objects from file to file.

Whenever a class, method, or named instance is created or edited, it is marked as changed. This allows the File Manager to prompt for a file in which to store new objects and see to it that changed objects are written out when **MAKEFILE** is called.

	The followin	g table shows the items in this section.
Name	Туре	Description
FILES?	Function	LOOPS adds a prompt for classes, methods and instances along with the normal Medley types.
ObjectModified	Method	Notifies the File Manager that an object has been changed or created.
OnFile	Method	Determines if a class is in FILELST .
SaveInstance	Method	Causes newly created instances to be noticed by the File Manager.
SaveInstance?	Method	Determines if an instance needs to be added to the list of instances to be saved.
DelFromFile	Method	Deletes an object from any file in FILELST in which it appears.
MoveToFile	Method	Class.MoveToFile moves a class and its methods from one file to another. Object.MoveToFile moves an instance from one file to another.
MoveToFile!	Method	Moves a class, all of its methods, and all of its subclasses and their methods from one file to another.
DontSave	IVProperty	Controls what parts of an instance are saved in a file.
OldInstance	Method	Sends a message to an object after it is loaded from a file.
(FILES?)		[Function]
Purpose/Behavior:	FILES?, you	anager types have been extended so that, when a call is made to a are prompted to add classes, methods and instances to files the normal Medley. For an example of FILES? , see Section 14.1, ang Files."
	automaticall files as soor the LOOPS they are cre or by specia more than o you to speci to create a r	is associated with a file, any methods that are added to it are y added to that file as well. Thus, it makes sense to put classes in n as possible. This could be done by repeated calls to FILES ?, but file browser allows classes to be automatically added to files as ated. Any class that is created by adding a root to a file browser lizing a class in a file browser is added to that brower's file. If ne file is associated with the browser, a menu appears to prompt fy a file for the new class. The LOOPS browser also can be used new file and associate it with a file browser. Thus, there is never wait until the end of a session to put classes and methods in files.
	should be p are construct should not b such tempo which shoul into files afte bracket (]) to ObjectMod instances of	o save instances on files. Of course, only those instances which resent after a file is first loaded should be saved. Instances which cted "on the fly" as a consequence of running a LOOPS program be saved. Only named instances are marked as changed so many rary instances may never be noticed. However, if named instances d not be saved are created, then you are prompted to put them er a call to FILES? and must respond by typing a right square be each one. Alternatively, it is possible to specialize the method ified so that it does not call MARKASCHANGED . Then any f classes which have or inherit the specialized method are not he File Manager regardless of whether or not they are named.
(← self ObjectModified name)		[Method of Object]

The following table shows the items in this section.

Purpose:

Notifies the File Manager that an object has been changed or newly created.

Behavior:	Uses the Fi	ile Manager command MARKASCHANGED. It does nothing if
		t given, thus unnamed objects are never marked.
Arguments:	self	A LOOPS object.
	name	Name of object specified in self.
	reason	Reason is MARKEDASCHANGED (see the <i>Interlisp Reference Manual</i> for information on MARKEDASCHANGED).
Returns:	self	
Categories:	Object	
Specializations:	Method	
(← self OnFile file)		[Method of Class]
Purpose:	Determines	s if an object is in a file in FILELST .
Behavior:	Calls WHE <i>Manual</i>).	REIS (see the Lisp Release Notes and the Interlisp-D Reference
		not given, it returns the name of the file in FILELST that the object ned in or NIL if <i>self</i> is not in a file.
	 If <i>file</i> is greater the second /li>	given, it must still be a member of FILELST , and T or NIL is
Arguments:	self	A LOOPS object.
	file	The file to be searched.
Returns:	Value depe	ends on the arguments; see Behavior .
Categories:	Class	
(← self SaveInstance name reas	son)	[Method of Object]
Purpose:	Causes nev	wly created instances to be noticed by the File Manager.
Behavior:	Sends self	the message ObjectModified .
Arguments:	self	A LOOPS object.
	name	Name of object specified in self.
	reason	Reason is MARKEDASCHANGED (see the <i>Interlisp Reference Manual</i> for information on MARKEDASCHANGED).
Returns:	self	
Categories:	Object	
(self SaveInstance? file outInstance?	stances)	[Method of Object]
Purpose:	Determines be saved in	s whether an instance needs to be added to the list of instances to a <i>file</i> .
Behavior:	by the LOC	see if the current instance is a member of <i>outInstances</i> . It is used DPS File Manager command INSTANCES to guarantee that the nce does not appear more than once in a given file.
	This metho user.	d must be specialized to be used; it cannot be used directly by the

Arguments:	self	A LOOPS object.
	file	The file to be searched.
	outInstances	A list of LOOPS names. See Behavior.
Returns:	T if the insta	nce should be saved on the file; NIL if it should not be saved.
Categories:	Object	

$(\leftarrow self \, DelFromFile)$

[Method of Object]

Purpose:	Deletes an o	bject from any file in FILELST in which it appears.
Behavior:	Searches through the filecoms of all files in FILELST and deletes the object everywhere it appears.	
Arguments:	self	A LOOPS object.
Returns:	Used for side effect only.	
Categories:	Object	
Specializations:	Class, Meth	od

(*self* **MoveToFile** *file*)

Purpose:	Moves an object from one file to another. If an object is a class, it, and all its methods, move.		
Behavior:	Adds the object to the filecoms of <i>file</i> so that the object will be saved on that file. If <i>file</i> is NIL, it prompts for a file form FILELST via a menu.		
Arguments:	self	A class or method.	
	file	File to which object is moving.	
Returns:	NIL		
Categories:	Object		
Specializes:	Object		

(← self MoveToFile! file fromFiles)

[Method of Class]

[IV Property Name]

[Method of Class]

Purpose:	Moves a class, all of its methods, and all of its subclasses and their methods from one file to another.		
Behavior:	Similar to MoveToFile.		
Arguments:	self file fromFiles	A LOOPS class. File to which object is moving. A list of files from which classes may be moved.	
Returns:	NIL		
Categories:	Class		

DontSave

Purpose/Behavior:

Controls what parts of an instance are saved in a file. Its value is a list of property names of the instance variable which should not be written out when

the instance is dumped. If **Value** is in the list, the instance variable's value is not saved. If the property is **Any**, nothing is saved except the instance variable name. (Must be added by the user.)

(\leftarrow self **OldInstance** name arg1 arg2 arg3 arg4 arg5)

<u> </u>	<u> </u>	
Purpose:	be specialize	ssage to an object after it is loaded from a file. This method can ed by applications that need to perform some operation on every it is created.
Behavior:	If <i>name</i> is no	on-NIL, the message SetName is sent to <i>self</i> .
		iables with an :initForm property are filled. See the discussion of Chapter 2, Instances.
	Sends the m <i>arg</i> 2.	nessage SaveInstance to <i>self</i> with the arguments <i>name</i> , <i>arg1</i> , and
Arguments:	self name arg1arg5	Evaluates to a class. LOOPS name of the class or instance. Optional arguments referenced by user-written specialization code.
Categories:	Object	
Specializations:	IndexedObje	ect

14.5 Storing Files

This section describes the functions and methods used by LOOPS and Medley to store files.

Name	Туре	Description
MAKEFILE	Function	Writes files that contain Medley data types which include LOOPS objects and methods.
PrettyPrintClass	Function	Prints classes in a file in a form that can be read back in.
PrettyPrintInstance	Function	Prints instances in a file in a form that can be read back in.
MakeFileSource	Method	Constructs the representation of an object that is appropriate for printing in a file.
FileOut	Method	Controls the printing of a LOOPS object in a file.

(MAKEFILE FILE)

[Function]

[Method of Object]

Purpose/Behavior:	When all LOOPS objects are associated with their files, the files are written by a call to MAKEFILE or MAKEFILES . This is identical to the standard use of MAKEFILE in Medley. See the <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference Manual</i> .	
Arguments:	FILE	Name of file to be written out.
Returns:	Full file name	

(PrettyPrintClass className file	e) [Function]
Purpose/Behavior:	Used by the File Manager command CLASSES to print out classes in a file in a form that can be read back in. It checks to make sure the class exists and then sends it the message FileOut . It is also used by the method PP to print classes to a display stream.
Arguments:	className The name of the class to be printed on the file file.
	file The file on which the class <i>className</i> is to be printed.
Returns:	Pointer to class in the form #,(\$ className)
(PrettyPrintInstance instanceNa	ame file) [Function]
Purpose:	Used by the File Manager command INSTANCES to print instances in a file in a form which can be read back in. Sends the message FileOut to instance.
Arguments:	<i>instanceName</i> Name of a LOOPS instance.
	file The file on which the instance instancename is to be printed.
Returns:	NIL
(← self MakeFileSource file)	[Method of Object]
Purpose:	Constructs the representation of an object that is appropriate for printing in a file.
Behavior:	Uses the relevant access functions to obtain the parts of the object and then stores them into a list structure.
Arguments:	self A LOOPS object.
	file The file on which self is to be printed.
Returns:	Loadable form of a LOOPS object.
Categories:	Object
Specializations:	Class, Method
Example:	63←(← (\$ TestW) MakeFileSource) (DEFINST Window (TestW (NEW0.1Y%:.;h.eN6 . 501)))
(← self FileOut file)	[Method of Object]
Purpose:	Controls the printing of a LOOPS object in a file.
Behavior:	Gets the appropriate source representation by sending the object the message MakeFileSource and prettyprints the result.
Arguments:	self A LOOPS object.
	file The file on which self is to be printed on if T prints to the Lisp Executive window.
Returns:	self
Categories:	Object
Specializations:	Class, Method

Example:

```
62_(__($ TestW) FileOut T)
(DEFINST Window (TestW (NEW0.1Y%:.;h.eN6 . 501)) )
#,($& TestW (NEW0.1Y%:.;h.eN6 . 501))
```

14.6 Compiling Files

LOOPS uses the new XAIE compiler and its macrolet facilities. When doing **CLEANUP** on LOOPS files your ***DEFAULT-CLEANUP-COMPILER*** should be set to 'CL:COMPILE-FILE. More information on this cleanup flag and the new compiler are available in the *Lisp Release Notes*.

[This page intentionally left blank]

Three main areas in LOOPS can affect performance:

- Garbage collection
- Instance variable access
- Method lookup

This chapter describes the impact of these areas on LOOPS. Also included is a section on cache clearing.

15.1 Garbage Collection

The Interlisp-D garbage collector maintains reference counts of each piece of data in the system. (Refer to the *Lisp Release Notes* and the *Interlisp-D Reference Manual* for information on reference counts.) There is potential for noticeable performance degradation if many items have reference counts greater than one. Object-oriented systems in general, and LOOPS in particular, can easily create objects that have multiple references.

The LOOPS system uses a number of methods to avoid creating items with large reference counts. Classes, for example, can easily have large reference counts since each instance of the class points to the class. Because of this, LOOPS does not maintain reference counts of classes. Performance is enhanced, but classes in LOOPS are not garbage collected. This should not present a problem as classes are not often destroyed.

Unique Identifiers (UIDs) also have multiple references: from the instance they name and from the table used by the LOOPS system to associate UIDs with instances. LOOPS avoids this problem by storing copies of the instance UID in the instance. This complicates testing for equality of UIDs, which is a rare event, but removes a potential garbage collection problem.

These and other implementation details substantially reduce the impact of LOOPS on the Interlisp-D garbage collector. In a typical running system, LOOPS objects accounted for less than 16% of the data items with reference count greater than one.

15.2 Instance Variable Access

LOOPS uses macros to speed the instance variable access from compiled code. Instance variable property access is compiled differently from instance variable value access, and various caching schemes are used to speed up repeated access to a given slot.

15.

LOOPS uses two layers of caching to speed up instance variable access:

• Local cache.

Instance variable access from compiled code uses a local cache. This cache remembers the class of *self* and the instance variable index the last time this piece of code was executed. If the class of *self* on the next pass through the code matches the stored value, then the stored instance variable index is used. In this case, instance variable access is very fast.

• Global cache.

A global cache is used by the instance variable access functions when the local cache fails. This global cache is a fixed size table of instance variable pairs. Looking in this cache for a given class is typically faster than computing the instance variable index.

You should be aware that instance variable access is optimized to be faster than accessing the properties of instance variables. Also, be aware that when instances are first created, the data for an instance variable may need to be found by performing a lookup through the class hierarchy. If the lookup goes through several classes, this can be slow. By guaranteeing that the instance variable data is stored in the instance, this lookup delay can be avoided.

The following macros are used to access instance variables. They are mentioned here to point out that calls to **GetValue** and **PutValue** could result in the compilation of any one of several different functions.

[Macro]

[Macro]

(GetValue self varName & OPTIONAL propName)

Purpose/Behavior:	Getl ^V Prop,	a call to one of the functions Cached-GetIVValue , Cached-GetIVValue , or GetIVProp . The particular function depends on arguments to GetValue .
Arguments:	self	A class or an instance.
	varName	Instance or class variable name.
	propName	Property name.
Returns:	Used for side	e effect only.

(PutValue self varName value & OPTIONAL propName)

Purpose/Behavior:	Compiles to a call to one of the functions Cached-PutIVValue , Cached- PutIVProp , PutIVValue , or PutIVProp . The particular function depends on details of the arguments to PutValue .	
Arguments:	self	A class or an instance.
	varName	Instance or class variable name.
	value	The new value for <i>varName</i> or <i>propName</i> .
	propName	Property name.
Returns:	Used for side effect only.	

15.3 Method Lookup

LOOPS uses two layers of caching to speed the method lookup:

• Local cache

Method lookup from compiled code uses a local cache when the selector can be determined at compile time. This cache remembers the class of *self* and the computed method the last time this message was sent. If the class of *self* on the next pass through the code matches the stored value, then the method is used. In this case, method lookup is very fast.

• Global cache

A global cache is used by the method lookup functions when the local cache fails. This global cache is a fixed size table of class / selector / method triples. Looking in this cache for a given class and selector is typically faster than searching the class hierarchy for the appropriate method.

15.4 Cache Clearing		
	Code that directly manipulates the structure of LOOPS objects sometimes needs to invalidate the caches used for instance variable access and message sending.	
	The following functions can be used to clear these caches if you suspect that they might be invalid.	
(ClearAllCaches)	[Function]	
Purpose/Behavior:	Clears all LOOPS and Interlisp-D runtime caches. This includes local and global instance variable access caches, local and global method lookup caches, and the system CLISP translations hash array.	
Returns:	NIL	

[This page intentionally left blank]

[Macro]

16.

LOOPS provides two special versions of message sending that start a separate process to run LOOPS methods. These are \leftarrow **Process** and \leftarrow **Process!** which are analogous to \leftarrow and \leftarrow **!**.

(←Process	obj sel arg1	argn)	

Purpose:	Starts a new process to run the selected method on the object, obj.		
Behavior:	The method indicated by <i>sel</i> is run in a separate process for the given instance or class, <i>obj.</i> See the <i>Interlisp-D Reference Manual</i> for a discussion of processes.		
Arguments:	obj	A LOOPS object.	
	sel	Name of the method to be executed as a process.	
	arg1 argn	Arguments for the method specified in sel.	
Returns:	Pointer to a process data type.		
Example:	Assume the method ClockTime is added to the class LCD , as follows:		

> **ClockTime** takes two arguments: **WaitTime**, the wait time between updates of the **LCD** reading, and **DisplaySeconds?**, a flag used to determine if seconds are to be displayed on the **LCD**. **ClockTime** runs an infinite loop which sets the **LCD** reading, updates the **LCD** display, and blocks the **ClockTime** loop to allow other system processes to run. The command

(\leftarrow Process (\$ LCDInstance1) ClockTime 60000)

adds the process **ClockTime** to the process list and **(\$ LCDInstance1)** becomes a digital clock which updates itself every minute.

(← Process! obj sel arg1 argn)		[Macro]
Purpose:	Starts a new process to run the selected method on the object <i>obj</i> . Like \leftarrow Process , except the argument <i>sel</i> is evaluated.	
Behavior:	Evaluates <i>sel</i> returns a selector for a method of <i>obj</i> . This method is rusparate process for the given instance or class, <i>obj</i> .	in on a
Arguments:	obj A LOOPS object.	
	<i>sel</i> Name of the method to be executed as a process.	
	arg1 argn Arguments needed for the method.	
Returns:	Pointer to the process data type.	
Example:	Assume the variable LCDClock is set to ClockTime , which is the met added to the LCD class as described for \leftarrow Process . The command	hod
	(\leftarrow Process! (\$ LCDInstance1) LCDClock 2000 T)	
	adds the process LCDClock to the process list and (\$ LCDInstance) becomes a digital clock with a seconds display which updates itself ev seconds.	ery two

This chapter describes the macros, functions, and methods used to read LOOPS objects from and print LOOPS objects to file storage, hash array storage, and the user display.

17.1 Reading Objects

17.

		This section describes the functions to read LOOPS objects.		
	Name	Туре	Description	
	\$	NLambda Function	Returns a pointer to the object; does not evaluate its argument.	
	\$!	Function	Returns a pointer to the object; evaluates its argument.	
	\$C	NLambda Function	Gets the class record.	
			ons use the Common Lisp form # , in the return display. This form ad-time evaluation and is briefly described here.	
	Form	Description		
	#, <form></form>	Reads <i><form></form></i> , evaluates it, and returns that value.		
	#, (\$& <form>)</form>	Form in which instances appear if they are not prettyprinted.		
	#, (\$C className)	Similar to #,(\$ <i>className</i>), except that it creates the class if it does not already exist.		
(\$ name)			[NLambda Function]	
	Purpose/Behavior:	evaluate nai	binter to the LOOPS object specified by <i>name</i> and does not <i>me</i> . If no object exists for <i>name</i> , NIL is returned. If *PRINT- set to T, the object will be prettyprinted in the Executive window.	
	Arguments:	name	A LOOPS name.	
Returns: Example:		Pointer to a LOOPS object or NIL; see Behavior.		
		In line 18, <i>name</i> is an instance. The value is returned and the DEFINST form is printed.		
		In line 19, <i>n</i> a	ame is a class whose class name is returned and printed.	
		In line 20, N therefore ret	otAnObject has not been declared as a LOOPS object and urns NIL.	
		18←(\$ Win #,(\$& Win	ndow1) dow (NEW0.1Y%:.;h.eN6 . 495))	

19←(\$ Window) #,(\$C Window) 20←(\$ NotAnObject) NIL

(\$! name)	[Lambda Function]	
Purpose/Behavior	Returns a pointer to the LOOPS object specified by name where name is evaluated. If no object exists for name, NIL is returned. If *PRINT-PRETTY* is set to T, the object will be prettyprinted in the Executive window.	
Arguments	: name Evaluates to a valid LOOPS name.	
Returns	: Pointer to a LOOPS object or NIL; see Behavior.	
(\$C name)	[NLambda Function]	
Purpose	: Allows forward references to classes.	
	Use (\$ <i>name</i>) instead of (\$C <i>name</i>).	
Behavior	: Varies according to the arguments.	
	• If there is a class record for <i>name</i> , the function returns the class name.	
	 If there is no class record for <i>name</i>, the function attempts to create the class. This differs from the behavior of (\$ <i>name</i>) which does not attempt any initialization if no LOOPS object is found. 	
Arguments	: name A LOOPS name.	
Returns	: Value depends on the arguments; see Behavior.	
Example	If <i>name</i> is not a LOOPS object, as shown in line 21, \$C defines and returns a class for <i>name</i> , as shown in line 22. Line 23 shows the default class which is created in the Common Lisp Executive by \$C when no class is found for <i>name</i> .	
	21←(\$ aCompletelyNewClass) NIL	
	22←(\$C aCompletelyNewClass) #,(\$C aCompletelyNewClass)	
	23←(← (\$C aCompletelyNewClass) PP) aCompletelyNewClass	
	(DEFCLASS aCompletelyNewClass (MetaClass Class) (Supers Tofu))	

17.2 Print Flags

This section describes three variables that affect the way that objects are printed in LOOPS:

ObjectDontPPFlag

	ObjectAlwaysPPFlag		
	 PRINT-PRETTY 		
	All these variables have a default value of NIL.		
	The ObjectDontPPFlag and ObjectDontPPFlag variables affect how contained objects are printed and are used to override the *PRINT-PRETTY* , which affects how the top-level objects are printed. (See the <i>Interlisp-D Reference Manual</i> for more information on the *PRINT-PRETTY* .) These variables interact as follows:		
	 If ObjectDontPPFlag is NIL and *PRINT-PRETTY* is T, objects are prettyprinted. 		
	 ObjectDontPPFlag is T overrides *PRINT-PRETTY* is T. 		
	 ObjectAlwaysPPFlag is T overrides *PRINT-PRETTY* is NIL. 		
ObjectDontPPFlag	[Variable]		
Purpose/Behavior:	Used internally to prevent recursive printing of objects. If ObjectDontPPFlag is set to a non-NIL value, and ObjectAlwaysPPFlag is set to NIL, only the object name is printed. If this flag is NIL, all of the information contained within an instance is printed. The setting of this flag interacts with *PRINT-PRETTY* as shown in the examples below.		
ObjectAlwaysPPFlag	[Variable]		
Purpose/Behavior:	Controls printing the long form of all instances. When this variable is set to a non-NIL value, the long form of all instances are printed. This is the same form generated by ($\leftarrow obj$ PP). The ObjectAlwaysPPFlag overrides the effect of the ObjectDontPPFlag . Printing the long form of instances can lead to infinite loops or very long printouts. For example, if you have an object referencing another object which in turn references the first object, printing causes an infinite loop. If you have references to other LOOPS objects in the object you are printing, the long form of every object that can be reached from the top object is printed.		
Example:	This example shows the interaction of all print flags.		
	23←(SETQ *PRINT-PRETTY* NIL) NIL		
	24←(SETQ ObjectDontPPFlag NIL) NIL		
	25←(← (\$ Window) New 'Window2) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 502))		
	26←(← (\$ Window2) Shape) (47 145 99 89)		
	27←(\$ Window2) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 502))		
	 Change the value of *PRINT-PRETTY* to T. 		
	28←(SETQ *PRINT-PRETTY* T) T		
	29←(\$ Window2) (DEFINST (Window2 (NEW0.1Y%:.;h.eN6 . 502)) (left 47) (bottom 145)		

```
(width 99)
           (height 89))

    Change the value of ObjectDontPPFlag to T.

30←(SETQ ObjectDontPPFlag T)
Т
31 \leftarrow (\$ Window2)
#,($& Window (NEW0.1Y%:.;h.eN6 . 502))

    Assume the following commands have been entered:

(DefineClass 'PPTest)
(\leftarrow (\$ PPTest) AddIV 'testIV)
( ($ PPTest) New 'PPTest1)
(\leftarrow (\$ PPTest) New 'PPTest2)
(\leftarrow @ ($ PPTest1) testIV ($ PPTest2))
(\leftarrow@ ($ PPTest2) testIV ($ PPTest1))
(SETQ *PRINT-PRETTY* T)
(SETQ ObjectDontPPFlag T)
(SETQ ObjectAlwaysPPFlag T)
• Print the instances.
53 \leftarrow (\$ PPTest1)
(DEFINST PPTest (PPTest1 (NEW0.1Y%:.;h.eN6 . 502))
                                                                 )

    Reset the *PRINT-PRETTY* and print the instances again.

54 \leftarrow (SETQ * PRINT - PRETTY * NIL)
NIL
55 \leftarrow (\$ PPTest1)
#,($& PPTest (NEW0.1Y%:.;h.eN6 . 513))
```

17.3 Printing Classes

		This section describes the methods used to print classes and information about classes.	
Name	Туре	Description	
FileOut	Method	Prints long pretty form of the class to a file or a display stream.	
PP	Method	Prettyprints the class definition to a file or a display stream.	
PP!	Method	Prints the information about the class from all levels of inheritance.	
PPV!	Method	Prints the variable information about the class from all levels of inheritance.	
		[Mathed of Class]	

 $(\leftarrow self FileOut file)$

[Method of Class]

Purpose: Prints the long pretty form of the class to a file or to display stream.

Prints a **DEFCLASS** form for the class *self*. The **DEFCLASS** form, which is Behavior: the way classes are defined, always includes the name of the class, the MetaClass, and the Supers. If there are ClassVariables and InstanceVariables defined for the class, these along with their values are also included in the DEFCLASS form. FileOut formats the output with special fonts and tab positions. Arguments: self A class. file The stream on which self is to be printed. If NIL, or not given, prints to the TTYDisplayStream. Returns: self Categories: Classes Class, Method Specializations: Example: This example shows the DEFCLASS form for TestClass. If a DEFCLASS form cannot be generated for self, a Break occurs with the message "var is not defined as a class. Type OK to ignore this class and go on." $24 \leftarrow (\leftarrow (\$ TestClass) FileOut)$ (DEFCLASS TestClass (* _ _)) (MetaClass Class Edited%: (Supers Object) (InstanceVariables (testIV 1234 testProp1 1 testProp2 2 doc (* _ _)))) #, (\$C TestClass)

 $(\leftarrow self PP file)$

[Method of Class]

Prettyprints LOOPS **OBJECT.CLASS.PP** to a file or to display stream. Purpose: Behavior: Prettyprints the class on *file*, if provided. If *file* is not given, look first to the **PPDefault**, which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream. The output is printed and formatted by the method Class.FileOut. Arguments: A pointer to a class. self file Stream to prettyprint to. Returns: Name of class. Categories: Class Specializes: Object Example: This example shows a call to **PP** on the class **SupersBrowser**, which uses the **TTYDISPLAYSTREAM** as the default output stream. $26 \leftarrow (\leftarrow (\$ SupersBrowser) PP)$ (DEFCLASS SupersBrowser **COMMENT** (MetaClass Class Edited%: "Browses upwards from a class doc to all of its supter.") (Supers ClassBrowser) (InstanceVariables (title "Supers browser")))

SupersBrowser

$(\leftarrow self PP! file)$	[Method of Class]
Purpose:	Prints the information about LOOPS OBJECT.CLASS.PP from all levels of inheritance.
Behavior:	Prints a listing of the following items along with any applicable documentation, values and arguments for each item: MetaClass , Supers , Instance Variables , Class Variables , Prototypes , and Methods .
	Prints the information on <i>file</i> , if provided. If <i>file</i> is not given, look first to the PPDefault , which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream .
Arguments:	self A pointer to a class.
	file Stream to print to.
Returns:	self
Categories:	Classes
Specializes:	Object
Example:	This example shows a partial output of the call to PP! on the class SupersBrowser which uses the TTYDISPLAYSTREAM as the default output stream. The dots indicate additional information.
	<pre>27~(~ (\$ SupersBrowser) PP!) #, (\$ SupersBrowser) MetaClass and its Properties Class Edited: (* smL 11-Jun-86 13:18) doc Browses upwards from a class to all of its supers. 17.4 Printing Objects

This section describes the methods for printing LOOPS objects.

Name	Туре	Description	
PrintOn	Method	Provides the default print function for LOOPS objects.	
FileOut	Method Prettyprints a LOOPS instance.		
PP	Method	Prettyprints an object to a file or display stream.	
PP!	Method	Prints all the information about the instance from all levels of inheritance.	
PPV!	Method	Prints the variable information about the instance from all levels of inheritance.	
(← self PrintOn file)		[Method of Object]	
Purpose:	Provides th	e default print function for LOOPS objects.	
Behavior:	standard L	orm suitable for the Lisp function DEFPRINT , which produces the DOPS object print form # ,(\$ <i>objname</i>). (See the <i>Lisp Release</i> the <i>Interlisp-D Reference Manual</i> for more information on C.)	
Arguments:	self	A LOOPS object.	
	file	A stream to print to.	
Returns:	("#," \$ ObjectName)		
Categories:	Object		
Example:	This example shows the results of calling PrintOn with the instance, Window1 .		
	28←(← (("#," \$)	\$ Windowl) PrintOn) Windowl)	
(←self FileOut file)		[Method of Object]	
Purpose:	Prettyprints	a LOOPS instance.	
Behavior:	object to th	is found for <i>self</i> , this method prints the DEFINST form for the <i>file</i> . For a description of FileOut where <i>self</i> is a class, see 3 "Printing Classes."	
	The DEFINST form always includes the name of the class to which the object belongs and the UID for the object. Names attached to the object and InstanceVariables bindings for the object are also included in the DEFINST form. FileOut formats the output with special fonts and tab positions.		
Arguments:	self	A LOOPS object.	
	file	Stream to print to.	
Returns:	self		
Categories:	Instances		
Example:	This examp	ble shows the DEFINST forms for the object Window1 .	
	(DEFINS NEW0.1Y (1	<pre>\$ Window1) FileOut) T Window (Window1 (%:.;h.eN6 . 495)) eft 288) ottom 242)</pre>	

(width 331)

(height 149)) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 495))

(← self PP file)	[Method of Object]			
Purpose:	Prettyprints an object to a file or display stream.			
Behavior:	Temporarily sets the ObjectDontPPFlag to prevent infinite loops in the print. Prettyprints the output with special fonts and tab positions and prints the DEFINST form of the object. If <i>file</i> is not given, look first to the PPDefault , which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream .			
Arguments:	self A LOOPS object.			
	file Stream to print to.			
Returns:	Name of object.			
Categories:	Object			
Specializations:	Class			
Example:	This example shows the results of sending the instance Window1 the message PP .			
	30←(← (\$ Window1) PP) (DEFINST Window (Window1 (NEW0.1Y%:.;h.eN6 . 495)) (left 288) (bottom 242) (width 331) (height 149)) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 495))			
(← self PP! file)	[Method of Object]			
Purpose:	Prints the information about the instance from all levels of inheritance.			
Behavior:	Prints a listing of the following items along with any applicable documentation, values and arguments for the each item: Instance Variables, Class Variables, and Methods.			
	values and arguments for the each item: Instance Variables, Class			
Arguments:	values and arguments for the each item: Instance Variables , Class Variables , and Methods . If <i>file</i> is not given, look first to the PPDefault , which is by default the Common			
Arguments:	values and arguments for the each item: Instance Variables , Class Variables , and Methods . If <i>file</i> is not given, look first to the PPDefault , which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream			
Arguments: Returns:	 values and arguments for the each item: Instance Variables, Class Variables, and Methods. If <i>file</i> is not given, look first to the PPDefault, which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream self A LOOPS object. 			
-	values and arguments for the each item: Instance Variables, Class Variables, and Methods.If file is not given, look first to the PPDefault, which is by default the Common Lisp Executive Window, and then to the TTYDisplayStreamselfA LOOPS object.fileStream to print to.			
Returns:	 values and arguments for the each item: Instance Variables, Class Variables, and Methods. If file is not given, look first to the PPDefault, which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream self A LOOPS object. file Stream to print to. self 			
Returns: Categories:	 values and arguments for the each item: Instance Variables, Class Variables, and Methods. If file is not given, look first to the PPDefault, which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream self A LOOPS object. file Stream to print to. self Object 			
Returns: Categories: Specializations:	 values and arguments for the each item: Instance Variables, Class Variables, and Methods. If file is not given, look first to the PPDefault, which is by default the Common Lisp Executive Window, and then to the TTYDisplayStream self A LOOPS object. file Stream to print to. self Object Class This example shows a partial output of a call to PP! on the instance Window1. 			

Instance Variables left NIL doc left position of window bottom NIL doc bottom position of window width 12 doc outer width of window, including border height 12 doc outer height of window, including border Class Variables RightButtonItems ((Close (Close (Close --))) Snap Paint --) doc Items to be done if Right button is selected Methods AfterMove Window.AfterMove doc NIL args NIL #, (\$& Window (NEW0.1Y%:.;h.eN6 . 495))

(\leftarrow self **PPV!** file)

Purpose: Prints the variable information about the instance from all levels of inheritance. Similar to (self PP! file) except that only the information about the Class Behavior: Variables and Instance Variables is printed. Arguments: self A LOOPS object. file Stream to print to. Returns: self Categories: Object Specializations: Class Example: This example shows a partial output of a call to **PPV!** on the instance LCDInstance. Dots indicate additional information. $31 \leftarrow (\leftarrow (\$ Window1) PPV!)$ #,(\$ Window1) Instance Variables **left NIL** doc left position of window bottom NIL doc bottom position of window width 12 doc outer width of window, including border height 12 doc outer height of window, including border Class Variables RightButtonItems ((Close (Close (Close --)

[Method of Object]

)) Snap Paint --) doc Items to be done if Right button is selected . . . #,(\$& Window (NEW0.1Y%:.;h.eN6 . 495))

17.5 Printing Active Values

This section describes methods and variables used for printing active values. For more information on active values, see Chapter 8, Active Values.

(← self AVPrintSource)	[Method of ActiveValue]		
Purpose:	Constructs a form used by DEFPRINT to write active values to files.		
Behavior:	An annotatedValue determines how it prints out by sending the AVPrintSource message to its wrapped ActiveValue .		
	The default method in ActiveValue returns a list of the form:		
("#,"\$AV className	avNames(ivName value propName value)(ivName))		
	which causes the annotatedValue to print out as		
#,(\$AV className av	Names(ivName value propName value)(ivName))		
Arguments:	self An ActiveValue		
Returns:	A form suitable for use by the Interlisp-D function DEFPRINT . Result should be a pair of the form (item1 . item2); item1 will be printed using PRIN1 , and item2 will be printed using PRIN2 (see the <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference Manual</i> description of DEFPRINT).		
	In the return list,		
	className Name of the class of the ActiveValue.		
	avNames List of names of <i>self</i> , the last element being the unique identifier (UID) of <i>self</i>		
	(ivName value propName value) List that describes the state of the instance variables of the ActiveValue .		
Categories:	Instances of the ActiveValue class		
Example:	The following command gets a pointer to an active value:		
	32←(GetValueOnly (\$ Window1) 'window) #,(\$AV LispWindowAV ((N^W0.1Y%:.;h.Lh9 . 503)) (localState {WINDOW}#374,55554))		
	The following shows the result of an AVPrintSource message. (This is typically passed on to DEFPRINT within the internals of the system.)		
	33←(←(GetValueOnly (\$ Window1) 'window) AVPrintSource) ("#," \$AV LispWindowAV ((N^W0.1Y%:.;h.Lh9 . 503)) (localState {WINDOW}#374,55554))		

DefaultActiveValueClassName

Purpose:

The class **ExplicitFnActiveValue** is the default class for active values. This class mimics the previous style of LOOPS active values (see Appendix A, Previous Active Values). For specialized applications, you may want a different class of active value to use for this purpose.

17.6 Printing Methods

	This section describes the following methods used to print methods:		
Name	Туре	Description	
PPDefault	Variable	Identifies where the output for prettyprinting is sent.	
PPMethod	Method	Prettyprints the method for a class.	
MethodDoc	Method	Prints the documentation for the method for a class.	
MethodSummary	Method	Prints a summary of the methods attached to a class.	
PPDefault		[Variable]	
Purpose:	PPMethod,	window used as the default output stream for the methods MethodDoc , and MethodSummary . Initially set to the Common ive Window.	
(← self PPMethod selector)		[Method of Class]	
Purpose:	Prettyprints the method specified by selector for the class self.		
Behavior:	If <i>selector</i> is not specified, this opens a menu of the methods attached to the class <i>self</i> . The method, as chosen either from the menu or passed to the method in <i>selector</i> , is prettyprinted to the primary output stream. If <i>self</i> is not a class, a break occurs with the error,"(\leftarrow (\$ <i>self</i>) PPMethod <i>selector</i>) not understood."		
	The output the Commo	is sent to the value of the variable PPDefault , which is by default n Lisp Executive Window.	
Arguments:	self	A LOOPS object.	
	selector	Method to print.	
Returns:	Class.Selector		
Categories:	Classes		
Example:	This example shows the results of prettyprinting the method Shape on the class Window using PPMethod .		
	35←(← (\$ Window) PPMethod 'Shape)	
	(Method	((Window Shape) self newRegion noUpdateFlg) (*	
	"Shapes	outside of region to specified shape." Shape1 [OR newRegion (GETREGION NIL NIL	

(WINDOWPROP (@ window) 'REGION] noUpdateFlg))

with (Window Shape) bold.

(← self MethodDoc selector)		[Method of Class]	
Purpose:	Prints the d self.	ocumentation for the method specified by selector for the class	
Behavior:	If selector is not specified, this opens a menu of all methods attached to the class from all levels of inheritance. When you choose an item, the documentation for that method, the arguments needed, and the class defining the method are prettyprinted to the PPDefault window, which is by default the Common Lisp Executive Window. You can continue to make selections from the menu or press a mouse button outside the menu to stop.		
Arguments:	self	A pointer to a class.	
	selector	Method to be printed.	
Returns:	NIL		
Categories:	Class		
Example:	This example shows the output from calling MethodDoc for the class LoopsIcon . Three methods were chosen from the menu in succession: AfterMove , BrowseObject , and Clear . BrowseObject is attached to Window so the class where it is defined is not explicitly listed. AfterMove and Clear are defined, respectively, on the classes NonRectangularWindow and Window .		
	36←(← (\$ LoopsIcon) MethodDoc)	
	select args: N doc: Th	LoopsIcon (from NonRectangularWindow) or: AfterMove IL e window has been moved. Update the d bottom.	
	BrowseO args: N	-	
	Clear args: N	LoopsIcon (from Window) selector: IL lls CLEARW on window.	

(*←* self **MethodSummary** dontPrintFlg printFile)

[Method of Class]

Purpose: Prints a summary of the methods attached to the class *self*.

Behavior: Prettyprints the documentation from the classes directly attached to the class *self.* Printing is done to the file *printFile.* If *printFile* is not specified, **MethodSummary** prints to the **PPDefault** window, which is by default the Common Lisp Executive Window. If the **ObjectDontPPFIg** is T, the output is not displayed in pretty format.

Arguments: *self* A pointer to a class.

	dontPrintFlg	If non-NIL, does not prettyprint.
	printFile	File to print to.
Returns:	NIL	
Categories:	Class	
Example:	the class lcc	e shows the results of sending the message MethodSummary to mWindow . Only information about the methods defined at the lindow are printed.
		IconWindow) MethodSummary) Items IconWindow.GetMenuItems args (itemType) doc NIL))

17.7 Unique Identifiers (UIDs)

Unique Identifiers (UIDs) are used to store and retrieve objects. In general, objects do not have UIDs, with the following exceptions:

- When an object is named.
- When an instance of an indexed object is created, it gets a UID.
- When an object is printed.

The following table shows the functions in this section.

Name	Туре	Description		
HasUID?	Function	Returns the UID for a specified object.		
UID	Function	Returns the UID for a specified object and creates a UID for the object if one does not already exist.		
GetObjFromUID	Function	Retrieves the LOOPS object records.		
MapObjectUID	Function	Applies a function to every LOOPS object that has a UID.		

(HasUID? obj)

Purpose: Returns the UID for obj.

Behavior: If the *obj* has a UID, the function returns the UID. If *obj* is an object but has no UID, it returns NIL. If *obj* is not an object, it generates an error with the message, "ARG NOT OBJECT."

Arguments: *obj* A LOOPS object.

Returns: The UID for obj.

Example: Line 39 shows the results of calling **HasUID?** for an instance **Window1**, line 40 for a class **Window**, and line 41 for a new instance of **Window**.

39←(HasUID? (\$ Window1)) (NEW0.1Y%:.;h.eN6 . 495) [Function]

```
40←(HasUID? ($ Window))
(NEW0.1Y%:.;h.eN6 . 255)
41←(HasUID? (← ($ Window) New))
NIL
```

(UID obj)

[Function]

Purpose:	Returns UID for <i>obj</i> . If object does not have UID, this function creates a UID for the <i>obj</i> .
Behavior:	If the object has a UID, this function returns the UID; otherwise it creates a UID for the object.
Arguments:	obj A LOOPS object.
Returns:	The UID for <i>obj.</i>
Example:	Line 45 shows the results of calling UID with the class Object . Line 46 shows the results of calling UID with an instance which does not have a UID.
	45←(UID (\$ Object)) (NEW0.1Y%:.;h.eN6 . 7)
	46←(UID (← (\$ Window) New)) (NEW0.1Y%:.;h.eN6 . 519)
(CotObiEromUID with	IEurotion
(GetObjFromUID uid)	[Function]
Purpose:	Retrieves the LOOPS object records of object whose UID is <i>uid</i> .
Behavior:	Returns the object associated with a UID, or returns NIL if <i>uid</i> is not a valid UID.

- Arguments: *uid* The internal identifier.
 - Returns: Pointer to the object.
 - Example: In this example, **Window1UID** was previously set to the UID for the instance **Window1**. **GetObjFromUID** retrieves the record for **Window1** using **Window1UID** and prettyprints the **DEFINST** form for **Window1** to the **TTYDisplayStream**.

42←(SETQ Window1UID (UID (\$ Window1] (NEW0.1Y%:.;h.eN6 . 495)

43←GetObjFromUID Window1UID) #,(\$& Window (NEW0.1Y%:.;h.eN6 . 495)

(MapObjectUID fn)

[Function]

- Purpose: Applies the function *fn* to every LOOPS object.
- Behavior: Maps the function *fn* to every UID object that has a UID.
- Arguments: fn Function to be applied.
 - Returns: Used as a side effect only.
 - Example: This example shows a partial listing of the results of applying the user-defined function **PPUID** (see line 47) to every LOOPS object using **MapObjectUID**. **PPUID** prints the UID of *obj* to the **TTY** display stream. A complete output of this call to **MapObjectUID** lists the UID for every LOOPS object currently defined in the system.

45←(DEFINEQ (PPUID (LAMBDA (OBJ) (PRIN2 (UID OBJ))))) (PPUID)

46←PP PPUID FNS definition for PPUID: (PPUID [LAMBDA (OBJ) **COMMENT** (PRIN2 (UID OBJ])

47← (MapObjectUID 'PPUID) (NEW0.1Y%:.;h.Lh9 . 526) (NEW0.1Y%:.;h.Lh9 . 527) (NEW0.1Y%:.;h.Lh9 . 524) (NEW0.1Y%:.;h.Lh9 . 525) (NEW0.1Y%:.;h.Lh9 . 522) (NEW0.1Y%:.;h.Lh9 . 523) . . . #<Hash-Table @ 66,72106> [This page intentionally left blank]

18. USER INPUT/OUTPUT MODULES

This chapter presents two modules that have been developed for displaying and allowing you to enter information. The Interlisp-D Inspector module and ?= handler have been enhanced to support LOOPS data types and message sending.

18.1 Inspector

The LOOPS interface uses and extends the capabilities of the Medley Inspector module. Instances and classes can be easily examined and modified through the interface that the Inspector module provides. This section describes the operations available with the LOOPS interface. For information on the Inspector module, see the *Interlisp-D Reference Manual*.

An inspector is a window opened on a specific piece of data, which for LOOPS means a class or an instance. Figure 18-1 shows an inspector on an instance of a window.

All Value:	s of Window (\$ (MWX0.;F5.o28.Z;
left	NIL
bottom	NIL
width	12
height	
	#,(\$AV LispWindowAV ((YI
title	
menus	T

Figure 18-1. Sample Inspector

Inspector windows contain two columns of information; the left column is called the property column, and the right column is called the value column.

You can scroll inspector windows, but these windows are not reshaped by actions such as switching from instance variables inspection to property inspection or adding new instance variables. This may cause some confusion, for example, if you create an inspector to be the correct size and add an instance variable, and that instance variable fails to appear.

An inspector is primarily an interactive facility. A programmatic interface is also available, which uses the LOOPS methods to customize the generic Interlisp-D functionality.

18.1.1 Overview of the User Interface

LOOPS provides two ways to create an inspector:

- Call the Lisp function **INSPECT** with the object to be inspected as the first argument.
- Use the LOOPS method Inspect, which is described below.

The user interface to the inspector is the same as that for the Medley environment; that is, you select an option from the left or right column with the left mouse button, and then trigger an action with the middle mouse button. The action opens a menu from which you can choose further options, like assigning a new value or adding an active value for breaking.

Another menu appears when you position the cursor on the title bar of an inspect window and press the middle mouse button. This menu allows you to change the inspector's contents, for instance to show all values or local ones for instance variables.

Three types of inspectors are available in LOOPS:

- Instance inspector
- Class inspector
- · Class instance variable inspector

The following sections describe the user interface for each inspector.

[Method of Object]
This provides a message form of the function to inspect the item self.
Calls (INSPECT self NIL INSPECTLOC).
INSPECTLOC A region where the inspector window should appear. If it is NIL, you are prompted to place a ghost image.
Object
The following command inspects an instance (\$ W1).
$17 \leftarrow (\leftarrow (\$ W1) \text{ Inspect})$

18.1.2 Using Instance Inspectors

Using an inspector window on an instance provides a clear, direct interface to all of the instance's variables and values. This interface also provides the mouse and keyboard options to change the contents of the inspector to show various aspects of the instance.

18.1.2.1 Titles of Instance Inspector Windows

When you inspect an object, the title of the inspector window reflects the contents of the inspector. If the object is an instance, the title contains the name of the class of the instance and the LOOPS name of the instance, if it has one, or the UID of the instance. Other types of inspectors have different title bars, as described in Section 18.1.3, "Using Class Inspectors," and Section 18.1.4, "Using ClassIV Inspectors."

Contrast the title bar of the following two examples.

(INSPECT (\leftarrow (\$ Window) New)) generates

All Values of Window (\$ (MWX0.;F5.o28.Z; left NIL bottom NIL width 12 height 12 window #,(\$AV LispWindowAV ((YI title NIL menus T	
(INSPECT (\leftarrow (\$ Window) New 'w1))	generates
All Values of Window (\$ w1). left NIL bottom NIL width 12 height 12 window #,(\$AV Lisp\indowAV ((YI title NIL menus T	

18.1.2.2 Menu for the Title Bar

The following menu appears when you position the cursor on the title bar of the inspector window and press the middle mouse button.

Local Val	ues of Window (\$ w1).
left	
bottom	
width	
height	
	<pre>#,(\$AV LispWindowAV ((MWX0.:F5</pre>
	#,NotSetValue
menus	#,NotSetValue

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

- **Class** Opens a second inspector, a Class Inspector as described in Section 18.1.3, "Using Class Inspectors," which inspects the class of the instance within this inspector.
- AllValues The default mode for instance inspectors. The values displayed in the right column of the inspector are determined by the function **GetValueOnly**, so active values (except #,NotSetValue) can be seen. The title of the inspector states that all values are being displayed.

All Values of Window (\$ w1).

NIL
bottom
NIL
width
12
height
12
window
,(\$AV Lisp\indowAV ((YIV0.C=N5.\+7 . 10)))
title
NIL
menus
Т

LocalValues The values displayed in the right column of the inspector are determined by the function **GetIVHere**. The title of the inspector states that only local values are being displayed. As with **AllValues**, active values are seen, and values that are not yet stored locally in the instance show a value of #,NotSetValue.

Local Values of Window (\$ w1).			
left			
bottom			
width	139		
height	63		
window	<pre>#,(\$AV Lisp\indowAV</pre>		
	≇ ,NotSetValue		
menus	∦ ,NotSetValue		

- Add/Delete Allows you to add or delete instance variables. Selecting this option pops up a new menu with two options:
 - Add

If you select **Add**, you are prompted to enter a name for the new instance variable. That instance variable is added locally to the instance and given the value of the variable **NotSetValue**. If you enter a name for an instance variable that currently exists, its value is reset to the value defined in the class.

Delete

If you select **Delete**, a menu appears with options that are the instance variables of the instance. If you select one that is not defined within the class, it is deleted. If the selected instance variable is defined by the class, a break occurs.

If the inspector is viewing the properties of an instance variable as opposed to all of the instance variables (see **IVs** below), the name entered under **Add** will be added as a property to that instance variable and given the value of the variable **NotSetValue**. If you try to delete an existing property, the menu that appears is a menu of property names.

- **IVs** Changes the view to be one that shows all of the instance variables and their values, not the properties. It is possible to change the view an inspector has on an instance to show only the properties of a given instance variable. This is described in Section 18.1.2.3, "Using Commands in the Left Column," in the description of the Properties option.
- **Save Value** Calls **PutSavedValue** with its value argument bound to the instance being inspected.
 - **Refetch** Refreshes the inspector. Inspectors do not automatically update when a change is made to an instance, unless made with the **Edit** command.
 - **Edit** Opens a display editor window in which you can modify the value of instance variables and properties, and add or delete instance variables local to the instance.

18.1.2.3 Menu for the Left Column

The following menu appears when the view of the inspector is all of the instance variables of the instance, and you select an item in the left column and press the middle mouse button.

PutValue >> Properties Breaklt >> Tracelt >> UnBreaklt

If the view of the inspector is only of properties, this menu contains only one option: **PutValue**.

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

- **PutValue** Allows you to assign a new value to the variable selected. Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:
 - PutValue

Prompts you to enter a new value for this instance variable. The new value is stored using **PutValue**.

• PutValueOnly

Prompts you to enter a new value for this instance variable. The new value is stored using **PutValueOnly**.

• Use saved value

The new value to be stored using **PutValueOnly** is the value of (SavedValue).

Properties Changes the view of the inspector to include only the value and properties of the selected instance variable as shown here:

All IVProps of Window (\$ w1).mer	nus				
Value	T "Coobo	Faa	Sawad	Manua	w:11	Casha
		FOF	Saveo	Menus.	¥111	Lache
TitleItems	NIL					
MiddleButtonItems						
LeftButtonItems	NIL					
Title	NIL					
DontSave	Any					

The title bar changes to indicate that the properties of an instance variable are being displayed, which instance is being displayed, and which instance variable of that instance is being displayed.

The Value item is provided purely as a convenience in this view and its menu options will only allow Putting a new value in it.

The following menu appears when the view of the inspector is an instance variable's properties, and you select an item in the left column and press the middle mouse button.

When the inspector's view is limited to IV properties the menu options act in a manner similar to that of IVs. This allows Putting, Breaking, Tracing and unBreaking of the properties instead of the IVs themselves.

If you now select the option **LocalValues** from the title bar menu, the title of the inspector changes to indicate that fact, and only properties that are stored locally in the instance appear, as shown here:

Local IVProps of Window (\$ w1).menus

Value #,NotSetValue

To return to a view that shows all instance variables, choose the **IVs** option from the title bar menu.

Breaklt Wraps a **BreakOnPutOrGet** active value around the value of an instance variable. Any read or write accesses to this instance variable will cause a break (see Chapter 12, Breaking and Tracing).

Note: Breaking a variable effectively breaks any IndirectVariable that points to it.

Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:

Break on Access

Performs the same action as Breaklt.

Break on Put

Installs a **BreakOnPut** active value. Trying to store a new value into this instance variable will cause a break, but reading the variable will not.

Tracelt Wraps a **TraceOnPutOrGet** active value around the value of this field. Any read or write accesses to this instance variable will be traced (see Chapter 12, Breaking and Tracing).

Note: Tracing a variable effectively traces any IndirectVariable that points to it.

Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:

• Trace on Access

Performs the same action as Tracelt.

Trace on Put

Installs a **TraceOnPut** active value. All writes into this instance variable will be traced, but reads will not.

UnBreaklt Removes any of the breaks or traces that have been installed on an instance variable. If there are multiple traces or breaks, this will remove the outermost one.

18.1.2.4 Menu for the Right Column

The following menu appears when the view of the inspector is all of the instance variables of the instance, and you select an item in the right column and press the middle mouse button.

PutValue >> Properties Breaklt >> Tracelt >> UnBreaklt Save Value Inspect

If the view of the inspector is only of properties of an instance variable, this menu contains only three options: **PutValue**, **Save Value**, and **Inspect**.

The only differences between these menus and the ones associated with the left column is the addition of two more options: **Save Value** and **Inspect**. The remaining options trigger identical behaviors as those of the menu associated with the left column.

Save Value Calls **PutSavedValue** with the selected value as its argument.

Inspect Calls the Lisp function **INSPECT** with the selected value as its argument, opening an additional inspector window.

In an inspector viewing the properties of an IV the right hand column middle button menu allows only the Put Value, SaveValue and Inspect options.

18.1.3 Using Class Inspectors

Classes can be inspected by using the Lisp **INSPECT** function or the LOOPS **Inspect** method (see Section 18.1.1, "Overview of the User Interface"). For example, to inspect the class **Window**, enter either of the following commands:

(INSPECT (\$ Window))
(← (\$ Window) Inspect)

The contents of a class cannot be changed from within an inspector window, so it is generally used for display as opposed to editing. However, the menu interface does provide ways to edit the contents of a class.

18.1.3.1 Titles of Class Inspector Windows

When you inspect a class, the title states that you are inspecting only local properties, and contains the name of the class.

The title contains the name of the class. The following example shows an inspector on the class **Window**. Since the value column is quite long, it has been truncated here.

Local proper	ties of Class Window
MetaClass	(Class Edited%: (* smL " 8-Apr∹
Supers	(Object)
IVs	(left bottom width height window
CVs	(TitleItems LeftButtonItems Shi
Methods	(AfterMove AfterReshape AttachL

18.1.3.2 Menu for the Title Bar

The title bar menu is associated with each inspector of a class. This menu appears when you position the cursor inside the title bar of the class inspector window and press the middle mouse button.

Browse I Edit	>
All	
Local	
Refetch	

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

- **Browse** Provides a quick way to open a class browser on the class being inspected. Selecting this option and dragging the mouse to the right pops up a submenu with the following options:
 - Browse

Opens a class browser with the class being inspected as the root class.

• BrowseSupers

Open a supers browser on the inspected class.

- Edit Opens an editing window on the class.
- All Causes the values shown in the right column to contain inherited as well as locally defined information. The title bar of the inspector changes to indicate this, as shown here:

All properties	of Class Window
MetaClass	(Class Edited%: (* smL " 8-Apr-87 17:35")
Supers	(Object Tofu)
IVs	(left bottom width height window title me
CVs	(RightButtonItems ShiftMiddleButtonItems
Methods	(WhenMenuItemHeld Update ToTop TitleSelec

- **Local** The default mode for class inspectors. This causes the values shown in the right column to contain only locally defined information, which is indicated in the title bar of the inspector.
- **Refetch** Refreshes the inspector. Inspectors do not automatically update when a change is made to an instance, unless made with the **Edit** command.

18.1.3.3 Menu for the Left Column

No actions occur when you select an item in the left column of a class inspector and press the middle mouse button.

18.1.3.4 Menu for the Right Column

Only one option, **Inspect**, is in the menu that appears when you select an item in the right column of a class inspector and press the middle mouse button.

Inspect

For the fields **MetaClass**, **Supers**, **CV**s, and **Methods**, selecting **Inspect** from the menu allows a choice of Interlisp-D inspectors. If the selected item in the class inspector is the values of the **IVs** field, then a ClassIVs inspector, described below, is created.

18.1.4 Using ClassIVs Inspectors

ClassIV inspectors provide an interface to the default values for all of the instance variables defined in a class. To create a ClassIV inspector,

- Open a class inspector.
- Select the values of the IVs field.
- Press the middle mouse button. This pops up and selects and **Inspect** menu, and automatically opens a ClassIVs inspector.

18.1.4.1 Titles of ClassIVs Inspector Windows

The title for a ClassIVs inspector indicates that the instance variables of a particular class are being inspected. This example shows how a ClassIVs inspector looks for the class **ClassBrowser**.

All IVs of Class ClassBroy	wser
left	NIL
bottom	NIL
width	64
height	32
window	<pre>#,(\$AV LispWindowAV ((YIV0.C=N5.₩+7 . 10)))</pre>
title	"Class browser"
menus	T
topAlign	NIL
startingList	NIL
goodList	NIL
badList	NIL
lastSelectedObject	
browseFont	<pre>#,(Defer (FONTCREATE (QUOTE (HELVETICA 10 BOLD)</pre>
LabelMaxLines	NIL
LabelMaxCharsWidth	
boxedNode	NIL
graphFormat	(LATTICE)
showGraphFn	SHOWGRAPH
viewingCategories	(Public)

18.1.4.2 Menu for the Title Bar

The following title bar menu is associated with each inspector of an instance. This menu appears when you position the cursor inside the title bar of the inspector window and press the middle mouse button.

AllValues
LocalValues
Add/Delete
lVs
Refetch

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

AllValues The default mode for ClassIV inspectors. Causes the inspector to show all instance variables, whether inherited or locally defined for the class, and states "AllIVs" in the title.

LocalValues Causes the inspector to show only locally defined instance variables. The following window shows how the title changes to indicate this:

Local IVs of Class Class	Browser	
title	"Class browser"	
viewingCategories	(Public)	I

Add/Delete Allows you to add or delete a ClassIV.

Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:

• Add

If you select **Add**, you are prompted to enter a name for the new instance variable. That instance variable is added to the class and given the default value NIL and a **doc** property with the value (* IV added by (USERNAME)). If you enter a name for an instance variable that currently exists, its default value is reset to NIL.

Delete

If you select **Delete**, a menu appears with the locally defined instance variables of the class. Selecting one deletes it from the class.

If the inspector is viewing the properties of an instance variable as opposed to all of the instance variables (see **IVs** below), the name entered under **Add** is added as a property to that instance variable and given the value NIL. If you try to delete an existing property, the menu that appears is a menu of property names.

IVs Returns the view to show the instance variables and their values, not the properties.

It is possible to change the view a ClassIVs inspector has on the instance variables of a class to show only the properties of a given instance variable. This is described in Section 18.1.4.4, "Menu for the Right Column."

Refetch Refreshes the inspector.

18.1.4.3 Menu for the Left Column

No actions occur if you select an item in the left column of a ClassIVs inspector with the middle mouse button.

18.1.4.4 Menu for the Right Column

The following menu appears when you select an item in the right column and press the middle mouse button:

nspea	st
Save	Value
Prope	rties

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

- **Inspect** Calls the Lisp function **INSPECT** with the selected value as its argument.
- Save Value Calls PutSavedValue with the selected value as its argument.
- **Properties** Changes the view of the inspector to display the value and properties of the selected instance variable, as shown in this example:

All propertie	es of window of Class ClassBrowser
Value	#,(\$AV LispWindowAV ((YIV0.C=N5.W←7 . 1
doc	"Holds real window. Ensured to be window
DontSave	(Value)

The title changes to include the following information:

- · The properties of an instance variable.
- The name of the instance variable.
- The name of the class.

If you now select either **AllValues** or **LocalValues** from the title menu, the title of the inspector changes to indicate that fact, and the appropriate information is displayed.

18.1.5 Functional Interface for Instance Inspectors

The methods described in this section belong mostly to the classes **Class** or **Object**. Inspectors are not LOOPS objects, so these methods are invoked indirectly within the system functionality of the inspector as a customization of the Interlisp-D inspectors. These methods are meant to be called only from within the context that you create interactively by pressing a mouse button when the cursor is on some portion of an inspector window; you do not invoke them directly. Many of the parameters are simply passed along in case the method creates a menu, and the option selected from the menu needs additional arguments.

In these methods, the arguments *self* and *datum* may the same; that is, the item being inspected. The message is sent to the item being inspected, so its position in the inheritance lattice determines which method from the classes **Class** or **Object** is invoked.

The following table shows the items in this section.

Name	Туре	Description
InspectFetch	Method	Returns the value of a left column inspector property that is displayed in the right column of an inspector window.
InspectStore	Method	Stores the value for an instance variable or its property.
InspectPropCommand	Method	After an item is selected in the left column of an inspector window, this triggers an action when the middle mouse button is pressed.
InspectProperties	Method	Determines what is displayed in the left column of an inspector window.
InspectTitle	Method	Creates a string to be used for an inspector window's title.
InspectValueCommand	Method	After an item is selected in the right column of an inspector window, this triggers an action when the middle button is pressed.
TitleCommand	Method	Triggers an action when the cursor is inside the title bar of the inspector window and the middle mouse button is held down.

(← self InspectFetch datum property window)

[Method of Object]

Purpose/Behavior:	Message sent by inspector to get the value of a left column inspector property that is displayed in the right column of an inspector window. Either GetValueOnly or GetIVHere is used to determine the value.		
Arguments:	self	The object being inspected.	
	datum	This may or may not be a list. If it is not a list, it is bound to the object being inspected; that is, <i>self</i> . It is set to a list within various methods associated with the inspectors. The contents of this list are interpreted by a number of the methods to control what data is displayed within the inspector window.	
		• The first element of the list is the object being inspected.	
		• The second element of the list, if not NIL, is typically the name of an instance variable. In the terminology of the inspector, it is an inspector property. For inspectors of instances, the inspector properties (the items in the left column) are the instance variables of the object being inspected. (There can be some confusion here caused by using the word properties either when referring to the left column data of an inspector or when referring to the properties associated with an instance variable).	
		 The third element of the list, if NIL, indicates that inherited values are to be displayed in the inspector window; if its value is LocalValues, then only locally stored information is displayed. 	
		The value of <i>datum</i> is stored on the inspector window property DATUM .	
	property	Used if <i>datum</i> is not a list. Refers to an element (instance variable or property name) contained within the left column of an inspector. For an instance inspector, this could be either the name of an instance variable or the name of a property, depending upon the state of the inspector; that is, whether you are viewing instances variable or the properties of a particular variable.	
	window	Lisp window of the inspector.	
Returns:	The value of a left column property that is displayed in the right column.		
Categories:	Object		
Specializations:	Class, InspectorClassIVs		
Example:	<pre>The following command fetches the value of instance W1's instance variable bottom: 15←(← (\$ W1) InspectFetch (LIST (\$ W1) 'window)) #,(\$AV LispWindowAV ((YIV0.C=N5.W←7 . 10)))</pre>		
	The followin	g command fetches the value of class Window's supers:	
	16←(← (\$ (Object)	3 Window) InspectFetch (\$ Window) 'Supers)	

(← self **InspectStore** datum property newValue window)

[Method of Object]

Purpose/Behavior:	PutValueOn	<i>Alue</i> as the value for an instance variable or its property using Iy . Where the value is stored, whether in the instance variable or operties, depends upon the values for <i>datum</i> and <i>property</i> .
Arguments:	datum	Instance or class being inspected. See InspectFetch , above, for details.
	property	Instance variable or property where value is to be stored. See InspectFetch , above, for details.
	newValue	New value for <i>property</i> .
	window	Lisp window of the inspector.
Categories:	Object	
Specializations:	Class, Inspe	ctorClassIVs
Example:	The following height :	g command changes the value of instance W1 's instance variable
	17←(← (\$ 400	W1) InspectStore (\$ W1) 'height 400)
	or	
	18←(← (\$ 400	W1) InspectStore 'W1 'height 400)
(self InspectPropCommand	datum proper	ty window) [Method of Object]

A prompt window will be attached to this window if you ask to PutValue, and the window's INSPECTW.FETCH function will be called, so the window must

Arguments:	datum	Instance or class being inspected. See InspectFetch, above, for details.	
Returns:	Value depends on the arguments; see Behavior.		
Categories:	Object		
Specializations:	Class, InspectorClassIVs		
Example:	The following command first shows the instance variables of instance W1 , then the properties of the instance variable height :		
		(\$ W1) InspectProperties 'W1) ottom width height window title menus)	
	$28 \leftarrow (\leftarrow $ (Value d	(\$ W1) InspectProperties (LIST 'W1 'height)) loc)	
(← self InspectTitle datum)		[Method of Object]	
Purpose:	Creates a	string to be used as a title for an inspector window.	
Behavior:	If <i>datum</i> is	not a list, this sets datum to (datum NIL NIL).	
	whether al variables o	on the values within the list <i>datum</i> , this creates a title showing I values or local values are shown and whether all instance or the properties of an instance variable are shown. The title also the LOOPS name or UID of <i>self</i> .	
Arguments:	datum	Instance or class being inspected. See InspectFetch , above, for details.	
Categories:	Object		
Specializations:	Class, Insp	pectorClassIVs	
Example:	Some exa	mples of the behavior of InspectTitle:	
		(\$ Window) InspectTitle) properties of Class Window"	
		(\$ W1) InspectTitle) ues of Window (\$ W1)."	
		(\$ Window) InspectTitle (LIST 'Window T)) operties of Class Window"	
		(\$ W1) InspectTitle (LIST 'W1 'height)) Props of Window (\$ W1).height"	

(<- self InspectValueCommand datum property value window)

[Method of Object]

Purpose:	This method is an interface between LOOPS and the mouse functions of the inspector, and should only be called through the Inspector. It is invoked when an item is selected in the right column of an inspector window and the middle mouse button is pressed.			
Behavior:	Opens a menu with several options. See Section 18.1.2.4, "Menu for the Right Column."			
Arguments:	datum	Instance or class being inspected. See InspectFetch, above, for details.		
	property	Instance variable or property being inspected. See InspectFetch , above, for details.		

 value
 This is inspected only if you select Inspect from menu.

 window
 Lisp window of the inspector.

 Categories:
 Object

 Specializations:
 Class, InspectorClassIVs

 Example:
 When the value of the instance variable height in instance W1 is selected in an inspector window, and the middle mouse button is pressed, a message like the following is sent:

 (← (\$ W1)
 InspectValueCommand (\$ W1) 'height 200 (WHICHW))

(← self **TitleCommand** datum window)

```
[Method of Object]
```

Purpose:	This method is an interface between LOOPS and the mouse functions of the inspector, and should only be called through the Inspector. It is invoked when the cursor is in the title bar of an inspector window and the middle mouse button is pressed.		
Behavior:	Brings up a menu with several options. See Section 18.1.2.2, "Menu for the Title Bar."		
Arguments:	datum	Instance or class being inspected. See InspectFetch , above, for details.	
	window	Lisp window of the inspector.	
Categories:	Object		
Specializations:	Class, Inspec	ctorClassIVs	
Example:		n the cursor inside the title bar of the inspector window for and press the middle mouse button, you send a message like the	
	$(\leftarrow$ (\$ W1)	TitleCommand NIL (WHICHW))	

18.1.6 Customizing the Inspector

The methods in Section 18.1.5, "Functional Interface for Instance Inspectors," have been specialized in the classes **Class** and **InspectorClassIVs** to create the behavior of the inspectors described in Section 18.1.1, "Overview of the User Interface."

If you want to create a specialized inspector, you need to create a subclass of **Object** or perhaps **Class** and specialize the methods within that new class. The class **InspectorClassIVs** has an instance variable named **class** that contains the name of the class being inspected within a particular instance of **InspectorClassIVs**. Similarly, the user-created inspector class may need an instance variable which contains the object being inspected so that the methods of this class can easily access it.

The methods that you need to specialize will depend upon how the behavior of the newly created inspector class should differ from those of an instance or class inspector.

As an example, assume that you want an inspector to show a subset of the instance variables of an instance. You could specialize the method **InspectProperties** to return that subset. To make **Window** show only the dimensions of a window, define the following method:

SEdit Window. InspectProperties Package; INTERLISP

(Method ((Window InspectProperties) self)
 "Have Window inspectors show only the window dimensions"
 '(width height left bottom))

(←New (\$ Window) Inspect) creates the following:

All Value:	sof₩
width	12
height	12
left	NIL
bottom	NIL

18.2 Extensions to ?=

The Interlisp-D environment allows you to begin typing a function to be evaluated in the Executive and pause in the midst of typing the arguments. At this point, if you type a "?=" followed by a carriage return, Interlisp-D prints the arguments to the pending function call and shows the bindings. LOOPS has extended this facility to include similar functionality for message sending and for record creation.

18.2.1 Message Sending

The ?= interface works with the following message-sending forms:

- ←
- ←Super
- ←New
- ←Proto
- ←Process
- SEND

LOOPS first tries to determine the class of the object receiving the message by examining the form following one of the above. If the message form begins with one of \leftarrow **New** or \leftarrow **Proto**, the object receiving the message is the class desired.

• If the system cannot determine the class of the object, you are prompted in the Prompt Window to enter in the name of the class or to type a right square bracket (]) to evaluate the form and determine that class from that. This handles cases such as

 $(\leftarrow$ (\leftarrow (\$ Window) New) ?=<CR>

 If the class can be determined and if you have not typed in a selector, a menu appears containing the options *generics* and *inherited* and any selectors local to the class. A submenu is associated with *generics* that contains selectors from the classes Tofu, Object, or Class, depending upon the class previously determined. The submenu associated with *inherited* are those selectors that are neither generic nor local to the class.

This is the menu that appears when you type

```
(←New ($ NonRectangularWindow) ?= <CR>
```

Which selector? AfterMove CreateWindow EditIcon EditMask Invert Shape Update *generics* *inherited*

If you choose one of these options, it is placed into the input buffer and the system prints the binding for *self*, what method will be executed, and the arguments expected. In the prompt window, the system prints the documentation of the method to be executed.

As an example, if you create an instance of a class browser **cb1**, type

 $22 \leftarrow (\leftarrow (\$ cb1) ?= < CR >$

and then choose **Shape** from the ***inherited*** drag-through menu, the Executive changes as shown here.

```
22←(←($ cb1) Shape
(←
self = ($ cb1)
Method = Window.Shape
newRegion noUpdateFlg)
```

A similar output occurs if you type in a selector and "?=" instead of choosing a selector from the menu.

If you type "?=" after entering one or more of the arguments, the arguments are printed with the bindings, as shown here.

```
23← (←($ cb1) Shape '(100 150 200 250) ?= <CR>
(←
self = ($ cb1)
Method = Window.Shape
newRegion (QUOTE (100 150 ...))
noUpdateFlq)
```

This interface also works when you are typing to the edit buffer window when using the display editor. It does not work to pick a selector within a display editor window and choose the **?=** item from the **EditCom** submenu.

18.2.2 Record Creation

The same mechanism the LOOPS uses to handle ?= for LOOPS objects is also used to extend it for the Interlisp Record module.

If you begin an input to the Executive with one of **CREATE**, **Create**, or **create**, type the record name or data type to be created next, and then type

?=<CR>

the system prints the names but not the bindings of the fields within the record being created.

For example, when you type

48 \leftarrow (CREATE POSITION XCOORD \leftarrow 123 ?=<CR>

the response is

(XCOORD YCOORD)

on the next line. The caret moves to the position of the ?= in the original line, and waits for you to enter a value.

[This page intentionally left blank]

This chapter describes the ways to manipulate LOOPS windows.

19.1 The Class Window

The class ${\bf Window}$ is the LOOPS interface to the Medley environment window system, which is used by LOOPS browsers and inspectors.

Window			[Class]
	Description:	object-orien	rovides a mechanism for manipulating Lisp windows through an ted interface. See Section 19.4, "Mouse and Menu Functionality," sion of how menus work with LOOPS Windows.
			stance of a LOOPS window is created, it has an instance variable o a Lisp window. This Lisp window is initialized with various perties:
		The prop	erty LoopsWindow points to the window object.
		The prop	erty RIGHTBUTTONFN is set to WindowRightButtonFn.
		The prop	erty BUTTONEVENTFN is set to WindowButtonEventFn.
		The prop	erty AFTERMOVEFN is set to WindowAfterMoveFn.
		The prop	erty RESHAPEFN is set to WindowReshapeFn.
	MetaClass:	Class	
	Supers:	Object	
	Class Variables:	Titleltems	A list that defines the menu that will appear when the left or middle mouse button is pressed and the cursor is in the title bar of the window. The default value is NIL.
		LeftButton	tems A list that defines the menu for the left button in the main window. The default value is ((Update)).
		ShiftLeftBu	A list that defines the menu for the left button in the main window when the Meta key is down. The default value is NIL.
		MiddleButt	onltems A list that defines the menu for the middle button in the main window. The default value is NIL.
		ShiftMiddle	ButtonItems A list that defines the menu for the middle button in the main window when the Meta key is down. The default value is NIL.

19.

	RightButto	nltems A list that defines the menu for the right button in the main window. The default value is ((Close)).
Instance Variables:	left	The location of the left side of the outside of the window in screen coordinates. The default value is NIL.
	bottom	The location of the bottom side of the outside of the window in screen coordinates. The default value is NIL.
	width	The outside width of the window. The default value is 12.
	height	The outside height of the window. The default value is 12.
	window	An active value that contains the Lisp window. The default value is #,(\$AV LispWindowAV).
	title	The title of the window. Default Value: NIL.
	menus	Also has the properties Title , LeftButtonItems , MiddleButtonItems , and TitleItems . These properties are caches for menus only if the value of the instance variable is T. Default Value: T.

19.2 Basic Window Methods

This section describes the basic methods to operate on windows.

Name	Туре	Description
AfterMove	Method	Updates the instance variables left and bottom.
AfterReshape	Method	Updates the instance variables left, bottom, width, and height.
Blink	Method	Causes the window to blink.
Bury	Method	Buries the window.
Clear	Method	Clears the window.
Close	Method	Closes the window.
CursorInside?	Method	Determines if the cursor is inside a window.
Destroy	Method	Destroys the window instance.
GetProp	Method	Gets a property from a specified window.
Hardcopy	Method	Makes a hardcopy on the default device.
HardcopyToFile	Method	Makes a hardcopy on a file.
HardcopyToPrinter	Method	Makes a hardcopy to a printer.
Invert	Method	Inverts the window; that is, reverses its black-white pattern.
Move	Method	Moves the window.
MousePackage	Method	Returns a package (defined to return the INTERLISP package).
MouseReadtable	Method	Returns a readtable (defined to return the INTERLISP readtable).

Open	Method	Opens the window.
Paint	Method	Calls PAINTW on the window.
ScrollWindow	Method	Scrolls the window.
SetProp	Method	Sets the property in the specified window.
Shape	Method	Reshapes the window.
Shape?	Method	Returns the current region for the window.
Shrink	Method	Shrinks the window to an icon.
Snap	Method	Takes a snapshot of the screen.
ТоТор	Method	Opens the window and brings it to the top.
Update	Method	Makes the window consistent with the instance variables.
WindowAfterMoveFn	Function	Sends the message AfterMove.
WindowReshapeFn	Function	Sends the message AfterReshape.

$(\leftarrow self)$	AfterMove)
---------------------	------------

[Method of Window]

[Method of Window]

[Method of Window]

Purpose/Behavior:	Updates the instance variables left and bottom of self.	
Arguments:	self	An instance of a window.
Returns:	Used for sid	le effect only.
Categories:	Window	

(self AfterReshape oldBitmapImage oldRegion oldScreenRegion)

Purpose/Behavior:	Updates the instance variables left , bottom , width , and height of <i>self</i> . Calls RESHAPEBYREPAINTFN ; see the <i>Interlisp-D Reference Manual</i> .	
Arguments:	self	An instance of a window.
Returns:	Used for side effect only.	
Categories:	Window	

(self Blink numBlinks)

Purpose/Behavior:	Inverts the window; that is, reverses its black-white pattern, and then returns to normal <i>numBlinks</i> times.	
Arguments:	self	Pointer to a window instance.
	numBlinks	Number of times for window to blink.
Returns:	NIL	
Categories:	Window	
Example:	The command	

	$(\leftarrow \text{ self Blink 5})$	
	sends a message to self to blink five times.	
(//-)		
$(\leftarrow self \mathbf{Bury})$	[Method of Window	<u>v]</u>
Purpose/Behavior:	Calls BURYW to bury the specified window.	
Arguments:	self Pointer to a window instance.	
Returns:	The LOOPS window.	
Categories:	Window	
(← self Clear)	[Method of Window	v]
Purpose/Behavior:	Calls CLEARW to clear the specified window.	
Arguments:	self Pointer to a window instance.	
Returns:	NIL	
Categories:	Window	
Specializations:	LatticeBrowser	
(← self Close)	[Method of Window	v]
Purpose/Behavior:	Closes the specified window and prompt window, if there is one.	
Arguments:	self Pointer to a window instance.	
Returns:	NIL	
Categories:	Window	
(← self CursorInside?)	[Method of Window	v]
Purpose/Behavior:	Determines if the cursor is inside the window.	
Arguments:	self Pointer to a LOOPS window.	
Returns:	Returns T if the cursor is inside the window, otherwise returns NIL.	
Categories:	Window	
$(\leftarrow self \text{ Destroy})$	[Method of Window	v]
Purpose/Behavior:	Destroys the calling instance, removes all ButtonFns, and closes the window	·.
Arguments:	self Pointer to a window instance.	
Returns:	NIL	
Categories:	Object	
Specializes:	Object	

 $(\leftarrow \textit{self GetProp prop})$

[Method of Window]

Purpose/Behavior:	Gets a property from a window.
Arguments:	self Pointer to a window instance.
	prop Property to get.
Returns:	The value of the specified property, if it exists; else NIL.
Categories:	Window
Example:	To determine the value of the window property BUTTONEVENTFN , enter
	$(\leftarrow (\$ window) GetProp 'BUTTONEVENTFN)$
(← self Hardcopy)	[Method of Window]
Purpose/Behavior:	Makes a hardcopy of the window on the default printer.
Arguments:	self Pointer to a window instance.
Categories:	Window
(← self HardcopyToFile)	[Method of Window]
Purpose/Behavior:	Makes a hardcopy of the window to a file. You are prompted for the file name.
Arguments:	self Pointer to a window instance.
Categories:	Window
0	
(self HardcopyToPrinter)	[Method of Window]
Purpose/Behavior:	Makes a hardcopy of the window on a printer. You are prompted for the name of the printer.
Arguments:	self Pointer to a window instance.
Categories:	Window
(← self Invert)	[Method of Window]
Purpose/Behavior:	Inverts the window; that is, reverses its black-white pattern.
Arguments:	self Pointer to a window instance.
Returns:	T if successful.
Categories:	Window
Specializations:	NonRectangularWindow
(← self Move xOrPos y)	[Method of Window]
Purpose/Behavior:	Moves the specified window. If no arguments are supplied, you will be prompted to position the window.
Arguments:	self Pointer to a window instance.
	 New left in screen coordinates or a new position for left and bottom. If x is a position, y is ignored.
	<i>y</i> New bottom in screen coordinates.

Returns:	(x . y)		
Categories:	Window		
Example:		nd ndow) Move) ow to become attached to the cursor, promp	ting for new location.
		nd Nove 200 100) wer left corner of the window to (200 . 100).	
(<i>←self</i> MousePackage)			[Method of Window]
Purpose/Behavior:	(LOOPS nov MousePack	package used during mouse interactions with v uses the INTERLISP package exclusively.) age method protects LOOPS windows from the nis protection, specialize this method to return	The the new packages.
Arguments:	self	An instance of a window.	
Returns:	The INTERL	ISP package.	
(←self MouseReadtable)			[Method of Window]
Purpose/Behavior:	Medley now with LOOPS method prote	readtable used during mouse interactions with has many different readtables; some readtables . (The Common Lisp readtables are not case ects LOOPS windows from the new readtable pecialize this method to return *READTABLE	oles do not work well e-sensitive.) This es. To remove this
Arguments:	self	An instance of a window.	
Returns:	The INTERL	ISP readtable.	
(← self Open)			[Method of Window]
Purpose/Behavior:	Opens the s	pecified window instance.	
Arguments:	self	Pointer to a window instance.	
Returns:	NIL		
Categories:	Window		
(← self Paint)			[Method of Window]
Purpose/Behavior:	Calls PAINT the prompt w	W on the specified window. You are promptivindow.	ted for instructions in
Arguments:	self	Pointer to a window instance.	
Returns:	NIL		
Categories:	Window		
$(\leftarrow self \ $ ScrollWindow $dspX \ dsp$	oY windowX w	indowY)	[Method of Window]
Purpose/Behavior:	windowX an	vindow to move the point <i>dspX, dspY</i> to <i>wind</i> d <i>windowY</i> are NIL, the default is to scroll so s in the lower left corner of the window. Any	that the point dspx,

		FLOATP. If the value is FIXP , then it is treated as an absolute If the value is FLOATP , then it is treated as a relative position.
Arguments:	self	Pointer to a window instance.
	dspX	The x point in the given window to move; x is in window coordinates if FIXP . If FLOATP , the value to move is based upon the width of the EXTENT property of the window; see the <i>Interlisp-D Reference Manual</i> .
	dspY	The y point in the given window to move; y is in window coordinates if FIXP . If FLOATP , the value to move is based upon the height of the EXTENT property of the window; see the <i>Interlisp-D Reference Manual</i> .
	windowX	The x point to scroll to in window coordinates if FIXP . If FLOATP , the value to move is based upon the width of the window.
	windowY	The x point to scroll to in window coordinates if FIXP . If FLOATP , the value to move is based upon the height of the window.
Returns:	The lower le <i>Reference l</i>	eft corner of the new DSPCLIPPINGREGION ; see the <i>Interlisp-D</i> Manual.
Categories:	Window	
(← self SetProp prop value)		[Method of Window]
Purpose/Behavior:		erlisp window property of the specified LOOPS window, passing value arguments through Interlisp function WINDOWPROP .
Arguments:	self	Pointer to a window instance.
Aiguments.		Property to set.
	prop	
	value	New value for property.
Returns:		lue of <i>prop</i> if it existed; else NIL.
Categories:	Window	
(← self Shape newRegion noU	pdateFlg)	[Method of Window]
Purpose/Behavior:		ne specified window. If <i>newRegion</i> is not specified, you are reshape the window with the cursor.
Arguments:	self	Pointer to a window instance.
	newRegion	A list specifying the new outer dimensions; the format for the list is (left bottom height width).
	noUpdateFi	g If NIL, reshapes the window.
Returns:	A list speci	iying the new region.
Categories:	Window	
Specializations:	NonRectan	gularWindow
Example:	The command	
		ndow1) Shape '(100 200 300 400))

returns

(100 200 300 400)

$(\leftarrow self$	Shape?)
--------------------	---------

[Method of Window]

Purpose/Behavior:	Returns the current region for the window.
Arguments:	self Pointer to a window instance.
Returns:	A list specifying outer dimensions of the window.
Categories:	Window
Example:	The command
	$(\leftarrow (\$ window1) Shape?)$
	returns
	(100 200 300 400)

(self **Shrink** toWhat iconPos expandFn)

[Method of Window]

Purpose/Behavior:	Shrinks the	window to a given icon.	
Arguments:	self Pointer to a window instance.		
	toWhat	The icon to shrink to; if NIL, an icon is creat	ed.
	iconPos	Position of icon on screen.	
	expandFn	Function to be called on expansion.	
Returns:	The icon.		
Categories:	Window		
Specializations:	LatticeBrows	ser	
(← self Snap)			[Method of Window]
Purpose/Behavior:	Calls Snap	W to take a snapshot of the window.	
Arguments:	self	Pointer to a window instance.	
Returns:	The window		
Categories:	Window		
(← self ToTop)			[Method of Window]
Purpose/Behavior:	Opens the w	vindow and brings it to the top of the screen.	
Arguments:	self	Pointer to a window instance.	
Returns:	The window		
Categories:	Window		
(← self Update)			[Method of Window]

Purpose/Behavior: Makes the window consistent with the instar	ince variables.
---	-----------------

Arguments:	self	Pointer to a window instance.
Returns:	NIL	
Categories:	Window	
Specializations:	NonRectang	gularWindow

(WindowAfterMoveFn window)			[Function]
Purpose/Behavior:	pointed to b	n is installed as the AFTERMOVEFN property of the Lis y a window object. This function extracts the window ob y LoopsWindow and sends it the message AfterMove .	
	This AFTEF	RMOVEFN is installed automatically by the system.	
Arguments:	window	The window just moved.	
Returns:	Used for sid	le effect only.	
(WindowShapeFn window oldBit	tmapImage ol	dRegion)	[Function]
Purpose/Behavior:	pointed to b property Lo	n is installed as the RESHAPEFN property of the Lisp w y a window. This function extracts the window object fro opsWindow and sends it the message AfterReshape oldBitmapImage oldRegion.	om the
	This RESH	APEFN is installed automatically by the system.	
Arguments:	window	The window just reshaped.	
	oldBitmapIn	nage See the <i>Lisp Release Notes</i> and the <i>Interlisp-D Refere</i> <i>Manual</i> for a discussion of window ReShapeFns .	ence
	oldRegion	See the Lisp Release Notes and the Interlisp-D Reference Manual for a discussion of window ReShapeFns .	ence
Returns:	Used for sic	le effect only.	

19.3 Prompt Windows

Prompt windows are windows attached to other windows and are used for displaying messages and for getting input. In LOOPS, these operate similarly to prompt windows in Lisp. Prompt windows are not instances of the class Window; they are only instances of the Interlisp data type **Window**.

The following table lists the methods and functions described in this section.

Name	Туре	Description	
Clear PromptWindow	Method	Clears the prompt window.	
ClosePromptWindow	Method	Closes the prompt window.	
GetPromptWindow	Method	Associates a prompt window with a LOOPS window.	
PromptEval	Function	Prompts for, reads, and evaluates an expression.	
PromptForList	Method	Prompts for a list of items.	
PromptForString	Method	Prompts for a string.	
PromptForWord	Method	Prompts for a word.	
PromptPrint	Method	Prints a message in the prompt window.	
PromptRead	Function	Prompts for and reads data.	
NiceMenu	Function	Creates a menu.	
SelectFile	Lambda NoSpread	Prompts for a file name.	
	Pro Pro all d	The methods PromptForList , PromptForString , and PromptForWord , as well as the functions PromptRead and PromptEval when called with a prompt window for a LOOPS window all disable normal mouse button events in the prompting browser and will not allow it to close until the prompt is completed.	

(<i>eself</i> ClearPromptWindow)			[Method of Window]
Purpose/Behavior:	Clears the p	prompt window associated with the window sel	lf.
Arguments:	self	Evaluates to a window instance.	
Returns:	NIL		
Categories:	Window		
(← self ClosePromptWindow)			[Method of Window]
Purpose/Behavior:	Closes the	prompt window associated with the window se	lf.
Arguments:	self	Evaluates to a window instance.	
Returns:	The symbol	CLOSED if a prompt window existed; else NII	L.
Categories:	Window		
(← self GetPromptWindow lines	fontDef)		[Method of Window]
Purpose/Behavior:		npt window for window <i>self</i> . If one exists, it is a dow is created.	returned; else a
Arguments:	self	Pointer to a window instance.	
	lines	Number of lines in window; default is 2.	
	fontDef	Font used in the window; if NIL, this defaults	to DEFAULTFONT.

Returns: Pointer to a prompt window.

Categories: Window

(PromptEval promptString window sameLine?)

(PromptEval promptString windo	ow sameLine?)	[Function]		
Purpose:	Prompts for	Prompts for, reads, and evaluates an expression.			
Behavior:	Temporarily moves the TTYDISPLAYSTREAM to <i>window</i> , if <i>window</i> is non-NIL, else to the system prompt window.				
	The <i>prompt</i> expression	The <i>promptString</i> is printed followed by a carriage return and the string "The expression read will be EVALuated."			
	NIL, else it returned.	"> " is printed on the same line as the above is printed on a new line. Data entered by the ISPX and LISPXREAD are used so that the IX history list. (See the <i>Lisp Release Notes</i> <i>Manual</i>).	e user is evaluated and entered data is placed		
	disa	en called with a prompt window for a LOOPS ables normal mouse button events in the pro not allow it to close until the prompt is comp	mpting browser and		
Arguments:	promptStrin	g A string to be printed.			
	window	A window where the prompting and readin Defaults to the system prompt window.	ng should occur.		
	sameLine?	If non-NIL, the data is read from the same expression read will be EVALuated."	line as the string "The		
Returns:	The data er	The data entered by the user after it has been evaluated.			
Example:	The command				
$26 \leftarrow (\leftarrow (\$ Winc$	dow) New (PromptEval "Specify new window for object name."))				
	causes the	following to appear in the Prompt Window:			
		new window for object name. ession read will be EVALuated.			
	>				
	Entering				
	'NewWindow				
	after the > causes the following return in the Executive Window.				
	#,(\$& Wir	ndow (NEW0.1Y%:.;h.eN6 . 501))			
(← self PromptForList promptS	tr initialString)		[Method of Window]		
Purpose/Behavior:	Prompts yo	u in prompt window for a list of symbols. If p	prompt window does		

Prompts you in prompt window for a list of symbols. It prompt window does not exist, one is created. Input is terminated by a carriage return. **TTYIN** is used for editing the user's input; see the *Interlisp-D Reference Manual*.

PromptForList disables normal mouse button events in the prompting browser and will not allow it to close until the prompt is completed. Note:

Arguments:	self	Pointer to a window instance.
	promptStr	Displayed in prompt window.
	initialString	Can be used as the default or the first item of the list.
Returns:	The list of w	vords entered in prompt window.
Categories:	Window	
Example:	If (\$ Windov	v1) is a window, then the command
	27←(← (\$ Window1) PromptForList "ENTER THE CODES ")
		prompt ENTER THE CODES to be displayed in an attached dow. The system waits for user input.
(← self PromptForString promp	otStr initialStr)	[Method of Window]
Purpose/Behavior:	Prompts yo one is creat	u in prompt window for a string. If a prompt window does not exist, ed. Input is terminated by a carriage return.
	TTYIN is us <i>Manual</i> .	ed for editing the user's input; see the Interlisp-D Reference
	pro	mptForString disables normal mouse button events in the mpting browser and will not allow it to close until the prompt is npleted.
Arguments:	self	Pointer to a window instance.
	promptStr	Displayed in prompt window.
	initialStr	Can be used as the default or the prefix to the string.
Returns:	The string e	entered in prompt window.
Categories:	Window	
Example:	If (\$ Windov	v1) is a window, then the command
	28←(← (\$ Window1) PromptForString "ENTER THE CODES ")
	causes the prompt wind	prompt ENTER THE CODES to be displayed in an attached dow . The system waits for user input.
(← self PromptForWord prompt	tStr initialWord	a) [Method of Window]
Purpose/Behavior:	Returns (CA	AR (← self PromptForList promptStr initialWord))
Arguments	solf	Evaluates to a window instance

pose/benavior.			
Arguments:	self	Evaluates to a window instance.	
	promptStr	Displayed in prompt window.	
	initialWord	Can be used as the default.	
Returns:	See Behavior.		
Categories:	Window		
Example:	If (\$ Window1) is a window, then the command		
	29←(← (\$	Window1) PromptForWord "NEW WORD ")	
prompts you with NEW WORD in an attached pr		with NEW WORD in an attached prompt window.	

(← self PromptPrint msg)		[Method of Win	idow]
Purpose/Behavior:		nessage in the prompt window associated with the specified ance. Creates the prompt window if it does not exist.	d
Arguments:	self	Evaluates to a window instance.	
	msg	Message displayed.	
Returns:	The messag	ge printed.	
Categories:	Window		
(PromptRead promptString wind	ow sameLine?	?) [Fund	ction]
Purpose:	Prompts for	and reads data.	
Behavior:	Temporarily NIL, else to	moves the TTYDISPLAYSTREAM to <i>window</i> , if <i>window</i> is no the system prompt window.	n-
	the above if	String is printed. The prompt "> " is printed on the same line a sameLine? is non-NIL, else it is printed on a new line. Data th l is read and returned.	as nat
		sts with PromptEval in that the entered data is not placed on t ry list (see the <i>Lisp Release Notes</i> and the <i>Interlisp-D Referer</i>	
	Pro	en called with a prompt window for a LOOPS window mptRead disables normal mouse button events in the prompt wser and will not allow it to close until the prompt is completed	
Arguments:	promptStrin	<i>g</i> A string to be printed.	
	window	A window where the prompting and reading should occur. Defaults to the system prompt window.	
	sameLine?	If non-NIL, the data is read from the same line as the <i>promptString</i> .	
Returns:	The data en	tered by the user.	
(NiceMenu items title)		[Fund	ction]
Purpose:	Provides an	interface to create a menu and displays the menu.	
Behavior:	Varies acco	rding to the arguments.	
	 If <i>items</i> is returns N 	s NIL, prints "No items for <i>title</i> " in the system prompt window a IIL.	nd
	<i>item</i> s, an	s non-NIL, this builds a menu with the TITLE <i>title</i> , with the ITE d with CHANGEOFFSETFLG set to T (see the <i>Interlisp-D</i> <i>e Manual</i>). If the length of <i>items</i> is more than 35, the menu ha columns.	
Arguments:	items	A form that can be placed in the ITEMS field of a menu.	
	title	A value that will be placed in the TITLE field of a menu.	
Returns:	Value deper	nds on the arguments; see Behavior.	

(SelectFile prompts)

[Lambda	NoSpread	Function1
Leannoad	100010000	i anotionij

Purpose: Prompts you for a file name.

Behavior: Takes on unlimited number of arguments and will **PROMPTPRINT** all the arguments.

Builds a menu with the items ***newFile*** and the files found on the variable **FILELST**.

If you select one of the files, that is returned.

If you select ***newFile***, you are prompted to enter a file name. An empty filecoms is built for that file name, and the file name is returned.

newFile has three subitems:

• *newFile*

See Behavior.

loadFile

You are prompted to enter a file name. A search is performed to try to find and load the compiled file. If that is not found, an attempt is made to load the source file. Returns NIL if the file is not found.

hiddenFile

A menu is displayed containing files that are on the variable **LOADEDFILELST** but not on **FILELST**.

Arguments: *prompts* A number of expressions to be printed in the system prompt window.

Returns: Value depends on the arguments; see Behavior.

19.4 Mouse and Menu Functionality

When a LOOPS window is instantiated, its instance variable **window** points to an instance of a Lisp window. This window has several properties set, among which are the following that are described in this section:

- The property **RIGHTBUTTONFN** that is set to **WindowRightButtonFn**.
- The property **BUTTONEVENTFN** that is set to **WindowButtonEventFn**.

This section will also explain the functionality of the above and how menus associated with LOOPS windows operate. For more information on Medley windows, see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*.

Name	Туре	Description
ButtonEventFn	Method	Sends either the message TitleSelection , LeftSelection , or MiddleSelection .
ClearMenuCache	Method	Deletes menus saved on the menus field of a browser.
ItemMenu	Method	Creates a simple one-level menu.
LeftSelection	Method	Triggers functionality when the cursor is in a window and the left button is pressed.

MiddleSelection	Method	Triggers functionality when the cursor is in a window and the middle button is pressed.
RightButtonFn	Method	Sends the message RightSelection.
RightSelection	Method	Triggers functionality when the cursor is in a window and the right button is pressed.
TitleSelection	Method	Triggers functionality when the cursor is in a window's title bar and the left or middle button is pressed.
WhenMenuItemHeld	Method	Displays in the prompt window what happens when option is selected.
WindowButtonEventFn	Function	Invokes the method ButtonEventFn.
WindowRightButtonFn	Function	Invokes the method RightButtonFn.

$(\leftarrow self ButtonEventFn)$

[Method of Window]

[Method of Window]

[Method of Window]

Purpose/Behavior:	If the cursor is not inside of the window pointed to by <i>self</i> , this sends the message TitleSelection to <i>self</i> .	
	If the left mouse button is pressed, this sends the message LeftSelection to <i>self</i> .	
	If the left mid to <i>self</i> .	ddle button is pressed, this sends the message MiddleSelection
Arguments:	self	An instance of a window.
Returns:	Used for sid	e effect only.
Categories:	Window	

(*self* ClearMenuCache)

Purpose/Behavior:Deletes menus saved in any properties of the instance variable menus of a
window. Use this method if you ever change the class variables describing a
menu, and you want the new menu to take effect.Arguments:selfPointer to a window instance.

Returns: self Categories: Window

(← self ItemMenu items title)

Purpose/Behavior:	Creates a simple one-level menu guaranteed not to be more than 750 bits high. A large number of menu options will cause a multiple column menu to be formed.	
Arguments:	self	Pointer to a window instance.
	items	The value of this is passed to the ITEMS field when the menu is created.
	title	The title for the menu's window.
Returns:	A menu.	

Categories:	Window
Example:	The command
	$32 \leftarrow (\leftarrow New (\$ Window))$ ItemMenu '(a b c))
	will create a menu with the three options.
(← self LeftSelection)	[Method of Window]
Purpose/Behavior:	Invokes a number of internal methods of Window . A menu will pop up. The options in the menu will be defined by the class variable LeftButtonItems (or ShiftLeftButtonItems if the Meta key is also pressed). If an option is selected from the menu, a message will be sent to <i>self</i> with a selector as specified by the chosen menu option.
Arguments:	self Pointer to a window instance.
Returns:	Used for side effect only.
Categories:	Window
Specializations:	LatticeBrowser
(← self MiddleSelection)	[Method of Window]
Purpose/Behavior:	Invokes a number of internal methods of Window . A menu will pop up. The options in the menu will be defined by the class variable MiddleButtonItems (or ShiftMiddleButtonItems if the Meta key is also pressed). If an option is selected from the menu, a message will be sent to <i>self</i> with a selector as specified by the chosen menu option.
Arguments:	self Pointer to a window instance.
Categories:	Window
Specializations:	LatticeBrowser
(← <i>self</i> RightSelection)	[Method of Window]
Purpose/Behavior:	Invokes a number of internal methods of Window . A menu will pop up. The options in the menu will be defined by the class variable RightButtonItems . If an option is selected from the menu, a message will be sent to <i>self</i> with a selector as specified by the chosen menu option.
Arguments:	self Pointer to a window instance.
Returns:	The menu.
Categories:	Window
(← <i>self</i> TitleSelection)	[Method of Window]
Purpose/Behavior:	Invokes a number of internal methods of Window . A menu will pop up. The options in the menu will be defined by the class variable TitleItems . If an option is selected from the menu, a message will be sent to <i>self</i> with a selector as specified by the chosen menu option.
Arguments:	self Pointer to a window instance.
Returns:	The choice if selected; else NIL.

Categories:	Window
Specializations:	LatticeBrowser
(← self WhenMenultemHeld iten	n) [Method of Window]
Purpose/Behavior:	Displays in the system prompt window what will happen when the menu item is chosen. The information displayed will either be the help string for the item or the documentation for the method pointed to by the item.
Arguments:	self Pointer to a window instance.
	item The menu item selector.
Returns:	NIL
Categories:	Window
WindowButtonEventFn	[Function]
Purpose/Behavior:	Invokes the method ButtonEventFn.
WindowPightButtonEn	[Function]
WindowRightButtonFn	[Function]
Purpose/Behavior:	Invokes the method RightButtonFn.
(WindowButtonEventFn window	/) [Function]
Purpose/Behavior:	This retrieves the value of the Lisp window property LoopsWindow . It sends the message ButtonEventFn to that window object. If the window object is an instance of NonRectangularWindow or one of its subclasses and if the cursor is not within the icon bitmap, nothing occurs.
	This is invoked automatically by the system when the cursor is inside of a window object and the left or middle mouse button is pressed.
Arguments:	<i>window</i> The window that contained the cursor when the mouse button was pressed.
Returns:	Used for side effect only.
(WindowRightButtonFn window) [Function]
Purpose/Behavior:	This retrieves the value of the Lisp window property LoopsWindow . It sends the message RightButtonFn to that window object. If the window object is an instance of NonRectangularWindow or one of its subclasses and if the cursor is not within the icon bitmap, nothing occurs.
	This is invoked automatically by the system when the cursor is inside of a window object and the left or middle mouse button is pressed.
Arguments:	<i>window</i> The window that contained the cursor when the mouse button was pressed.
Returns:	Used for side effect only.

19.4.1 Menu Item Structure

The default behavior for the methods **LeftSelection**, **MiddleSelection**, and **RightSelection** causes a menu to pop up. The options that will appear in a

menu are defined in various class variables of the window object being selected. (**IconWindows** are an exception). When an option is selected from a menu, a message is sent to the window with no arguments.

The value of the various class variables can be an item list, such as (item1....itemn) where each item can be one of:

• selector

In this case, the *selector* appears in the menu, and it is the selector of the message sent to the window.

• (prompt selector help-string)

In this case, the *prompt* appears in the menu, and *selector* is the selector of the message sent to the window. *help-string* is printed when the cursor is over the item and the mouse is pressed.

 (prompt subitemStructure help-string) where subitemStructure = (defaultSelector itemlist)

This form allows a menu to contain submenus. In this case, the *prompt* appears in the main menu, and *defaultSelector* is the selector of the message sent to the window if the main menu item is selected. *itemlist* defines the submenu behavior.

For example, in the class **Window**, the class variable **LeftButtonItems** has the following value:

((Update (QUOTE Update) "Update window to agree with object IVs"))

The class variable RightButtonItems has the value:

((Close (Close (Close Destroy))) Snap Paint Clear Bury Repaint (Hardcopy (HardcopyToFile HardcopyToPrinter))) Move Shape Shrink)

19.4.2 Caching Menus

When a menu is created by pressing a mouse button on a LOOPS window, the menu is cached on a property of the instance variable **menus** if **menus** has the value T. The name of the property where it is stored has the same name as the class variable that describes the menu. The method **ClearMenuCache** will set these properties to NIL, causing the menus to be deleted from the window instance.

19.5 Subclasses of Window

This section describes the classes **NonRectangularWindow**, **IconWindow**, and **LoopsIcon** and functionality associated with them.

Name	Туре	Description
NonRectangularWindow	Class	Provides the capability for windows to act as icons.
CreateWindow	Method	Creates a window that acts like an icon.
EditIcon	Method	Edits an icon bitmap.
EditMask	Method	Edits a mask bitmap.

[Class]

Invert	Method	Inverts the image of an icon; that is, reverses its black-white pattern.
Shape	Method	Prevents the window from being shaped by calling LoopsHelp.
IconWindow	Class	Provides some menu options for icon windows.
Loopsicon	Class	Provides an icon that is part of the LOOPS user interface.
PutSavedValue	Function	Stores a value. This is called from within browser and inspector menu events.
SavedValue	Function	Retrieves a saved value.

NonRectangularWindow

Description:

MetaClass:

Instance Variables:

Supers:

Provides the capability for windows to act as icons.
Class
Window
icon Allows a bitmap to be used as an icon to be stored in the instance. If the bitMap property is set to a symbol whose value is a bitmap, then that bitmap will be used. The default value is NIL.
mask Allows a bitmap to be used as an icon mask to be stored in the instance. If the bitMap property is set to a symbol whose value is null.

(← self CreateWindow) [Method of NonRectangularWindow] Purpose: Creates a window that acts like an icon. Behavior: Determines if icon and mask or the property bitMap have values. If so, it uses those within a call to ICONW. If not, it sends the messages EditIcon and EditMask. This method is invoked by the system if the instance variable window is not yet bound to a value and it is accessed. Arguments: self A window instance. Value returned from ICONW. Returns: Categories: Window Specializes: Window $(\leftarrow self EditIcon)$ [Method of NonRectangularWindow]

Purpose:	Edits an icon bitmap.		
Behavior:	Calls EDITBM with the value of the instance variable icon and assigns icon to the returned value.		
Arguments:	self	A window instance.	
Returns:	Value returned from EDITBM.		
Categories:	NonRectangularWindow		

(← self EditMask)	[Method of NonRectangularWindow]
Purpose:	Edits a mask bitmap.
Behavior:	Calls EDITBM withthe value of the instance variable mask if it is non-NIL, or a copy of icon , and assigns mask to the returned value.
Arguments:	self A window instance.
Returns:	Value returned from EDITBM.
Categories:	NonRectangularWindow
(← self Invert)	[Method of NonRectangularWindow]
Purpose:	Inverts the image of an icon; that is, reverses its black-white pattern.
Behavior:	Modifies the bitmap of the ICONIMAGE window property of the Lisp window pointed to by <i>self</i> .
Arguments:	self A window instance.
Returns:	Used for side effect only.
Categories:	Window
Specializes:	Window
(← self Shape)	[Method of NonRectangularWindow]
Purpose/Behavior:	Prevents the window from being shaped by calling LoopsHelp .
	This method is provided to restrict the shaping of this class of window, not to provide additional functionality.
Arguments:	self A window instance.
Returns:	Used for side effect only.
Categories:	Window
Specializes:	Window
lconWindow	[Class]
Description:	Provides some menu options for icon windows.
	The menu behavior of this class is different from the class Window in that the item lists are stored on instance variables and not class variables.
MetaClass:	Class
Supers:	NonRectangularWindow
Instance Variables:	RightButtonItems A list that defines the menu that will appear when the right mouse button is pressed when the cursor is in the window. The default value is (Move).
	MiddleButtonItems A list that defines the menu that will appear when the middle mouse button is pressed when the cursor is in the window. The default value is NIL.

LeftButtonItems

A list that defines the menu that will appear when the left mouse button is pressed when the cursor is in the window. The default value is (Move).

ShiftMiddleButtonItems

A list that defines the menu that will appear when the middle mouse button is pressed when the cursor is in the window and the **Meta** key is pressed. The default value is NIL.

ShiftLeftButtonItems

A list that defines the menu that will appear when the left mouse button is pressed when the cursor is in the window and the **Meta** key is pressed. The default value is (Move).

Loopsicon		[Class]
Description:		ts the LOOPS icon which is part of the LOOPS user interface to wsers (see Chapter 10, Browsers).
MetaClass:	Class	
Supers:	NonRecta	ngularWindow
Class Variables:	RightButt	onltems A list that defines the menu that will appear when the right mouse button is pressed when the cursor is in the window. The default value is (Close Move).
	MiddleBu	ttonItems A list that defines the menu that will appear when the middle mouse button is pressed when the cursor is in the window. The default value is (("Browse File" ())).
	LeftButto	nItems A list that defines the menu that will appear when the left mouse button is pressed when the cursor is in the window. The default value is (("Browse Class" ())).
Instance Variables:	savedValu	ue Used by the functions PutSavedValue and SavedValue. The default value is NIL.
	icon	The property bitMap has the value BlackLoopsIconBM. The default value is NIL.
	mask	The property bitMap has the value LoopsIconShadow. The default value is NIL.
(PutSavedValue value)		[Function]
Purpose:	Stores a v	alue. This is called from within browser and inspector menu events.
Behavior:	Loopsico	nstance variable savedValue of the prototype instance of the class n to <i>value</i> . Also sets the top level binding of IT to <i>value</i> ; see the <i>Reference Manual</i> for information on IT .
Arguments:	value	Any arbitrary data.
Returns:	value	
(SavedValue)		[Function]
Purpose:	Retrieves	a saved value.

Behavior/Returns:

Gets the value of the instance variable savedValue of the prototype instance of the class Loopsicon.

19.6 Lisp Windows

The methods in this section define the interface between LOOPS windows and Lisp windows. These methods are used internally by the system, and will rarely be used or specialized by users.

Name	Туре	Description
AttachLispWindow	Method	Gives a LOOPS window a Lisp window.
CreateWindow	Method	Creates a Lisp window.
DetachLispWindow	Method	Forgets about the current Lisp window.
GetWrappedValue	Method	Gets the value wrapped in the active value.
HasLispWindow	Method	Checks if a Lisp window has ever been created for the LOOPS window.
PutWrappedValue	Method	Replaced the value wrapped in the active value.

(<- self AttachLispWindow window)

[Method of Window]

Used to associate a LOOPS window with a Medley window. This detaches any currently attached window before attaching a new one, and fills in the instance variables left , bottom , width , height , and title from the Lisp window.	
self	An instance of a LOOPS window.
window	Must be a window pointer.
Used for side effect only.	
Window	
	any current instance va self window Used for sid

(← self CreateWindow)

[Method of Window]

Purpose/Behavior:	Creates a Lisp window for a LOOPS window but does not open it.	
Arguments:	self	Pointer to a LOOPS window.
Returns:	The window	<i>I</i> .
Categories:	Window	
Specializations:	NonRectan	gularWindow

(← self DetachLispWindow)

achLispWindow)		[Method of Window]
Purpose/Behavior:	Removes t	he pointer from the LOOPS window to the Lisp window.
Arguments:	self	Pointer to a LOOPS window.
Returns:	Used for si	de effect only.

Categories:	Window		
(← self GetWrappedValue conta	ainingObj varN	lame propName type)	[Method of LispWindowAV]
Purpose/Behavior:	Used by the local state of	e system to fetch the Medley window of this active value is not a window, it	from a LOOPS window. If the is made a window.
Arguments:	self	An instance of LispWindowAV.	
	containingC	<i>bj</i> A LOOPS window.	
	varName	Variable associated with the wrapp	bed value.
	propName	Used internally.	
	type	Used internally.	
Returns:	A Lisp wind	ow.	
Categories:	LispWindow	/Av	
Specializes:	LocalStateA	ActiveValue	
(← self HasLispWindow)			[Method of Window]
Purpose/Behavior:	Checks if L	isp window has ever been created fo	or this LOOPS window.
Arguments:	self	A LOOPS window.	
Returns:	The window	v pointer, if one exists; else NIL.	
Categories:	Window		
(← self PutWrappedValue cont	ainingObj varN	Name newvalue propName)	[Method of LispWindowAV]
Purpose/I	Behavior: F	Places the window <i>newvalue</i> as local	state of the active value.
Arguments:	self	An instance of LispWindowAV.	
	containingC	<i>bj</i> A LOOPS window.	
	varName	Variable associated with the wrapp	bed value.
	propName	Used internally.	
	type	Used internally.	
Returns:	The window	v pointer, if one exists.	
Categories:	LispWindow	/AV	
Specializes:	LocalStateA	ActiveValue

20. SYSTEM VARIABLES AND FUNCTIONS

This section describes the following system variables and functions. These variables are set within the file **LOADLOOPS** or when the function **LOADLOOPS** is executed.

Name	Туре	Description
LoopsVersion	Variable	Identifies a release of LOOPS.
LoopsDate	Variable	Identifies the date when the function LOADLOOPS is executed.
FEATURES	Variable	Has the symbol LOOPS added to it when the function LOADLOOPS is evaluated.
LoadLoopsForms	Variable	Contains a list of forms that are evaluated when LOOPS is loaded.
LispUserFilesForLoo	ps	Variable Contains a list of files required by LOOPS.
OptionalLispuserFlle	s Variable	Contains a list of files that is loaded when LOOPS is loaded.
LOOPSDIRECTORY	Variable	Contains the connected directory when LOADLOOPS is loaded.
LOOPSLIBRARYDIRI	ECTORY Variable	Contains the directory where the LOOPS library files reside.
LOOPSUSERSDIREC	TORY Variable	Contains the directory where the LOOPS Users' Modules files reside.
LOOPSUSERSRULES	SDIRECTORY Variable	, Contains the directory where the LOOPS Rules User Module file resides.
LoopsPatchFiles	Variable	Contains a list of LOOPS files that are loaded when LOOPS is loaded.
LOOPSFILES	Variable	Contains a list of LOOPS files that are loaded by the function LOADLOOPS .
ClearAllCaches	Function	Clears all caches used by LOOPS.
ClearAllCaches	Variable	Contains a list of forms that are evaluated within a call to the function ClearAllCaches .

LoopsVersion

[Variable]

Set to uniquely identify a release of LOOPS.

LoopsDate

[Variable]

Set to the value of (DATE) when the function **LOADLOOPS** is evaluated.

FEATURES		[Variable]
	Has the symbol LOOPS added to it when the function LOADLOOPS evaluated. See the <i>Common Lisp: the Language</i> for more information *FEATURES *.	
LoadLoopsForms		[Variable]
	Contains a list of forms that are evaluated when LOOPS is loaded. to NIL using the File Manager command INITVARS (see the <i>Lisp Re</i> <i>Notes</i> and the <i>Interlisp-D Reference Manual</i>).	
LispUserFilesForLoops		[Variable]
	Contains a list of files required by LOOPS. Initialized to (GRAPHER	t).
OptionalLispuserFiles		[Variable]
	Contains a list of files that is loaded when LOOPS is loaded. Initializusing the File Manager command INITVARS .	zed to NIL
LOOPSDIRECTORY		[Variable]
	Initialized to the directory from which the file LOADLOOPS is loaded File Manager command INITVARS .	d using the
		[Variable]
	Contains the directory where the LOOPS library files reside.	
LOOPSUSERSDIRECTORY		[Variable]
	Contains the directory where the LOOPS Users' Modules files reside	э.
	DRY	[Variable]
	Contains the directory where the LOOPS Rules User Module file res	ides.
LoopsPatchFiles		[Variable]
	Contains a list that can be passed to FILESLOAD (see the <i>Lisp Rel</i> <i>Notes</i> and the <i>Interlisp-D Reference Manual</i>) and is used during the LOOPS. Initialized to ((LOAD FROM VALUEOF LOOPSDIRECTO MASTERSCOPE MSPARSE).	loading of
LOOPSFILES		[Variable]
	Contains the list of LOOPS files loaded by LOADLOOPS when build LOOPS sysout.	ding a
(ClearAllCaches)		[Function]
Purpose:	Clears all caches used by LOOPS	

 Behavior:
 In addition to clearing some caches used to speed up method and instance variable lookup, this clears the hash array CLISPARRAY (see the Lisp Release Notes and the Interlisp-D Reference Manual) and sends the ClearMenuCache message to any open LOOPS windows or their icons.

 Returns:
 NIL

 ClearAllCaches
 [Variable]

 Contains a list of forms, each of which is evaluated within a call to the function

ClearAllCaches. Initially set to NIL.

Overview of the Manual

The *Xerox LOOPS Reference Manual* provides a detailed description of all the methods, functions, classes, and other items available in Xerox's Lisp Object-Oriented Programming System, Xerox LOOPS (TM). This manual describes the Lyric/Medley Release of Xerox LOOPS, which runs under the Lyric and Medley (with a small patch) releases of Xerox Lisp.

This manual is for people who are familiar with Xerox LOOPS programming principles, and is not intended to teach you Xerox LOOPS or how to use it. Please contact your LOOPS distributor for information about classes and training material.

Organization of the Manual and How to Use It

This manual is divided into chapters, with most chapters focusing on a particular aspect of Xerox LOOPS. The organization of this manual is similar to the *Interlisp-D Reference Manual*.

A Table of Contents is included at the beginning of the manual to help you find specific material. Chapters that have four levels of headings also have internal Tables of Contents. At the end of the manual, a Glossary is included to define terms within the context of Xerox LOOPS.

All readers should review Chapter 1, Introduction, before referring to specific material.

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type. Optional arguments are indicated by a dash (-).
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a message sending form appears as follows:

(_ self Selector Arg1 Arg2 -)

• Examples appear in the following typeface:

89_(_LOGIN)

• All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Method names often appear in the form ClassName.SelectorName.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

- Purpose: Gives a short statement of what the item does.
- Behavior: Provides the details of how the item operates.
- Arguments: Describes each argument in the following format:

argument Description

- Returns: States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.
- Categories: A way to group related methods. For example, all the methods releated to Masterscope on the class **FileBrowser** have the category Masterscope, not **FileBrowser**. This item appears only for methods.
- Specializes: The next higher class in the class hierarchy that contains a method with the same selector; only appear for methods. For example, **the manual entry for RectangularWindow.Open** would say that it specializes **Window.Open**, since **Window** is the first superclass of **RectangularWindow** that implements a method for **Open**.
- Specializations: The next lower class(es) in the class hierarchy that contains method(s) with the same selector; only appears for methods. For example, the manual entry for **Window.Open** would say that it has a specialization of **RectangularWindow.Open** since **RectangularWindow** is a subclass of **Window** and has its own version of **Open** method.
 - Example: An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See Chapter 18, Reading and Printing, for details.

[This page intentionally left blank]

This file includes notes on conventions for Xerox LOOPS Reference Manual, Koto Release. This manual is packaged with the Xerox LOOPS Release Notes and Xerox LOOPS Library Packages Manual to form one binder, part number 3103310.

Writer: Rosie (Raven) Kontur

Printing Date: <DD> <MM> 1987

Directories and Files

The directory {ERIS}<Doc>LoopsKoto>Ref> contains the files for the manual. This directory has the following subdirectories:

- {ERIS}<Doc>LoopsKoto>Ref>X-Index> contains IMPTR files needed to produce the index as well as the index itself.
- {ERIS}<Doc>LoopsKoto>Ref>Z-ReleaseInfo> contains this file on writing conventions and a file on production details.

Filenames describe the contents of the file. For example, the filename

{ERIS}<Doc>LoopsKoto>Ref>Ch01-Intro.tedit

contains Chapter 1, Introduction.

Some chapters (for example, 5, 10, and 19) have internal tables of contents. Chapter 10, which is the largest chapter and has the most bitmaps, is divided among three files.

Assemble the files in the following order for the manual:

{ERIS}<Doc>LoopsKoto>Ref>A1-TitlePage.tedit ERIS < Doc>LoopsKoto>Ref>A2-TOC.tedit ERIS < Doc>LoopsKoto>Ref>A3-LOF.tedit [ERIS]<Doc>LoopsKoto>Ref>A4-Preface.tedit ERIS <- Doc>LoopsKoto>Ref>Ch01-Intro.tedit [ERIS]<Doc>LoopsKoto>Ref>Ch02-Instances.tedit ERIS < Doc>LoopsKoto>Ref>Ch03-Classes.tedit ERIS < Doc>LoopsKoto>Ref>Ch04-Metaclasses.tedit ERIS}<Doc>LoopsKoto>Ref>Ch05-TOC.tedit ERIS < Doc>LoopsKoto>Ref>Ch05-ActiveValue.tedit ERIS}<Doc>LoopsKoto>Ref>Ch06-Methods.tedit ERIS}<Doc>LoopsKoto>Ref>Ch07-MsgForms.tedit ERIS < Doc>LoopsKoto>Ref>Ch08-IterStmts.tedit ERIS}<Doc>LoopsKoto>Ref>Ch09-Misc.tedit ERIS}<Doc>LoopsKoto>Ref>Ch10-TOC.tedit ERIS < Doc>LoopsKoto>Ref>Ch10a-Browsers1.tedit ERIS < Doc>LoopsKoto>Ref>Ch10b-Browsers2.tedit ERIS < Doc>LoopsKoto>Ref>Ch10c-Browsers3.tedit {ERIS}<Doc>LoopsKoto>Ref>Ch11-Errors.tedit {ERIS}<Doc>LoopsKoto>Ref>Ch12-Breaking.tedit {ERIS}<Doc>LoopsKoto>Ref>Ch13-Editing.tedit {ERIS}<Doc>LoopsKoto>Ref>Ch14-FilePkg.tedit [ERIS]<Doc>LoopsKoto>Ref>Ch15-Masterscope.tedit ERIS < Doc>LoopsKoto>Ref>Ch16-Performance.tedit ERIS < Doc>LoopsKoto>Ref>Ch17-Processes.tedit ERIS < Doc>LoopsKoto>Ref>Ch18-ReadPrint.tedit ERIS}<Doc>LoopsKoto>Ref>Ch19-TOC.tedit ERIS < Doc>LoopsKoto>Ref>Ch19-UserIOPkgs.tedit ERIS < Doc>LoopsKoto>Ref>Ch20-Windows.tedit

{ERIS}<Doc>LoopsKoto>Ref>PndxA-Previous.tedit {ERIS}<Doc>LoopsKoto>Ref>ZZ-Glossary.tedit {ERIS}<Doc>LoopsKoto>Ref>X-Index>Index-Final.tedit

About the Index

Creating a properly formatted index takes a certain amount of work (about 2 hours).

- Type in your Executive (TEDIT (MAKE.IM.INDEX T NIL '(filenames) NIL))
- Save the resulting file in {ERIS}<Doc>LoopsKoto>Ref>RefIndex-Raw.tedit.
- Now start dithering. The task is the change all the separators in the file. For example, the index program returns pages in the form 1.2; 10.5,38; 18.3-4. The Index format we use is in the form 1-2; 10-5; 10-38; 18-3. Unfortunately, you can't make all the necessary changes in a global substitute, since many of the separators are also in the text and the comma requires that you repeat the chapter number. Here goes:
 - -- Fix the commas. Do a Find on a comma (,). Everyhwere a comma occurs in a page number, change it to a semicolon (;) and repeat the chapter number and a dot before the page number. For example, 10.5,38 becomes 10-5; 10-38.
 - -- Fix the dashes. Do a Find on a dash (-). Everyhwere a dash occurs in a page number, delete it and the following page number.
 - -- Fix the period. Except for he form #., you can use a global substitute from a period to a dash (. to -). This takes about 20-30 minutes, as there about 700 substitutions.

I really recommend saving the file at this point.

- Hardcopy the index. Make whatever page breaks and other changes you feel are necessary. Make a final hardcopy and save the file.

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

- (_ self Selector Arg1 Arg2)
- Examples appear in the following typeface:

89_(_LOGIN)

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form ClassName.SelectorName.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

- Purpose: Gives a short statement of what the item does.
- Behavior: Provides the details of how the item operates.
- Arguments: Describes each argument in the following format:
 - argument Description
 - Returns: States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.
- Categories: A way to group related methods. For example, all the methods releated to Masterscope on the class **FileBrowser** have the category Masterscope, not **FileBrowser**. This item appears only for methods.
- Specializes: The next higher class in the class hierarchy that contains a method with the same selector. For example, **RectangularWindow.Open** can specialize **Window.Open**. This appears only for methods.
- Specializations: The next lower class in the class hierarchy that contains a method with the same selector. For example, **Window.Open** is a specialization of **RectangularWindow.Open**. This appears only for methods.
 - Example: An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See Chapter 18, Reading and Printing, for details.

Style Sheet Addenda

Here are some guidelines I used when writing the LOOPS manuals. Items appear in rather random order.

- Avoid contractions.
- Avoid subscripts. Use WORD1 rather than WORD1 to avoid inconsistent line leading.
- Avoid wording that starts "Note that..." or "Notice that...". Either make it a note with correct format or eliminate the "Note that".
- Use semicolons rather than m-dashes.
- Each item in the template starts with an initial capital letter; e.g., "Describes..."
- The arguments are identical in the call and in the argument description.
- Parenthesies appear around expressions and square brackets appear around the name of the functionality.
- The arrow in the expression is the NS character ←, not _. These characters appear similarly when printed, but differently on the screen. See the section, "Special Notes and Cautions," for details.
- A period appears after the word None, after argument descriptions, and Returns: item.
- Items are set to or return T (instead of true).
- Menus contain options, not items or selections.

- You drag (not roll) the mouse to the right of a menu option to see its submenu.
- Use "above" and "below" when referrering to things in the same section, section numbers and names when referrering to things in the same chapter, and chapter numbers and names when referrering to things in another chapter.
- Please study the following style sheet carefully before you start to edit. The various appearances of active value and annotated values are especially crazy making.

These things appear in **bold**: class variables functions instance variables messages methods variables

ActiveValue - specific class/instance active value - general information activeValue - previous implementation of ActiveValue

annotatedValue - data type **AnnotatedValue** - specific class annotated values - general information

Bitmaps, Graphs, and Sketches

Scale for bitmaps is 0.8.

Special Notes and Cautions

Make sure you have changed the underscore to be a left arrow before loading any files. To do this,

- Enter the following commands into your Executive:

```
(GETCHARBITMAP (CHARCODE _) '(MODERN 10 MRR))
(EDITBM IT)
```

- When the bitmap editor apears, delete the underscore and insert the following left arrow:

- Finally, enter the following commands into your Executive to store the pattern:

(PUTCHARBITMAP (CHARCODE _) '(MODERN 10 MRR) IT) (PUTCHARBITMAP (CHARCODE _) '(MODERN 10 BRR) IT) (PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 MRR) IT) (PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 BRR) IT) (PUTCHARBITMAP (CHARCODE _) '(TERMINAL 12 BRR) IT)

This file includes notes on the production of *Xerox LOOPS Reference Manual*, Koto Release. This manual is packaged with the *Xerox LOOPS Release Notes* and *Xerox LOOPS Library Packages Manual* to form one binder, part number 3103310.

Writer: Rosie (Raven) Kontur

Printing Date: <DD> <MM> 1987

Files Needed

To edit or print the manual, make sure you have the following files loaded:

IMTOOLS SKETCH GRAPHER

Fonts Used

{ERIS}<LISP>FONTS>

Modern font 18-point bold 14-point bold 12-point bold 10-point regular 10-point italic 10-point bold

Terminal font 12-point bold 10-point regular 10-point bold

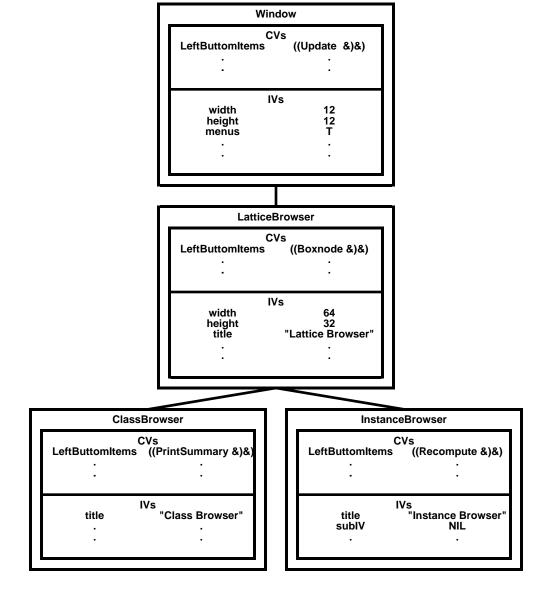

Printing Information

The manual was printed under a Lyric sysout on the Tsunami printer.

Artwork

- The art for the Beta Release was created in Pasadena, and is not in any files here.
- The file {ERIS}<Doc>LoopsBeta>BinderCover.tedit contains the cover page for the binder.
- The file {ERIS}<Doc>LoopsBeta>CommentForm.tedit contains the comment form for the entire documentation set. The prepaid mailer (see department file) must be added to complete this form.

 The details for packaging are in the following files: {ERIS}<Doc>loops>ProductionSpecs>configuration-request.tedit {ERIS}<Doc>loops>ProductionSpecs>Packaging.tedit

- abstract class A class which cannot be instantiated, for example, ActiveValue.
 - active value The mechanism that carries out access-oriented programming for variables in Xerox LOOPS. Active values send messages as a side effect of having an object's variable referenced.
 - activeValue The previous implementation of the active value concept.
- ActiveValue An abstract class that defines the general protocol followed by all active value objects.
- annotatedValue A special Interlisp-D data type that wraps each ActiveValue instance.
- **AnnotatedValue** An abstract class that allows an annotatedValue to be treated as an object.
 - browser A window that allows you to examine and change items in a data structure.
 - class A description of one or more similar objects; that is, objects containing the sames types of data fields and responding to the same messages.
- class inheritance The means by which a class inherits variables, values, and methods from its super class(es).
 - class lattice A network showing the inheritance relationship among classes.
- class variable (CV) A variable that contains information shared by all instances of the class. A class variable is typically used for information about a class taken as a whole.
 - inheritance The means by which you can organize information in objects, create objects that are similar to other objects, and update objects in a simplified way.
 - Inspector A Xerox Lisp display program that has been modified to allow you to view classes, objects, and active values.
 - instance An object described by a particular class. Every object within Xerox LOOPS is an instance of exactly one class.
- instance variable (IV) A variable that contains information specific to an instance.
 - instantiate To make a new instance of a class.
 - lattice An arrangement of nodes in a hierarchical network, which allows for multiple parents of each node.
 - Masterscope A Xerox Lisp Library Module program analysis tool that has been modified to allow analysis of Xerox LOOPS files.
 - message A command sent to an object that activates a method defined in the object's class. The object responds by computing a value that is returned to the sender of the message.
 - metaclass Classes whose instances are classes or abstract classes.
 - method What an object applies to the arguments of a message it receives. This is similar to a procedure in procedure-oriented programming, except that here, you determine the message to send and the object receiving the message determines the method to apply, instead of the calling routine determining which procedure to apply.

- mixin A class that is used in conjunction with another class to create a subclass. Mixins never have instances, and hence have **AbstractClass** as their metaclass.
- object A data structure that contains data and a pointer to functionality that can manipulate the data.
- property list A place for storing additional information on classes, their variables, and their methods.
 - selector Part of a message that is sent to an object. The object uses the selector to determine which method is appropriate to apply to the message arguments.
 - self A method argument that represents the receiver of the message.
- specialization The process of creating a subclass from a class, or the result of that process.
 - subclass A class that is a specialization of another class.
 - super class A class from which a given class inherits variables, values, and methods.
 - Tofu An acronym for Top of the universe, which is the highest class in the Xerox LOOPS hierarchy.
- Unique Identifier (UID) An alphanumeric identifier that Xerox LOOPS uses to store and retrieve objects. Objects do not have UIDs unless they are named, are instances of indexed objects, or are instances printed to a file.
 - wrap Objects have fields that can contain data. Some **ActiveValue** can be added so this data is stored within it. When this occurs, the **ActiveValue** wraps the data.

Text was written and produced with Venue text formatting tools; Xerox printers were used to produce text masters. LOOPS is a multiple-paradigm programming system designed to be used in a variety of artificial intelligence applications. LOOPS requires the Medley Release of Lisp.

1.1 System Configuration

You need the following minimum configuration to run Xerox LOOPS:

1186 Workstation	1108 Workstation
40 megabyte disk drive	40-42 megabyte disk drive
2 megabyte memory	2 megabyte memory

1.2 What's Included in This Release

Xerox LOOPS includes the following items:

• Software on floppy disks.

See Chapter 2, Changes from Koto LOOPS, for how the Lyric/Medley Release of LOOPS is different from the Koto Release.

• Documentation in binders.

See Chapter 3, Release Documentation, for details of release documentation.

This chapter describes how the current release of LOOPS, Lyric/Medley LOOPS, differs from the Koto Release. With the addition of a patch file, the current Loops release will also run under the Medley release. The inclusion of the patch file is automatically handled by the LOOPS installation process. To convert Koto LOOPS files into Lyric/Medley LOOPS files, see the LOOPS Users' Modules CONVERT-LOOPS-FILES.

A number of significant fixes to both the documentation and software have been made. In addition, LOOPS behaves differently due to new features of Lisp found beginning with the Lyric release:

• LOOPS vs. Packages

Lyric has Common Lisp functionality, including packages and new caseinsensitive readtables. All LOOPS symbols are in the INTERLISP: or IL: package, and LOOPS is case-sensitive, so it is much easier to type LOOPS expressions into an Interlisp Exec (see the *Lisp Release Notes, Lyric Release*, for more on different Exec types).

Editing

2.

Lyric has a new default structure editor, SEdit. DEdit is still available as a Lyric Library Module, but most people find SEdit to be much faster and easier to use. SEdit has no specific LOOPS support features yet, but the features it has support LOOPS rather well. As an example, all Lyric LOOPS development was done using SEdit. See the *Lisp Release Notes, Lyric and Medley Releases,* for more information on SEdit.

• Source File Management

LOOPS source forms are no longer LAMBDATRAN forms; instead they use the definer system which also handles Common Lisp forms in Lyric and Medley (see the *Common Lisp Implementation Notes* for more on definers). This has several consequences:

- The source file format for Lyric/Medley LOOPS is different. A conversion utility is provided which takes Koto LOOPS source files and converts them to Lyric/Medley LOOPS format. The converter will not work correctly on source files from the prototype Buttress version of LOOPS. These files must first be converted using Koto LOOPS.
- LOOPS source forms are no longer of filetype FNS; they are instead METHOD-FNS.
- Comments may appear anywhere in a definer form, since the definer system removes them before making the form executable. This also means that various comments that the LOOPS system uses as help information (doc properties and first comments in method code) now need to be strings rather than comments, so the definer system will not remove them. The conversion utility handles this for most important comments; new code should use strings in these places.
- Method bodies can now be CL:LAMBDAs or IL:LAMBDAs, by using the **Method** function and specifying a keyword when creating the method. A LOOPS CL:LAMBDA method can have Common Lisp features like &rest and :keywords.

Masterscope

Masterscope is now a LOOPS Library Module, to match Masterscope becoming a Lisp Library Module in the Lyric release of XAIE, primarily because Masterscope does not support Common Lisp yet. Masterscope still supports LOOPS, however, and many bugs in that support from Buttress and Koto LOOPS have been fixed.

When using LOOPS Masterscope, quote all Method Names that you use. The Masterscope parser currently will not recognize Method Names unless they are quoted.

• ICONW

ICONW is now a part of Lisp and no longer needs to be loaded to run LOOPS.

New Compiler

Lyric/Medley LOOPS uses the new Lyric compiler, which handles Common Lisp. This has several consequences:

- **_Super** and the other similar functions are now lexically scoped; that is, it is now illegal to call **_Super** anywhere but within a method body, and any selector given must be the same as the selector for that method.
- Files compiled by the new compiler have no FILECOMS. Use

(LOADFROM <FILE> NIL 'ALLPROP)

to load Source files so that LOOPS browsers can find them.

- The .DFASL output of the new compiler loads much faster than .DCOMs or the .LCOMs of Lyric.

The ByteCompiler is no longer supported for compilation of LOOPS files. With the new compiler and its macrolet facilities, a cleanup of LOOPS files requires that *DEFAULT-CLEANUP-COMPILER* be set to 'CL:COMPILE-FILE. The *Lisp Release Notes, Lyric Release,* contain more information on the new compiler and the cleanup flag. The ByteCompiler is no longer supported for compilation of LOOPS files.

LOOPS Library Modules

SSDigimeter will be removed from Gauges in the next release of LOOPS. DigiMeters are inherently self scaling because Meters are. Therefore, **SSDigiMeter** is redundant . Note that SSDigiMeters are also generally slower than DigiMeters.

Overview of the Manual

These Release Notes describe the Lyric/Medley Release of software for Xerox's Lisp Object-Oriented Programming System, LOOPS (TM). This document is directed to the people responsible for installing and testing LOOPS.

This manual describes the Lyric/Medley Release of LOOPS, which runs under the Lyric and Medley (with a small patch) Releases of Lisp.

Organization of the Manual and How to Use It

These Release Notes contain important information about the Lyric/Medley Release of LOOPS. The following chapters outline the major features of LOOPS, and highlight the principal differences between this and previous versions of LOOPS.

All readers should carefully read Chapter 1, Release Overview, Chapter 5, Reporting Procedure, and Chapter 6, Known Problems. Reading Chapter 2, Changes from Koto LOOPS, and Chapter 3, Release Documentation, is recommended for all readers. People responsible for installing LOOPS should read Chapter 4, Installation Procedures.

Conventions

These Release Notes use the following conventions:

- Case is significant in LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

 $(\leftarrow self$ Selector Arg1 Arg2)

· Examples appear in the following typeface:

 $89 \leftarrow (\leftarrow \text{LOGIN})$

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

Overview of the Manual

These Release Notes describe the Lyric/Medley Release of software for Xerox's Lisp Object-Oriented Programming System, Xerox LOOPS (TM). This document is directed to the people responsible for installing and testing Xerox LOOPS.

This manual describes the Lyric/Medley Release of Xerox LOOPS, which runs under the Lyric and Medley (with a small patch) Releases of Xerox Lisp.

Organization of the Manual and How to Use It

These Release Notes contain important information about the Lyric/Medley Release of Xerox LOOPS. The following chapters outline the major features of Xerox LOOPS, and highlight the principal differences between this and previous versions of LOOPS.

All readers should carefully read Chapter 1, Release Overview, Chapter 5, Reporting Procedure, and Chapter 6, Known Problems. Reading Chapter 2, Changes form Koto LOOPS, and Chapter 3, Release Documentation, is recommended for all readers. People responsible for installing Xerox LOOPS should read Chapter 4, Installation Procedures.

Conventions

These Release Notes use the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown.
- · Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(_ self Selector Arg1 Arg2)

• Examples appear in the following typeface:

89_(_LOGIN)

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.
- · Cautions describe possible dangers to hardware or software.
- Notes describe related text.

Xerox LOOPS Users' Modules Manual

Interlisp-D Reference Manual

Common Lisp: the Language by Guy Steele

Xerox Common Lisp Implementation Notes, Lyric Release

Xerox Lisp Release Notes, Lyric and Medley Releases

Xerox Lisp Library Modules Manual, Lyric and Medley Release

Xerox LOOPS is a multiple-paradigm programming system designed to be used in a variety of artificial intelligence applications. Xerox LOOPS runs on the Xerox 1100 series of Artificial Intelligence Workstations and requires the Lyric or Medley Release of Lisp running on the Xerox Artificial Intelligence Environment (XAIE).

1.1 System Configuration

You need the following minimum configuration to run Xerox LOOPS:

1186 Workstation	1108 Workstation
40 megabyte disk drive	40-42 megabyte disk drive
2 megabyte memory	2 megabyte memory

1.2 What's Included in This Release

Xerox LOOPS includes the following items:

• Software on floppy disks.

See Chapter 2, Changes from Koto LOOPS, for how the Lyric/Medley Release of Xerox LOOPS is different from the Koto Release.

• Documentation in binders.

See Chapter 3, Release Documentation, for details of release documentation.

This chapter describes how the current release of Xerox LOOPS, Lyric/Medley LOOPS, differs from the Koto Release. The current Xerox LOOPS release runs under the Lyric release of Xerox Lisp. With the addition of a patch file, the current Xerox Loops release will also run under the Xerox Lisp Medley release. The inclusion of the patch file is automatically handled by the LOOPS installation process. To convert Koto LOOPS files into Lyric/Medley LOOPS files, see the Xerox LOOPS Users' Modules CONVERT-LOOPS-FILES.

A number of significant fixes to both the documentation and software have been made. In addition, Xerox LOOPS behaves differently due to new features of Xerox Lisp found beginning with the Lyric release:

• Xerox LOOPS vs. Packages

Lyric has Common Lisp functionality, including packages and new caseinsensitive readtables. All Xerox LOOPS symbols are in the INTERLISP: or IL: package, and Xerox LOOPS is case-sensitive, so it is much easier to type Xerox LOOPS expressions into an Interlisp Exec (see the *Xerox Lisp Release Notes, Lyric Release*, for more on different Exec types).

• Editing

2.

Lyric has a new default structure editor, SEdit. DEdit is still available as a Lyric Library Module, but most people find SEdit to be much faster and easier to use. SEdit has no specific Xerox LOOPS support features yet, but the features it has support Xerox LOOPS rather well. As an example, all Lyric LOOPS development was done using SEdit. See the Xerox Lisp Release Notes, Lyric and Medley Releases, for more information on SEdit.

Source File Management

Xerox LOOPS source forms are no longer LAMBDATRAN forms; instead they use the definer system which also handles Common Lisp forms in Lyric and Medley (see the *Xerox Common Lisp Implementation Notes* for more on definers). This has several consequences:

- The source file format for Lyric/Medley LOOPS is different. A conversion utility is provided which takes Koto LOOPS source files and converts them to Lyric/Medley LOOPS format. The converter will not work correctly on source files from the prototype Buttress version of LOOPS. These files must first be converted using Koto LOOPS.
- Xerox LOOPS source forms are no longer of filetype FNS; they are instead METHOD-FNS.
- Comments may appear anywhere in a definer form, since the definer system removes them before making the form executable. This also means that various comments that the Xerox LOOPS system uses as help information (doc properties and first comments in method code) now need to be strings rather than comments, so the definer system will not remove them. The conversion utility handles this for most important comments; new code should use strings in these places.
- Method bodies can now be CL:LAMBDAs or IL:LAMBDAs, by using the Method function and specifying a keyword when creating the method. A

Xerox LOOPS CL:LAMBDA method can have Common Lisp features like &rest and :keywords.

Masterscope

Masterscope is now a Xerox LOOPS Library Module, to match Masterscope becoming a Xerox Lisp Library Module in the Lyric release of XAIE, primarily because Masterscope does not support Common Lisp yet. Masterscope still supports Xerox LOOPS, however, and many bugs in that support from Buttress and Koto LOOPS have been fixed.

When using LOOPS Masterscope, quote all Method Names that you use. The Masterscope parser currently will not recognize Method Names unless they are quoted.

• ICONW

ICONW is now a part of Xerox Lisp and no longer needs to be loaded to run LOOPS.

• New Compiler

Lyric/Medley LOOPS uses the new Lyric compiler, which handles Common Lisp. This has several consequences:

- **__Super** and the other similar functions are now lexically scoped; that is, it is now illegal to call **__Super** anywhere but within a method body, and any selector given must be the same as the selector for that method.
- Files compiled by the new compiler have no FILECOMS. Use

(LOADFROM <FILE> NIL 'ALLPROP)

to load Source files so that Xerox LOOPS browsers can find them.

- The .DFASL output of the new compiler loads much faster than .DCOMs or the .LCOMs of Lyric.

The ByteCompiler is no longer supported for compilation of LOOPS files. With the new compiler and its macrolet facilities, a cleanup of LOOPS files requires that *DEFAULT-CLEANUP-COMPILER* be set to 'CL:COMPILE-FILE. The Xerox Lisp Release Notes, Lyric Release, contain more information on the new compiler and the cleanup flag. The ByteCompiler is no longer supported for compilation of LOOPS files.

LOOPS Library Modules

SSDigimeter will be removed from Gauges in the next release of LOOPS. DigiMeters are inherently self scaling because Meters are. Therefore, **SSDigiMeter** is redundant . Note that SSDigiMeters are also generally slower than DigiMeters.

This chapter describes the documentation that is part of Xerox LOOPS.

3.1 Xerox LOOPS Reference Manual

3.

This manual provides a detailed description of all the methods, functions, classes, and other items available in Xerox LOOPS. This manual is for people who are already familiar with Xerox LOOPS programming principles.

3.2 Xerox LOOPS Library Modules Manual

This manual describes the Xerox LOOPS Library Modules: Gauges, Masterscope, and Virtual Copies. This manual is for people who want to use the additional features that these Library Modules provide.

3.3 Xerox LOOPS Users' Modules Manual

This manual describes the various Xerox LOOPS Users' Modules. This manual is for people who want to use the additional features that these Users' Modules provide.

This chapter describes how to install the Xerox LOOPS program files, Library Modules program files, and Users' Modules program files on both the 1186 and 1108 workstations. The installation procedure for Xerox LOOPS is the same for both the Lyric and Medley releases.

4.1 Overview of the Distribution Kits

4.

The distribution kits for Xerox LOOPS are different for the 1186 and the 1108.

4.1.1 1186 Distribution Kit

The distribution kit for Xerox LOOPS on the 1186 consists of four 5-1/4" diskettes:

- Lyric/Medley LOOPS System #1, which contains Xerox LOOPS program files.
- Lyric/Medley LOOPS System #2, which contains Xerox LOOPS program files.
- Lyric/Medley LOOPS Library, which contains the program files for the Xerox LOOPS Library Modules.
- Lyric/Medley LOOPS Users, which contains the program files for Xerox LOOPS Users' Modules.

4.1.2 1108 Distribution Kit

The distribution kit for Xerox LOOPS on the 1108 consists of three 8" diskettes:

- Lyric/Medley LOOPS System, which contains Xerox LOOPS program files.
- Lyric/Medley LOOPS Library, which contains the program files for the Xerox LOOPS Library Modules.
- Lyric/Medley LOOPS Users, which contains the program files for Xerox LOOPS Users' Modules.

4.2 Preparation

Before installing Xerox LOOPS, make sure that you have performed the following steps:

 Load the Lyric or Medley version of Xerox Lisp. Have your Lyric or Medley Release Kit handy if you are not on a network, as you may need to load parts of Lyric or Medley Xerox Lisp not previously loaded.

A standard partition of 8 MB is acceptable. A LOOPS sysout with an average number of LISP Library and LOOPS Users' Modules will require about 11,000 pages or 5 MB.

- Boot Xerox Lisp
- Open an Interlisp Executive Window.
- Make certain the time is set.

Machines on a Xerox network automatically get the current time of day from the net when they boot. If you are not on a network, make certain that the function (DATE) returns the current date and time. If it does not, then use the function (SETTIME) to correct it.

CAUTION

Rebooting a VMEM.PURE.STATE sysout without an Ethernet connection and without the time being set will erroneously allow you to create objects without informing you that the time is not set.

4.3 Installation

The Lyric/Medley LOOPS installation tool makes the installation of Xerox LOOPS, its Library Modules, and Users' Modules almost identical for 1186 and 1108 workstations. The differences are in the names of floppies. 1186 floppies are smaller, so there are more of them to hold the same data. The installation tool will determine what workstation you are using and prompt you with the appropriate floppy names.

- 1. Have your Lyric/Medley Release Kit handy, or, if you are connected to a network, set the **DIRECTORIES** and **DISPLAYFONTDIRECTORIES** variables appropriately so the sysout can find your Lyric library and font files.
- 2. Make the floppy drive your connected directory:

CONN {FLOPPY}

DIR {FLOPPY}

3. If you are using an 1108 workstation, insert the floppy labeled *Lyric LOOPS System*. If you are using an 1186 workstation, insert the floppy labeled *Lyric LOOPS System #1*. Enter the following into your Exec:

LOAD(LOOPS)

A menu will appear that looks like this:

Loops System Install from floppies Load into sysout

4. Select the menu option Install from floppies.

The following menu will appear:

Loops directories	Click here when done
LOOPSDIRECTORY	{DSK} <lispfiles>LOOPS></lispfiles>
LOOPSLIBRARYDIRECTORY	{DSK} <lispfiles>LOOPS>LIBRARY></lispfiles>
LOOPSUSERSDIRECTORY	{DSK} <lispfiles>LOOPS>USERS></lispfiles>
LOOPSUSERSRULESDIRECTORY	{DSK} <lispfiles>LOOPS>RULES></lispfiles>

This menu shows the current (or default, if unset) values of the variables LOOPS examines when it loads things.

- If you want LOOPS installed on your local disk under {DSK}<LISPFILES>LOOPS>, just select **Click here when done**. LOOPS requires approximately 2200 pages on the local disk.
- If you want LOOPS installed somewhere else, select the directory names using the left mouse button. Change the directory names by backspacing over them and typing new locations; select **Click here when done** when you are finished.
- 5. The installation tool prompts you for floppies with this menu:

Please insert floppy Lyric LOOPS System Click here when done

It copies the LOOPS files from the floppies to the directories you just specified in the menu.

When the installation tool asks you for a floppy, insert the floppy in the drive, then select **Click here when done**.

As the last installation step, the installation tool modifies the file LOOPS, writes it out to LOOPSDIRECTORY, and compiles it.

When installation is finished, the first menu reappears:

6. Select the menu option **Load into sysout** to load LOOPS into your system. The following menu appears:

Load Which?		
Loops		
Loops Masterscope		
Gauges		
LoopsBackwards		
VirtualCopy		

7. Select **LOOPS** from the menu to load LOOPS from the location where you installed it.

Once LOOPS is loaded the LOOPS System menu reappears. To load one of the other LOOPS library or User modules, select the appropriate name in the Load Which? menu.

8. Position your mouse cursor anywhere on the screen except for the Load Which? menu, then press the left mouse button to exit the installation procedure.

To load LOOPS in the future, after the installation procedure is finished, load the LOOPS.DFASL file which the installation procedure created:

(CNDIR LOOPS DIRECTORY)

(LOAD 'LOOPS.DFASL)

This will load the rest of LOOPS.

When you perform a CNDIR, LOOPS DIRECTORY in the example above is the directory you defined in Step 4; e.g.,

(CNDIR '{DSK}<LISPFILES>LOOPS>)

LISPUSERSDIRECTORIES should point to a directory containing GRAPHER.LCOM, and DISPLAYFONTDIRECTORIES should point to a directory containing the Helvetica display font files from your Lyric or Medley XAIE distribution floppies.

CAUTION

LOOPS uses the new XAIE compiler and its macrolet facilities. When LOOPS is loaded, it sets your ***DEFAULT-CLEANUP-COMPILER*** to **'CL:COMPILE-FILE**. More information on this cleanup flag and the new compiler is available in the *Xerox Lisp Release Notes, Lyric Release*.

If you have problems with this release, file an Action Request (AR) Bug Report.

5.

This chapter is a compilation of known problems in the Lyric/Medley Release of Xerox LOOPS. These problems are in the form of Action Requests (ARs) from the Xerox AR data base, followed by a brief description.

The ARs are divided into the following categories:

Installation

6.

- Instances
- Classes
- MetaClasses
- · Active values
- Browsers
- Breaking and tracing
- File Manager
- Masterscope
- Extensions to ?=
- Windows
- System Variables and Functions
- Xerox LOOPS Library Packages
- Conversion to newer releases

6.1 Installation

1	AR	Description
	10169	During the installation process, if fonts need to be loaded the LOOPS installer will try to write them to the directory on the front (CAR) of the list DISPLAYFONTDIRECTORIES .
		Workaround: Be sure that this is a directory you can write to, e.g. by pushing the name of a local directory onto the list like "{dsk} <lispfiles>fonts>." Grapher is loaded into the current sysout without being copied to a local directory; you may wish to do this and put that directory on your DIRECTORIES list.</lispfiles>

6.2 Instances

AR	Description
9225	The implementation of multiple names for instances has NOT been changed in the Lyric/Medley release of LOOPS. However, some conditions which previously caused instances to appear twice on a file have been fixed.

6.3 Classes AR Description 8881 The Supers MACRO is not documented. It retrieves the supers of the given class. It accepts a class object as an argument and returns a list of class objects. 9134 Caution: ListAttribute (page 3-27) finds non-local IVPROPS on classes. 9881 To use the method CVMissing, it is necessary to define a class called MyClass which is a specialization of the class Class. Then the CVMissing method is specialized at this level (in MyClass). Finally, a class Foo is defined whose metaclass is MyClass. At this point the expression (GetClassValue ((\$ Foo) New) 'NewCV) can be evaluated and a new class variable will be created. 9884 To create a class / instance variable without a value the variable should be set to the value of NotSetValue.

6.4 MetaClasses

A	R	Description
1	0049	A new low level accessor function has been defined for programmers who wish to implement their own inheritance schemes.
		(FetchMethodLocally classobj selector)
		If <i>classobj</i> has a method for <i>selector</i> returns its name, otherwise NIL.

6.5 Active Values

AR	Description
9158	If an IndirectVariable points at an ActiveValue in a remote object then the remote active value's Get or PutWrappedValue method is

triggered with the **containingObj** argument holding the object containing the **IndirectVariable**.

6.6 Browsers		
	AR	Description
	9244	The behavior of LatticeBrowser and ClassBrowser are different for AddRoot.
		Workaround: The example for AddRoot in section 10.5.3 should be changed to:
		The following creates an instance of LatticeBrowser and adds Tofu as a root:
		54_ (_ (\$ LatticeBrowser) New 'LB1) 55_ (_ (\$ LB1) AddRoot 'Tofu)
	9851	Section 10.3.2.7 "Extending Functionality with the Left Mouse Button:" should be modified as follows.
		On the 1186 the COPY key is similar to SHIFT , the MOVE and CTRL keys behave similarly, and META and SAME are similar as well.
	9859	The specialization of LatticeBrowser methods into ClassBrowser methods is not enumerated. In section 10.5 "Programmer's Interface to Lattice Browsers," some methods are described which take different arguments when invoked on Class Browsers, e.g., BoxNode sent to a ClassBrowser does not allow the unboxPrevious flag.
	10010	The documentation for NewItem in section 10.5.3 has the following additional information:
		Purpose: Gets an object, prompting the user if necessary.
		Behavior:to be added. NewItem accepts only names and maps them to objects using \$! . If no name is entered at the prompt (by pressing return), NewItem returns NIL .
	10367	When specializing a method from the class browser, if there are no methods to inherit, other than generic methods from Object , the menu lists methods already defined in the current class. Be careful about specializing methods defined directly under Object .

6.7 Breaking and Trac	ing	
	AR	Description
	10356	BT will not show the send frames for broken methods.
		Workaround: You can do BT! and grab the method name from the *APPLY* frame. Inspect the METHOD-FNS definition of it.

6.8 File Manager

AR	Description
9159	Renaming a method does not smash the associated old symbol's function definition.
9166	Renaming a method does not remove the associated old method- fns definition from the file manager's change list.
10484	CLASS coms compiled by Lyric/Medley LOOPS are combined into a single large form that is read all at once. This causes occasional "Class x not defined, defining one now." messages to appear. Aside from the inconvenience of not seeing the names of classes during compilation, this should not cause problems.

6.9 MasterScope

AR	Description	
9911	When LOOPS MasterScope analyzes forms like	
	(LET* ((A B) (C (F A))))	
	dwim asks about what it thinks is an unbound use of A. Th analysis is correct, however.	e

6.10 Exte	ensions to ?=	
	AR	Description
	9828	?= documentation for the ClassBrowser methods is not available.

AR	Description	
9243	PutSavedValue and SavedValue have not been removed from this release of Xerox LOOPS. We no longer plan to remove them.	
10040	There are two new methods on the Window class:	
	(_ window Open?)	
	returns non-NIL if window is a LOOPS Window and is open.	
	(_ window Shade shade)	
	shades a LOOPS Window if it's open. The <i>shade</i> argument defaults to the value of GRAYSHADE1 .	

6.12 System Variables and Functions

- AR Description
- 9222 The variable LispUserFilesForLoops actually names Lisp Library modules.

6.13 Xerox LOOPS Library Modules

AR	Description
9797	After VirtualCopyMixin classes are "destroyed," instances of them can still be created without an error occurring.
9868	If a gauge is Attach 'ed to one value, and then Attach 'ed to another value the title of the gauge will not change even though the gauge will display the new value.
9871	Sending a Shape message to a Meter with the ExtraSpaceFlag set to T has no effect.

6.14 Conversion to Newer Releases

AR	Description	

10404 There is currently no really convenient way of converting instance files from Buttress into Koto and Lyric/Medley. However, one can load LOOPSBACKWARDS, which modifies the OLD-INTERLISP-FILE readtable to handle the older style instances. Then one can read instances individually from the file and write them into a new file. In the new file they will be correctly formatted in the new manner. [This page intentionally left blank]

1108 distribution kit 7 1186 distribution kit 7 [This page intentionally left blank]

This appendix describes how to install the LOOPS System files, Library Modules files, and Users' Modules files on the Sun Workstation.

Overview of the Distribution Kit

The distribution kit for LOOPS on the Sun consists of a single 1/4-inch tape cartridge. It contains the complete release in "tar" format and creates appropriate directories when its contents are extracted.

Preparation

Preparing to install LOOPS requires that the Medley release of Lisp is already installed and that adequate file space is available.

Before installing LOOPS, remember that

- the Medley 1.0-S release of Lisp must already be installed on your Sun Workstation;
- the complete LOOPS distribution requires about 1.2 MBytes of file space.

Installation

The software installation procedure shows the steps required for installing the Lyric/Medley LOOPS software on a Sun Workstation with Medley 1.0-S already installed. Examples are given where appropriate. Only those users who are system administrators and have **root** privileges can install the LOOPS, Lyric/Medley release.

Before starting software installation, remember that the LOOPS software requires about 1.2 MBytes of file space.

1. Log in under your username.

login yourname

prompt%

where yourname is replaced by your username.

2. Check for available space with the df command:

prompt% df

Filesystem	kbytes	used	avail	capacity	Mounted on
/dev/xy0a	7437	5470	1223	82%	/
/dev/xy0h	148455	4900	128709	96%	/usr/misc

3. Determine if you need to run su to make a directory for the distribution. If so, type in su:

prompt% **su**

4. Make a directory for the distribution. This directory should be named /usr/local/lde/loops. If you have enough space on the file system containing /usr/local/lde, then

prompt# mkdir /usr/local/lde/loops/

If you don't have enough space on /usr/local/lde, go to step 6.

5. Make yourself owner of this directory:

prompt# /etc/chown yourname /usr/local/lde/loops/

where yourname is your username.

6. If you don't have space on the file system which contains /usr/local/lde, but do have space somewhere else, for instance on /usr1, then make the directory there and link /usr/local/lde/loops to it:

prompt# mkdir /usr1/loops

prompt# /etc/chown yourname /usr/usr1/loops

prompt# ln -s /usr1/loops /usr/local/lde/loops

7. If you ran su, leave the privileged shell by typing:

prompt% exit

- 8. Insert the ¹/₄-inch cartridge tape, containing the LOOPS software, in the drive.
- 9. Connect to /usr/local/lde/loops:

prompt# cd /usr/local/lde/loops

10. Load the Medley software from tape. Indicate the appropriate device abbreviation for your tape by replacing **xx** in the example below with

ar for the Archive drive,

st for a SCSI tape drive.

This example shows the command entry sequence:

prompt# tar xvpf /dev/rxx0

As the software is loaded (a process that takes some time) the system prints a series of lines in the following form:

x ./system/LOOPS., 28552 bytes, 56 tape blocks

The x at the beginning of the line indicates that the file is being extracted from the tape.

This creates directories named:

/usr/local/lde/loops/system/

/usr/local/lde/loops/library/

/usr/local/lde/loops/users/

This is a good time to set the protection of the extracted directories and files so that the work group using LOOPS has at least read access to them.

- 11. Boot Medley Lisp.
- 12. Open an Interlisp Executive Window.
- 13. Make certain the time is set correctly.
- 14. Set the **DIRECTORIES** and **DISPLAYFONTDIRECTORIES** variables appropriately so the sysout can find your Lyric/Medley library and font files.
- 15. Make the LOOPS System directory your connected directory:

CONN {DSK}/usr/local/lde/loops/system/

16. Enter the following into your Exec:

LOAD (LOOPS)

A menu appears that looks like this:

Loops system Install from distribution Load into sysout

17. Select the menu option Install from distribution.

The following menu appears:

Loops directories	Click here when done
LOOPSDIRECTORY	{DSK} <lispfiles>LOOPS></lispfiles>
LOOPSLIBRARYDIRECTORY	{DSK} <lispfiles>LOOPS>LIBRARY></lispfiles>
LOOPSUSERSDIRECTORY	{DSK} <lispfiles>LOOPS>USERS></lispfiles>
LOOPSUSERSRULESDIRECTORY	{DSK} <lispfiles>LOOPS>RULES></lispfiles>

This menu shows the current (or default, if unset) values of the variables LOOPS examines when it loads things.

If you have installed LOOPS under /usr/local/lde/loops/ click the mouse on the menu items to set these directories to point where the tape was unloaded:

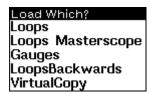

LOOPSDIRECTORY	{dsk}/usr/local/lde/loops/system/
LOOPSLIBRARYDIRECTORY	dsk}/usr/local/lde/loops/library/
LOOPSUSERSDIRECTORY	dsk//usr/local/lde/loops/users/
LOOPSUSERSRULESDIRECTOR	RY {dsk}/usr/local/lde/loops/users/

As the last installation step, the installation tool automatically modifies the file LOOPSSITE, writes it out to **LOOPSDIRECTORY**, and compiles it.

When this setp is finished, the first menu reappears:

Loops system Install from distribution Load into sysout

18. Select the menu option **Load into sysout** to load LOOPS into your system. The following menu appears:

19. Select **LOOPS** from the menu to load LOOPS from the location where you installed it.

Once LOOPS is loaded the LOOPS System menu reappears. To load one of the other LOOPS library or Users' modules, select the appropriate name in the Load Which? menu.

20. Position your mouse cursor anywhere on the screen except for the Load Which? menu, then press the left mouse button to exit the installation procedure.

Lyric/Medley LOOPS is now installed on your Sun Workstation.

Loading After Installation

This section describes how to reload LOOPS into a newly started Lisp sysout after LOOPS has been previously installed.

- 1. Start up Medley on your Sun Workstation.
- 2. Open an INTERLISP Exec window.
- 3. Make sure **DIRECTORIES** points to a directory containing GRAPHER.LCOM, and **DISPLAYFONTDIRECTORIES** points to a directory containing the Helvetica display font files from your Lisp distribution kit.
- 4. Connect to the directory containing the LOOPS system files:

(CNDIR '{DSK}/USR/LOCAL/LDE/LOOPS/SYSTEM/)

5. Load LOOPS loader program:

(FILESLOAD LOADLOOPS)

6. Run the LOOPS loader program:

(LOADLOOPS)

This procedure loads only the LOOPS system files. Please see the manuals describing the LOOPS Library and Users' Modules for their loading procedures.

CAUTION

LOOPS uses the new compiler and its macrolet facilities. When LOOPS is loaded, it sets your ***DEFAULT-CLEANUP-COMPILER*** to **'CL:COMPILE-**

FILE. More information on this cleanup flag and the new compiler is available in the *Lisp Release Notes*, in your Lyric or Medley Lisp kit.

[This page intentionally left blank]

INTRODUCTION TO RULE-ORIENTED PROGRAMMING IN LOOPS

The core of decision-making expertise in many kinds of problem solving can be expressed succinctly in terms of rules. The following sections describe facilities in LOOPS for representing rules, and for organizing knowledge-based systems with rule-oriented programming. The LOOPS rule language provides an experimental framework for developing knowledge-based systems. The rule language and programming environment are integrated with the object-oriented, data-oriented, and procedure-oriented parts of LOOPS.

Rules in LOOPS are organized into production systems (called RuleSets) with specified control structures for selecting and executing the rules. The work space for RuleSets is an arbitrary LOOPS object.

Decision knowledge can be factored from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions. An audit trail records inferential support in terms of the rules and data that were used. Such trails are important for knowledge-based systems that must be able to account for their results. They are also essential for guiding belief revision in programs that need to reason with incomplete information.

1.1 Introduction

1.

Production rules have been used in expert systems to represent decision-making knowledge for many kinds of problem-solving. Such rules (also called *if-then* rules) specify actions to be taken when certain conditions are satisfied. Several rule languages have been developed in the past few years and used for building expert systems. The following sections describe the concepts and facilities for rule-oriented programming in LOOPS.

LOOPS has the following major features for rule-oriented programming:

- (1) Rules in LOOPS are organized into ordered sets of rules (called RuleSets) with specified control structures for selecting and executing the rules. Like subroutines, RuleSets are building blocks for organizing programs hierarchically.
- (2) The work space for rules in LOOPS is an arbitrary LOOPS object. The names of the instance variables provide a name space for variables in the rules.
- (3) Rule-oriented programming is integrated with object-oriented, data-oriented, and procedureoriented programming in LOOPS.
- (4) RuleSets can be invoked in several ways: In the object-oriented paradigm, they can be invoked as methods by sending messages to objects. In the data-oriented paradigm, they can be invoked

as a side-effect of fetching or storing data in active values. They can also be invoked directly from Lisp programs. This integration makes it convenient to use the other paradigms to organize the interactions between RuleSets.

- (5) RuleSets can also be invoked from rules either as predicates on the LHS of rules, or as actions on the RHS of rules. This provides a way for RuleSets to control the execution of other RuleSets.
- (6) Rules can automatically leave an audit trail. An audit trail is a record of inferential support in terms of rules and data that were used. Such trails are important for programs that must be able to account for their results. They can also be used to guide belief revision in programs that must reason with incomplete information.
- (7) Decision knowledge can be separated from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions.
- (8) The rule language provides a concise syntax for the most common operations.
- (9) There is a fast and efficient compiler for translating RuleSets into Interlisp functions.
- (10) LOOPS provides facilities for debugging rule-oriented programs.

The following sections are organized as follows: Section 1.2, "Basic Concepts," outlines the basic concepts of rule-oriented programming in LOOPS. It contains many examples that illustrate techniques of rule-oriented programming. Section 1.3, "Organizing a Rule-Oriented Program," describes the rule syntax, and the remaining sections in this chapter discuss the facilities for creating, editing, and debugging RuleSets in LOOPS.

1.2 Basic Concepts

Rules express the conditional execution of actions. They are important in programming because they can capture the core of decision-making for many kinds of problem-solving. Rule-oriented programming in LOOPS is intended for applications to expert and knowledge-based systems.

The following sections outline some of the main concepts of rule-oriented programming. LOOPS provides a special language for rules because of their central role, and because special facilities can be associated with rules that are impractical for procedural programming languages. For example, LOOPS can save specialized audit trails of rule execution. Audit trails are important in knowledge systems that need to explain their conclusions in terms of the knowledge used in solving a problem. This capability is essential in the development of large knowledge-intensive systems, where a long and sustained effort is required to create and validate knowledge bases. Audit trails are also important for programs that do non-monotonic reasoning. Such programs must work with incomplete information, and must be able to revise their conclusions in response to new information.

1.3 Organizing a Rule-Oriented Program

In any programming paradigm, it is important to have an organizational scheme for composing large systems from smaller ones. Stated differently, it is important to have a method for partitioning large programs into nearly-independent and manageably-sized pieces. In the procedure-oriented paradigm, programs are decomposed into procedures. In the object-oriented paradigm, programs are decomposed into bijects. In the rule-oriented paradigm, programs are decomposed into *RuleSets*. A LOOPS program that uses more than one programming paradigm is factored across several of these dimensions.

There are three approaches to organizing the invocation of RuleSets in LOOPS:

Procedure-oriented Approach. This approach is analogous to the use of subroutines in procedureoriented programming. Programs are decomposed into RuleSets that call each other and return values when they are finished. *SubRuleSets* can be invoked from multiple places. They are used to simplify the expression in rules of complex predicates, generators, and actions.

Object-oriented Approach. In this approach, RuleSets are installed as methods for objects. They are invoked as methods when messages are sent to the objects. The method RuleSets are viewed analogously to other procedures that implement object message protocols. The value computed by the RuleSet is returned as the value of the message sending operation.

Data-oriented Approach. In this approach, RuleSets are installed as access functions in active values. A RuleSet in an active value is invoked when a program gets or puts a value in the LOOPS object. As with active values with Lisp functions for the *getFn* or *putFn*, these RuleSet active values can be triggered by any LOOPS program, whether rule-oriented or not.

These approaches for organizing RuleSets can be combined to control the interactions between bodies of decision-making knowledge expressed in rules. For example, Figure 1 shows the RuleSet of consumer instructions for testing a washing machine. The work space for the ruleSet is a LOOPS object of the class **WashingMachine**. The control structure While1 loops through the rules trying an escalating sequence of actions, starting again at the beginning of some rule is applied. Some rules, called one-shot rules, are executed at most once. These rules are indicated by preceding them with a one in braces ({1}).

```
RuleSet Name: CheckWashingMachine;
WorkSpace Class: WashingMachine;
Control Structure: while1;
While Condition: ruleApplied;
(* What a consumer should do when a washing machine failes.)
IF .Operational THEN (STOP T);
IF load>1.0 THEN .ReduceLoad;
If ~pluggedInTo THEN .PlugIn;
{1} IF pluggedInTo THEN .PlugIn;
{1} IF pluggedInTo:voltage=0 THEN breaker.Reset;
{1} IF pluggedInTo:voltage<110 THEN SPGE.Call;
{1} THEN dealer.RequestService;
{1} THEN manufacturer.Complain;
{1} THEN $ConsumerBoard.Complain;
{1} THEN (STOP T);
```

Figure 1. Basic RuleSet

1.4 Control Structures for Selecting Rules

RuleSets in LOOPS consist of an ordered list of rules and a control structure. Together with the contents of the rules and the data, a RuleSet control structure determines which rules are executed. Execution is determined by the contents of rules in that the conditions of a rule must be satisfied for it to be executed. Execution is also controlled by data in that different values in the data allow different rules to be satisfied. Criteria for iteration and rule selection are specified by a RuleSet control structure. There are two primitive control structures for RuleSets in LOOPS which operate as follows:

before the general rules.

Do1	[RuleSet Control Structure]
	The first rule in the RuleSet whose conditions are satisfied is executed. The value of the RuleSet is the value of the rule. If no rule is executed, the RuleSet returns NIL .
	The Do1 control structure is useful for specifying a set of mutually exclusive actions, since at most one rule in the RuleSet will be executed for a given invocation. When a RuleSet contains rules for

specific and general situations, the specific rules should be placed

[RuleSet	Control	Structure]
----------	---------	------------

Starting at the beginning of the RuleSet, every rule is executed whose conditions are satisfied. The value of the RuleSet is the value of the last rule executed. If no rule is executed, the RuleSet returns **NIL**.

The **DoAll** control structure is useful when a variable number of additive actions are to be carried out, depending on which conditions are satisfied. In a single invocation of the RuleSet, all of the applicable rules are invoked.

Figure 2 illustrates the use of a **Do1** control structure to select one of three mutually exclusive actions.

DoAll

RuleSet Name: SimulateWashingMachine; WorkSpace Class: WashingMachine; Control Structure: Dol ; (* Rules for controlling the wash cycle of a washing machine.) IF controlSetting = 'RegularFabric THEN .Fill .Wash .Pause .SpinAndDrain .SprayAndRinse .SpinAndDrain .Fill. DeepRinse .Pause .DampDry; IF controlSetting = 'PermanentPress THEN .Fill .Wash .Pause .SpinAndPartialDrain .FillCold .SpinAndPartialDrain .FillCold .Pause .SpinAndDrain .FillCold. DeepRinse .Pause .DampDry; IF controlSetting = 'DelicateFabric THEN .FillSoak1 .Agitate .Soak4 .Agitate .Soak1 .SpinAndDrain .SprayAndRinse .SpinAndDrain .Fill .DeepRinse .Pause .DampDry;

Figure 2. RuleSet showing Do1

There are two control structures in LOOPS that specify iteration in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

 While1
 [RuleSet Control Structure]

 This is a cyclic version of Do1. If the while-condition is satisfied, the first rule is executed whose conditions are satisfied. This is

the first rule is executed whose conditions are satisfied. This is repeated as long as the while condition is satisfied or until a **Stop** statement or transfer call is executed (see Section 2.14, "Stop Statements"). The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

WhileAll

[RuleSet Control Structure]

This is a cyclic version of **DoAII**. If the while-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the while condition is satisfied or until a **Stop** statement is executed. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

The "while-condition" is specified in terms of the variables and constants accessible from the RuleSet. The constant **T** can be used to specify a RuleSet that iterates forever (or until a **Stop** statement or transfer is executed). The special variable **ruleApplied** is used to specify a RuleSet that continues as long as some rule was executed in the last iteration. Figure 3 illustrates a simple use of the **WhileAll** control structure to specify a sensing/acting feedback loop for controlling the filling of a washing machine tub with water.

> RuleSet Name: FillTub; WorkSpace Class: WashingMachine; Control Structure: WhileAll ; Temp Vars: waterLimit; WhileCond: Т; (* Rules for controlling the filling of a washing tub with water.) {1!} IF loadSetting = 'Small THEN waterLimit 10; {1!} IF loadSetting = 'Meduim THEN waterLimit 13.5; 1!} IF loadSetting = 'Large THEN waterLimit 17; {1!} IF loadSetting = 'ExtraLarge THEN waterLimit_20; (* Respond to a change of temperature setting at any time.) IF termperatureSetting = 'Hot THEN HotWaterValve.Open ColdWaterValve.Close; IF termperatureSetting = 'Warm THEN HotWaterValve.Open ColdWaterValve.Open; IF termperatureSetting = 'Cold THEN HotWaterValve.Close ColdWaterValve.Open; (* Stop when the water reaches its limit.) IF waterLevelSensor.Test >= waterLimit THEN HotWaterValve.Close ColdWaterValve.Close (Stop T);

> > Figure 3. RuleSet with WhileAll

There are two control structures in LOOPS that specify iteration over a set of elements in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

FOR1	[RuleSet Control Structure]
	This is a cyclic version of Do1 . If the iteration-condition (or while- condition) is satisfied, the first rule is executed whose conditions are satisfied or until a Stop statement is executed. This is repeated as long as the iteration condition is satisfied. The value of the RuleSet is the value of the last rule that was executed, or NIL if no rule was executed.
FORALL	[RuleSet Control Structure]
	This is a cyclic version of DoAll . If the iteration-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the iteration condition is satisfied or until a Stop statement is executed. The value of the RuleSet is the value of the last rule that was executed, or NIL if no rule was executed.

The "iteration-condition" is specified in terms of the variables and constants accessible from the RuleSet. The simplest condition is

(FOR <iterVar> IN <setExpr> DO ruleSet);

The **setExpr** will be parsed with the RuleSet parser. The symbol **ruleSet** is a reserved word, and must be spelled as shown (no changes in capitalization).

Here is an example of iteration:

Control Structure: FORALL; Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO ruleSet);

For each buyer in the list produced by RoadStops, the ruleSet will be run. In a **FOR1**, the iteration will go on to the next buyer as soon as one rule executes. In a **FORALL**, all rules in the RuleSet will be tried.

For nested iteration one can use a slightly more complicated form, as illustrated by the following example:

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO (FOR seller in (RoadStops (\$ Producer)) DO ruleSet)) ;

An experienced Lisp user can see that this resembles the CLISP iteration construct. In fact, except that you can (must) use the RuleSet syntax in the construct, it is the CLISP construct, and any such construct can be used. A DO1 or DOALL ruleSet will be substituted for the occurrence of the atom ruleSet, depending on whether the Control Structure is a FOR1 or FORALL.

As an abbreviation, if the construct does not contain the atom ruleSet, then (DO ruleSet) is appended to the Iteration Condition for a **FOR1** or **FORALL**. Thus one could write the first example as:

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)))

1.5 One-Shot Rules

One of the design objectives of LOOPS is to clarify the rules by factoring out control information whenever possible. This objective is met in part by the declaration of a control structure for RuleSets.

Another important case arises in cyclic control structures in which some of the rules should be executed only once. This was illustrated in the Washing Machine example in Figure 1 where we wanted to prevent the RuleSet from going into an infinite loop of resetting the breaker, when there was a short circuit in the Washing Machine. Such rules are also useful for initializing data for RuleSets as in the example in Figure 3.

In the absence of special syntax, it would be possible to encode the information that a rule is to be executed only once as follows:

Control Structure: While1 Temporary Vars: triedRule3;

•••

IF ~**triedRule3** condition₁ condition₂ **THEN triedRule3_T** action₁;

In this example, the variable **triedRule3** is used to control the rule so that it will be executed at most once in an invocation of a RuleSet. However, the prolific use of rules with such control clauses in large systems has led to the common complaint that control clauses in rule languages defeat the expressiveness and conciseness of the rules. For the case above, LOOPS provides a shorthand notation as follows:

{1} **IF** condition₁ condition₂ **THEN** action₁;

The brace notation means exactly the same thing in the example above, but it more concisely and clearly indicates that the rule executes only once. These rules are called "one shot" or "execute-once" rules.

In some cases, it is desired not only that a rule be executed at most once, but that it be tested at most once. This corresponds to the following:

Control Structure: While1 Temporary Vars: triedRule3;

•••

IF ~triedRule3 triedRule3_T condition₁ condition₂ THEN action₁;

In this case, the rule will not be tried more than once even if some of the conditions fail the first time that it is tested. The LOOPS shorthand for these rules (pronounced "one shot bang") is

{1!} **IF** condition₁ condition₂ **THEN** action₁;

These rules are called "try-once" rules.

The two kinds of one-shot rules are our first examples of the use of meta-descriptions preceding the rule body in braces. See Section 1.7, "Saving an Audit Trail of Rule Invocation," for information on using meta-descriptions for describing the creation of audit trails.

1.6 First/Last Rules

It is sometimes useful to have rules which fire before or after the ordinary part of the RuleSet is invoked, independent of the form of the control structure. For example, in a DO1, such "FIRST " rules could be used for initialization. These now exist, and are notated by putting a $\{F\}$ for a first rule in the MetaDescription field, and a $\{L\}$ for a last rule. If a RuleSet has L rules which execute, the value of the RuleSet is the value of the last rule which executed.

1.7 Saving an Audit Trail of Rule Invocation

A basic property of knowledge-based systems is that they use knowledge to infer new facts from older ones. (Here we use the word "facts" as a neutral term, meaning any information derived or given, that is used by a reasoning system.) Over the past few years, it has become evident that reasoning systems need to keep track not only of their conclusions, but also of their reasoning steps. Consequently, the design of such systems has become an active research area in AI. The audit trail facilities of LOOPS support experimentation with systems that can not only use rules to make inferences, but also keep records of the inferential process itself.

1.7.1 Motivations and Applications

Debugging. In most expert systems, knowledge bases are developed over time and are the major investment. This places a premium on the use of tools and methods for identifying and correcting bugs in knowledge bases. By connecting a system's conclusions with the knowledge that it uses to derive them, audit trails can provide a substantial debugging aid. Audit trails provide a focused means of identifying potentially errorful knowledge in a problem solving context.

Explanation Facilities. Expert systems are often intended for use by people other than their creators, or by a group of people *pooling* their knowledge. An important consideration in validating expert systems is that reasoning should be *transparent*, that is, that a system should be able to give an account of its reasoning process. Facilities for doing this are sometimes called *explanation systems*

and the creation of powerful explanation systems is an active research area in AI and cognitive science. The audit trail mechanism provides an essential computational prerequisite for building such systems.

Belief Revision. Another active research area is the development of systems that can "change their minds". This characteristic is critical for systems that must reason from incomplete or errorful information. Such systems get leverage from their ability to make assumptions, and then to recover from bad assumptions by efficiently reorganizing their beliefs as new information is obtained. Research in this area ranges from work on non-monotonic logics, to a variety of approaches to belief revision. The facilities in the rule language make it convenient to use a user-defined calculus of belief revision, at whatever level of abstraction is appropriate for an application.

1.7.2 Overview of Audit Trail Implementation

When *audit mode* is specified for a RuleSet, the compilation of assignment statements on the righthand sides of rules is altered so that audit records are created as a side-effect of the assignment of values to instance variables. Audit records are LOOPS objects, whose class is specified in RuleSet declarations. The audit records are connected with associated instance variables through the value of the **reason** properties of the variables.

Audit descriptions can be associated with a RuleSet as a whole, or with specific rules. Rule-specific audit information is specified in a property-list format in the meta-description associated with a rule. For example, this can include *certainty factor* information, categories of inference, or categories of support. Rule-specific information overrides RuleSet information.

During rule execution in audit mode, the audit information is evaluated after the rule's LHS has been satisfied and before the rule's RHS is applied. For each rule applied, a single audit record is created and then the audit information from the property list in the rule's meta-description is put into the corresponding instance variables of the audit record. The audit record is then linked to each of the instance variables that have been set on the RHS of the rule by way of the **reason** property of the instance variable.

Additional computations can be triggered by associating active values with either the audit record class or with the instance variables. For example, active values can be specified in the audit record classes in order to define a uniform set of side-effects for rules of the same category. In the following example, such an active value is used to carry out a "certainty factor" calculation.

1.7.3 An Example of Using Audit Trails

The following example illustrates one way to use the audit trail facilities. Figure 4 illustrates a RuleSet which is intended to capture the decisions for evaluating the potential purchase of a washing machine. As with any purchasing situation, this one includes the difficulty of incomplete information about the product. For example in this RuleSet, the reliability of the washing machine is estimated to be 0.5 in the absence of specific information from *Consumer Reports*. The meta-descriptions for the rules, which appear in braces, categorize them in terms of the *basis of belief* (the category *basis* is either a fact or estimate) and a *certainty factor (cf)* that is supposed to measure the "implication power" of the

rule. Within the braces, the variable on the left of the assignment statement is always interpreted as meaning a variable in the audit record, and the variables on the right are always interpreted as variables accessible within the RuleSet. This makes it straightforward to experiment with user-defined audit trails and experimental methods of belief revision. (Realistic belief revision systems are usually more sophisticated than this example.)

The result of running the RuleSet is an evaluation report for each candidate machine. Since the RuleSet was run in audit mode, each entry in the evaluation report is tagged with a reason that points to an audit record. Figure 5 illustrates the evaluation report for one machine and one of its audit records. In this example, each of the entries in the report has a reason and a cumulative certainty (cc) property in addition to the value. The value of the reason properties are audit records created as a side effect of running the RuleSet. The auditing process records the meta-description information of each rule in its audit record. This information can be used later for generating explanations or as a basis for belief revision. The auditing process can have side effects. For example, the active in the **cf** variable or the audit record performs a computation to maintain a calculated cumulative certainty in the reliability variable of the evaluation report.

The meta-descriptions for **basis** and **cf** are saved directly in the audit record. The *certainty factor* calculation in this combines information from the audit description with other information already associated with the object. To do this, the **cf** description triggers an active value inherited by the audit record from its class. This active value computes a *cumulative certainty* in the evaluation report. (Other variations on this idea would include certainty information descriptive of the premises of the rule.)

```

1.8 Comparison with Other Rule Languages

This section considers the rationale behind the design of the LOOPS rule language, focusing on ways that it diverges from other rule languages. In general, this divergence was driven by the following observation:

When a rule is heavy with control information, it obscures the domain knowledge that the rule is intended to convey.

Rules are harder to create, understand, and modify when they contain too much control information. This observation led us to find ways to factor control information out of the rules.

1.8.1 The Rationale for Factoring Meta-Level Syntax

One of the most striking features of the syntax of the LOOPS rule language is the factored syntax for meta-descriptions, which provides information about the rules themselves. Traditional rule languages only factor rules into conditions on the left hand side (LHS) and actions on the right hand side (RHS), without general provisions for meta-descriptions.

Decision knowledge expressed in rules is most perspicuous when it is not mixed with other kinds knowledge, such as control knowledge. For example, the following rule:

IF ~triedRule4 pluggedInTo:voltage=0 THEN triedRule4_T breaker.Reset;

is more obscure than the corresponding one-shot rule from Figure 1:

{1} IF pluggedInTo:voltage=0 THEN breaker.Reset;

which factors the control information (that the rule is to be applied at most once) from the domain knowledge (about voltages and breakers). In the LOOPS rule language, a meta-description (MD) is specified in braces in front of the LHS of a rule. For another example, the following rule from Figure 4:

{(basis_Fact cf_.8)}

IF buyer:familySize>2 machine:capacity<20 THEN suitability_'Poor;

uses an MD to indicate that the rule has a particular **cf** ("certainty factor") and **basis** category for belief support. The MD in this example factors the description of the inference category of the rule from the action knowledge in the rule.

In a large knowledge-based system, a substantial amount of control information must be specified in order to preclude combinatorial explosions. Since earlier rule languages fail to provide a means for factoring meta-information, they must either mix it with the domain knowledge or express it outside the rule language. In the first option, intelligibility is degraded. In the second option, the transparency of the system is degraded because the knowledge is hidden.

1.8.2 The Rationale for RuleSet Hierarchy

Some advocates of production systems have praised the flatness of traditional production systems, and have resisted the imposition of any organization to the rules. The flat organization is sometimes touted as making it *easy to add rules*. The argument is that other organizations diminish the power of pattern-directed invocation and make it more complicated to add a rule.

In designing LOOPS, we have tended to discount these arguments. We observe that there is no inherent property of production systems that can make rules additive. Rather, *additivity* is a consequence of the independence of particular sets of rules. Such independence is seldom achieved in large *sets* of rules. When rules are dependent, rule invocation needs to be carefully ordered.

Advocates of a flat organization tend to organize large programs as a single very large production system. In practice, most builders of production systems have found it essential to create groups of rules.

Grouping of rules in flat systems can be achieved in part by using *context* clauses in the rules. Context clauses are clauses inserted into the rules which are used to alter the flow of control by naming the context explicitly. Rules in the same "context" all contain an extra clause in their conditions that compares the context of the rules with a current context. Other rules redirect control by switching the current context. Unfortunately, this approach does not conveniently lend itself to the reuse of groups of rules by different parts of a program. Although context clauses admit the creation of "subroutine contexts", they require you to explicitly program a stack of return locations in cases where contexts are invoked from more than one place. The decision to use an implicit calling stack for RuleSet invocation in LOOPS is another example of the our desire to simplify the rules by factoring out control information.

1.8.3 The Rationale for RuleSet Control Structures

Production languages are sometimes described as having a *recognize-act cycle*, which specifies how rules are selected for execution. An important part of this cycle is the *conflict resolution strategy*, which specifies how to choose a production rule when several rules have conditions that are satisfied. For example, the **OPS5** production language has a conflict resolution strategy (**MEA**) which prevents rules

from being invoked more than once, prioritizes rules according to the recency of a change to the data, and gives preference to production rules with the most specific conditions.

In designing the rule language for LOOPS, we have favored the use of a small number of specialized control structures to the use of a single complex conflict resolution strategy. In so doing, we have drawn on some control structures in common use in familiar programming languages. For example, **Do1** is like Lisp's **COND**, **DoAII** is like Lisp's **PROG**, **WhileAII** is similar to **WHILE** statements in many programming languages.

The specialized control structures are intended for concisely representing programs with different control relationships among the rules. For example, the **DoAll** control structure is useful for rules whose effects are intended to be additive and the **Do1** control structure is appropriate for specifying mutually exclusive actions. Without some kind of iterative control structure that allows rules to be executed more than once, it would be impossible to write a simulation program such as the washing machine simulation in Figure 1.

We have resisted a reductionist argument for having only one control structure for all programming. For example, it could be argued that the control structure **Do1** is not strictly necessary because any RuleSet that uses **Do1** could be rewritten using **DoAII**. For example, the rules

Control Structure: Do1;

IF $a_1 b_1 c_1$ THEN $d_1 e_1$; IF $a_2 b_2 c_2$ THEN $d_2 e_2$; IF $a_3 b_3 c_3$ THEN $d_3 e_3$;

could be written alternatively as

Control Structure: DoAll; Task Vars: firedSomeRule;

IF $a_1 b_1 c_1$ THEN firedSomeRule_T $d_1 e_1$; IF ~firedSomeRule $a_2 b_2 c_2$ THEN firedSomeRule_T $d_2 e_2$; IF ~firedSomeRule $a_3 b_3 c_3$ THEN firedSomeRule_T $d_3 e_3$;

However, the **Do1** control structure admits a much more concise expression of mutually exclusive actions. In the example above, the **Do1** control structure makes it possible to abbreviate the rule conditions to reflect the assumption that earlier rules in the RuleSet were not satisfied.

For some particular sets of rules the conditions are naturally mutually exclusive. Even for these rules **Do1** can yield additional conciseness. For example, the rules:

Control Structure: Do1;

IF $a_1 b_1 c_1$ THEN $d_1 e_1$; IF $\sim a_1 b_1 c_1$ THEN $d_2 e_2$; IF $\sim a_1 \sim b_1 c_1$ THEN $d_3 e_3$;

can be written as

Control Structure: Do1;

IF $a_1 b_1 c_1$ **THEN** $d_1 e_1$; **IF** $b_1 c_1$ **THEN** $d_2 e_2$; **IF** c_1 **THEN** $d_3 e_3$;

Similarly it could be argued that the **Do1** and **DoAII** control structures are not strictly necessary because such RuleSets can always be written in terms of **While1** and **WhileAII**. Following this reductionism to its end, we can observe that every RuleSet could be re-written in terms of **WhileAII**.

1.8.4 The Rationale for an Integrated Programming Environment

RuleSets in LOOPS are integrated with procedure-oriented, object-oriented, and data-oriented programming paradigms. In contrast to single-paradigm rule systems, this integration has two major benefits. It facilitates the construction of programs which don't entirely fit the rule-oriented paradigm. Rule-oriented programming can be used selectively for representing just the appropriate decision-making knowledge in a large program. Integration also makes it convenient to use the other paradigms to help organize the interactions between RuleSets.

Using the object-oriented paradigm, RuleSets can be invoked as methods for LOOPS objects. Figure 6 illustrates the installation of the RuleSet **SimulateWashingMachineRules** to carry out the **Simulate** method for instances of the class **WashingMachine**. This definition of the class **WashingMachine** specifies that Lisp functions are to be invoked for Fill and Wash messages. For example, the Lisp function **WashingMachine.Fill** is to be applied when a Fill message is received. When a Simulate message is received, the RuleSet **SimulateWashingMachineRules** is to be invoked with the washing machine as its work space. Simulate message to invoke the RuleSet may be sent by any LOOPS program, including other RuleSets.

The use of object-oriented paradigm is facilitated by special RuleSet syntax for sending messages to objects, and for manipulating the data in LOOPS objects. In addition, RuleSets, work spaces, and tasks are implemented as LOOPS objects.

```

(Wash WashingMachine.Wash doc (* Perofrm the wash cycle.))
(Simulate UseRuleSet RuleSet SimulateWashingMachineRules)
.
.
.
]
```

Figure 6. RuleSet Invoked as a Method

Using the data-oriented paradigm, RuleSets can be installed in active values so that they are triggered by side-effect when LOOPS programs get or put data in objects. For example:

```
[DEFINST WashingMachine (StefiksMaytagWasher "uid2")
(controlSetting RegularFabric)
(loadSetting #(Medium NIL RSPut) RSPutFn CheckOverLoadRules)
(waterLevelSensor "uid3")
```

The above code illustrates a RuleSet named **CheckOverLoadRules** which is triggered whenever a program changes the **loadSetting** variable in the **WashingMachine** instance in the figure. This dataoriented triggering can be caused by any LOOPS program when it changes the variable, whether or not that program is written in the rules language.

THE RULE LANGUAGE

This chapter describes the syntax and semantics of the rule language.

2.1 Language Introduction

A rule in LOOPS describes actions to be taken when specified conditions are satisfied. A rule has three major parts called the *left hand side* (LHS) for describing the conditions, the *right hand side* (RHS) for describing the actions, and the *meta-description* (MD) for describing the rule itself. In the simplest case without a meta-description, there are two equivalent syntactic forms:

LHS -> RHS;

IF LHS THEN RHS;

The **If** and **Then** tokens are recognized in several combinations of upper and lower case letters. The syntax for LHSs and RHSs is given below. In addition, a rule can have no conditions (meaning always perform the actions) as follows:

-> RHS;

if T then RHS;

Rules can be preceded by a meta-description in braces as in:

{MD} LHS -> RHS;

{MD} If *LHS* Then *RHS*;

{MD} RHS;

Examples of meta-information include rule-specific control information, rule descriptions, audit instructions, and debugging instructions. For example, the syntax for one-shot rules shown in Section 1.5, "One-Shot Rules:"

{1} IF condition₁ condition₂ THEN action₁;

is an example of a meta-description. Another example is the use of meta-assignment statements for describing audit trails and rules. These statements are discussed in Section 1.7, "Saving an Audit Trail of Rule Invocation."

LHS Syntax: The clauses on the LHS of a rule are evaluated in order from left to right to determine whether the LHS is satisfied. If they are all satisfied, then the rule is satisfied. For example:

2.

A B C+D (Prime D) -> RHS;

In this rule, there are four clauses on the LHS. If the values of some of the clauses are **NIL** during evaluation, the remaining clauses are not evaluated. For example, if **A** is non-**NIL** but **B** is **NIL**, then the LHS is not satisfied and **C+D** will not be evaluated.

RHS Syntax: The RHS of a rule consists of actions to be performed if the LHS of the rule is satisfied. These actions are evaluated in order from left to right. Actions can be the invocation of RuleSets, the sending of LOOPS messages, Interlisp function calls, variables, or special termination actions.

RuleSets always return a value. The value returned by a RuleSet is the value of the last rule that was executed. Rules can have multiple actions on the right hand side. Unless there is a **Stop** statement or transfer call as described later, the value of a rule is the value of the last action. When a rule has no actions on its RHS, it returns **NIL** as its value.

Comments: Comments can be inserted between rules in the RuleSet. They are enclosed in parentheses with an asterisk for the first character as follows:

(* This is a comment)

2.2 Kinds of Variables

LOOPS distinguishes the following kinds of variables:

RuleSet arguments: All RuleSets have the variable **self** as their workspace. References to **self** can often be elided in the RuleSet syntax. For example, the expression **self.Print** means to send a **Print** message to **self**. This expression can be shortened to **.Print**. Other arguments can be defined for RuleSets. These are declared in an **Args:** declaration.

Instance variables: All RuleSets use a LOOPS object for their workSpace. In the LHS and RHS of a rule, the first interpretation tried for an undeclared literal is as an instance variable in the work space. Instance variables can be indicated unambiguously by preceding them with a colon, (e.g., :*varName* or *obj:varName*).

Class variables: Literals can be used to refer to class variables of LOOPS objects. These variables must be preceded by a double colon in the rule language, (e.g., ::*classVarName* or *obj::classVarName*).

Temporary variables: Literals can also be used to refer to temporary variables allocated for a specific invocation of a RuleSet. These variables are initialized to **NIL** when a RuleSet is invoked. Temporary variables are declared in the **Temporary Vars** declaration in a RuleSet.

Audit record variables: Literals can also be used to refer to instance variables of audit records created by rules. These literals are used only in *meta-assignment* statements in the MD part of a rule. They are used to describe the information saved in audit records, which can be created as a side-effect of rule execution. These variables are ignored if a RuleSet is not compiled in *audit* mode. Undeclared variables appearing on the left side of assignment statements in the MD part of a rule are treated as

audit record variables by default. These variables are declared indirectly -- they are the instance variables of the class declared as the *Audit Class* of the RuleSet.

Interlisp variables: Literals can also be used to refer to Interlisp variables during the invocation of a RuleSet. These variables can be global to the Interlisp environment, or are bound in some calling function. Interlisp variables can be used when procedure-oriented and rule-oriented programs are intermixed. Interlisp variables must be preceded by a backSlash in the syntax of the rule language (e.g., *VispVarName*).

Reserved Words: The following literals are treated as read-only variables with special interpretations:

self	[Variable]
	The current work space.
rs	[Variable]
	The current RuleSet.
caller	[Variable]
	The RuleSet that invoked the current RuleSet, or NIL if invoked otherwise.
ruleApplied	[Variable]
	Set to \mathbf{T} if some rule was applied in this cycle. (For use only in while-conditions).
The following reserved words are	intended mainly for use in creating audit trails:

ruleObject		[Variable]
	Variable bound to the object representing the rule itself.	
ruleNumber		[Variable]
	Variable bound to the sequence number of the rule in a F	RuleSet.
ruleLabel		[Variable]
	Variable bound to the label of a rule or NIL .	
reasons		[Variable]
	Variable bound a list of audit records supporting the instavariables mentioned on the LHS of the rule. (Computed time.)	

auditObject	[Va	riable]
	Variable bound to the object to which the reason record will be attached. (Computed at run time.)	÷
auditVarName	[Va	riable]
	Variable bound to the name of the variable on which the rease be attached as a property.	on will

Other Literals: As described later, literals can also refer to Interlisp functions, LOOPS objects, and message selectors. They can also be used in strings and quoted constants.

The determination of the meaning of a literal is done at compile time using the declarations and syntax of RuleSets. The characters used in literals are limited to alphabetic characters and numbers. The first character of a literal must be alphabetic.

The syntax of literals also includes a compact notation for sending unary messages and for accessing instance variables of LOOPS objects. This notation uses *compound literals*. A compound literal is a literal composed of multiple parts separated by a periods, colons, and commas.

2.3 Rule Forms

Quoted Constants: The quote sign is used to indicate constant literals:

a b=3 c='open d=f e='(This is a quoted expression) -> ...

In this example, the LHS is satisfied if **a** is non-**NIL**, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** is the list (**This is a quoted expression**).

Strings: The double quote sign is used to indicate string constants:

IF a b=3 c='open d=f e=="This is a string" THEN (WRITE "Begin configuration task") ... ;

In this example, the LHS is satisfied if **a** is non-**NIL**, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** equal to the string "**This is a string**".

Interlisp Constants: The literals T and NIL are interpreted as the Interlisp constants of the same name.

a (Foo x NIL b) -> x_T ...;

In this example, the function **Foo** is called with the arguments **x**, **NIL**, and **b**. Then the variable **x** is set to **T**.

2.4 Infix Operators and Brackets

To enhance the readability of rules, a few infix operators are provided. The following are infix binary operators in the rule syntax:

+		[Rule Infix Operator]
	Addition.	
<u>++</u>		[Rule Infix Operator]
	Addition modulo 4.	
		[Rule Infix Operator]
	Subtraction.	
		[Rule Infix Operator]
	Subtraction modulo 4.	
*		[Rule Infix Operator]
	Multiplication.	
1		[Rule Infix Operator]
	Division.	
>		[Rule Infix Operator]
	Greater than.	
<		[Rule Infix Operator]
	Less than.	
>=		[Rule Infix Operator]
	Greater than or equal.	
<=		[Rule Infix Operator]
	Less than or equal.	
=		[Rule Infix Operator]
	EQ simple form of equals. Works for ator integers.	ns, objects, and small
~=		[Rule Infix Operator]
	NEQ. (Not EQ.)	

==		[Rule Infix Operator]
	EQUAL long form of equals.	
<<		[Rule Infix Operator]
	Member of a list. (FMEMB)	
the rule syntax	x provides two unary operators as follows:	
		[Rule Unary Operator]
	Minus.	
~		[Rule Unary Operator]
	Not.	

The precedence of operators in rule syntax follows the usual convention of programming languages. For example

1+5*3 = 16

In addition,

and

[3 < 2 + 4] = T

Brackets can be used to control the order of evaluation:

[1+5]*3 = 18

Ambiguity of the minus sign: Whenever there is an ambiguity about the interpretation of a minus sign as a unary or binary operator, the rule syntax interprets it as a binary minus. For example

a-b c d -e [-f] (g -h) (_ (\$ Foo) Move -j) -> ...

In this example, the first and second minus signs are both treated as binary subtraction statements. That is, the first three clauses are (1) **a-b**, (2) **c** and (3) **d-e**. Because the rule syntax allows arbitary spacing between symbols and there is no syntax to separate clauses on the LHS of a rule, the interpretation of "**d** -**e**" is as a single clause (with the subtraction) instead of two clauses. To force the interpretation as a unary minus operator, one must use brackets as illustrated in the next clause. In this clause, the minus sign in the clause [-f] is treated as a unary minus because of the brackets. The minus sign in the function call (**g** -**h**) is treated as unary because there is no preceding argument.

2.5 Interlisp Functions and Message Sending

Calls to Interlisp functions are parenthesized with the function name as the first literal after the left parenthesis. Each expression after the function name is treated as an argument to the function. For example:

a (Prime b) [a -b] -> c (Display b c+4 (Cursor x y) 2) ;

In this example, **Prime**, **Display**, and **Cursor** are interpreted as the names of Interlisp functions. Since the expression **[a -b]** is surrounded by brackets instead of parentheses, it is recognized as meaning **a** minus **b** as opposed to a call to the function **a** with the argument minus **b**. In the example above, the call to the Interlisp function **Display** has four arguments: **b**, **c+4**, the value of the function call **(Cursor x y)**, and **2**.

The use of Interlisp functions is usually outside the spirit of the rule language. However, it enables the use of Boolean expressions on the LHS beyond simple conjunctions. For example:

a (OR (NOT b) x y) z -> ... ;

LOOPS Objects and Message Sending: LOOPS classes and other named objects can be referenced by using the dollar notation. The sending of LOOPS messages is indicated by using a left arrow. For example:

IF cell_(_ (\$ LowCell) Occupied? 'Heavy) THEN (_ cell Move 3 'North);

In the LHS, an **Occupied?** message is sent to the object named **LowCell**. In the message expression on the RHS, there is no dollar sign preceding **cell**. Hence, the message is sent to the object that is the value of the variable **cell**.

For unary messages (i.e., messages with only the selector specified and the implicit argument **self**), a more compact notation is available as described selow.

Unary Message Sending: When a period is used as the separator in a compound literal, it indicates that a unary message is to be sent to an object. (We will alternatively refer to a period as a *dot*.) For example:

tile.Type='BlueGreenCross command.Type='Slide4 -> ... ;

In this example, the object to receive the unary message **Type** is referenced indirectly through the **tile** instance variable in the work space. The left literal is the variable **tile** and its value must be a LOOPS object at execution time. The right literal must be a method selector for that object.

The dot notation can be combined with the dollar notation to send unary messages to named LOOPS objects. For example,

\$Tile.Type='BlueGreenCross ...

In this example, a unary **Type** message is sent to the LOOPS object whose name is **Tile**.

The dot notation can also be used to send a message to the work space of the RuleSet, that is, **self**. For example, the rule

IF scale>7 THEN .DisplayLarge;

would cause a DisplayLarge message to be sent to self. This is an abbreviation for

IF scale>7 THEN self.DisplayLarge;

2.6 Variables and Properties

When a single colon (:) is used in a literal, it indicates access to an instance variable of an object. For example:

tile:type='BlueGreenCross command:type=Slide4 -> ... ;

In this example, access to the LOOPS object is indirect in that it is referenced through an instance variable of the work space. The left literal is the variable **tile**, and its value must be a LOOPS object when the rule is executed. The right literal **type** must be the name of an instance variable of that object. The compound literal **tile:type** refers to the value of the **type** instance variable of the object in the instance variable **tile**.

The colon notation can be combined with the dollar notation to access a variable in a named LOOPS object. For example,

\$TopTile:type='BlueGreenCross ...

refers to the type variable of the object whose LOOPS name is TopTile.

A double colon notation (::) is provided for accessing class variables. For example

truck::MaxGas<45 ::ValueAdded>600 -> ... ;

In this example, **MaxGas** is a class variable of the object bound to **truck**. **ValueAdded** is a class variable of **self**.

A colon-comma notation (:,) is provided for accessing property values of class and instance variables. For example

wire:,capacitance>5 wire:voltage:,support='simulation -> ...

In the first clause, **wire** is an instance variable of the work space and **capacitance** is a property of that variable. The interpretation of the second clause is left to right as usual: (1) the object that is the value of the variable **wire** is retrieved, and (2) the **support** property of the **voltage** variable of that object is retrieved. For properties of class variables

::Wire:,capacitance>5 node::Voltage:,support='simulation -> ...

In the first clause, **wire** is a class variable of the work space and **capacitance** is a property of that variable. In the second clause, **node** is an instance variable bound to some object. **Voltage** is a class variable of that object, and **Support** is a property of that class variable.

The property notation is illegal for ruleVars and lispVars since those variables cannot have properties.

2.7 Computing Selectors and Variable Names

The short notations for instance variables, properties, and unary messages all show the selector and variable names *as they actually appear* in the object.

object.selector object:ivName object::cvName object:varname:,propName

(_ object selector arg₁ arg₂)

For example,

apple:flavor

refers to the **flavor** instance variable of the object bound to the variable **apple**. In Interlisp terminology, this implies implicit quoting of the name of the instance variable (**flavor**).

In some applications it is desired to be able to compute the names. For this, the LOOPS rule language provides analogous notations with an added exclamation sign (!). After the exclamation sign, the interpretation of the variable being evaluated starts over again. For example

apple: !\x

refers to the same thing as **apple:flavor** if the Interlisp variable **x** is bound to **flavor**. The fact that **x** is a Lisp variable is indicated by the backslash. If **x** is an instance variable of **self** or a temporary variable, we could use the notation:

apple:!x

If **x** is a class variable of **self**, we could use the notation:

apple:!::x

All combinations are possible, including:

object.!selector object.!selector object.!::selector object:!ivName object:!cvName object:!varname:,propName

(_! object selector arg₁ arg₂)

2.8 Recursive Compound Literals

Multiple colons or periods can be used in a literal, For example:

a:b:c

means to (1) get the object that is the value of \mathbf{a} , (2) get the object that is the value of the \mathbf{b} instance variable of \mathbf{a} , and finally (3) get the value of the \mathbf{c} instance variable of that object.

Similarly, the notation

a.b:c

means to get the **c** variable of the object returned after sending a **b** message to the object that is the value of the variable **a**. Again, the operations are carried out left to right: (1) the object that is the value of the variable **a** is retrieved, (2) it is sent a **b** message which must return an object, and then (3) the value of the **c** variable of that object is retrieved.

Compound literal notation can be nested arbitrarily deeply.

2.9 Assignment Statements

An assignment statement using a left arrow can be used for setting all kinds of variables. For example,

x_a;

sets the value of the variable \mathbf{x} to the value of \mathbf{a} . The same notation works if \mathbf{x} is a task variable, rule variable, class variable, temporary variable, or work space variable. The right side of an assignment statement can be an expression as in:

x_a*b + 17*(LOG d);

The assignment statement can also be used with the colon notation to set values of instance variables of objects. For example:

y:b_0;

In this example, first the object that is the value of y is computed, then the value of its instance variable **b** is set to **0**.

Properties: Assignment statements can also be used to set property values as in:

box:x:,origin_47 fact:,reason_currentSupport;

Nesting: Assignment statements can be nested as in

a_b_c:d_3;

This statement sets the values of **a**, **b**, and the **d** instance variable of **c** to **3**. The value of an assignment statement itself is the new assigned value.

2.10 Meta-Assignment Statements

Meta-assignment statements are assignment statements used for specifying rule descriptions and audit trails. These statements appear in the MD part of rules.

Audit Trails: The default interpretation of meta-assignment statements for undeclared variables is as audit trail specifications. Each meta-assignment statement specifies information to be saved in audit records when a rule is applied. In the following example from Figure 4, the audit record must have variables named **basis** and **cf**:

{(basis_Fact cf_1.)} IF buyer:familySize>2 machine:capacity<20 THEN suitability_'Poor;

In this example, the RHS of the rule assigns the value of the work space instance variable **suitability** to '**Poor** if the conditions of the rule are satisfied. In addition, if the RuleSet was compiled in *audit* mode, then during RuleSet execution an audit record is created as a side-effect of the assignment. The audit record is attached to the **reason** property of the suitability variable. It has instance variables **basis** and **cf**.

In general, an audit description consists of a sequence of meta-assignment statements. The assignment variable on the left must be an instance variable of the audit record. The class of the audit record is declared in the *Audit Class* declaration of the RuleSet. The expression on the right is in terms of the variables accessible by the RuleSet. If the conditions of a rule are satisfied, an audit record is instantiated. Then the meta-assignment statements are evaluated in the execution context of the RuleSet and their values are put into the audit record. A separate audit record is created for each of the object variables that are set by the rule.

2.11 Push and Pop Statements

A compact notation is provided for pushing and popping values from lists. To push a new value onto a list, the notation _+ is used:

myList_+newItem;

focus:goals_+newGoal;

To pop an item from a list, the _- notation is used:

item_-myList;

nextGoal_-focus:goals;

As with the assignment operator, the push and pop notation works for all kinds of variables and properties. They can be used in conjunction with infix operator << for membership testing.

2.12 Invoking RuleSets

One of the ways to cause RuleSets to be executed is to invoke them from rules. This is used on the LHS of rules to express predicates in terms of RuleSets, and on the RHS of rules to express actions in terms of RuleSets. A short double-dot syntax(..) for this is provided that invokes a RuleSet on a work space:

Rs1..ws1

In this example, the RuleSet bound to the variable **Rs1** is invoked with the value of the variable **ws1** as its work space. The value of the invocation expression is the value returned by the RuleSet. The double-dot syntax can be combined with the dollar notation (\$) to invoke a RuleSet by its LOOPS name, as in

\$MyRules..ws1

which invokes the RuleSet object that has the LOOPS name MyRules.

This form of RuleSet invocation is like subroutine calling, in that it creates an implicit stack of arguments and return addresses. This feature can be used as a mechanism for *meta-control* of RuleSets as in:

IF breaker:status='Open THEN source_\$OverLoadRules..washingMachine;

IF source='NotFound THEN \$ShortCircuitRules..washingMachine;

In this example, two "meta-rules" are used to control the invocation of specialized RuleSets for diagnosing overloads or short circuits.

2.13 Transfer Calls

An important optimization in many recursive programs is the elimination of tail recursion. For example, suppose that the RuleSet A calls B, B calls C, and C calls A recursively. If the first invocation of A must do some more work after returning from B, then it is useful to save the intermediate states of each of the procedures in frames on the calling stack. For such programs, the space allocation for the stack must be enough to accommodate the maximum depth of the calls.

There is a common and special case, however, in which it is unnecessary to save more than one frame on the stack. In this case each RuleSet has no more work to do after invoking the other RuleSets, and the value of each RuleSet is the value returned by the RuleSet that it invokes. RuleSet invocation in this case amounts to the evaluation of arguments followed by a direct transfer of control. We call such invocations transfer calls.

The LOOPS rule language extends the syntax for RuleSet invocation and message sending to provide this as follows:

RS..*ws

The RuleSet **RS** is invoked on the work space **ws**. With transfer calls, RuleSet invocations can be arbitrarily deep without using proportional stack space.

2.14 Stop Statements

To provide premature terminations in the execution of a RuleSet, the Stop statement is provided.

(Stop value)

[RuleSet Statement]

value is the value to be returned by the RuleSet.

[This page intentionally left blank]

Overview of the Manual

This manual describes the Users' Modules for Xerox's Lisp Object-Oriented Programming System, LOOPS (TM), to developers.

Note: Venue does not support LOOPS Users' Modules. However, each Users' Module contains the name and network mailing address of the person who wrote or last modified that module, and the date it was written or last modified.

This manual describes the Lyric/Medley Release of the LOOPS Users' Modules, which run under the Lyric and Medley Releases of Lisp.

Organization of the Manual and How to Use It

This manual is divided into chapters, with each chapter describing a separate Users' Module.

To use the manual, read the chapter that corresponds to the Users' Module you want to use. A general Table of Contents is provided to help you locate specific information.

Conventions

This manual uses the following conventions:

- Case is significant in LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(\leftarrow self Selector Arg1 Arg2)

• Examples appear in the following typeface:

 $89 \leftarrow (\leftarrow \texttt{LOGIN})$

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.

- Methods often appear in the form ClassName.SelectorName.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

USING RULES IN LOOPS

The LOOPS rules language is supported by an integrated programming environment for creating, editing, compiling, and debugging RuleSets. This section describes how to use that environment.

3.1 Creating RuleSets

RuleSets are named LOOPS objects and are created by sending the class **RuleSet** a **New** message as follows:

(_ (\$ RuleSet) New)

After entering this form, the user will be prompted for a LOOPS name as

RuleSet name: RuleSetName

Afterwards, the RuleSet can be referenced using LOOPS dollar sign notation as usual. It is also possible to include the RuleSet name in the **New** message as follows:

(_ (\$ RuleSet) New NIL RuleSetName)

3.2 Editing RuleSets

A RuleSet is created empty of rules. The RuleSet editor is used to enter and modify rules. The editor can be invoked with an **EditRules** message (or **ER** shorthand message) as follows:

(_ RuleSet EditRules)

(_ RuleSet ER)

If a RuleSet is installed as a method of a class, it can be edited conveniently by selecting the **EditMethod** option from a browser containing the class. Alternatively, the **EditMethod** message can be used:

(_ ClassName EditMethod selector)	[Message]
-----------------------------------	-----------

Both approaches to editing retrieve the source of the RuleSet and put the user into the TTYIN or TEdit editor, treating the rule source as text.

Initially, the source is a template for RuleSets as shown in Figure 7. The rules are entered after the comment at the bottom. The declarations at the beginning are filled in as needed and superfluous declarations can be discarded.

```
RuleSet Name: RuleSetName;
WorkSpace Class: ClassName;
Control Structure: doAll;
While Condition: ;
Audit Class: StandardAuditRecord;
Rule Class: Rule;
Task Class:
            ;
Meta Assignments:
                   ;
Temporary Vars:
                ;
Lisp Vars:
            ;
Debug Vars:
Compiler Options: ;
  (* Rules for whatever.
                          Comment goes here.)
```

Figure 7. Initial Template for a RuleSet

You can then edit this template to enter rules and set the declarations at the beginning. In the current version of the rule editor, most of these declarations are left out. If you choose the **EditAllDecls** option in the RuleSet editor menu, the declarations and default values will be printed in full.

The template is only a guide. Declarations that are not needed can be deleted. For example, if there are no temporary variables for this RuleSet, the **Temporary Vars** declaration can be deleted. If the control structure is not one of the **while** control structures, then the **While Condition** declaration can be deleted. If the compiler option **A** is not chosen, then the **Audit Class** declaration can be deleted.

When you leave the editor, the RuleSet is compiled automatically into a Lisp function.

If a syntax error is detected during compilation, an error message is printed and you are given another opportunity to edit the RuleSet.

3.3 Copying RuleSets

Sometimes it is convenient to create new RuleSets by editing a copy of an existing RuleSet. For this purpose, the method **CopyRules** is provided as follows:

(_ oldRuleSet CopyRules newRuleSetName) [Message]

This creates a new RuleSet by some of the information from the pespectives of the old RuleSet. It also updates the source text of the new RuleSet to contain the new name.

3.4 Saving RuleSets on Lisp Files

RuleSets can be saved on Lisp files just like other LOOPS objects. In addition, it is usually useful to save the Lisp functions that result from RuleSet compilation. In the current implementation, these functions have the same names as the RuleSets themselves. To save RuleSets on a file, it is necessary to add two statements to the file commands for the file as follows:

(FNS * MyRuleSetNames) (INSTANCES * MyRuleSetNames)

where **MyRuleSetNames** is a Lisp variable whose value is a list of the names of the RuleSets to be saved.

If RuleSets are methods associated with a class, and they are saved by using (FILES?), then the file package saves the appropriate entries. The user does not have to be concerned with editing the filecoms of the file being made.

3.5 Printing RuleSets

To print a RuleSet without editing it, one can send a **PPRules** or **PPR** message as follows:

(_ RuleSet PPRules)	[Message]

(_ RuleSet PPR) [Message]

A convenient way to make hardcopy listings of RuleSets is to use the function **ListRuleSets**. The files will be printed on the **DEFAULTPRINTINGHOST** as is standard in Interlisp-D. **ListRuleSets** can be given four kinds of arguments as follows:

(ListRuleSets RuleSetName) (ListRuleSets ListOfRuleSetNames) (ListRuleSets ClassName) (ListRuleSets FileName)

In the *ClassName* case, all of the RuleSets that have been installed as methods of the class will be printed. In the last case, all of the RuleSets stored in the file will be printed.

3.6 Running RuleSets from LOOPS

RuleSets can be invoked from LOOPS using any of the usual protocols.

Procedure-oriented Protocol: The way to invoke a RuleSet from LOOPS is to use the RunRS function:

(RunRS RuleSet workSpace arg2 ... argN)

[Function]

workSpace is the LOOPS object to be used as the work space. This is "procedural" in the sense that the RuleSet is invoked by its name. *RuleSet* can be either a RuleSet object or its name.

Object-oriented Protocol: When RuleSets are installed as methods in LOOPS classes, they can be invoked in the usual way by sending a message to an instance of the class. For example, if **WashingMachine** is a class with a RuleSet installed for its **Simulate** method, the RuleSet is invoked as follows:

(_washingMachineInstance Simulate)

Data-oriented Protocol: When RuleSets are installed in active values, they are invoked by side-effect as a result of accessing the variable on which they are installed.

3.7 Installing RuleSets as Methods

RuleSets can also be used as methods for classes. This is done by installing automatically-generated invocation functions that invoke the RuleSets. For example:

[DEFCLASS WashingMachine

```
(MetaClass Class doc (* comment) ...)
...
(InstanceVariables (owner ...))
(Methods
(Simulate RunSimulateWMRules)
(Check RunCheckWMRules
doc (* Rules to Check a washing machine.))
```

...]

When an instance of the class **WashingMachine** receives a **Simulate** message, the RuleSet **SimulateWMRules** will be invoked with the instance as its work space.

To simplify the definition of RuleSets intended to be used as Methods, the function **DefRSM** (for "Define Rule Set as a Method") is provided:

(DefRSM ClassName Selector RuleSetName) [Function]

If the optional argument *RuleSetName* is given, **DefRSM** installs that RuleSet as a method using the *ClassName* and *Selector*. It does this by automatically generating an installation function as a method to invoke the RuleSet. **DefRSM** automatically documents the installation function and the method. If the argument *RuleSetName* is **NIL**, then **DefRSM** creates the

RuleSet object, puts the user into an Editor to enter the rules,

compiles the rules into a Lisp function, and installs the RuleSet as before.

DefRSM can be invoked with the browser as follows:

- Position the cursor over a class in a browser.
- Press the middle mouse button. A menu pops up.
- Select the Add option in this menu, and drag the mouse to the right to display the submenu that includes the "DefRSM" option. You are prompted to enter a selector name.

After a RuleSet has been installed as a method by using **DefRSM**, you can then edit that RuleSet by selecting the "EditMethod" option from the browser editing menu.

3.8 Installing RuleSets in Active Values

Note: The following section and any other references to active values within the rule documentation refer to active values as they were implemented in the Buttress release. The functionality of triggering rules from active values has not been tested using the current implementation of active values. It should work to use the **ExplicitFnActiveValue** class to implement this behavior.

RuleSets can also be used in data-oriented programming so that they are invoked when data is accessed. To use a RuleSet as a *getFn*, the function **RSGetFn** is used with the property **RSGet** as follows:

•••

(InstanceVariables

(myVar #(myVal RSGetFn NIL) RSGet RuleSetName))

••••

RSGetFn is a LOOPS system function that can be used in an active value to invoke a RuleSet in response to a LOOPS get operation (e.g., **GetValue**) is performed. It requires that the name of the RuleSet be found on the **RSGet** property of the item. **RSGetFn** activates the RuleSet using the local state as the work space. The value returned by the RuleSet is returned as the value of the get operation.

To use a RuleSet as a *putFn*, the function **RSPutFn** is used with the property **RSPut** as follows:

....

(InstanceVariables

(myVar #(myVal NIL RSPutFn) RSPut RuleSetName))

••••

RSPutFn is a function that can be used in an active value to invoke a RuleSet in response to a LOOPS put operation (e.g., **PutValue**). It requires that the name of the RuleSet be found on the **RSPut** property of the item. **RSGetFn** activates the RuleSet using the *newValue* from the put

operation as the work space. The value returned by the RuleSet is put into the local state of the active value.

3.9 Tracing and Breaking RuleSets

LOOPS provides breaking and tracing facilities to aid in debugging RuleSets. These can be used in conjunction with the auditing facilities and the rule executive for debugging RuleSets. The following summarizes the compiler options for breaking and tracing:

- **T** Trace if rule is satisfied. Useful for creating a running display of executed rules.
- **TT** Trace if rule is tested.
- **B** Break if rule is satisfied.
- **BT** Break if rule is tested. Useful for stepping through the execution of a RuleSet.

Specifying the declaration **Compiler Options: T**; in a RuleSet indicates that tracing information should be displayed when a rule is satisfied. To specify the tracing of just an individual rule in the RuleSet, the **T** meta-descriptions should be used as follows:

{T} IF cond **THEN** action;

This tracing specification causes LOOPS to print a message whenever the LHS of the rule is tested, or the RHS of the rule is executed. It is also possible to specify that the values of some variables (and compound literals) are to be printed when a rule is traced. This is done by listing the variables in the **Debug Vars** declaration in the RuleSet:

Debug Vars: a a:b a:b.c;

This will print the values of **a**, **a:b**, and **a:b.c** when any rule is traced or broken.

Analogous specifications are provided for breaking rules. For example, the declaration **Compiler Options: B;** indicates that LOOPS is to enter the rule executive (see Section 3.10, "The Rule Exec") after the LHS is satisfied and before the RHS is executed. The rule-specific form:

{B} IF cond **THEN** action;

indicates that LOOPS is to break before the execution of a particular rule.

Sometimes it is convenient in debugging to display the source code of a rule when it is traced or broken. This can be effected by using the **PR** compiler option as in

Compiler Options: T PR;

which prints out the source of a rule when the LHS of the rule is tested and

Compiler Options: B PR;

which prints out the source of a rule when the LHS of a rule is satisfied, and before entering the break.

3.10 The Rule Exec

A Read-Compile-Evaluate-Print loop, called the rule Executive, is provided for the rule language. The rule Executive can be entered during a break by invoking the Lisp function **RE**. During RuleSet execution, the rule executive can be entered by typing **^f** (<control>-f) on the keyboard.

On the first invocation, **RE** prompts the user for a window. It then displays a stack of RuleSet invocations in a menu to the left of this window in a manner similar to the Interlisp-D Break Package. Using the left mouse button in this window creates an Inspector window for the work space for the RuleSet. Using the middle mouse button pretty prints the RuleSet in the default prettyprint window.

In the main rule Executive window, **RE** prompts the user with "**re:**". Anything in the rule language (other than declarations) that is typed to this Executive will be compiled and executed immediately and its value printed out. For example, you may type rules to see whether they execute or variable names to determine their values. For example:

re: trafficLight:color Red re:

this example shows how to get the value of the **color** variable of the **trafficLight** object. If the value of a variable was set by a RuleSet running with auditing, then a **why** question can be typed to the rule executive as follows:

re: why trafficLight:color

IF highLight:color = 'Green farmRoadSensor:cars timer.TL THEN highLight:color _ 'Yellow timer.Start;

Rule 3 of RuleSet LightRules Edited: Conway "13-Oct-82"

re:

The rule executive may be exited by typing **OK**.

3.11 Auditing RuleSets

Two declarations at the beginning of a RuleSet affect the auditing. Auditing is turned on by the compiler option A. The simplest form of this is

Compiler Options: A;

The **Audit Class** declaration indicates the class of the audit record to be used with this RuleSet if it is compiled in *audit* mode.

Audit Class: StandardAuditRecord;

A **Meta Assignments** declaration can be used to indicate the audit description to be used for the rules unless overridden by a rule-specific meta-assignment statement in a meta-descriptor.

Meta Assignments: cf_.5 support_'GroundWff;

3.12 Loading Rules

Set the variable LOOPSUSERSDIRECTORIES to include the directory where the Rules files are stored.

Load the file LOOPSRULES-ROOT.LCOM, which will load the following files from LOOPSUSERSDIRECTORIES:

- LOOPSBACKWARDS.LCOM
- LOOPSMIXIN
- LOOPSRULES.LCOM
- LOOPSRULESP.LCOM
- LOOPSRULESC.LCOM
- LOOPSRULESD.LCOM, which will load the file TTY.LCOM from LISPUSERSDIRECTORIES.

Editing rules will be easier if TEdit is loaded. Loading the Rules does not automatically load TEdit.

3.13 Known Problems

In a rule, the expression \$pipe.ri..\$p compiles to (RunRS (QUOTE (\$ pipe)) (\$ p)), which fails.

Meta-assignment statements cannot handle expressions. This means that statements like {cf $_$.5} work fine, but {validity $_$ 'fact} fails.

A value of 1 in a meta-descriptor statement is always taken to be a one-shot designator. You cannot have a meta-descriptor statement like $\{cf_1\}$. However, the number 1.0 can be used; the meta-descriptor statement, $\{cf_1.0\}$, works.

Rules have not been tested without loading TEdit in order to edit RuleSets.

CONVERT-LOOPS-FILES

By: Bob Bane (Bane.pa@Xerox.com)

5-Feb-88

INTRODUCTION

CONVERT-LOOPS-FILES allows you to convert files from the Koto release of LOOPS to the Medley release. The changes from the Koto release are described in detail in the *LOOPS Release Notes*.

PROCEDURE

To convert Koto LOOPS Files to Lyric/Medley Loops:

- 1. Your files must be from Koto LOOPS. Pre-Koto LOOPS files must first be run through the Buttress->Koto converter in a Koto LOOPS sysout.
- 2. Install and load your Lyric LOOPS sysout. You need to have TEdit loaded, as the converter uses it.
- 3. Load the file CONVERSION-AIDS.DFASL, which defines the function

```
(CONVERT-LOOPS-FILES <list-of-files> <dump-files-p>)
```

where:

<dump-files-p> Determines disposition of files.

- If non-NIL, converted files will be dumped back out immediately.
- If :COMPILE, they will be compiled.
- If :COMPILE/LOAD, they will be compiled and the compiled code loaded.
- 4. Call CONVERT-LOOPS-FILES with the names of the files you want converted and an appropriate option.

Note the following:

- CONVERT-LOOPS-FILES makes more than one pass over the files being converted; the first pass is a TEdit textual change to make the files loadable into Medley LOOPS. If you specify version numbers in your <list-of-files>, these changes will be made in place on your original files.
- The converter doesn't work completely automatically on systems consisting of several files that automatically load themselves with FILES coms; the converter may try to load subfiles before they are converted. It may be necessary to RETURN NIL from the LOAD calls in the break windows that will occur when this problem comes up. Aside from that, the converter works reasonably well, and has been used to convert large LOOPS systems with almost no source code changes from Koto Loops.

LOOPSBACKWARDS

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSBACKWARDS allows you to run files which were previously converted from the Buttress release of LOOPS to the Koto release. Unlike the Koto version of LOOPSBACKWARDS conversion methods for moving files from Buttress LOOPS to Koto LOOPS are included but **not supported**. *We strong recommend that you convert LOOPS source code from Buttress to Koto using the Koto release of LOOPS.* Conversion of Koto LOOPS source code to Lyric LOOPS is done using the CONVERSION-AIDS users' module.

The changes between the Buttress and Koto releases are described in detail in the *LOOPS Release Notes* for the **Koto** release. Old features that are included in LOOPSBACKWARDS are summarized here:

- Many functions that were removed from the Buttress release are defined.
- The messages List and List! are available.
- The operation of old style active values, from the Buttress release, are provided.
- Support for reading old style macros, such as #(localState getFn putFn) or #\$Mumble, is available.

LOOPSBACKWARDS is an unsupported LOOPS users module. It is strongly recommended that it only be used as part of an effort to upgrade very old LOOPS code to newer releases. It will allow very old LOOPS code to run well enough that it can be rewritten for a newer release.

INSTALLATION

LOOPSVCOPY will be automatically loaded by LOOPSBACKWARDS.

FUNCTIONS

LOOPSBACKWARDS includes **ExplicitFnActiveValue** and **DefAVP**. **ExplicitFnActiveValue** allows the user code triggered by Get- or Put- accesses to be stored within functions which are pointed to by instance variables rather than requiring the redefinition of **GetWrappedValue** or **PutWrappedValue**. These functions must have the form specified in the **DefAVP** function.

ExplicitFnActiveValue		[Class]	
Purpose:	Mimics the b	behavior of the Buttress style of active values.	
Behavior:	called, Put-	es to the wrapped variable cause the getFn to be accesses cause putFn to be called. Enables the old /alue to look like the new style without changing any	
	GetWrappe	s called by the ExplicitFnActiveValue dValue method. This method passes to the getFn the defined by DefAVP as described in the LOOPS Users'	
	PutWrappe	s called by the ExplicitFnActiveValue dValue method. This method passes to the putFn the defined by DefAVP as described in the LOOPS Users'	
Instance Variables:	localState	A place for data storage.	
	getFn	The name of a function applied when the active variable is read.	
	putFn	The name of a function applied when the active variable is changed.	
Example:			
32← (← (\$ #,(\$& Bin (bin4) H53.]99 . 521))	
33← (← (\$ #,(\$& Expli	<pre>33← (← (\$ ExplicitFnActiveValue) New 'EFAV1) #,(\$& ExplicitFnActiveValue (DAW0.1Y:.H53.]99 . 522)) 34←(DEFINEQ (PrintOnGet</pre>		
(
35←(←@ (\$ PrintOnGet	EFAV1) get	Fn 'PrintOnGet)	
	36←(← (\$ EFAV1) AddActiveValue (\$ bin4) 'height) #,(\$A #,NestedNotSetValue PrintOnGet NIL)		
37←(←@ (\$ 123	bin4) heig	ght 123)	
38←(@ (\$ b:	in4) height	L)	

I am: #,(\$ EFAV1) 123

(DefAVP fnName putFlg)

[Function]

1 8/		· · · · · · · · · · · · · · · · · · ·	
Purpose:	Creates a template for defining an active value function.		
Behavior:	Creates a template and leaves you in the Interlisp function display editor.		
Arguments:	fnName Name of the function.		
	putFlg	T indicates function is a putFn , NIL indicates a getFn .	
Returns:	The function name on exit from the editor .		
Example:	In each of the following cases the template only is shown. User code is to be added immediately after the comment by using the display editor.		
66←(DefAVP 'AGetFn) AGetFn			
67←PP* AGetFn (AGetFn [LAMBDA (self varName localSt propName activeVal type) (* This is a getFn. The value of this getFn is returned as the value of the enclosing GetValue.) localSt]) (AGetFn)			
68←(DefAVP 'APutFn T) APutFn			
69←PP* APutFn (APutFn [LAMBDA (self varName newValue propName activeVal type) (* This is a putFn. ***NOTE*** The value of this function will be returned as the value of any enclosing PutValue. This usually means that you want to return the value returned by PutLocalState.) (PutLocalState activeVal newValue self varName propName type]) (APutFn)			

LOOPSMIXIN

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSMIXIN defines several small classes that can be mixed into your application classes. It also defines the class **Perspective** and its support classes, which are used in the implementation of LOOPS Rules. Perspectives allow you to view one object as having more than one class at a time; they have not been tested extensively outside of Rules and are known to have major bugs which don't affect Rules, so they are not documented here.

LOOPSMIXIN Classes

DatedObject - Defines the instance variables **created** and **creator** which are set at object creation time to the values of (DATE) and (USERNAME).

NamedObject - Defines the instance variable name and initializes it to an ActiveValue that insures that the LOOPS system name for the containing object is uniquely name; i.e. storing a name for the object in name causes the previous name for the object to be removed with **DeleteObjectName** and the new name for the object to be asserted with **NameEntity**.

GlobalNamedObject - A subclass of NamedObject that works the same way as NamedObject.

ListMetaClass - Specializes the New and DestroyInstance methods to keep a list of all instances of that class in the class property AllInstances for that class.

StrucMeta - A MetaClass useful for creating new classes. Specializes the **New** method to create a Class object by copying the instance variable and class variable descriptions of the current class. Class variables with a non-NIL Local property will not be copied.

TempClass - Specializes the **New** method to always create objects of this class using the **NewTemp** method, insuring that the objects will be temporary objects.

Perspective, Node, Template, TextItem - These classes are used in LOOPS Rules.

Overview of the Manual

This manual describes the Users' Modules for Xerox's Lisp Object-Oriented Programming System, Xerox LOOPS (TM), to developers.

Note: Xerox does not support Xerox LOOPS Users' Modules. However, each Users' Module contains the name and network mailing address of the person who wrote or last modified that module, and the date it was written or last modified.

This manual describes the Lyric/Medley Release of the Xerox LOOPS Users' Modules, which run under the Lyric and Medley Releases of Xerox Lisp.

Organization of the Manual and How to Use It

This manual is divided into chapters, with each chapter describing a separate Users' Module.

To use the manual, read the chapter that corresponds to the Users' Module you want to use. A general Table of Contents is provided to help you locate specific information.

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(_ self Selector Arg1 Arg2)

• Examples appear in the following typeface:

89_(_LOGIN)

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.

- Methods often appear in the form ClassName.SelectorName.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

References

The following books and manuals augment this manual. Xerox LOOPS Reference Manual Xerox LOOPS Release Notes Xerox LOOPS Library Modules Manual Interlisp-D Reference Manual Common Lisp: the Language by Guy Steele Xerox Common Lisp Implementation Notes, Lyric Release Xerox Lisp Release Notes, Lyric Release and Medley Release Xerox Lisp Library Modules Manual, Lyric Release and Medley Release This file includes notes on conventions for Xerox LOOPS Users' Modules Manual, Lyric Beta Release. This manual is packaged in one binder.

Writer: Raven Kontur Brewster

Printing Date: 22 February 1988

Directories and Files

The directory {ERIS}<Doc>Loops>Lyric>Beta>UserMods> contains the files for the manual. This directory has the following subdirectories:

{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Z-ReleaseInfo> contains this file on writing conventions and a file on production details.

Filenames describe the contents of the file. For example, the filename

{ERIS}<Doc>Loops>Lyric>Beta>UserMods>LoopsMixin.tedit

contains the chapter on LoopsMixin.

Assemble the files in the following order for the manual:

- {ERIS}<Doc>Loops>Lyric>Beta>UserMods>A1-TitlePage.tedit
- ERIS < Doc>Loops>Lyric>Beta>UserMods>A2-TOC.tedit
- ERIS <- Doc>Loops>Lyric>Beta>UserMods>A3-Preface.tedit
- ERIS < Doc>Loops>Lyric>Beta>UserMods>Converter.tedit
- ERIS/<Doc>Loops>Lyric>Beta>UserMods>LoopsBackwards.tedit
- {ERIS}<Doc>Loops>Lyric>Beta>UserMods>LoopsMixin.tedit

{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules-A1-TitlePage.tedit {ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules-A2-TOC.tedit

- ERIS </br>
- ERIS/<Doc>Loops>Lyric>Beta>UserMods>Rules1-Intro.tedit
- ERIS < Doc>Loops>Lyric>Beta>UserMods>Rules2-Language.tedit ERIS < Doc>Loops>Lyric>Beta>UserMods>Rules3-Use.tedit
- ERIS <- Doc>Loops>Lyric>Beta>UserMods>RulesA-Convert.tedit

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(_ self Selector Arg1 Arg2)

Examples appear in the following typeface:

89_(LOGIN)

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form ClassName.SelectorName.
- · Cautions describe possible dangers to hardware or software.
- Notes describe related text.

Style Sheet Addenda

Here are some guidelines I used when writing the LOOPS manuals. Items appear in rather random order.

- Avoid contractions.
- Avoid subscripts. Use WORD1 rather than WORD1 to avoid inconsistent line leading.
- Avoid wording that starts "Note that..." or "Notice that...". Either make it a
 note with correct format or eliminate the "Note that".
- Use semicolons rather than m-dashes.
- Each item in the template starts with an initial capital letter; e.g., "Describes..."
- The arguments are identical in the call and in the argument description.
- Parenthesies appear around expressions and square brackets appear around the name of the functionality.
- The arrow in the expression is the NS character ←, not _. These characters appear similarly when printed, but differently on the screen. See the section, "Special Notes and Cautions," for details.
- A period appears after the word None, after argument descriptions, and Returns: item.
- Items are set to or return T (instead of true).
- Menus contain options, not items or selections.
- You drag (not roll) the mouse to the right of a menu option to see its submenu.
- Use "above" and "below" when referrering to things in the same section, section numbers and names when referrering to things in the same chapter, and chapter numbers and names when referrering to things in another chapter.
- Please study the following style sheet carefully before you start to edit. The various appearances of active value and annotated values are especially crazy making.

These things appear in **bold**: class variables functions instance variables messages methods variables ActiveValue - specific class/instance active value - general information activeValue - previous implementation of ActiveValue AnnotatedValue - data type AnnotatedValue - specific class annotated values - general information bitmap data type data type file package filecoms inspector Lisp Library package localState - instance variable non-NIL prettyprints supers list

Paragraph Formatting

Bitmaps, Graphs, and Sketches

Scale for bitmaps is 0.75.

Special Notes and Cautions

Make sure you have changed the underscore to be a left arrow before loading and printing any files. To do this,

- Enter the following commands into your Executive:

```
(GETCHARBITMAP (CHARCODE _) '(MODERN 10 MRR))
(EDITBM IT)
```

- When the bitmap editor apears, delete the underscore and insert the following left arrow:

- Finally, enter the following commands into your Executive to store the pattern:

(PUTCHARBITMAP	(CHARCODE)	'(MODERN 10 MRR) IT)	
(PUTCHARBITMAP	(CHARCODE	_)	'(MODERN 10 BRR) IT)	
(PUTCHARBITMAP	(CHARCODE	_)	'(TERMINAL 10 MRR) I	T)
(PUTCHARBITMAP	(CHARCODE	_)	'(TERMINAL 10 BRR) I	T)
(PUTCHARBITMAP	(CHARCODE	_)	'(TERMINAL 12 BRR) I	T)

CONVERT-LOOPS-FILES

By: Bob Bane (Bane.pa@Xerox.com)

5-Feb-88

INTRODUCTION

CONVERT-LOOPS-FILES allows you to convert files from the Koto release of Xerox LOOPS to the Lyric/Medley release. The changes from the Koto release are described in detail in the *Xerox LOOPS Release Notes*.

PROCEDURE

To Convert Koto LOOPS Files to Lyric/Medley Loops:

- 1. Your files must be from Koto LOOPS. Pre-Koto LOOPS files must first be run through the Buttress->Koto converter in a Koto LOOPS sysout.
- 2. Install and load your Lyric LOOPS sysout. You need to have TEdit loaded, as the converter uses it.
- 3. Load the file CONVERSION-AIDS.DFASL, which defines the function

```
(CONVERT-LOOPS-FILES <list-of-files> <dump-files-p>)
```

where:

<list-of-files> A filename or a list of filenames to be converted.

<dump-files-p> Determines disposition of files.

- If non-NIL, converted files will be dumped back out immediately.
- If :COMPILE, they will be compiled.
- If :COMPILE/LOAD, they will be compiled and the compiled code loaded.
- 4. Call CONVERT-LOOPS-FILES with the names of the files you want converted and an appropriate option.

Note the following:

- CONVERT-LOOPS-FILES makes more than one pass over the files being converted; the first pass is a TEdit textual change to make the files loadable into Lyric/Medley LOOPS. If you specify version numbers in your <list-of-files>, these changes will be made in place on your original files.
- The converter doesn't work completely automatically on systems consisting of several files that automatically load themselves with FILES coms; the converter may try to load subfiles before they are converted. It may be necessary to RETURN NIL from the LOAD calls in the break windows that will occur when this problem comes up. Aside from that, the converter works reasonably well, and has been used to convert large LOOPS systems with almost no source code changes from Koto Loops.

LOOPSBACKWARDS

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSBACKWARDS allows you to run files which were previously converted from the Buttress release of Xerox LOOPS to the Koto release. Unlike the Koto version of LOOPSBACKWARDS conversion methods for moving files from Buttress LOOPS to Koto LOOPS are included but **not supported**. We strong recommend that you convert LOOPS source code from Buttress to Koto using the Koto release of LOOPS. Conversion of Koto LOOPS source code to Lyric LOOPS is done using the CONVERSION-AIDS users' module.

The changes between the Buttress and Koto releases are described in detail in the *Xerox LOOPS Release Notes* for the **Koto** release. Old features that are included in LOOPSBACKWARDS are summarized here:

- Many functions that were removed from the Buttress release are defined.
- The messages List and List! are available.
- The operation of old style active values, from the Buttress release, are provided.
- Support for reading old style macros, such as #(localState getFn putFn) or #\$Mumble, is available.

LOOPSBACKWARDS is an unsupported LOOPS users module. It is strongly recommended that it only be used as part of an effort to upgrade very old LOOPS code to newer releases. It will allow very old LOOPS code to run well enough that it can be rewritten for a newer release.

INSTALLATION

LOOPSVCOPY will be automatically loaded by LOOPSBACKWARDS.

FUNCTIONS

LOOPSBACKWARDS includes **ExplicitFnActiveValue** and **DefAVP**. **ExplicitFnActiveValue** allows the user code triggered by Get- or Put- accesses to be stored within functions which are pointed to by instance variables rather than requiring the redefinition of **GetWrappedValue** or **PutWrappedValue**. These functions must have the form specified in the **DefAVP** function.

Purpose:	ehavior of the Buttress style of active values.					
Behavior: Get- accesses to the wrapped variable cause the g called, Put- accesses cause putFn to be called. Ena style activeValue to look like the new style without ch functionality.						
	The getFn is called by the ExplicitFnActiveValu GetWrappedValue method. This method passes to the getFn th arguments defined by DefAVP as described in the <i>Xerox LOOP</i> <i>Users' Modules</i> .					
	The putFn is called by the ExplicitFnA PutWrappedValue method. This method passes to the arguments defined by DefAVP as described in the Xer Users' Modules.					
Instance Variables:	localState	A place for data storage.				
	getFn	The name of a function applied when the active variable is read.				
	putFn	The name of a function applied when the active variable is changed.				
Example:						
32_ (_ (\$ Bin) New 'bin4) #,(\$& Bin (DAW0.1Y:.H53.]99 . 521))						
33_ (_ (\$ E: #,(\$& Expli	33_ (_ (\$ ExplicitFnActiveValue) New 'EFAV1) #,(\$& ExplicitFnActiveValue (DAW0.1Y:.H53.]99 . 522))					
	34_(DEFINEQ (PrintOnGet (self varName localSt propName activeVal type) (PRINTOUT T "I am:" , activeVal T) localSt)) (PrintOnGet)					
35_(_@ (\$ E PrintOnGet	FAV1) getFr	n 'PrintOnGet)				
		tiveValue (\$ bin4) 'height) alue PrintOnGet NIL)				
37_(_@ (\$ b. 123	in4) height	= 123)				
38_(@ (\$ bi:	123 38_(@ (\$ bin4) height)					

I am: #,(\$ EFAV1) 123

(**DefAVP** *fnName putFlg*)

[Function]

Purpose:	Creates a template for defining an active value function.	
Behavior:	Creates a template and leaves you in the Interlisp function display editor.	
Arguments:	fnName	Name of the function.
	putFlg	T indicates function is a putFn , NIL indicates a getFn .
Returns:	The function name on exit from the editor .	
Example:	In each of the following cases the template only is shown. User code is to be added immediately after the comment by using the display editor.	
66_(DefAVP 'AGetFn) AGetFn		
<pre>67_PP* AGetFn (AGetFn [LAMBDA (self varName localSt propName activeVal type)</pre>		
68_(DefAVP 'APutFn T) APutFn		
69_PP* APutFn (APutFn [LAMBDA (self varName newValue propName activeVal type) (* This is a putFn. ***NOTE*** The value of this function will be returned as the value of any enclosing PutValue. This usually means that you want to return the value returned by PutLocalState.) (PutLocalState activeVal newValue self varName propName type]) (APutFn)		

LOOPSMIXIN

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSMIXIN defines several small classes that can be mixed into your application classes. It also defines the class **Perspective** and its support classes, which are used in the implementation of Xerox LOOPS Rules. Perspectives allow you to view one object as having more than one class at a time; they have not been tested extensively outside of Rules and are known to have major bugs which don't affect Rules, so they are not documented here.

LOOPSMIXIN Classes

DatedObject - Defines the instance variables **created** and **creator** which are set at object creation time to the values of (DATE) and (USERNAME).

NamedObject - Defines the instance variable name and initializes it to an ActiveValue that insures that the Xerox LOOPS system name for the containing object is uniquely name; i.e. storing a name for the object in name causes the previous name for the object to be removed with **DeleteObjectName** and the new name for the object to be asserted with **NameEntity**.

GlobalNamedObject - A subclass of NamedObject that works the same way as NamedObject.

ListMetaClass - Specializes the New and DestroyInstance methods to keep a list of all instances of that class in the class property AllInstances for that class.

StrucMeta - A MetaClass useful for creating new classes. Specializes the **New** method to create a Class object by copying the instance variable and class variable descriptions of the current class. Class variables with a non-NIL Local property will not be copied.

TempClass - Specializes the **New** method to always create objects of this class using the **NewTemp** method, insuring that the objects will be temporary objects.

Perspective, Node, Template, TextItem - These classes are used in Xerox LOOPS Rules.

This file includes notes on the production of *Xerox LOOPS Users' Modules Manual*, Lyric Beta Release. This manual is packaged in one binder.

Writer: Raven Kontur Brewster

Printing Date: 22 February 1988

1.

INTRODUCTION TO RULE-ORIENTED PROGRAMMING IN XEROX LOOPS

The core of decision-making expertise in many kinds of problem solving can be expressed succinctly in terms of rules. The following sections describe facilities in Xerox LOOPS for representing rules, and for organizing knowledge-based systems with rule-oriented programming. The Xerox LOOPS rule language provides an experimental framework for developing knowledge-based systems. The rule language and programming environment are integrated with the object-oriented, data-oriented, and procedure-oriented parts of Xerox LOOPS.

Rules in Xerox LOOPS are organized into production systems (called RuleSets) with specified control structures for selecting and executing the rules. The work space for RuleSets is an arbitrary Xerox LOOPS object.

Decision knowledge can be factored from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions. An audit trail records inferential support in terms of the rules and data that were used. Such trails are important for knowledge-based systems that must be able to account for their results. They are also essential for guiding belief revision in programs that need to reason with incomplete information.

1.1 Introduction

Production rules have been used in expert systems to represent decision-making knowledge for many kinds of problem-solving. Such rules (also called *if-then* rules) specify actions to be taken when certain conditions are satisfied. Several rule languages have been developed in the past few years and used for building expert systems. The following sections describe the concepts and facilities for rule-oriented programming in Xerox LOOPS.

Xerox LOOPS has the following major features for rule-oriented programming:

- (1) Rules in Xerox LOOPS are organized into ordered sets of rules (called RuleSets) with specified control structures for selecting and executing the rules. Like subroutines, RuleSets are building blocks for organizing programs hierarchically.
- (2) The work space for rules in Xerox LOOPS is an arbitrary Xerox LOOPS object. The names of the instance variables provide a name space for variables in the rules.
- (3) Rule-oriented programming is integrated with object-oriented, data-oriented, and procedureoriented programming in Xerox LOOPS.
- (4) RuleSets can be invoked in several ways: In the object-oriented paradigm, they can be invoked as methods by sending messages to objects. In the data-oriented paradigm, they can be invoked

as a side-effect of fetching or storing data in active values. They can also be invoked directly from Lisp programs. This integration makes it convenient to use the other paradigms to organize the interactions between RuleSets.

- (5) RuleSets can also be invoked from rules either as predicates on the LHS of rules, or as actions on the RHS of rules. This provides a way for RuleSets to control the execution of other RuleSets.
- (6) Rules can automatically leave an audit trail. An audit trail is a record of inferential support in terms of rules and data that were used. Such trails are important for programs that must be able to account for their results. They can also be used to guide belief revision in programs that must reason with incomplete information.
- (7) Decision knowledge can be separated from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions.
- (8) The rule language provides a concise syntax for the most common operations.
- (9) There is a fast and efficient compiler for translating RuleSets into Interlisp functions.
- (10) Xerox LOOPS provides facilities for debugging rule-oriented programs.

The following sections are organized as follows: Section 1.2, "Basic Concepts," outlines the basic concepts of rule-oriented programming in Xerox LOOPS. It contains many examples that illustrate techniques of rule-oriented programming. Section 1.3, "Organizing a Rule-Oriented Program," describes the rule syntax, and the remaining sections in this chapter discuss the facilities for creating, editing, and debugging RuleSets in Xerox LOOPS.

1.2 Basic Concepts

Rules express the conditional execution of actions. They are important in programming because they can capture the core of decision-making for many kinds of problem-solving. Rule-oriented programming in Xerox LOOPS is intended for applications to expert and knowledge-based systems.

The following sections outline some of the main concepts of rule-oriented programming. Xerox LOOPS provides a special language for rules because of their central role, and because special facilities can be associated with rules that are impractical for procedural programming languages. For example, Xerox LOOPS can save specialized audit trails of rule execution. Audit trails are important in knowledge systems that need to explain their conclusions in terms of the knowledge used in solving a problem. This capability is essential in the development of large knowledge-intensive systems, where a long and sustained effort is required to create and validate knowledge bases. Audit trails are also important for programs that do non-monotonic reasoning. Such programs must work with incomplete information, and must be able to revise their conclusions in response to new information.

1.3 Organizing a Rule-Oriented Program

In any programming paradigm, it is important to have an organizational scheme for composing large systems from smaller ones. Stated differently, it is important to have a method for partitioning large programs into nearly-independent and manageably-sized pieces. In the procedure-oriented paradigm, programs are decomposed into procedures. In the object-oriented paradigm, programs are decomposed into objects. In the rule-oriented paradigm, programs are decomposed into *RuleSets*. A Xerox LOOPS program that uses more than one programming paradigm is factored across several of these dimensions.

There are three approaches to organizing the invocation of RuleSets in Xerox LOOPS:

Procedure-oriented Approach. This approach is analogous to the use of subroutines in procedureoriented programming. Programs are decomposed into RuleSets that call each other and return values when they are finished. *SubRuleSets* can be invoked from multiple places. They are used to simplify the expression in rules of complex predicates, generators, and actions.

Object-oriented Approach. In this approach, RuleSets are installed as methods for objects. They are invoked as methods when messages are sent to the objects. The method RuleSets are viewed analogously to other procedures that implement object message protocols. The value computed by the RuleSet is returned as the value of the message sending operation.

Data-oriented Approach. In this approach, RuleSets are installed as access functions in active values. A RuleSet in an active value is invoked when a program gets or puts a value in the Xerox LOOPS object. As with active values with Lisp functions for the *getFn* or *putFn*, these RuleSet active values can be triggered by any Xerox LOOPS program, whether rule-oriented or not.

These approaches for organizing RuleSets can be combined to control the interactions between bodies of decision-making knowledge expressed in rules. For example, Figure 1 shows the RuleSet of consumer instructions for testing a washing machine. The work space for the ruleSet is a Xerox LOOPS object of the class **WashingMachine**. The control structure While1 loops through the rules trying an escalating sequence of actions, starting again at the beginning of some rule is applied. Some rules, called one-shot rules, are executed at most once. These rules are indicated by preceding them with a one in braces ({1}).

```
RuleSet Name: CheckWashingMachine;
WorkSpace Class: WashingMachine;
Control Structure: while1 ;
While Condition: ruleApplied;
(* What a consumer should do when a washing machine failes.)
  IF .Operational THEN (STOP T);
  IF load>1.0 THEN .ReduceLoad;
  If ~pluggedInTo THEN .PlugIn;
{1}
     IF pluggedInTo:voltage=0 THEN breaker.Reset;
{1}
    IF pluggedInTo:voltage<110 THEN SPGE.Call;
\{1\}
    THEN dealer.RequestService;
{1} THEN manufacturer.Complain;
{1}
    THEN $ConsumerBoard.Complain;
\{1\} THEN (STOP T);
```

Figure 1. Basic RuleSet

1.4 Control Structures for Selecting Rules

RuleSets in Xerox LOOPS consist of an ordered list of rules and a control structure. Together with the contents of the rules and the data, a RuleSet control structure determines which rules are executed. Execution is determined by the contents of rules in that the conditions of a rule must be satisfied for it to be executed. Execution is also controlled by data in that different values in the data allow different rules to be satisfied. Criteria for iteration and rule selection are specified by a RuleSet control structure. There are two primitive control structures for RuleSets in Xerox LOOPS which operate as follows:

Do1 [RuleSet Control Structure]

The first rule in the RuleSet whose conditions are satisfied is executed. The value of the RuleSet is the value of the rule. If no rule is executed, the RuleSet returns **NIL**.

The **Do1** control structure is useful for specifying a set of mutually exclusive actions, since at most one rule in the RuleSet will be executed for a given invocation. When a RuleSet contains rules for specific and general situations, the specific rules should be placed before the general rules.

DoAll

[RuleSet Control Structure]

Starting at the beginning of the RuleSet, every rule is executed whose conditions are satisfied. The value of the RuleSet is the value of the last rule executed. If no rule is executed, the RuleSet returns **NIL**.

The **DoAll** control structure is useful when a variable number of additive actions are to be carried out, depending on which conditions are satisfied. In a single invocation of the RuleSet, all of the applicable rules are invoked.

Figure 2 illustrates the use of a **Do1** control structure to select one of three mutually exclusive actions.

RuleSet Name: SimulateWashingMachine; WorkSpace Class: WashingMachine; Control Structure: Do1 ; (* Rules for controlling the wash cycle of a washing machine.) IF controlSetting = 'RegularFabric THEN .Fill .Wash .Pause .SpinAndDrain .SprayAndRinse .SpinAndDrain .Fill. DeepRinse .Pause .DampDry; IF controlSetting = 'PermanentPress THEN .Fill .Wash .Pause .SpinAndPartialDrain .FillCold .SpinAndPartialDrain .FillCold .Pause .SpinAndDrain .FillCold. DeepRinse .Pause .DampDry; IF controlSetting = 'DelicateFabric THEN .FillSoak1 .Agitate .Soak4 .Agitate .Soak1 .SpinAndDrain .SprayAndRinse .SpinAndDrain .Fill .DeepRinse .Pause .DampDry;

Figure 2. RuleSet showing Do1

There are two control structures in Xerox LOOPS that specify iteration in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

While1	[RuleSet Control Structure]
	This is a cyclic version of Do1 . If the while-condition is satisfied, the first rule is executed whose conditions are satisfied. This is
	repeated as long as the while condition is satisfied or until a Stop

repeated as long as the while conditions are satisfied. This is statement or transfer call is executed (see Section 2.14, "Stop Statements"). The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

WhileAll

[RuleSet Control Structure]

This is a cyclic version of **DoAll**. If the while-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the while condition is satisfied or until a **Stop** statement is executed. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

The "while-condition" is specified in terms of the variables and constants accessible from the RuleSet. The constant **T** can be used to specify a RuleSet that iterates forever (or until a **Stop** statement or transfer is executed). The special variable **ruleApplied** is used to specify a RuleSet that continues as long as some rule was executed in the last iteration. Figure 3 illustrates a simple use of the **WhileAll** control structure to specify a sensing/acting feedback loop for controlling the filling of a washing machine tub with water.

RuleSet Name: FillTub; WorkSpace Class: WashingMachine; Control Structure: WhileAll ; Temp Vars: waterLimit; WhileCond: Τ; (* Rules for controlling the filling of a washing tub with water.) {1!} IF loadSetting = 'Small THEN waterLimit 10; {1!} IF loadSetting = 'Meduim THEN waterLimit 13.5; 1! } IF loadSetting = 'Large THEN waterLimit 17; {1!} IF loadSetting = 'ExtraLarge THEN waterLimit 20; (* Respond to a change of temperature setting at any time.) IF termperatureSetting = 'Hot THEN HotWaterValve.Open ColdWaterValve.Close; IF termperatureSetting = 'Warm THEN HotWaterValve.Open ColdWaterValve.Open; IF termperatureSetting = 'Cold THEN HotWaterValve.Close ColdWaterValve.Open; (* Stop when the water reaches its limit.) IF waterLevelSensor.Test >= waterLimit THEN HotWaterValve.Close ColdWaterValve.Close (Stop T);

Figure 3. RuleSet with WhileAll

There are two control structures in Xerox LOOPS that specify iteration over a set of elements in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

FOR1	[RuleSet Control Structure]
	This is a cyclic version of Do1 . If the iteration-condition (or while- condition) is satisfied, the first rule is executed whose conditions are satisfied or until a Stop statement is executed. This is repeated as long as the iteration condition is satisfied. The value of the RuleSet is the value of the last rule that was executed, or NIL if no rule was executed.
FORALL	[RuleSet Control Structure]
	This is a cyclic version of DoAll . If the iteration-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the iteration condition is satisfied or until a Stop statement is executed. The value of the RuleSet is the

value of the last rule that was executed, or NIL if no rule was

The "iteration-condition" is specified in terms of the variables and constants accessible from the RuleSet. The simplest condition is

(FOR <iterVar> IN <setExpr> DO ruleSet);

The **setExpr** will be parsed with the RuleSet parser. The symbol **ruleSet** is a reserved word, and must be spelled as shown (no changes in capitalization).

Here is an example of iteration:

Control Structure: FORALL; Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO ruleSet);

executed.

For each buyer in the list produced by RoadStops, the ruleSet will be run. In a **FOR1**, the iteration will go on to the next buyer as soon as one rule executes. In a **FORALL**, all rules in the RuleSet will be tried.

For nested iteration one can use a slightly more complicated form, as illustrated by the following example:

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO (FOR seller in (RoadStops (\$ Producer)) DO ruleSet)) ;

An experienced Lisp user can see that this resembles the CLISP iteration construct. In fact, except that you can (must) use the RuleSet syntax in the construct, it is the CLISP construct, and any such construct can be used. A DO1 or DOALL ruleSet will be substituted for the occurrence of the atom ruleSet, depending on whether the Control Structure is a FOR1 or FORALL.

As an abbreviation, if the construct does not contain the atom ruleSet, then (DO ruleSet) is appended to the Iteration Condition for a **FOR1** or **FORALL**. Thus one could write the first example as:

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)))

1.5 One-Shot Rules

One of the design objectives of Xerox LOOPS is to clarify the rules by factoring out control information whenever possible. This objective is met in part by the declaration of a control structure for RuleSets.

Another important case arises in cyclic control structures in which some of the rules should be executed only once. This was illustrated in the Washing Machine example in Figure 1 where we wanted to prevent the RuleSet from going into an infinite loop of resetting the breaker, when there was a short circuit in the Washing Machine. Such rules are also useful for initializing data for RuleSets as in the example in Figure 3.

In the absence of special syntax, it would be possible to encode the information that a rule is to be executed only once as follows:

Control Structure: While1 Temporary Vars: triedRule3;

•••

IF ~**triedRule3** *condition*₁ *condition*₂ **THEN triedRule3_T** *action*₁;

In this example, the variable **triedRule3** is used to control the rule so that it will be executed at most once in an invocation of a RuleSet. However, the prolific use of rules with such control clauses in large systems has led to the common complaint that control clauses in rule languages defeat the expressiveness and conciseness of the rules. For the case above, Xerox LOOPS provides a shorthand notation as follows:

{1} **IF** condition₁ condition₂ **THEN** action₁;

The brace notation means exactly the same thing in the example above, but it more concisely and clearly indicates that the rule executes only once. These rules are called "one shot" or "execute-once" rules.

In some cases, it is desired not only that a rule be executed at most once, but that it be tested at most once. This corresponds to the following:

Control Structure: While1 Temporary Vars: triedRule3;

•••

IF ~**triedRule3 triedRule3**_**T** condition₁ condition₂ **THEN** action₁;

In this case, the rule will not be tried more than once even if some of the conditions fail the first time that it is tested. The Xerox LOOPS shorthand for these rules (pronounced "one shot bang") is

{1!} **IF** condition₁ condition₂ **THEN** action₁;

These rules are called "try-once" rules.

The two kinds of one-shot rules are our first examples of the use of meta-descriptions preceding the rule body in braces. See Section 1.7, "Saving an Audit Trail of Rule Invocation," for information on using meta-descriptions for describing the creation of audit trails.

1.6 First/Last Rules

It is sometimes useful to have rules which fire before or after the ordinary part of the RuleSet is invoked, independent of the form of the control structure. For example, in a DO1, such "FIRST " rules could be used for initialization. These now exist, and are notated by putting a $\{F\}$ for a first rule in the MetaDescription field, and a $\{L\}$ for a last rule. If a RuleSet has L rules which execute, the value of the RuleSet is the value of the last rule which executed.

1.7 Saving an Audit Trail of Rule Invocation

A basic property of knowledge-based systems is that they use knowledge to infer new facts from older ones. (Here we use the word "facts" as a neutral term, meaning any information derived or given, that is used by a reasoning system.) Over the past few years, it has become evident that reasoning systems need to keep track not only of their conclusions, but also of their reasoning steps. Consequently, the design of such systems has become an active research area in AI. The audit trail facilities of Xerox LOOPS support experimentation with systems that can not only use rules to make inferences, but also keep records of the inferential process itself.

1.7.1 Motivations and Applications

Debugging. In most expert systems, knowledge bases are developed over time and are the major investment. This places a premium on the use of tools and methods for identifying and correcting bugs in knowledge bases. By connecting a system's conclusions with the knowledge that it uses to derive them, audit trails can provide a substantial debugging aid. Audit trails provide a focused means of identifying potentially errorful knowledge in a problem solving context.

Explanation Facilities. Expert systems are often intended for use by people other than their creators, or by a group of people *pooling* their knowledge. An important consideration in validating expert systems is that reasoning should be *transparent*, that is, that a system should be able to give an account of its reasoning process. Facilities for doing this are sometimes called *explanation systems*

and the creation of powerful explanation systems is an active research area in AI and cognitive science. The audit trail mechanism provides an essential computational prerequisite for building such systems.

Belief Revision. Another active research area is the development of systems that can "change their minds". This characteristic is critical for systems that must reason from incomplete or errorful information. Such systems get leverage from their ability to make assumptions, and then to recover from bad assumptions by efficiently reorganizing their beliefs as new information is obtained. Research in this area ranges from work on non-monotonic logics, to a variety of approaches to belief revision. The facilities in the rule language make it convenient to use a user-defined calculus of belief revision, at whatever level of abstraction is appropriate for an application.

1.7.2 Overview of Audit Trail Implementation

When *audit mode* is specified for a RuleSet, the compilation of assignment statements on the righthand sides of rules is altered so that audit records are created as a side-effect of the assignment of values to instance variables. Audit records are Xerox LOOPS objects, whose class is specified in RuleSet declarations. The audit records are connected with associated instance variables through the value of the **reason** properties of the variables.

Audit descriptions can be associated with a RuleSet as a whole, or with specific rules. Rule-specific audit information is specified in a property-list format in the meta-description associated with a rule. For example, this can include *certainty factor* information, categories of inference, or categories of support. Rule-specific information overrides RuleSet information.

During rule execution in audit mode, the audit information is evaluated after the rule's LHS has been satisfied and before the rule's RHS is applied. For each rule applied, a single audit record is created and then the audit information from the property list in the rule's meta-description is put into the corresponding instance variables of the audit record. The audit record is then linked to each of the instance variables that have been set on the RHS of the rule by way of the **reason** property of the instance variable.

Additional computations can be triggered by associating active values with either the audit record class or with the instance variables. For example, active values can be specified in the audit record classes in order to define a uniform set of side-effects for rules of the same category. In the following example, such an active value is used to carry out a "certainty factor" calculation.

1.7.3 An Example of Using Audit Trails

The following example illustrates one way to use the audit trail facilities. Figure 4 illustrates a RuleSet which is intended to capture the decisions for evaluating the potential purchase of a washing machine. As with any purchasing situation, this one includes the difficulty of incomplete information about the product. For example in this RuleSet, the reliability of the washing machine is estimated to be 0.5 in the absence of specific information from *Consumer Reports*. The meta-descriptions for the rules, which appear in braces, categorize them in terms of the *basis of belief* (the category *basis* is either a fact or estimate) and a *certainty factor (cf)* that is supposed to measure the "implication power" of the

rule. Within the braces, the variable on the left of the assignment statement is always interpreted as meaning a variable in the audit record, and the variables on the right are always interpreted as variables accessible within the RuleSet. This makes it straightforward to experiment with user-defined audit trails and experimental methods of belief revision. (Realistic belief revision systems are usually more sophisticated than this example.)

The result of running the RuleSet is an evaluation report for each candidate machine. Since the RuleSet was run in audit mode, each entry in the evaluation report is tagged with a reason that points to an audit record. Figure 5 illustrates the evaluation report for one machine and one of its audit records. In this example, each of the entries in the report has a reason and a cumulative certainty (cc) property in addition to the value. The value of the reason properties are audit records created as a side effect of running the RuleSet. The auditing process records the meta-description information of each rule in its audit record. This information can be used later for generating explanations or as a basis for belief revision. The auditing process can have side effects. For example, the active in the **cf** variable or the audit record performs a computation to maintain a calculated cumulative certainty in the reliability variable of the evaluation report.

The meta-descriptions for **basis** and **cf** are saved directly in the audit record. The *certainty factor* calculation in this combines information from the audit description with other information already associated with the object. To do this, the **cf** description triggers an active value inherited by the audit record from its class. This active value computes a *cumulative certainty* in the evaluation report. (Other variations on this idea would include certainty information descriptive of the premises of the rule.)

```
RuleSet Name: EvaluateWashingMachine;

Figure 5. Example of an Audit Trail

1.8 Comparison with Other Rule Languages

This section considers the rationale behind the design of the Xerox LOOPS rule language, focusing on ways that it diverges from other rule languages. In general, this divergence was driven by the following observation:

When a rule is heavy with control information, it obscures the domain knowledge that the rule is intended to convey.

Rules are harder to create, understand, and modify when they contain too much control information. This observation led us to find ways to factor control information out of the rules.

1.8.1 The Rationale for Factoring Meta-Level Syntax

One of the most striking features of the syntax of the Xerox LOOPS rule language is the factored syntax for meta-descriptions, which provides information about the rules themselves. Traditional rule languages only factor rules into conditions on the left hand side (LHS) and actions on the right hand side (RHS), without general provisions for meta-descriptions.

Decision knowledge expressed in rules is most perspicuous when it is not mixed with other kinds knowledge, such as control knowledge. For example, the following rule:

IF ~triedRule4 pluggedInTo:voltage=0 THEN triedRule4_T breaker.Reset;

is more obscure than the corresponding one-shot rule from Figure 1:

{1} IF pluggedInTo:voltage=0 THEN breaker.Reset;

which factors the control information (that the rule is to be applied at most once) from the domain knowledge (about voltages and breakers). In the Xerox LOOPS rule language, a meta-description (MD) is specified in braces in front of the LHS of a rule. For another example, the following rule from Figure 4:

{(basis_Fact cf_.8)} IF buyer:familySize>2 machine:capacity<20 THEN suitability_'Poor;

uses an MD to indicate that the rule has a particular **cf** ("certainty factor") and **basis** category for belief support. The MD in this example factors the description of the inference category of the rule from the action knowledge in the rule.

In a large knowledge-based system, a substantial amount of control information must be specified in order to preclude combinatorial explosions. Since earlier rule languages fail to provide a means for factoring meta-information, they must either mix it with the domain knowledge or express it outside the rule language. In the first option, intelligibility is degraded. In the second option, the transparency of the system is degraded because the knowledge is hidden.

1.8.2 The Rationale for RuleSet Hierarchy

Some advocates of production systems have praised the flatness of traditional production systems, and have resisted the imposition of any organization to the rules. The flat organization is sometimes touted as making it *easy to add rules*. The argument is that other organizations diminish the power of pattern-directed invocation and make it more complicated to add a rule.

In designing Xerox LOOPS, we have tended to discount these arguments. We observe that there is no inherent property of production systems that can make rules additive. Rather, *additivity* is a consequence of the independence of particular sets of rules. Such independence is seldom achieved in large *sets* of rules. When rules are dependent, rule invocation needs to be carefully ordered.

Advocates of a flat organization tend to organize large programs as a single very large production system. In practice, most builders of production systems have found it essential to create groups of rules.

Grouping of rules in flat systems can be achieved in part by using *context* clauses in the rules. Context clauses are clauses inserted into the rules which are used to alter the flow of control by naming the context explicitly. Rules in the same "context" all contain an extra clause in their conditions that compares the context of the rules with a current context. Other rules redirect control by switching the current context. Unfortunately, this approach does not conveniently lend itself to the reuse of groups of rules by different parts of a program. Although context clauses admit the creation of "subroutine contexts", they require you to explicitly program a stack of return locations in cases where contexts are invoked from more than one place. The decision to use an implicit calling stack for RuleSet invocation in Xerox LOOPS is another example of the our desire to simplify the rules by factoring out control information.

1.8.3 The Rationale for RuleSet Control Structures

Production languages are sometimes described as having a *recognize-act cycle*, which specifies how rules are selected for execution. An important part of this cycle is the *conflict resolution strategy*, which specifies how to choose a production rule when several rules have conditions that are satisfied. For

example, the **OPS5** production language has a conflict resolution strategy (**MEA**) which prevents rules from being invoked more than once, prioritizes rules according to the recency of a change to the data, and gives preference to production rules with the most specific conditions.

In designing the rule language for Xerox LOOPS, we have favored the use of a small number of specialized control structures to the use of a single complex conflict resolution strategy. In so doing, we have drawn on some control structures in common use in familiar programming languages. For example, **Do1** is like Lisp's **COND**, **DoAII** is like Lisp's **PROG**, **WhileAII** is similar to **WHILE** statements in many programming languages.

The specialized control structures are intended for concisely representing programs with different control relationships among the rules. For example, the **DoAll** control structure is useful for rules whose effects are intended to be additive and the **Do1** control structure is appropriate for specifying mutually exclusive actions. Without some kind of iterative control structure that allows rules to be executed more than once, it would be impossible to write a simulation program such as the washing machine simulation in Figure 1.

We have resisted a reductionist argument for having only one control structure for all programming. For example, it could be argued that the control structure **Do1** is not strictly necessary because any RuleSet that uses **Do1** could be rewritten using **DoAII**. For example, the rules

Control Structure: Do1;

IF $a_1 b_1 c_1$ THEN $d_1 e_1$; IF $a_2 b_2 c_2$ THEN $d_2 e_2$; IF $a_3 b_3 c_3$ THEN $d_3 e_3$;

could be written alternatively as

Control Structure: DoAll; Task Vars: firedSomeRule;

IF $a_1 b_1 c_1$ THEN firedSomeRule_T $d_1 e_1$; IF ~firedSomeRule $a_2 b_2 c_2$ THEN firedSomeRule_T $d_2 e_2$; IF ~firedSomeRule $a_3 b_3 c_3$ THEN firedSomeRule_T $d_3 e_3$;

However, the **Do1** control structure admits a much more concise expression of mutually exclusive actions. In the example above, the **Do1** control structure makes it possible to abbreviate the rule conditions to reflect the assumption that earlier rules in the RuleSet were not satisfied.

For some particular sets of rules the conditions are naturally mutually exclusive. Even for these rules **Do1** can yield additional conciseness. For example, the rules:

Control Structure: Do1;

IF $a_1 b_1 c_1$ **THEN** $d_1 e_1$; **IF** $\sim a_1 b_1 c_1$ **THEN** $d_2 e_2$; **IF** $\sim a_1 \sim b_1 c_1$ **THEN** $d_3 e_3$; can be written as

Control Structure: Do1;

IF $a_1 b_1 c_1$ **THEN** $d_1 e_1$; **IF** $b_1 c_1$ **THEN** $d_2 e_2$; **IF** c_1 **THEN** $d_3 e_3$;

Similarly it could be argued that the **Do1** and **DoAll** control structures are not strictly necessary because such RuleSets can always be written in terms of **While1** and **WhileAll**. Following this reductionism to its end, we can observe that every RuleSet could be re-written in terms of **WhileAll**.

1.8.4 The Rationale for an Integrated Programming Environment

RuleSets in Xerox LOOPS are integrated with procedure-oriented, object-oriented, and data-oriented programming paradigms. In contrast to single-paradigm rule systems, this integration has two major benefits. It facilitates the construction of programs which don't entirely fit the rule-oriented paradigm. Rule-oriented programming can be used selectively for representing just the appropriate decision-making knowledge in a large program. Integration also makes it convenient to use the other paradigms to help organize the interactions between RuleSets.

Using the object-oriented paradigm, RuleSets can be invoked as methods for Xerox LOOPS objects. Figure 6 illustrates the installation of the RuleSet **SimulateWashingMachineRules** to carry out the **Simulate** method for instances of the class **WashingMachine**. This definition of the class **WashingMachine** specifies that Lisp functions are to be invoked for Fill and Wash messages. For example, the Lisp function **WashingMachine.Fill** is to be applied when a Fill message is received. When a Simulate message is received, the RuleSet **SimulateWashingMachineRules** is to be invoked with the washing machine as its work space. Simulate message to invoke the RuleSet may be sent by any Xerox LOOPS program, including other RuleSets.

The use of object-oriented paradigm is facilitated by special RuleSet syntax for sending messages to objects, and for manipulating the data in Xerox LOOPS objects. In addition, RuleSets, work spaces, and tasks are implemented as Xerox LOOPS objects.

```

   (Wash WashingMachine.Wash doc (* Perofrm the wash cycle.))
   (Simulate UseRuleSet RuleSet SimulateWashingMachineRules)
   .
   .
   .
]
```

Figure 6. RuleSet Invoked as a Method

Using the data-oriented paradigm, RuleSets can be installed in active values so that they are triggered by side-effect when Xerox LOOPS programs get or put data in objects. For example:

```
[DEFINST WashingMachine (StefiksMaytagWasher "uid2")
(controlSetting RegularFabric)
(loadSetting #(Medium NIL RSPut) RSPutFn CheckOverLoadRules)
(waterLevelSensor "uid3")
]
```

The above code illustrates a RuleSet named **CheckOverLoadRules** which is triggered whenever a program changes the **loadSetting** variable in the **WashingMachine** instance in the figure. This dataoriented triggering can be caused by any Xerox LOOPS program when it changes the variable, whether or not that program is written in the rules language. 2.

THE RULE LANGUAGE

This chapter describes the syntax and semantics of the rule language.

2.1 Language Introduction

A rule in Xerox LOOPS describes actions to be taken when specified conditions are satisfied. A rule has three major parts called the *left hand side* (LHS) for describing the conditions, the *right hand side* (RHS) for describing the actions, and the *meta-description* (MD) for describing the rule itself. In the simplest case without a meta-description, there are two equivalent syntactic forms:

LHS -> RHS;

IF LHS THEN RHS;

The **If** and **Then** tokens are recognized in several combinations of upper and lower case letters. The syntax for LHSs and RHSs is given below. In addition, a rule can have no conditions (meaning always perform the actions) as follows:

-> RHS;

if T then RHS;

Rules can be preceded by a meta-description in braces as in:

{MD} LHS -> RHS;

{*MD*} If *LHS* Then *RHS*;

{MD} RHS;

Examples of meta-information include rule-specific control information, rule descriptions, audit instructions, and debugging instructions. For example, the syntax for one-shot rules shown in Section 1.5, "One-Shot Rules:"

{1} IF condition₁ condition₂ THEN action₁;

is an example of a meta-description. Another example is the use of meta-assignment statements for describing audit trails and rules. These statements are discussed in Section 1.7, "Saving an Audit Trail of Rule Invocation."

LHS Syntax: The clauses on the LHS of a rule are evaluated in order from left to right to determine whether the LHS is satisfied. If they are all satisfied, then the rule is satisfied. For example:

A B C+D (Prime D) -> RHS;

In this rule, there are four clauses on the LHS. If the values of some of the clauses are **NIL** during evaluation, the remaining clauses are not evaluated. For example, if **A** is non-**NIL** but **B** is **NIL**, then the LHS is not satisfied and **C+D** will not be evaluated.

RHS Syntax: The RHS of a rule consists of actions to be performed if the LHS of the rule is satisfied. These actions are evaluated in order from left to right. Actions can be the invocation of RuleSets, the sending of Xerox LOOPS messages, Interlisp function calls, variables, or special termination actions.

RuleSets always return a value. The value returned by a RuleSet is the value of the last rule that was executed. Rules can have multiple actions on the right hand side. Unless there is a **Stop** statement or transfer call as described later, the value of a rule is the value of the last action. When a rule has no actions on its RHS, it returns **NIL** as its value.

Comments: Comments can be inserted between rules in the RuleSet. They are enclosed in parentheses with an asterisk for the first character as follows:

(* This is a comment)

2.2 Kinds of Variables

Xerox LOOPS distinguishes the following kinds of variables:

RuleSet arguments: All RuleSets have the variable **self** as their workspace. References to **self** can often be elided in the RuleSet syntax. For example, the expression **self.Print** means to send a **Print** message to **self**. This expression can be shortened to **.Print**. Other arguments can be defined for RuleSets. These are declared in an **Args:** declaration.

Instance variables: All RuleSets use a Xerox LOOPS object for their workSpace. In the LHS and RHS of a rule, the first interpretation tried for an undeclared literal is as an instance variable in the work space. Instance variables can be indicated unambiguously by preceding them with a colon, (e.g., :*varName* or *obj:varName*).

Class variables: Literals can be used to refer to class variables of Xerox LOOPS objects. These variables must be preceded by a double colon in the rule language, (e.g., ::*classVarName* or *obj::classVarName*).

Temporary variables: Literals can also be used to refer to temporary variables allocated for a specific invocation of a RuleSet. These variables are initialized to **NIL** when a RuleSet is invoked. Temporary variables are declared in the **Temporary Vars** declaration in a RuleSet.

Audit record variables: Literals can also be used to refer to instance variables of audit records created by rules. These literals are used only in *meta-assignment* statements in the MD part of a rule. They are used to describe the information saved in audit records, which can be created as a side-effect of rule execution. These variables are ignored if a RuleSet is not compiled in *audit* mode. Undeclared variables appearing on the left side of assignment statements in the MD part of a rule are treated as

audit record variables by default. These variables are declared indirectly -- they are the instance variables of the class declared as the *Audit Class* of the RuleSet.

Interlisp variables: Literals can also be used to refer to Interlisp variables during the invocation of a RuleSet. These variables can be global to the Interlisp environment, or are bound in some calling function. Interlisp variables can be used when procedure-oriented and rule-oriented programs are intermixed. Interlisp variables must be preceded by a backSlash in the syntax of the rule language (e.g., *VispVarName*).

Reserved Words: The following literals are treated as *read-only* variables with special interpretations:

self	[Variable]
	The current work space.
rs	[Variable]
	The current RuleSet.
caller	[Variable]
	The RuleSet that invoked the current RuleSet, or NIL if invoked otherwise.
ruleApplied	[Variable]
	Set to ${\bf T}$ if some rule was applied in this cycle. (For use only in while-conditions).

The following reserved words are intended mainly for use in creating audit trails:

ruleObject		[Variable]
	Variable bound to the object representing the rule itself.	
ruleNumber		[Variable]
	Variable bound to the sequence number of the rule in a F	RuleSet.
ruleLabel		[Variable]
	Variable bound to the label of a rule or NIL .	
reasons		[Variable]
	Variable bound a list of audit records supporting th variables mentioned on the LHS of the rule. (Computime.)	

auditObject	[Variable]
	Variable bound to the object to which the reason record will be attached. (Computed at run time.)
auditVarName	[Variable]
	Variable bound to the name of the variable on which the reason will be attached as a property.

Other Literals: As described later, literals can also refer to Interlisp functions, Xerox LOOPS objects, and message selectors. They can also be used in strings and quoted constants.

The determination of the meaning of a literal is done at compile time using the declarations and syntax of RuleSets. The characters used in literals are limited to alphabetic characters and numbers. The first character of a literal must be alphabetic.

The syntax of literals also includes a compact notation for sending unary messages and for accessing instance variables of Xerox LOOPS objects. This notation uses *compound literals*. A compound literal is a literal composed of multiple parts separated by a periods, colons, and commas.

2.3 Rule Forms

Quoted Constants: The quote sign is used to indicate constant literals:

a b=3 c='open d=f e='(This is a quoted expression) -> ...

In this example, the LHS is satisfied if **a** is non-**NIL**, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** is the list **(This is a quoted expression)**.

Strings: The double quote sign is used to indicate string constants:

IF a b=3 c='open d=f e=="This is a string" THEN (WRITE "Begin configuration task") ... ;

In this example, the LHS is satisfied if **a** is non-NIL, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** equal to the string "This is a string".

Interlisp Constants: The literals **T** and **NIL** are interpreted as the Interlisp constants of the same name.

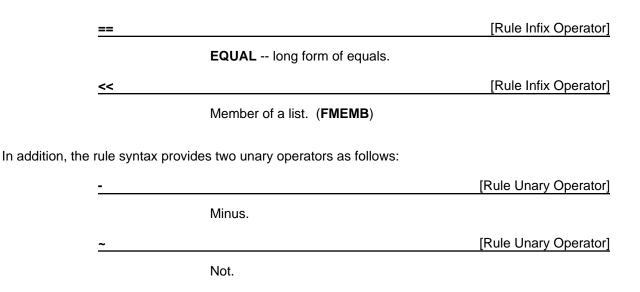

a (Foo x NIL b) -> x_T ...;

In this example, the function **Foo** is called with the arguments **x**, **NIL**, and **b**. Then the variable **x** is set to **T**.

2.4 Infix Operators and Brackets

To enhance the readability of rules, a few infix operators are provided. The following are infix binary operators in the rule syntax:

+	[Rule Infix Operator
	Addition.
++	[Rule Infix Operator
	Addition modulo 4.
	[Rule Infix Operator
	Subtraction.
	[Rule Infix Operator
	Subtraction modulo 4.
*	[Rule Infix Operator
	Multiplication.
1	[Rule Infix Operator
	Division.
>	[Rule Infix Operator
	Greater than.
<	[Rule Infix Operator
	Less than.
>=	[Rule Infix Operator
	Greater than or equal.
<=	[Rule Infix Operator
	Less than or equal.
=	[Rule Infix Operator
	EQ simple form of equals. Works for atoms, objects, and smaintegers.
~=	[Rule Infix Operator
	NEQ. (Not EQ.)

The precedence of operators in rule syntax follows the usual convention of programming languages. For example

1+5*3 = 16

and

[3 < 2 + 4] = T

Brackets can be used to control the order of evaluation:

[1+5]*3 = 18

Ambiguity of the minus sign: Whenever there is an ambiguity about the interpretation of a minus sign as a unary or binary operator, the rule syntax interprets it as a binary minus. For example

a-b c d -e [-f] (g -h) (_ (\$ Foo) Move -j) -> ...

In this example, the first and second minus signs are both treated as binary subtraction statements. That is, the first three clauses are (1) \mathbf{a} - \mathbf{b} , (2) \mathbf{c} and (3) \mathbf{d} - \mathbf{e} . Because the rule syntax allows arbitary spacing between symbols and there is no syntax to separate clauses on the LHS of a rule, the interpretation of " \mathbf{d} - \mathbf{e} " is as a single clause (with the subtraction) instead of two clauses. To force the interpretation as a unary minus operator, one must use brackets as illustrated in the next clause. In this clause, the minus sign in the clause [-f] is treated as a unary minus because of the brackets. The minus sign in the function call (\mathbf{g} - \mathbf{h}) is treated as unary because there is no preceding argument. Similarly, the - \mathbf{j} in the message expression is treated as unary because there is no preceding argument.

2.5 Interlisp Functions and Message Sending

Calls to Interlisp functions are parenthesized with the function name as the first literal after the left parenthesis. Each expression after the function name is treated as an argument to the function. For example:

a (Prime b) [a -b] -> c (Display b c+4 (Cursor x y) 2) ;

In this example, **Prime**, **Display**, and **Cursor** are interpreted as the names of Interlisp functions. Since the expression **[a -b]** is surrounded by brackets instead of parentheses, it is recognized as meaning **a** minus **b** as opposed to a call to the function **a** with the argument minus **b**. In the example above, the call to the Interlisp function **Display** has four arguments: **b**, **c+4**, the value of the function call **(Cursor x y)**, and **2**.

The use of Interlisp functions is usually outside the spirit of the rule language. However, it enables the use of Boolean expressions on the LHS beyond simple conjunctions. For example:

a (OR (NOT b) x y) z -> ... ;

Xerox LOOPS Objects and Message Sending: Xerox LOOPS classes and other named objects can be referenced by using the dollar notation. The sending of Xerox LOOPS messages is indicated by using a left arrow. For example:

IF cell_(_ (\$ LowCell) Occupied? 'Heavy) THEN (_ cell Move 3 'North);

In the LHS, an **Occupied?** message is sent to the object named **LowCell**. In the message expression on the RHS, there is no dollar sign preceding **cell**. Hence, the message is sent to the object that is the value of the variable **cell**.

For unary messages (i.e., messages with only the selector specified and the implicit argument **self**), a more compact notation is available as described selow.

Unary Message Sending: When a period is used as the separator in a compound literal, it indicates that a unary message is to be sent to an object. (We will alternatively refer to a period as a *dot*.) For example:

tile.Type='BlueGreenCross command.Type='Slide4 -> ... ;

In this example, the object to receive the unary message **Type** is referenced indirectly through the **tile** instance variable in the work space. The left literal is the variable **tile** and its value must be a Xerox LOOPS object at execution time. The right literal must be a method selector for that object.

The dot notation can be combined with the dollar notation to send unary messages to named Xerox LOOPS objects. For example,

\$Tile.Type='BlueGreenCross ...

In this example, a unary **Type** message is sent to the Xerox LOOPS object whose name is **Tile**.

The dot notation can also be used to send a message to the work space of the RuleSet, that is, **self**. For example, the rule

IF scale>7 THEN .DisplayLarge;

would cause a DisplayLarge message to be sent to self. This is an abbreviation for

IF scale>7 THEN self.DisplayLarge;

2.6 Variables and Properties

When a single colon (:) is used in a literal, it indicates access to an instance variable of an object. For example:

tile:type='BlueGreenCross command:type=Slide4 -> ... ;

In this example, access to the Xerox LOOPS object is indirect in that it is referenced through an instance variable of the work space. The left literal is the variable **tile**, and its value must be a Xerox LOOPS object when the rule is executed. The right literal **type** must be the name of an instance variable of that object. The compound literal **tile:type** refers to the value of the **type** instance variable of the object in the instance variable **tile**.

The colon notation can be combined with the dollar notation to access a variable in a named Xerox LOOPS object. For example,

\$TopTile:type='BlueGreenCross ...

refers to the type variable of the object whose Xerox LOOPS name is TopTile.

A double colon notation (::) is provided for accessing class variables. For example

truck::MaxGas<45 ::ValueAdded>600 -> ... ;

In this example, **MaxGas** is a class variable of the object bound to **truck**. **ValueAdded** is a class variable of **self**.

A colon-comma notation (:,) is provided for accessing property values of class and instance variables. For example

wire:,capacitance>5 wire:voltage:,support='simulation -> ...

In the first clause, **wire** is an instance variable of the work space and **capacitance** is a property of that variable. The interpretation of the second clause is left to right as usual: (1) the object that is the value of the variable **wire** is retrieved, and (2) the **support** property of the **voltage** variable of that object is retrieved. For properties of class variables

::Wire:,capacitance>5 node::Voltage:,support='simulation -> ...

In the first clause, **wire** is a class variable of the work space and **capacitance** is a property of that variable. In the second clause, **node** is an instance variable bound to some object. **Voltage** is a class variable of that object, and **Support** is a property of that class variable.

The property notation is illegal for ruleVars and lispVars since those variables cannot have properties.

2.7 Computing Selectors and Variable Names

The short notations for instance variables, properties, and unary messages all show the selector and variable names as they actually appear in the object.

object.selector object:ivName object::cvName object:varname:,propName

(_ object selector arg₁ arg₂)

For example,

apple:flavor

refers to the **flavor** instance variable of the object bound to the variable **apple**. In Interlisp terminology, this implies implicit quoting of the name of the instance variable (**flavor**).

In some applications it is desired to be able to compute the names. For this, the Xerox LOOPS rule language provides analogous notations with an added exclamation sign (!). After the exclamation sign, the interpretation of the variable being evaluated starts over again. For example

apple:!\x

refers to the same thing as **apple:flavor** if the Interlisp variable \mathbf{x} is bound to **flavor**. The fact that \mathbf{x} is a Lisp variable is indicated by the backslash. If \mathbf{x} is an instance variable of **self** or a temporary variable, we could use the notation:

apple:!x

If **x** is a class variable of **self**, we could use the notation:

apple:!::x

All combinations are possible, including:

object.!selector object.!selector object.!::selector object:!ivName object:!cvName object:!varname:,propName

(_! object selector arg₁ arg₂)

2.8 Recursive Compound Literals

Multiple colons or periods can be used in a literal, For example:

a:b:c

means to (1) get the object that is the value of \mathbf{a} , (2) get the object that is the value of the \mathbf{b} instance variable of \mathbf{a} , and finally (3) get the value of the \mathbf{c} instance variable of that object.

Similarly, the notation

a.b:c

means to get the **c** variable of the object returned after sending a **b** message to the object that is the value of the variable **a**. Again, the operations are carried out left to right: (1) the object that is the value of the variable **a** is retrieved, (2) it is sent a **b** message which must return an object, and then (3) the value of the **c** variable of that object is retrieved.

Compound literal notation can be nested arbitrarily deeply.

2.9 Assignment Statements

An assignment statement using a left arrow can be used for setting all kinds of variables. For example,

x_a;

sets the value of the variable \mathbf{x} to the value of \mathbf{a} . The same notation works if \mathbf{x} is a task variable, rule variable, class variable, temporary variable, or work space variable. The right side of an assignment statement can be an expression as in:

x_a*b + 17*(LOG d);

The assignment statement can also be used with the colon notation to set values of instance variables of objects. For example:

y:b_0;

In this example, first the object that is the value of **y** is computed, then the value of its instance variable **b** is set to **0**.

Properties: Assignment statements can also be used to set property values as in:

box:x:,origin_47 fact:,reason_currentSupport;

Nesting: Assignment statements can be nested as in

a_b_c:d_3;

This statement sets the values of **a**, **b**, and the **d** instance variable of **c** to **3**. The value of an assignment statement itself is the new assigned value.

2.10 Meta-Assignment Statements

Meta-assignment statements are assignment statements used for specifying rule descriptions and audit trails. These statements appear in the MD part of rules.

Audit Trails: The default interpretation of meta-assignment statements for undeclared variables is as audit trail specifications. Each meta-assignment statement specifies information to be saved in audit records when a rule is applied. In the following example from Figure 4, the audit record must have variables named **basis** and **cf**:

{(basis_Fact cf_1.)} IF buyer:familySize>2 machine:capacity<20 THEN suitability_'Poor;

In this example, the RHS of the rule assigns the value of the work space instance variable **suitability** to **'Poor** if the conditions of the rule are satisfied. In addition, if the RuleSet was compiled in *audit* mode, then during RuleSet execution an audit record is created as a side-effect of the assignment. The audit record is attached to the **reason** property of the suitability variable. It has instance variables **basis** and **cf**.

In general, an audit description consists of a sequence of meta-assignment statements. The assignment variable on the left must be an instance variable of the audit record. The class of the audit record is declared in the *Audit Class* declaration of the RuleSet. The expression on the right is in terms of the variables accessible by the RuleSet. If the conditions of a rule are satisfied, an audit record is instantiated. Then the meta-assignment statements are evaluated in the execution context of the RuleSet and their values are put into the audit record. A separate audit record is created for each of the object variables that are set by the rule.

2.11 Push and Pop Statements

A compact notation is provided for pushing and popping values from lists. To push a new value onto a list, the notation _+ is used:

myList_+newItem;

focus:goals_+newGoal;

To pop an item from a list, the _- notation is used:

item_-myList;

nextGoal_-focus:goals;

As with the assignment operator, the push and pop notation works for all kinds of variables and properties. They can be used in conjunction with infix operator << for membership testing.

2.12 Invoking RuleSets

One of the ways to cause RuleSets to be executed is to invoke them from rules. This is used on the LHS of rules to express predicates in terms of RuleSets, and on the RHS of rules to express actions in terms of RuleSets. A short double-dot syntax(..) for this is provided that invokes a RuleSet on a work space:

Rs1..ws1

In this example, the RuleSet bound to the variable **Rs1** is invoked with the value of the variable **ws1** as its work space. The value of the invocation expression is the value returned by the RuleSet. The double-dot syntax can be combined with the dollar notation (\$) to invoke a RuleSet by its Xerox LOOPS name, as in

\$MyRules..ws1

which invokes the RuleSet object that has the Xerox LOOPS name MyRules.

This form of RuleSet invocation is like subroutine calling, in that it creates an implicit stack of arguments and return addresses. This feature can be used as a mechanism for *meta-control* of RuleSets as in:

IF breaker:status='Open THEN source_\$OverLoadRules..washingMachine;

IF source='NotFound THEN \$ShortCircuitRules..washingMachine;

In this example, two "meta-rules" are used to control the invocation of specialized RuleSets for diagnosing overloads or short circuits.

2.13 Transfer Calls

An important optimization in many recursive programs is the elimination of tail recursion. For example, suppose that the RuleSet A calls B, B calls C, and C calls A recursively. If the first invocation of A must do some more work after returning from B, then it is useful to save the intermediate states of each of the procedures in frames on the calling stack. For such programs, the space allocation for the stack must be enough to accommodate the maximum depth of the calls.

There is a common and special case, however, in which it is unnecessary to save more than one frame on the stack. In this case each RuleSet has no more work to do after invoking the other RuleSets, and the value of each RuleSet is the value returned by the RuleSet that it invokes. RuleSet invocation in this case amounts to the evaluation of arguments followed by a direct transfer of control. We call such invocations transfer calls.

The Xerox LOOPS rule language extends the syntax for RuleSet invocation and message sending to provide this as follows:

RS..*ws

The RuleSet **RS** is invoked on the work space **ws**. With transfer calls, RuleSet invocations can be arbitrarily deep without using proportional stack space.

2.14 Stop Statements

To provide premature terminations in the execution of a RuleSet, the Stop statement is provided.

(Stop value)

[RuleSet Statement]

value is the value to be returned by the RuleSet.

[This page intentionally left blank]

USING RULES IN LOOPS

The Xerox LOOPS rules language is supported by an integrated programming environment for creating, editing, compiling, and debugging RuleSets. This section describes how to use that environment.

3.1 Creating RuleSets

RuleSets are named Xerox LOOPS objects and are created by sending the class **RuleSet** a **New** message as follows:

(_ (\$ RuleSet) New)

After entering this form, the user will be prompted for a Xerox LOOPS name as

RuleSet name: RuleSetName

Afterwards, the RuleSet can be referenced using Xerox LOOPS dollar sign notation as usual. It is also possible to include the RuleSet name in the **New** message as follows:

(_ (\$ RuleSet) New NIL RuleSetName)

3.2 Editing RuleSets

A RuleSet is created empty of rules. The RuleSet editor is used to enter and modify rules. The editor can be invoked with an **EditRules** message (or **ER** shorthand message) as follows:

(_ RuleSet EditRules) (_ RuleSet ER)

If a RuleSet is installed as a method of a class, it can be edited conveniently by selecting the **EditMethod** option from a browser containing the class. Alternatively, the **EditMethod** message can be used:

(_ ClassName EditMethod selector) [Message]

Both approaches to editing retrieve the source of the RuleSet and put the user into the TTYIN or TEdit editor, treating the rule source as text.

Initially, the source is a template for RuleSets as shown in Figure 7. The rules are entered after the comment at the bottom. The declarations at the beginning are filled in as needed and superfluous declarations can be discarded.

RuleSet Name: RuleSetName; WorkSpace Class: ClassName; Control Structure: doAll; While Condition: Audit Class: StandardAuditRecord; Rule Class: Rule; Task Class: ; Meta Assignments: ; Temporary Vars: ; Lisp Vars: ; Debug Vars: Compiler Options: ; (* Rules for whatever. Comment goes here.)

Figure 7. Initial Template for a RuleSet

You can then edit this template to enter rules and set the declarations at the beginning. In the current version of the rule editor, most of these declarations are left out. If you choose the **EditAllDecls** option in the RuleSet editor menu, the declarations and default values will be printed in full.

The template is only a guide. Declarations that are not needed can be deleted. For example, if there are no temporary variables for this RuleSet, the **Temporary Vars** declaration can be deleted. If the control structure is not one of the **while** control structures, then the **While Condition** declaration can be deleted. If the compiler option **A** is not chosen, then the **Audit Class** declaration can be deleted.

When you leave the editor, the RuleSet is compiled automatically into a Lisp function.

If a syntax error is detected during compilation, an error message is printed and you are given another opportunity to edit the RuleSet.

3.3 Copying RuleSets

Sometimes it is convenient to create new RuleSets by editing a copy of an existing RuleSet. For this purpose, the method **CopyRules** is provided as follows:

(_ oldRuleSet CopyRules newRuleSetName) [Message]

This creates a new RuleSet by some of the information from the pespectives of the old RuleSet. It also updates the source text of the new RuleSet to contain the new name.

3.4 Saving RuleSets on Lisp Files

RuleSets can be saved on Lisp files just like other Xerox LOOPS objects. In addition, it is usually useful to save the Lisp functions that result from RuleSet compilation. In the current implementation, these functions have the same names as the RuleSets themselves. To save RuleSets on a file, it is necessary to add two statements to the file commands for the file as follows:

(FNS * MyRuleSetNames) (INSTANCES * MyRuleSetNames)

where **MyRuleSetNames** is a Lisp variable whose value is a list of the names of the RuleSets to be saved.

If RuleSets are methods associated with a class, and they are saved by using (FILES?), then the file package saves the appropriate entries. The user does not have to be concerned with editing the filecoms of the file being made.

3.5 Printing RuleSets

To print a RuleSet without editing it, one can send a **PPRules** or **PPR** message as follows:

_ RuleSet PPRules) [Message]

RuleSet PPR) [Message]

A convenient way to make hardcopy listings of RuleSets is to use the function **ListRuleSets**. The files will be printed on the **DEFAULTPRINTINGHOST** as is standard in Interlisp-D. **ListRuleSets** can be given four kinds of arguments as follows:

(ListRuleSets RuleSetName) (ListRuleSets ListOfRuleSetNames) (ListRuleSets ClassName) (ListRuleSets FileName)

In the *ClassName* case, all of the RuleSets that have been installed as methods of the class will be printed. In the last case, all of the RuleSets stored in the file will be printed.

3.6 Running RuleSets from Xerox LOOPS

RuleSets can be invoked from Xerox LOOPS using any of the usual protocols.

Procedure-oriented Protocol: The way to invoke a RuleSet from Xerox LOOPS is to use the **RunRS** function:

(RunRS RuleSet workSpace arg2 ... argN)

[Function]

workSpace is the Xerox LOOPS object to be used as the work space. This is "procedural" in the sense that the RuleSet is invoked by its name. *RuleSet* can be either a RuleSet object or its name.

Object-oriented Protocol: When RuleSets are installed as methods in Xerox LOOPS classes, they can be invoked in the usual way by sending a message to an instance of the class. For example, if **WashingMachine** is a class with a RuleSet installed for its **Simulate** method, the RuleSet is invoked as follows:

(_ washingMachineInstance Simulate)

Data-oriented Protocol: When RuleSets are installed in active values, they are invoked by side-effect as a result of accessing the variable on which they are installed.

3.7 Installing RuleSets as Methods

RuleSets can also be used as methods for classes. This is done by installing automatically-generated invocation functions that invoke the RuleSets. For example:

```
[DEFCLASS WashingMachine
(MetaClass Class doc (* comment) ...)
...
(InstanceVariables (owner ...))
(Methods
(Simulate RunSimulateWMRules)
(Check RunCheckWMRules
doc (* Rules to Check a washing machine.))
```

...]

When an instance of the class **WashingMachine** receives a **Simulate** message, the RuleSet **SimulateWMRules** will be invoked with the instance as its work space.

To simplify the definition of RuleSets intended to be used as Methods, the function **DefRSM** (for "Define Rule Set as a Method") is provided:

(DefRSM ClassName Selector RuleSetName)

[Function]

If the optional argument *RuleSetName* is given, **DefRSM** installs that RuleSet as a method using the *ClassName* and *Selector*. It does this by automatically generating an installation function as a method to invoke the RuleSet. **DefRSM** automatically documents the installation function and the method.

If the argument *RuleSetName* is **NIL**, then **DefRSM** creates the RuleSet object, puts the user into an Editor to enter the rules,

compiles the rules into a Lisp function, and installs the RuleSet as before.

DefRSM can be invoked with the browser as follows:

- Position the cursor over a class in a browser.
- Press the middle mouse button. A menu pops up.
- Select the Add option in this menu, and drag the mouse to the right to display the submenu that includes the "DefRSM" option. You are prompted to enter a selector name.

After a RuleSet has been installed as a method by using **DefRSM**, you can then edit that RuleSet by selecting the "EditMethod" option from the browser editing menu.

3.8 Installing RuleSets in Active Values

Note: The following section and any other references to active values within the rule documentation refer to active values as they were implemented in the Buttress release. The functionality of triggering rules from active values has not been tested using the current implementation of active values. It should work to use the **ExplicitFnActiveValue** class to implement this behavior.

RuleSets can also be used in data-oriented programming so that they are invoked when data is accessed. To use a RuleSet as a *getFn*, the function **RSGetFn** is used with the property **RSGet** as follows:

•••

(InstanceVariables

(myVar #(myVal RSGetFn NIL) RSGet RuleSetName))

•••

RSGetFn is a Xerox LOOPS system function that can be used in an active value to invoke a RuleSet in response to a Xerox LOOPS get operation (e.g., **GetValue**) is performed. It requires that the name of the RuleSet be found on the **RSGet** property of the item. **RSGetFn** activates the RuleSet using the local state as the work space. The value returned by the RuleSet is returned as the value of the get operation.

To use a RuleSet as a *putFn*, the function **RSPutFn** is used with the property **RSPut** as follows:

....

(InstanceVariables

(myVar #(myVal NIL RSPutFn) RSPut RuleSetName))

•••

RSPutFn is a function that can be used in an active value to invoke a RuleSet in response to a Xerox LOOPS put operation (e.g., **PutValue**). It requires that the name of the RuleSet be found on the **RSPut** property of the item. **RSGetFn** activates the RuleSet using the *newValue* from the put

operation as the work space. The value returned by the RuleSet is put into the local state of the active value.

3.9 Tracing and Breaking RuleSets

Xerox LOOPS provides breaking and tracing facilities to aid in debugging RuleSets. These can be used in conjunction with the auditing facilities and the rule executive for debugging RuleSets. The following summarizes the compiler options for breaking and tracing:

- **T** Trace if rule is satisfied. Useful for creating a running display of executed rules.
- **TT** Trace if rule is tested.
- **B** Break if rule is satisfied.
- **BT** Break if rule is tested. Useful for stepping through the execution of a RuleSet.

Specifying the declaration **Compiler Options: T**; in a RuleSet indicates that tracing information should be displayed when a rule is satisfied. To specify the tracing of just an individual rule in the RuleSet, the **T** meta-descriptions should be used as follows:

{T} IF cond **THEN** action;

This tracing specification causes Xerox LOOPS to print a message whenever the LHS of the rule is tested, or the RHS of the rule is executed. It is also possible to specify that the values of some variables (and compound literals) are to be printed when a rule is traced. This is done by listing the variables in the **Debug Vars** declaration in the RuleSet:

Debug Vars: a a:b a:b.c;

This will print the values of **a**, **a:b**, and **a:b.c** when any rule is traced or broken.

Analogous specifications are provided for breaking rules. For example, the declaration **Compiler Options: B;** indicates that Xerox LOOPS is to enter the rule executive (see Section 3.10, "The Rule Exec") after the LHS is satisfied and before the RHS is executed. The rule-specific form:

{B} IF cond **THEN** action;

indicates that Xerox LOOPS is to break before the execution of a particular rule.

Sometimes it is convenient in debugging to display the source code of a rule when it is traced or broken. This can be effected by using the **PR** compiler option as in

Compiler Options: T PR;

which prints out the source of a rule when the LHS of the rule is tested and

Compiler Options: B PR;

which prints out the source of a rule when the LHS of a rule is satisfied, and before entering the break.

3.10 The Rule Exec

A Read-Compile-Evaluate-Print loop, called the rule Executive, is provided for the rule language. The rule Executive can be entered during a break by invoking the Lisp function **RE**. During RuleSet execution, the rule executive can be entered by typing **^f** (<control>-f) on the keyboard.

On the first invocation, **RE** prompts the user for a window. It then displays a stack of RuleSet invocations in a menu to the left of this window in a manner similar to the Interlisp-D Break Package. Using the left mouse button in this window creates an Inspector window for the work space for the RuleSet. Using the middle mouse button pretty prints the RuleSet in the default prettyprint window.

In the main rule Executive window, **RE** prompts the user with "**re:**". Anything in the rule language (other than declarations) that is typed to this Executive will be compiled and executed immediately and its value printed out. For example, you may type rules to see whether they execute or variable names to determine their values. For example:

re: trafficLight:color Red re:

this example shows how to get the value of the **color** variable of the **trafficLight** object. If the value of a variable was set by a RuleSet running with auditing, then a **why** question can be typed to the rule executive as follows:

re: why trafficLight:color

IF highLight:color = 'Green farmRoadSensor:cars timer.TL THEN highLight:color _ 'Yellow timer.Start;

Rule 3 of RuleSet LightRules Edited: Conway "13-Oct-82"

re:

The rule executive may be exited by typing **OK**.

3.11 Auditing RuleSets

Two declarations at the beginning of a RuleSet affect the auditing. Auditing is turned on by the compiler option A. The simplest form of this is

Compiler Options: A;

The **Audit Class** declaration indicates the class of the audit record to be used with this RuleSet if it is compiled in *audit* mode.

Audit Class: StandardAuditRecord;

A **Meta Assignments** declaration can be used to indicate the audit description to be used for the rules unless overridden by a rule-specific meta-assignment statement in a meta-descriptor.

Meta Assignments: cf_.5 support_'GroundWff;

3.12 Loading Rules

Set the variable LOOPSUSERSDIRECTORIES to include the directory where the Rules files are stored.

Load the file LOOPSRULES-ROOT.LCOM, which will load the following files from LOOPSUSERSDIRECTORIES:

- LOOPSBACKWARDS.LCOM
- LOOPSMIXIN
- LOOPSRULES.LCOM
- LOOPSRULESP.LCOM
- LOOPSRULESC.LCOM
- LOOPSRULESD.LCOM, which will load the file TTY.LCOM from LISPUSERSDIRECTORIES.

Editing rules will be easier if TEdit is loaded. Loading the Rules does not automatically load TEdit.

3.13 Known Problems

In a rule, the expression \$pipe.ri..\$p compiles to (RunRS (QUOTE (\$ pipe)) (\$ p)), which fails.

Meta-assignment statements cannot handle expressions. This means that statements like $\{cf ..., .5\}$ work fine, but $\{validity _ 'fact\}$ fails.

A value of 1 in a meta-descriptor statement is always taken to be a one-shot designator. You cannot have a meta-descriptor statement like $\{cf_1\}$. However, the number 1.0 can be used; the meta-descriptor statement, $\{cf_1.0\}$, works.

Rules have not been tested without loading TEdit in order to edit RuleSets.

[This page intentionally left blank.]

The primary change to rules was the removal of the **VarLength** mixin as a super class of **RuleSetSource**. Rules are now stored on the IV **ruleList** of **RuleSetSource**. If any user had added properties to a rule with a construct similar to the following expression, these will need to be reimplemented in some fashion:

(PutNthValue (\$ some-Instance-Of-A-RuleSetSource) ruleNumber prop)

A number of other changes were made to account for changes from Buttress LOOPS to the product release. These should not be noticeable to the general user.

A utility was built to allow rules that were saved in Buttress to be loaded into the product release of LOOPS. In order to convert from Buttress, follow this procedure.

- Load the necessary files for Rules as described in the Section 3.12, "Loading Rules."
- Load the file LOOPSRULESBACKWARDS. This redefines ConvertLoopsFiles to add functionality for converting rules.
- Do not load the Buttress files that need to be converted. Instead call:

(ConvertLoopsFiles *files-to-convert* T T)

This will load, convert, remake, and recompile the files specified by *files-to-convert*.

Any rules that were saved with auditing turned on will need to run through the rule compiler. The old rule compiler output a form that was (_ (\$ StandardAuditRecord) NewTemp). The message **NewTemp** no longer exists. The rule compiler now puts out the form (_ (\$ StandardAuditRecord) New).

If rules were saved with auditing turned on, then call (ConvertLoopsFiles *files-to-convert* T). Deleting the final "T", will not enable the cleanup. After recompiling the rules to eliminate the message **NewTemp**, remake your files.

[This page intentionally left blank]

HOW TO SET UP FOR TESTING LOOPS Start with a fresh LISP.SYSOUT from {erinyes}<lisp>lyric>basics>, dated 27-Apr-87. Give no INIT file Log in. Type into the exec: (SETQ IL:DISPLAYFONTDIRECTORIES '("{ERINYES}<lisp>LYRIC>FONTS>")) CONN {ERINYES}<lisp>Lyric>library> (il:load 'TEDÍT.lcom) (il:tedit '{erinyes}<cate3>loops>LOOPS-setup.tedit) This should bring up this document. Shift selected all lines below here into the EXEC: (il:load 'FILEBROWSER.lcom) CONN {erinyes}<lisp>lyric>lispusers> (il:load 'WHO-LINE.dfasl) (il:load 'filewatch.lcom) CONN {erinyes}<lispusers>lyric> (il:load 'CROCK.lcom) CONN {erinyes}<test>lisp>lyric>internal>library> (il:load 'do-test.dfasl) (setq il:*DEFAULT-CLEANUP-COMPILER* 'cl:COMPILE-FILE) (setq il:ch.default.domain "AISNORTH") (SETQ IL:CH.DEFAULT.ORGANIZATION "XEROX") CONN |{PELE:AISNorth:Xerox}<CATE3>| (il:closew il:logow) (IL:CHANGEBACKGROUND 42405) (il:crock) Follow the instructions for loading loops from the release notes manual. As long as the workstation can get the font files from the network, steps 1-3 can be ignored in the Installation of Loops (4.3 of Release Notes) For step 4: The modified network version: CONN {ERINYES}<lisp>Lyric>library> (il:load 'grapher.lcom) For steps 5-6: Insert Lyric LOOPS System #1 floppy, then type: (il:fb '{floppy}) and copy all files to {dsk}<lispfiles>loops> Do the same for the Lyric LOOPS System #2 floppy Then type or shift select in an Interlisp window:

CONN "{DSK}<lispfiles>loops>"
(LOAD 'LOOPS)
Stuff the following lines into a temp file in core then shift select out the
sysout command.
(il:sysout '{erinyes}<cate3>loops>test-loops.sysout)
(il:login)
(il:fb '{erinyes}<cate3>loops>)
; Make sure the Loops stuff is copied to <lispfiles>loops>
load the right software, and change to loops stuff

[Class]

CACHEOBJECT

By: sML (Lanning.pa@Xerox.com)

4-Sep-86

INTRODUCTION

The file CACHEOBJECT defines a Loops mixin that defines a protocol for instances that cache computed values.

CLASSES

ObjectWithCache

Instance of the class ObjectWithCache follow a standard protocol for manipulating a dynamic cache. The cache is not stored when an ObjectWithCache is saved on a file.

(← self ClearCache) [Method of ObjectWithCache]
 Clears the entire cache of self.
 (← self ClearCacheEntry name) [Method of ObjectWithCache]
 Removes the cache entry for name on self.
 (← self GetCache name) [Function]
 Returns the value of the cache entry for name on self. If there is no cached value, returns NIL.
 (← self PutCache name datum) [Function]

Stores datum as the value of the cache entry for name on self. Returns datum.

LOOPS-FB

By: sML (Lanning.pa@Xerox.com)

INTRODUCTION

LOOPS-FB adds a command to the Lisp File Browsers for opening Loops browsers on files.

Loading the file will automatically add a "Browse" command to all new Lisp FIle Browsers. Selecting the "Browse" item will open a Loops FileBrowser on each of the currently selected files. The files will be loaded first if they are not currently loaded.

LOOPSIDLE

By: sML (Lanning.pa@Xerox.com)

4-Sep-86

INTRODUCTION

LOOPSIDLE make IDLE "bouncing box" function bounce a Loops icon about about the screen.

VARIABLES

BouncingLoopsIcon

[Variable]

The (value of the) variable BouncingLoopsIcon is an expanded copy of the Loops icon. LOOPSIDLE sets IDLE.BOUNDING.BOX to (the value of) BouncingLoopsIcon.

Loops Image Objects

Unknown IMAGEOBJ type Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFnGETFN: LoopsImageObjectGetFn

Interlisp IMAGEOBJS are "objects" that know how to display themselves on IMAGESTREAMS. IMAGEOBJS are most often used to insert non-character items into a TEdit document. Standard Interlisp IMAGEOBJS are available for displaying bitmaps, graphs, and horizontal bars.

Interlisp IMAGEOBJS are not objects in the sense of Loops: there is no provision for specialization of existing IMAGEOBJS and no default behavior is provided. Creation of a new type of IMAGEOBJS requires some effort. Functions must be specified for printing, reading, displaying, and handling button events for the new IMAGEOBJ type.

Loops image objects are Loops objects that can be used as Interlisp IMAGEOBJS. They let the programer use the full power of the Loops environment in the creation of new IMAGEOBJS.

The LoopsImageObjects file defines a number of classes that can be used to create Interlisp IMAGEOBJS, and an interface that makes it easy to insert these Loops image objects into a TEdit

document. Section Unknown IMAGEOBJ type document; section Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn describes some predefined Loops image object classes; sections Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn to Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn to GETFN: LoopsImageObjectGetFn describe the Loops image object protocol, for people wishing to define their own Loops image objects.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

> Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFnInserting Loops image objects into a TEdit document is easy.

(LIO)

[Function]

The standard way to insert IMAGEOBJS into a TEdit file is via the CONTROL-O character. Hitting CONTROL-O lets you type in a LISP form, and the value of this form is an IMAGEOBJ that will be inserted into the document at the current location. (LIO) will present you with a menu of all known Loops image object classes. If you select a class from this menu, (LIO) will return the IMAGEOBJ that points to a new Loops image object of the specified class. If the instance has IVs that can be edited, you will be given a chance to edit the instance first.

LIOInsertCharCodes

[Variable]

When the Loops image object package is loaded, it redefines the interpretation in TEdit of the characters specified by the variable LIOInsertCharCodes. Hitting one of these characters is equivilent to hitting CONTROL-O and then typing in the form (LIO). The default value of LIOInsertCharCodes is (the value of) (LIST (CHARCODE #W) (CHARCODE #w)). This is an INITVAR, so you override the default before you load the package.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFnMany of these objects display themselves as text. This can be confusing for the user, who can easily mistake the object for a sequence of characters. To avoid this possibility for confusion, these objects appear boxed when displayed in a TEdit window. The box will not appear in a printed document.

The character looks of these objects can be set from TEdit in the same way that normal characters can have their looks set: select the object and use TEdit's Character Looks Menu, or the Looks item on the title bar pop-up menu. Note that the object can have only a single character looks--all the characters in the object will be displayed with the same looks. There is no way to change the looks of single characters displayed by a Loops image object.

These objects often violate the principle of WYSIWYG (What You See Is What You Get) in that they display more text in a TEdit window then they do when printed. They let you know what text will appear in print by displaying all non-printing text inverted. Thus, the object that displays in a TEdit

window as Index: IndexEntry will show up as the string "IndexEntry" when printed. (Note the interaction of this inversion with the boxing mentioned in the previous paragraph: the inversion is performed after the boxing, so that the entire object will still appear boxed if displayed inverted (as in TEdit's highlighting to indicate pending-delete).)

These objects respond to a button event by presenting a menu of options to the user. The items in the menu depend on the class of the object. All objects include a menu item for storing the Loops instance in (SavedValue), and for inspecting the instance. If the instance has IVs that can be set by the user, the menu will include an "Edit" item. The "Edit" item will bring up the standard Loops instance editor on the object. If the instance has a textual IV, the menu will include an option to edit the value of this IV in a new TEdit window.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Many people include in a TEdit file the time the file was last edited, or the name of the file that holds the document. The following classes can be used to automate this process.

WhenLastSaved

A WhenLastSaved image object will display a time stamp indidating the time the TEdit document was last saved. For example, a WhenLastSaved instance in this document might produce the image <u>3.Jan-86 18;21;15 by sml</u> when displayed to a TEdit window (but would appear without the box when hardcopied).

If the document has not been saved since the WhenLastSaved object was inserted, the WhenLastSaved object will display the string "NotYetSaved" instead of the time stamp.

WhereLastSaved

A WhereLastSaved image object is much like a WhenLastSaved object, except that it displays the name of the file that the TEdit document was last saved in, instead of the time last saved.

WhenLastSaved and WhereLastSaved objects are used in the running footers in this document.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Using image objects, it is easy to build an index table for a TEdit document.

IndexEntry

An IndexEntry object associates a string with a page number for inclusion in an index. The IV text of an IndexEntry will be added to the accumulated index, together with the number of the page containing the object. If the IV displayText? is non-NIL (the default), then the text string will also appear in the document, otherwise the object will be invisible in the final hardcopy. For example, an IndexEntry that adds a reference to the string "IndexEntry" appears in a TEdit window as

[Class]

[Class]

Index: IndexEntry. If the displayText? IV were NIL, it would appear as Index: IndexEntry when displayed in a TEdit window, but would be invisible when printed.

InitIndex

An InitIndex object must appear in a TEdit document before any IndexEntry object. The InitIndex object initializes the collection of the index table. It will be invisible when printed.

CollectIndex

A CollectIndex object should appear after all the IndexEntry objects that appear in a TEdit document. It will sort the index and print the index information into a new TEdit window (you will be prompted for the window). You can then format the text, save it away, print it, or discard it. The IVs looks, paraLooks, firstPageFormat, rectoPageFormat, and versoPageFormat determine the initial formatting of the index. See the TEdit documentation for a discussion of the definition of these fields. The CollectIndex object will not be visible in the printed document.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Automatic chapter and section numbering, and generation of a table of contents, is provided by the following classes.

SectionHeading

SectionHeading objects have three IVs: level, text, and displayText?. The level IV determines the subsection nesting of the object. Each SectionHeading object in the document increments the current section number at the given level. Smaller level numbers will not be affected. Larger level numbers are reset to zero. For example, a sequence of SectionHeading objects with level IVs of 1, 2, 1, 2, 2, 3, 2, and 1 will produce final section numbers of 1., 1.1., 2., 2.1., 2.2., 2.2.1., 2.3., and 3.

The text IV determines the section title for inclusion in the table of contents. If the displayText? is non-NIL (the default), the text will also be displayed in the document.

As an example, when first displayed in a TEdit window the SectionHeading for this subsection

h.n. Building a Table of Contents. If the displayText? IV were NIL, the text would have been inverted to indicate that it will not be present in the final hardcopy: n.n. Building a Table of Contents. Once the containing document had been

[Class]

[Class]

hardcopied, the object displayed the section number used at hardcopy time instead of the placeholder "n.n.". (Due to a "bug", you have to redisplay the window to see the updated section numbers.)

InitTOC

An InitTOC object must appear in a TEdit document before any SectionHeading object. The InitTOC object initializes the collection of the table of contents. The IV initialSectionNumbers can be used to initialize the first section numbers to values other than 1. For example, if the initialSectionNumbers IV is (2 1 3), and the first SectionHeading object has a level IV of 3, it will be given the subsection number "2.1.4.". The InitTOC object will be invisible when printed.

CollectTOC

A CollectTOC object should be placed at the end of a document, after all SectionHeading objects, to collect the table of contents information into a new TEdit stream. When the document is hardcopied, a new TEdit stream will be opened containing the accumulated table of contents. You can then format this TEdit document as you wish. CollectTOC uses the same IVs as does the CollectIndex to determine the initial formatting of the table of contents. The CollectTOC object not be visible in the final hardcopy.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

The following classes provide a somewhat clumsy way of having page and section references included an a document. Because there is no lookahead in the TEdit page formatting, documents containing these objects must be hardcopied twice. The first time will compute the correct page and section numbers, the second time will incorporate them into the document.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

PageNote

At hardcopy time, a PageNote object remembers the current page number, associating it with the value of its tag IV. See the PageReference class, below.

PageReference

At hardcopy time, a PageReference object looks up the value of its tag IV to see if a PageNote object has noted a page number for that tag. If there is page number stored, the PageReference object will display the number, otherwise it will display the string "nn". If the PageNote occurs before

[Class]

[Class]

[Class]

the PageReference object in the document, this reference will be found the first time the document is printed. If the PageNote occurs after the PageReference object, a second hardcopy must be generated.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

SectionNote

At hardcopy time, a SectionNote object remembers the current section number, associating it with the value of its tag IV. See the SectionReference class, below.

SectionReference

At hardcopy time, a SectionReference object looks up the value of its tag IV to see if a SectionNote object has noted a section number for that tag. If there is section number stored, the SectionReference object will display the number, otherwise it will display the string "n.". If the SectionNote occurs before the SectionReference object in the document, this reference will be found the first time the document is printed. If the SectionNote occurs after the SectionReference object, a second hardcopy must be generated.

SectionReferences are used in this document in the last paragraph of the first section.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

The following class illustrates the posiblity of nesting image objects inside of other image objects.

BoxedImageObject

IVs: boxShade (the shade of the box: either a shade or a form that will be evaluated to a shade; e.g. GRAYSHADE), boxWhiteSpace (blank space between the boxed object and the box), boxWidth (the width of the box), boxedObject (a LoopsImageObject).

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

A common document form consists of a table of text entries. These are easy to build in TEdit when each entry fits within its row without having to occupy multiple lines.

[Class]

[Class]

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn.

Example: BoxedImageObjects and TableTextObjects

The following class takes care of the case where the table entries are too large to fit on a single line.

TableTextObject

describes a (possibly multiple line) table entry. The class TableTextObject defines five important IVs.

[IV of TableTextObject]

[IV of TableTextObject]

[Class]

contains the text that will be displayed in the table entry.

widthInWs

defines the width of the table entry. This width is measured in "W"s, in the current font. If the text is too long, it will be broken at word boundaries and displayed in multiple lines. The default value is 10.

nLines

defines the maximum number of lines to be used to print the text. If nLines is NIL (the default), the object will be as tall as it needs to be to display the entire text subject to the width constraint specified by the widthInWs IV.

[IV of TableTextObject]

[IV of TableTextObject]

determines the horizontal justification of the individual lines within the table entry. Possible values are left (for left-justify), center (for centered text), and right (for right-justify). The defualt is left.

verticalJustify

determines the vertical justification of the lines within the table entry. Possible values are top (the first line will be flush with the top of the table entry), center (the text will be centered vertically), and bottom (the last line of text will be at the bottom of the entry). The defualt is bottom. Note that this IV only has an effect if the IV nLines is specified.

justify

text

[IV of TableTextObject]

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Image objects can be used to include prettyprinted forms in a document.

PPImageObject	[Class]
prettyprints a form in the image stream. The relevant IVs of PPImageObject	are:
form	[IV of PPImageObject]
~mumble~	
minWidth	[IV of PPImageObject]
~mumble~	
maxWidth	[IV of PPImageObject]
~mumble~	
Due to an unfortunate bug in Interlisp, PPImageObject work correctly on disp	lay devices .

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Example: PPImageObject

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFhoops image objects are Loops objects that are wrapped around an Interlisp IMAGEOBJ. The IMAGEOBJ in turn points back to the Lops image object. When Interlisp "sends a message" to the underlying IMAGEOBJ (more correctly, applies one of the IMAGEOBJ's IMAGEFNS to the IMAGEOBJ), the IMAGEOBJ forwards this message on to the Loops image object. The translation from Interlisp IMAGEOBJ protocol to Loops image object protocol is accomplished by a special set of IMAGEFNS and the LoopsImageObject class.

LoopsImageObject

[AbstractClass]

~mumble~

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

The following methods implement the IMAGEFNS for the Loops image object. These message are not intended to be sent by the user; they are sent automatically by TEdit and other packages.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

[Method of LoopsImageObject]

[Method of LoopsImageObject]

returns an instance of the record IMAGEBOX with fields XSIZE, YSIZE, XKERN, and YDESC. This is used by TEdit to determine the size of the object for formatting purposes. Specializations of LoopsImageObject should override this method.

```
( self Display imageStream)
```

should actually display the object on the *imageStream*. Specializations of LoopsImageObject should override this method.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

(_ self ButtonEventIn windowStream selection relX relY window textStream button)

[Method of LoopsImageObject]

~mumble~

(_ self CopyButtonEventIn windowStream)

[Method of LoopsImageObject]

[Method of LoopsImageObject]

~mumble~

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

(_ self Copy)

~mumble~

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn Due to restrictions imposed by IMAGEOBJects, LoopsImageObjects cannot duplicate the full generality of saving and retoring Loops objects. Specialized subclasses of LoopsImageObjects cannot change how they are stored or read back in. However, the following methods do give the user some control over what extra information is dumped out when a LoopsImageObjects is stored.

(_ self BeforePutToFile stream)	[Method of LoopsImageObject]
~mumble~	
(_ self AfterPutToFile fileStream)	[Method of LoopsImageObject]
~mumble~	
(_ self AfterGetFromFile textStream)	[Method of LoopsImageObject]
~mumble~	
(_ self PrePrint)	[Method of LoopsImageObject]
~mumble~	
Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn	
(_ self WhenCopied targetWindowStream	
sourceTextStream targetTextStream)	[Method of LoopsImageObject]
~mumble~	
(_ self WhenDeleted targetWindowStream	
<pre>sourceTextStream targetTextStream)</pre>	[Method of LoopsImageObject]
~mumble~	
(_ self WhenInserted targetWindowStream	
<pre>sourceTextStream targetTextStream)</pre>	[Method of LoopsImageObject]
~mumble~	
(_ self WhenMoved targetWindowStream	
<pre>sourceTextStream targetTextStream)</pre>	[Method of LoopsImageObject]
~mumble~	

(_ self WhenOperatedOn windowStream howOperatedOn

[Method of LoopsImageObject]

~mumble~

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

selection textStream)

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

The class LoopsImageObject provides a number of other methods that can be used by specializations of the above methods.

(_ self CachedImageBox imageStream) [Method of LoopsImageObject]

returns the image box computed by the last ImageBox method. This is often used inside the Display method to avoid resending the ImageBox message.

(_ self DisplayImageStream? imageStream) [Method of LoopsImageObject]

returns NIL unless the image stream is a display image stream.

(_ self PrintText imageStream text font) [Method of LoopsImageObject]

prints the string *text* in the font *font*, centered in the object's CachedImageBox.

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

Certain subclasses of LoopsImageObject capture some commonly desired functionality. These may be useful to anyone interested in building their own Loops image objects.

TEditImageObject

The class TEditImageObject contains a few methods that are only applicable when the object is being displayed in a TEdit stream.

(_ self CurrentFont imageStream)

[Method of TEditImageObject]

[AbstractClass]

returns the font of the image object in the current TEdit stream.

(_ self TextStream imageStream)	[Method of TEditImageObject]
returns the text stream that is being displayed in <i>imageStream</i> .	
(_ self TEditIV ivName textStream)	[Method of TEditImageObject]
edits the text stored in the IV <i>ivName</i> of <i>self</i> in a new TEdit window. The image object should be part of the TEdit stream <i>textStream</i> . The textStream argument is used to update the display when the IV has been edited.	
(_ self AllObjects textStream)	[Method of TEditImageObject]
returns a list of all imageobjects contained in <i>textStream</i> , in order.	
WhenSavedImageObject	[AbstractClass]
~mumble~	
HardcopySideEffectObject	[AbstractClass]
~mumble~	
LabelImageMixin	[AbstractClass]
~mumble~	
EditableImageObjectMixin	[AbstractClass]
~mumble~	
TEditableImageObjectMixin	[AbstractClass]
~mumble~	

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

On occasion, it may be useful to wrap a Loops image object around an existing Interlisp IMAGEOBJ, say to wrap a BoxedImageObject around it.

ImageObjectWrapper

Unknown IMAGEOBJ type GETFN: LoopsImageObjectGetFn

LOOPSINDEX

By: sML (Lanning.pa@Xerox.com)

4-Sep-86

INTRODUCTION

LOOPSINDEX sets up the SINGLEFILEINDEX package to dump out classes, methods, and instances in an intelligible way. LOOPSINDEX can be loaded into any Interlisp sysout: you do not need to have Loops loaded to load LOOPSINDEX.

LOOPSINDEX adds appropriate entries to the lists SINGLEFILEINDEX.TYPES and SINGLEFILEINDEX.FILTERS to cause SINGLEFILEINDEX to index all classes, methods, and instances defined on a file. See the documentation of SINGLEFILEINDEX for a detailed description of these variables.

LOOPSINDEX will load SINGLEFILEINDEX if it is not already loaded.

HOW TO SET UP FOR TESTING LOOPS Start with a fresh LISP.SYSOUT from {erinyes}<lisp>lyric>basics>, dated 27-Apr-87. Give no INIT file Log in. Type into the exec: (SETQ IL:DISPLAYFONTDIRECTORIES '("{ERINYES}<lisp>LYRIC>FONTS>")) CONN {ERINYES}<lisp>Lyric>library> (il:load 'TEDÍT.lcom) (il:tedit '{erinyes}<cate3>loops>LOOPS-setup.tedit) This should bring up this document. Shift selected all lines below here into the EXEC: (il:load 'FILEBROWSER.lcom) CONN {erinyes}<lisp>lyric>lispusers> (il:load 'WHO-LINE.dfasl) (il:load 'filewatch.lcom) CONN {erinyes}<lispusers>lyric> (il:load 'CROCK.lcom) CONN {erinyes}<test>lisp>lyric>internal>library> (il:load 'do-test.dfasl) (setq il:*DEFAULT-CLEANUP-COMPILER* 'cl:COMPILE-FILE) (setq il:ch.default.domain "AISNORTH") (SETQ IL:CH.DEFAULT.ORGANIZATION "XEROX") CONN |{PELE:AISNorth:Xerox}<CATE3>| (il:closew il:logow) (IL:CHANGEBACKGROUND 42405) (il:crock) Follow the instructions for loading loops from the release notes manual. As long as the workstation can get the font files from the network, steps 1-3 can be ignored in the Installation of Loops (4.3 of Release Notes) For step 4: The modified network version: CONN {ERINYES}<lisp>Lyric>library> (il:load 'grapher.lcom) For steps 5-6: Insert Lyric LOOPS System #1 floppy, then type: (il:fb '{floppy}) and copy all files to {dsk}<lispfiles>loops> Do the same for the Lyric LOOPS System #2 floppy Then type or shift select in an Interlisp window:

CONN "{DSK}<lispfiles>loops>"
(LOAD 'LOOPS)
Stuff the following lines into a temp file in core then shift select out the
sysout command.
(il:sysout '{erinyes}<cate3>loops>test-loops.sysout)
(il:login)
(il:fb '{erinyes}<cate3>loops>)
; Make sure the Loops stuff is copied to <lispfiles>loops>
load the right software, and change to loops stuff

The basic loop is (TIMEALL form 10000).
