The functions below can be used to perform version recognition without actually calling OPENSTREAM to open the file. Note that these functions only tell the truth about the moment at which they are called, and thus cannot in general be used to anticipate the name of the file opened by a comparable OPENSTREAM. They are sometimes, however, helpful hints.

(FULLNAME X RECOG)  
[Function]  
If X is an open stream, simply returns the full file name of the stream. Otherwise, if X is a file name given as a string or symbol, performs version recognition, as follows:

If X is recognized in the recognition mode specified by RECOG as an abbreviation for some file, returns the file’s full name, otherwise NIL. RECOG is one of the following:

OLD Choose the newest existing version of the file. Return NIL if no file named X exists.

OLDEST Choose the oldest existing version of the file. Return NIL if no file named X exists.

NEW Choose a new (not yet existing) version of the file. That is, if versions of X already exist, then choose a version number one higher than highest existing version; else choose version 1. For some file systems, FULLNAME returns NIL if you do not have the access rights necessary for creating a new file named X.

OLD/NEW Try OLD, then NEW. That is, choose the newest existing version of the file, if any; else choose version 1. This usually only makes sense if you are intending to open X for access BOTH.

RECOG = NIL defaults to OLD. For all other values of RECOG, generates an error ILLEGAL ARG.

If X already contains a version number, the RECOG argument will never change it. In particular, RECOG = NEW does not require that the file actually be new. For example, (FULLNAME ‘FOO.;2 ‘NEW) may return {ERIS}<LISP>FOO.;2 if that file already exists, even though (FULLNAME ‘FOO ‘NEW) would default the version to a new number, perhaps returning {ERIS}<LISP>FOO.;5.

(INFILEP FILE)  
[Function]  
Equivalent to (FULLNAME FILE ‘OLD). That is, returns the full file name of the newest version of FILE if FILE is recognized as specifying the name of an existing file that could potentially be opened for input, NIL otherwise.
(OUTFILEP FILE)  

[Function]  

Equivalent to (FULLNAME FILE 'NEW).

Note that INFILEP, OUTFILEP and FULLNAME do not open any files; they are pure predicates. In general they are also only hints, as they do not necessarily imply that the caller has access rights to the file. For example, INFILEP might return non-NIL, but OPENSTREAM might fail for the same file because the file is read-protected against you, or the file happens to be open for output by another user at the time. Similarly, OUTFILEP could return non-NIL, but OPENSTREAM could fail with a FILE SYSTEM RESOURCES EXCEEDED error.

Note also that in a shared file system, such as a remote file server, intervening file operations by another user could contradict the information returned by recognition. For example, a file that was INFILEP might be deleted, or between an OUTFILEP and the subsequent OPENSTREAM, another user might create a new version or delete the highest version, causing OPENSTREAM to open a different version of the file than the one returned by OUTFILEP. In addition, some file servers do not well support recognition of files in output context. Thus, in general, the “truth” about a file can only be obtained by actually opening the file; creators of files should rely on the name of the stream opened by OPENSTREAM, not the value returned from these recognition functions. In particular, for the reasons described earlier, programmers are discouraged from using OUTFILEP or (FULLNAME NAME 'NEW).

Using File Names Instead of Streams

In earlier implementations of Interlisp, from the days of Interlisp-10 onward, the “handle” used to refer to an open file was not a stream, but rather the file’s full name, represented as a symbol. When the file name was passed to any I/O function, it was mapped to a stream by looking it up in a list of open files. This scheme was sometimes convenient for typing in file commands at the executive, but was very poor for serious programming in two major ways. First, the mapping from file name to stream on every input/output operation is inefficient. Second, and more importantly, using the file name as the handle on an open stream means that it is not possible to have more than one stream open on a given file at once.

As of this writing, Medley is in a transition period, where it still supports the use of symbol file names as synonymous with open streams, but this use is not recommended. The remainder of this section discusses this usage of file names for the benefit of those reading older programs and wishing to convert them as necessary to work properly when this compatibility feature is removed.

File Name Efficiency Considerations

It is possible for a program to be seriously inefficient using a file name as a stream if the program is not using the file’s full name, the name returned by OPENFILE (below). Any time that an input/output function is called with a file name other than the full file name, Interlisp must perform recognition on the partial file name in order to determine which open file is intended. Thus if repeated operations are to be performed, it is considerably more efficient to use the full file name.
STREAMS & FILES

returned from OPENFILE than to repeatedly use the possibly incomplete name that was used to open the file.

There is a more subtle problem with partial file names, in that recognition is performed on your entire directory, not just the open files. It is possible for a file name that was previously recognized to denote one file to suddenly denote a different file. For example, suppose a program performs (infile 'FOO), opening FOO.1, and reads several expressions from FOO. Then you interrupt the program, create a FOO.2 and resume the program (or a user at another workstation creates a FOO.2). Now a call to READ giving it FOO as its FILE argument will generate a FILE NOT OPEN error, because FOO will be recognized as FOO.2.

Obsolete File Opening Functions

The following functions are now considered obsolete, but are provided for backwards compatibility:

(OPENFILE FILE ACCESS RECOG PARAMETERS) [Function]
Opens FILE with access rights as specified by ACCESS, and recognition mode RECOG, and returns the full name of the resulting stream. Equivalent to (FULLNAME (OPENSTREAM FILE ACCESS RECOG PARAMETERS)).

(INFILE FILE) [Function]
Opens FILE for input, and sets it as the primary input stream. Equivalent to (INPUT (OPENSTREAM FILE 'INPUT 'OLD))

(OUTFILE FILE) [Function]
Opens FILE for output, and sets it as the primary output stream. Equivalent to (OUTPUT (OPENSTREAM FILE 'OUTPUT 'NEW)).

(IOFILE FILE) [Function]
Equivalent to (OPENFILE FILE 'BOTH 'OLD); opens FILE for both input and output. Does not affect the primary input or output stream.

Converting Old Programs

At some point in the future, the Medley file system will change so that each call to OPENSTREAM returns a distinct stream, even if a stream is already open to the specified file. This change is required in order to deal rationally with files in a multiprocessing environment.

This change will of necessity produce the following incompatibilities:

1. The functions OPENFILE, INPUT, and OUTPUT will return a STREAM, not a full file name. To make this less confusing in interactive situations, STREAMs will have a print format that reveals the underlying file’s actual name,
2. A greater penalty will ensue for passing as the FILE argument to I/O operations anything other than the object returned from OPENFILE. Passing the file's name will be significantly slower than passing the stream (even when passing the "full" file name), and in the case where there is more than one stream open on the file it might even act on the wrong one.

3. OPENP will return NIL when passed the name of a file rather than a stream (the value of OPENFILE or OPENSTREAM).

Users should consider the following advice when writing new programs and editing existing programs, in order that they will continue to operate well when this change is made:

Because of the efficiency and ambiguity considerations described earlier, users have long been encouraged to use only full file names as FILE arguments to I/O operations. The "proper" way to have done this was to bind a variable to the value returned from OPENFILE and pass that variable to all I/O operations; such code will continue to work. A less proper way to obtain the full file name, but one which has to date not incurred any obvious penalty, is that which binds a variable to the result of an INFILEP and passes that to OPENFILE and all I/O operations. This has worked because INFILEP and OPENFILE both return a full file name, an invalid assumption in this future world. Such code should be changed to pass around the value of the OPENFILE, not the INFILEP.

Code that calls OPENP to test whether a possibly incomplete file name is already open should be recoded to pass to OPENP only the value returned from OPENFILE or OPENSTREAM.

Code that uses ordinary string functions to manipulate file names, and in particular the value returned from OPENFILE, should be changed to use the functions UNPACKFILENAME.STRING and PACKFILENAME.STRING. Those functions work both on file names (strings) and streams (coercing the stream to the name of its file).

Code that tests the value of OUTPUT for equality to some known file name or T should be examined carefully and, if possible, recoded.

To see more directly the effects of passing around STREAMs instead of file names, replace your calls to OPENFILE with calls to OPENSTREAM. OPENSTREAM is called in exactly the same way, but returns a STREAM. Streams can be passed to READ, PRINT, CLOSEF, etc just as the file's full name can be currently, but using them is more efficient. The function FULLNAME, when applied to a stream, returns its full file name.

Using Files with Processes

Because Medley does not yet support multiple streams per file, problems can arise if different processes attempt to access the same file. You have to be careful not to have two processes manipulating the same file at the same time, since the two processes will be sharing a single input
stream and file pointer. For example, it will not work to have one process TCOMPL a file while another process is running LISTFILES on it.

File Attributes

Any file has a number of "file attributes", such as the read date, protection, and bytesize. The exact attributes that a file can have is dependent on the file device. The functions GETFILEINFO and SETFILEINFO allow you to conveniently access file attributes:

(GETFILEINFO FILE ATTRIB) [Function]

Returns the current setting of the ATTRIB attribute of FILE.

(SETFILEINFO FILE ATTRIB VALUE) [Function]

Sets the attribute ATTRIB of FILE to be VALUE. SETFILEINFO returns T if it is able to change the attribute ATTRIB, and NIL if unsuccessful, either because the file device does not recognize ATTRIB or because the file device does not permit the attribute to be modified.

The FILE argument to GETFILEINFO and SETFILEINFO can be an open stream (or an argument designating an open stream, see Chapter 25), or the name of a closed file. SETFILEINFO in general requires write access to the file.

The attributes recognized by GETFILEINFO and SETFILEINFO fall into two categories: permanent attributes, which are properties of the file, and temporary attributes, which are properties only of an open stream to the file. The temporary attributes are only recognized when FILE designates an open stream; the permanent attributes are usually equally accessible for open and closed files. However, some devices are willing to change the value of certain attributes of an open stream only when specified in the PARAMETERS argument to OPENSTREAM (see above), not on a later call to SETFILEINFO.

The following are currently recognized as permanent attributes of a file:

BYTESIZE The byte size of the file. Medley currently only supports byte size 8.

LENGTH The number of bytes in the file. Alternatively, the byte position of the end-of-file. Like (GETEOPTR FILE), but FILE does not have to be open.

SIZE The size of FILE in pages.

CREATIONDATE The date and time, as a string, that the content of FILE was "created". The creation date changes whenever the content of the file is modified, but remains unchanged when a file is transported,
unmodified, across file systems. Specifically, 
COPYFILE and RENAMEFILE (see below) preserve the file's creation date. Note that this is different from the concept of "creation date" used by some operating systems (e.g., Tops20).

WRITEDATE The date and time, as a string, that the content of FILE was last written to this particular file system. When a file is copied, its creation date does not change, but its write date becomes the time at which the copy is made.

READDATE The date and time, as a string, that FILE was last read, or NIL if it has never been read.

CREATIONDATE, WRITEDATE and READDATE, respectively, in integer form, as IDATE (Chapter 12) would return. This form is useful for comparing dates.

AUTHOR The name of the user who last wrote the file.

TYPE The "type" of the file, some indication of the nature of the file’s content. The "types" of files allowed depends on the file device. Most devices recognize the symbol TEXT to mean that the file contains just characters, or BINARY to mean that the file contains arbitrary data.

Some devices support a wider range of file types that distinguish among the various sorts of files one might create whose content is "binary". All devices interpret any value of TYPE that they do not support to be BINARY. Thus, GETFILEINFO may return the more general value BINARY instead of the original type that was passed to SETFILEINFO or OPENSTREAM. Similarly, COPYFILE, while attempting to preserve the TYPE of the file it is copying, may turn, say, an INTERPRESS file into a mere BINARY file.

The way in which some file devices (e.g., Xerox file servers) support a wide range of file types is by representing the type as an integer, whose interpretation is known by the client. The variable FILEING.TYPES is used to associate symbolic types with numbers for these devices. This list initially contains some of the well-known assignments of
STREAMS & FILES

type name to number; you can add additional elements to handle any private file types. For example, suppose there existed an NS file type MAZEFILE with numeric value 5678. You could add the element (MAZEFILE 5678) to FILING.TYPES and then use MAZEFILE as a value for the TYPE attribute to SETFILEINFO or OPENSTREAM. Other devices are, of course, free to store TYPE attributes in whatever manner they wish, be it numeric or symbolic. FILING.TYPES is merely considered the official registry for Xerox file types.

For most file devices, the TYPE of a newly created file, if not specified in the PARAMETERS argument to OPENSTREAM, defaults to the value of DEFAULTFILETYPE, initially TEXT.

The following are currently recognized as temporary attributes of an open stream:

ACCESS  The current access rights of the stream (see the beginning of this chapter). Can be one of INPUT, OUTPUT, BOTH, APPEND; or NIL if the stream is not open.

ENDOFSTREAMOP  The action to be taken when a stream is at "end of file" and an attempt is made to take input from it. The value of this attribute is a function of one argument, the stream. The function can examine the stream and its calling context and take any action it wishes. If the function returns normally, its should return either T, meaning to try the input operation again, or the byte that BIN would have returned had there been more bytes to read. Ordinarily, one should not let the ENDOFSTREAMOP function return unless one is only performing binary input from the file, since there is no way in general of knowing in what state the reader was at the time the end of file occurred, and hence how it will interpret a single byte returned to it.

The default ENDOFSTREAMOP is a system function that causes the error END OF FILE. The behavior of that error can be further modified for a particular stream by using the EOF option of WHENCLOSE (see below).

EOL  The end-of-line convention for the stream. This can be CR, LF, or CRLF, indicating with what byte or sequence of bytes the "End Of Line" character is
represented on the stream. On input, that sequence of bytes on the stream is read as `(CHARCODE EOL)` by `READCCODE` or the string reader. On output, `(TERPRI)` and `(PRINTCCODE (CHARCODE EOL))` cause that sequence of bytes to be placed on the stream.

The end of line convention is usually not apparent to you. The file system is usually aware of the convention used by a particular remote operating system, and sets this attribute accordingly. If you believe a file actually is stored with a different convention than the default, it is possible to modify the default behavior by including the `EOL` attribute in the `PARAMETERS` argument to `OPENSTREAM`.

**BUFFERS**

Value is the number of 512-byte buffers that the stream maintains at one time. This attribute is only used by certain random-access devices (currently, the local disk, floppy, and Leaf servers); all others ignore it.

Streams open to files generally maintain some portion of the file buffered in memory, so that each call to an I/O function does not require accessing the actual file on disk or a file server. For files being read or written sequentially, not much buffer space is needed, since once a byte is read or written, it will never need to be seen again. In the case of random access streams, buffering is more complicated, since a program may jump around in the file, using `SETFILEPTR` (Chapter 25). In this case, the more buffer space the stream has, the more likely it is that after a `SETFILEPTR` to a place in the file that has already been accessed, the stream still has that part of the file buffered and need not go out to the device again. This benefit must, of course, be traded off against the amount of memory consumed by the buffers.

### Closing and Reopening Files

The function `WHENCLOSE` permits you to associate certain operations with open streams that govern how and when the stream will be closed. You can specify that certain functions will be executed before `CLOSEF` closes the stream and/or after `CLOSEF` closes the stream. You can make a particular stream be invisible to `CLOSEALL`, so that it will remain open across user invocations of `CLOSEALL`. 
(WHENCLOSE FILE PROP\_1 VAL\_1 \ldots PROP\_N VAL\_N) [NoSpread Function]

FILE must designate an open stream other than T (NIL defaults to the primary input stream, if other than T, or primary output stream if other than T). The remaining arguments specify properties to be associated with the full name of FILE. WHENCLOSE returns the full name of FILE as its value.

WHENCLOSE recognizes the following property names:

**BEFORE** VAL is a function that CLOSEF will apply to the stream just before it is closed. This might be used, for example, to copy information about the file from an in-core data structure to the file just before it is closed.

**AFTER** VAL is a function that CLOSEF will apply to the stream just after it is closed. This capability permits in-core data structures that know about the stream to be cleaned up when the stream is closed.

**CLOSEALL** VAL is either YES or NO and determines whether FILE will be closed by CLOSEALL (YES) or whether CLOSEALL will ignore it (NO). CLOSEALL uses CLOSEF, so that any AFTER functions will be executed if the stream is in fact closed. Files are initialized with CLOSEALL set to YES.

**EOF** VAL is a function that will be applied to the stream when an end-of-file error occurs, and the ERRORTYPELST entry for that error, if any, returns NIL. The function can examine the context of the error, and can decide whether to close the stream, RETFROM some function, or perform some other computation. If the function supplied returns normally (i.e., does not RETFROM some function), the normal error machinery will be invoked.

The default EOF behavior, unless overridden by this WHENCLOSE option, is to call the value of DEFAULTEOFCLOSE (below).

For some applications, the ENDOFSTREAMOP attribute (see above) is a more useful way to intercept the end-of-file error. The ENDOFSTREAMOP attribute comes into effect before the error machinery is ever activated.

Multiple AFTER and BEFORE functions may be associated with a file; they are executed in sequence with the most recently associated function executed...
first. The CLOSEALL and EOF values, however, will override earlier values, so only the last value specified will have an effect.

DEFAULTEOFCLOSE

[Variable]

Value is the name of a function that is called by default when an end of file error occurs and no EOF option has been specified for the stream by WHENCLOSE. The initial value of DEFAULTEOFCLOSE is NIL, meaning take no special action (go ahead and cause the error). Setting it to CLOSEF would cause the stream to be closed before the rest of the error machinery is invoked.

Local Hard Disk Device

Warning: This section describes the Medley functions that control the local hard disk drive available on some computers. All of these functions may not work on all computers running Medley. For more information on using the local hard disk facilities, see the users guide for your computer.

This section describes the local file system currently supported on the Xerox 1108 and 1186 computers. The Xerox 1132 supports a simpler local file system. The functions below are no-ops on the Xerox 1132, except for DISKPARTITION (which returns a disk partition number), and DISKFREEPAGES. On the Xerox 1132, different numbered partitions are referenced by using devices such as {DSK1}, {DSK2}, etc. {DSK} always refers to the disk partition that Interlisp is running on. The 1132 local file system does not support the use of directories.

The hard disk used with the Xerox 1108 or 1186 may be partitioned into a number of named "logical volumes." Logical volumes may be used to hold the Interlisp virtual memory file (see Chapter 12), or Interlisp files. For information on initializing and partitioning the hard disk, see the users guide for your computer. In order to store Interlisp files on a logical volume, it is necessary to create a lisp file directory on that volume (see CREATEDSKDIRECTORY, below).

So long as there exists a logical volume with a Lisp directory on it, files on this volume can be accessed by using the file device called {DSK}. Medley can be used to read, write, and otherwise interact with files on local disk disks through standard Interlisp input/output functions. All I/O functions such as LOAD, OPENSTREAM, READ, PRINT, GETFILEINFO, COPYFILE, etc., work with files on the local disk.

If you do not have a logical volume with a Lisp directory on it, Interlisp emulates the {DSK} device by a core device, a file device whose backing store is entirely within the Lisp virtual memory. However, this is not recommended because the core device only provides limited scratch space, and since the core device is contained in virtual memory, it (and the files stored on it) will be erased when the virtual memory file is reloaded.

Each logical volume with a Lisp directory on it serves as a directory of the device {DSK}. Files are referred to by forms such as
Thus, the file \texttt{INIT.LISP} on the volume \texttt{LISPFILES} would be called \texttt{(DSK}<LISPFILES>INIT.LISP).

Subdirectories within a logical volume are supported, using the > character in file names to delimit subdirectory names. For example, the file name \texttt{(DSK}<LISPFILES>DOC>DESIGN.TEDIT} designates the file names \texttt{DESIGN.TEDIT} on the subdirectory \texttt{DOC} on the logical volume \texttt{LISPFILES}.

If a logical volume name is not specified, it defaults in an unusual but simple way: the logical volume defaults to the next logical volume that has a lisp file directory on it including or after the volume containing the currently running virtual memory. For example, if the local disk has the logical volumes \texttt{LISP}, \texttt{TEMP}, and \texttt{LISPFILES}, the \texttt{LISP} volume contains the running virtual memory, and only the \texttt{LISP} volume has a Lisp file directory on it, then \texttt{(DSK)INIT.LISP} refers to the file \texttt{(DSK}<LISPFILES>INIT.LISP}. All the functions below default logical volume names in a similar way, except for those such as \texttt{CREATEDSKDIRECTORY}. To determine the current default lisp file directory, evaluate \texttt{(DIRECTORYNAME '{DSK})}.

\begin{verbatim}
(CREATEDSKDIRECTORY VOLUMENAME) [Function]
    Creates a Lisp file directory on the logical volume VOLUMENAME, and returns the name of
    the directory created. It is only necessary to create a Lisp file directory the first time the
    logical volume is used. After that, the system automatically recognizes and opens access
    to the logical volumes that have Lisp file directories on them.

(PURGEDSKDIRECTORY VOLUMENAME) [Function]
    Erases all Lisp files on the volume VOLUMENAME, and deletes the Lisp file directory.

(LISPDIRECTORYP VOLUMENAME) [Function]
    Returns T if the logical volume VOLUMENAME has a lisp file directory on it.

(VOLUMES) [Function]
    Returns a list of the names of all of the logical volumes on the local hard disk (whether
    they have lisp file directories or not).

(VOLUMESIZE VOLUMENAME) [Function]
    Returns the total size of the logical volume VOLUMENAME in disk pages.

(DISKFREEPAGES VOLUMENAME) [Function]
    Returns the total number of free disk pages left on the logical volume VOLUMENAME.

(DISKPARTITION) [Function]
    Returns the name of the logical volume containing the virtual memory file that Interlisp is
    currently running in (see Chapter 12).
\end{verbatim}
(DSKDISPLAY NEWSTATE)  
[Function]  
Controls a display window that displays information about the logical volumes on the 
local hard disk (logical volume names, sizes, free pages, etc.). DSKDISPLAY opens or 
closes this display window depending on the value of NEWSTATE (one of ON, OFF, or 
CLOSED), and returns the previous state of the display window.

If NEWSTATE is ON, the display window is opened, and it is automatically updated 
whenever the file system state changes (this can slow file operations significantly). If 
NEWSTATE is OFF, the display window is opened, but it is not automatically updated. If 
NEWSTATE is CLOSED, the display window is closed. The display mode is initially set to 
CLOSED.

Once the display window is open, you can update it or change its state with the mouse. 
Left-buttoning the display window updates it, and middle-buttoning the window brings 
up a menu that allows you to change the display state.

Note: DSKDISPLAY uses the value of the variable DSKDISPLAY.POSITION 
for the position of the lower-left corner of the disk display window 
when it is opened. This variable is changed if the disk display 
window is moved.

(SCAVENGEDSKDIRECTORY VOLUMENAME SILENT)  
[Function]  
Rebuilds the lisp file directory for the logical volume VOLUMENAME. This may repair 
damage in the unlikely event of file system failure, signified by symptoms such as infinite 
looping or other strange behavior while the system is doing a directory search. Calling 
SCAVENGEDSKDIRECTORY will not harm an intact volume.

Normally, SCAVENGEDSKDIRECTORY prints out messages as it scavenges the directory. If 
SILENT is non-NIL, these messages are not printed.

Note: Some low-level disk failures may cause "HARD DISK ERROR" errors 
to occur. To fix such a failure, it may be necessary to log out of 
Interlisp, scavenge the logical volume in question using Pilot tools, 
and then call SCAVENGEDSKDIRECTORY from within Interlisp. See 
the users guide for your computer for more information.

Floppy Disk Device

Warning: This section describes the Medley functions that control the floppy disk drive available on some 
computers. All of these functions may not work on all computers running Medley. For more information on 
using the floppy disk facilities, see the users guide for your computer.

The floppy disk drive is accessed through the device {FLOPPY}. Medley can be used to read, write, 
and otherwise interact with files on floppy disks through standard Interlisp input/output functions. 
All I/O functions such as LOAD, OPENSTREAM, READ, PRINT, GETFILEINFO, COPYFILE, etc., work 
with files on floppies.
Note that floppy disks are a removable storage medium. Therefore, it is only meaningful to perform I/O operations to the floppy disk drive, rather than to a given floppy disk. In this section, the phrase “the floppy” is used to mean “the floppy that is currently in the floppy disk drive.”

For example, the following sequence could be used to open a file XXX.TXT on the floppy, print “Hello” on it, and close it:

```lisp
(setq xxx (openstream '{floppy}xxx.txt 'output 'new)
(print "Hello" xxx)
(closeref xxx)
```

(FLOPPY.MODE MODE) [Function]

Medley can currently read and write files on floppies stored in a number of different formats. At any point, the floppy is considered to be in one of four “modes,” which determines how it reads and writes files on the floppy. FLOPPY.MODE sets the floppy mode to the value of MODE, one of PILOT, HUGEPILOT, SYSOUT, or CPM, and returns the previous floppy mode. The floppy modes are interpreted as follows:

**PILOT** This is the normal floppy mode, using floppies in the Xerox Pilot floppy disk format. This file format allows all of the normal Medley I/O operations. This format also supports file names with arbitrary levels of subdirectories. For example, it is possible to create a file named `{floppy}<lisp>project>foo.txt`.

**HUGEPILOT** This floppy mode is used to access files that are larger than a single floppy, stored on multiple floppies. There are some restrictions with using “huge” files. Some I/O operations are not meaningful for “huge” files. When a stream is created for output in this mode, the LENGTH file attribute must be specified when the file is opened, so that it is known how many floppies will be needed. When an output file is created, the floppy (or floppies) are automatically erased and reformatted (after confirmation from you).

HUGEPILOT mode is primarily useful for saving big files to and from floppies. For example, the following could be used to copy the file `{ERIS}<lisp>bigfile.txt` onto the huge Pilot file `{FLOPPY}bigfile.save`:

```lisp
(floppy.mode 'hugepilot)
(copyfile '{ERIS}<lisp>bigfile.txt '{FLOPPY}bigfile.save)
```
and the following would restore the file:

(FLOPPY.MODE 'HUGEPILOT)

(COPYFILE '{FLOPPY}BigFile.save '{ERIS}<Lisp>Bigfile.txt)

During each copying operation, you will be prompted to insert "the next floppy" if {ERIS}<Lisp>Bigfile.txt takes multiple floppies.

SYSOUT  Similar to HUGEPILOT mode, SYSOUT mode is used for storing sysout files (Chapter 12) on multiple floppy disks. You are prompted to insert new floppies as they are needed.

This mode is set automatically when SYSOUT or MAKESYS is done to the floppy device: (SYSOUT '{FLOPPY}) or (MAKESYS '{FLOPPY}). Notice that the file name does not need to be specified in SYSOUT mode; unlike HUGEPILOT mode, the file name Lisp.sysout is always used.

Note: The procedure for loading sysout files from floppies depends on the particular computer being used. For information on loading sysout files from floppies, see the users Guide for your computer.

Explicitly setting the mode to SYSOUT is useful when copying a sysout file to or from floppies. For example, the following can be used to copy the sysout file {ERIS}<Lisp>Lisp.sysout onto floppies (it is important to set the floppy mode back when done):

(FLOPPY.MODE 'SYSOUT)
(COPYFILE '{ERIS}<Lisp>Lisp.sysout '{FLOPPY})
(FLOPPY.MODE 'PILOT)

CPM  Medley supports the single-density single-sided (SDSS) CPM floppy format (a standard used by many computers). CPM-formatted floppies are totally different than Pilot floppies, so you should call FLOPPY.MODE to switch to CPM mode when planning to use CPM floppies. After switching to CPM mode, FLOPPY.FORMAT can be used to create CPM-formatted floppies, and the usual input/output operations work with CPM floppy files.
Note: There are a few limitations on CPM floppy format files: (1) CPM file names are limited to eight or fewer characters, with extensions of three or fewer characters; (2) CPM floppies do not have directories or version numbers; and (3) CPM files are padded out with blanks to make the file lengths multiples of 128.

(FLOPPY.FORMAT NAME AUTOCONFIRMFLG SLOWFLG)

FLOPPY.FORMAT erases and initializes the track information on a floppy disk. This must be done when new floppy disks are to be used for the first time. This can also be used to erase the information on used floppy disks.

NAME should be a string that is used as the name of the floppy (106 characters max). This name can be read and set using FLOPPY.NAME (below).

If AUTOCONFIRMFLG is NIL, you will be prompted to confirm erasing the floppy, if it appears to contain valid information. If AUTOCONFIRMFLG is T, you are not prompted to confirm.

If SLOWFLG is NIL, only the Pilot records needed to give your floppy an empty directory are written. If SLOWFLG is T, FLOPPY.FORMAT will completely erase the floppy, writing track information and critical Pilot records on it. SLOWFLG should be set to T when formatting a brand-new floppy.

Note: Formatting a floppy is a very compute-intensive operation for the I/O hardware. Therefore, the cursor may stop tracking the mouse and keystrokes may be lost while formatting a floppy. This behavior goes away when the formatting is finished.

Warning: The floppy mode set by FLOPPY.MODE (above) affects how FLOPPY.FORMAT formats the floppy. If the floppy is going to be used in Pilot mode, it should be formatted under (FLOPPY.MODE ’PILOT). If it is to be used as a CMP floppy, it should be formatted under (FLOPPY.MODE ’CPM). The two types of formatting are incompatible.

(FLOPPY.NAME NAME)

If NAME is NIL, returns the name stored on the floppy disk. If NAME is non-NIL, then the name of the floppy disk is set to NAME.

(FLOPPY.FREE.PAGES)

Returns the number of unallocated free pages on the floppy disk in the floppy disk drive.

Note: Pilot floppy files are represented by contiguous pages on a floppy disk. If you are creating and deleting a lot of files on a floppy, it is advisable to keep such a floppy less than 75 percent full.

(FLOPPY.CAN.READP)

Returns non-NIL if there is a floppy in the floppy drive.
Note: FLOPPY.CAN.READP does not provide any debouncing (protection against not fully closing the floppy drive door). It may be more useful to use FLOPPY.WAIT.FOR.FLOPPY (below).

(FLOPPY.CAN.WRITEP) [Function]

Returns non-NIL if there is a floppy in the floppy drive and the floppy drive can write on this floppy.

It is not possible to write on a floppy disk if the "write-protect notch" on the floppy disk is punched out.

(FLOPPY.WAIT.FOR.FLOPPY NEWFLG) [Function]

If NEWFLG is NIL, waits until a floppy is in the floppy drive before returning.

If NEWFLG is T, waits until the existing floppy in the floppy drive, if any, is removed, then waits for a floppy to be inserted into the drive before returning.

(FLOPPY.SCAVENGE) [Function]

Attempts to repair a floppy whose critical records have become confused (causing errors when file operations are attempted). May also retrieve accidently-deleted files, provided they haven’t been overwritten by new files.

(FLOPPY.TO.FILE TOFILE) [Function]

Copies the entire contents of the floppy to the "floppy image" file TOFILE, which can be on a file server, local disk, etc. This can be used to create a centralized copy of a floppy, that different users can copy to their own floppy disks (using FLOPPY.FROM.FILE).

Note: A floppy image file for an 8-inch floppy is about 2500 pages long, regardless of the number of pages in use on the floppy.

(FLOPPY.FROM.FILE FROMFILE) [Function]

Copies the "floppy image" file FROMFILE to the floppy. FROMFILE must be a file produced by FLOPPY.TO.FILE.

(FLOPPY.ARCHIVE FILES NAME) [Function]

FLOPPY.ARCHIVE formats a floppy inserted into the floppy drive, giving the floppy the name NAME#1. FLOPPY.ARCHIVE then copies each file in FILES to the freshly formatted floppy. If the first floppy fills up, FLOPPY.ARCHIVE uses multiple floppies (named NAME#2, NAME#3, etc.), each time prompting you to insert a new floppy.

The function DIRECTORY (see below) is convenient for generating a list of files to archive. For example,

```
(FLOPPY.ARCHIVE
   (DIRECTORY '{ERIS}<Lisp>Project>*)
   'Project)
```
will archive all files on the directory `{ERIS}<Lisp>Project` to floppies (named Project#1, Project#2, etc.).

(FLOPPY.UNARCHIVE HOST/DIRECTORY)  [Function]

FLOPPY.UNARCHIVE copies all files on the current floppy to the directory HOST/DIRECTORY. For example, (FLOPPY.UNARCHIVE `{ERIS}<Lisp>Project`) will copy each file on the current floppy to the directory `{ERIS}<Lisp>Project`. If there is more than one floppy to restore from archive, FLOPPY.UNARCHIVE should be called on each floppy disk.

I/O Operations to and from Strings

It is possible to treat a string as if it were the contents of a file by using the following function:

(OPENSTRINGSTREAM STR ACCESS)  [Function]

Returns a stream that can be used to access the characters of the string STR. ACCESS may be either INPUT, OUTPUT, or BOTH; NIL defaults to INPUT. The stream returned may be used exactly like a file opened with the same access, except that output operations may not extend past the end of the original string. Also, string streams do not appear in the value of (OPENP).

For example, after performing

(SETQ STRM (OPENSTRINGSTREAM "THIS 2 (IS A LIST)"))

the following succession of reads could occur:

(READ STRM)  => THIS
(RATOM STRM) => 2
(READ STRM)  => (IS A LIST)
(EOFP STRM)  => T

Compatibility Note: In Interlisp-10 it was possible to take input from a string simply by passing the string as the FILE argument to an input function. In order to maintain compatibility with this feature, Medley provides the same capability. This not terribly clean feature persists in the present implementation to give users time to convert old code. This means that strings are not equivalent to symbols when specifying a file name as a stream argument. In a future release, the old Interlisp-10 string-reading feature will be decommissioned, and OPENSTRINGSTREAM will be the only way to perform I/O on a string.

Temporary Files and the CORE Device

Many operating systems have a notion of "scratch file", a file typically used as temporary storage for data most naturally maintained in the form of a file, rather than some other data structure.
file can be used as a normal file in most respects, but is automatically deleted from the file system after its useful life is up, e.g., when the job terminates, or you log out. In normal operation, you need never explicitly delete such files, since they are guaranteed to disappear soon.

A similar functionality is provided in Medley by core-resident files. Core-resident files are on the device CORE. The directory structure for this device and all files on it are represented completely within your virtual memory. These files are treated as ordinary files by all file operations; their only distinguishing feature is that all trace of them disappears when the virtual memory is abandoned.

Core files are opened and closed by name the same as any other file, e.g., (OPENSTREAM '{CORE}<FOO>FIE.DCOM 'OUTPUT). Directory names are completely optional, so files can also have names of the form {CORE}NAME.EXT. Core files can be enumerated by DIRECTORY (see below). While open, they are registered in (OPENP). They do consume virtual memory space, which is only reclaimed when the file is deleted. Some caution should thus be used when creating large CORE files. Since the virtual memory of an Medley workstation usually persists far longer than the typical process on a mainframe computer, it is still important to delete CORE files after they are no longer in use.

For many applications, the name of the scratch file is irrelevant, and there is no need for anyone to have access to the file independent of the program that created it. For such applications, NODIRCORE files are preferable. Files created on the device lisp NODIRCORE are core-resident files that have no name and are registered in no directory. These files “disappear”, and the resources they consume are reclaimed, when all pointers to the file are dropped. Hence, such files need never be explicitly deleted or, for that matter, closed. The “name” of such a file is simply the stream object returned from (OPENSTREAM '{NODIRCORE} 'OUTPUT), and it is this stream object that must be passed to all input/output operations, including CLOSEF and any calls to OPENSTREAM to reopen the file.

(COREDEVICE NAME NODIRFLG) [Function]

Creates a new device for core-resident files and assigns NAME as its device name. Thus, after performing (COREDEVICE ‘FOO), one can execute (OPENSTREAM ‘{FOO}BAR 'OUTPUT) to open a file on that device. Medley is initialized with the single core-resident device named CORE, but COREDEVICE may be used to create any number of logically distinct core devices.

If NODIRFLG is non-NIL, a core device that acts like {NODIRCORE} is created.

Compatibility note: In Interlisp-10, it was possible to create scratch files by using file names with suffixes ;S or ;T. In Medley, these suffixes in file names are simply ignored when output is directed to a particular host or device. However, the function PACKFILENAME.STRING is defined to default the device name to CORE if the file has the TEMPORARY attribute and no explicit host is provided.
NULL Device

The NULL device provides a source of content-free "files". \(\text{(OPENSTREAM} \ '\{\text{NULL}\} \ '\text{OUTPUT})\) creates a stream that discards all output directed at it. \(\text{(OPENSTREAM} \ '\{\text{NULL}\} \ '\text{INPUT})\) creates a stream that is perpetually at end-of-file (i.e., has no input).

Deleting, Copying, and Renaming Files

\((\text{DELFILE FILE})\) [Function]

Deletes FILE if possible. The file must be closed. Returns the full name of the file if deleted, else NIL. Recognition mode for FILE is OLDEST, i.e., if FILE does not have a version number specified, then DELFILE deletes the oldest version of the file.

\((\text{COPYFILE FROMFILE TOFILE})\) [Function]

Copies FROMFILE to a new file named TOFILE. The source and destination may be on any combination of hosts/devices. COPYFILE attempts to preserve the TYPE and CREATIONDATE where possible. If the original file’s file type is unknown, COPYFILE attempts to infer the type (file type is BINARY if any of its 8-bit bytes have their high bit on).

COPYFILE uses COPYCHARS (Chapter 25) if the source and destination hosts have different EOL conventions. Thus, it is possible for the source and destination files to be of different lengths.

\((\text{RENAMEFILE OLDFILE NEWFILE})\) [Function]

Renames OLDFILE to be NEWFILE. Causes an error, FILE NOT FOUND if FILE does not exist. Returns the full name of the new file, if successful, else NIL if the rename cannot be performed.

If OLDFILE and NEWFILE are on the same host/device, and the device implements a renaming primitive, RENAMEFILE can be very fast. However, if the device does not know how to rename files in place, or if OLDFILE and NEWFILE are on different devices, RENAMEFILE works by copying OLDFILE to NEWFILE and then deleting OLDFILE.

Searching File Directories

\(\text{DIRECTORIES}\) [Variable]

Global variable containing the list of directories searched (in order) by SPELLFILE and FINDFILE (below) when not given an explicit DRLST argument. In this list, the atom NIL stands for the login directory (the value of LOGINHOST/DIR), and the atom T stands for the currently connected directory. Other elements should be full directory specifications, e.g., \{TWENTY}PS::<LISPUSERS>, not merely LISPUSERS.
LISPUSERSDIRECTORIES

[Variable]

Global variable containing a list of directories to search for "library" package files. Used by the FILES file package command (Chapter 17).

(SPELLFILE FILE NOPRINTFLG NSFLG DRLST)

[Function]

Searches for the file name FILE, possibly performing spelling correction (see Chapter 20). Returns the corrected file name, if any, otherwise NIL.

If FILE has a directory field, SPELLFILE attempts spelling correction against the files in that particular directory. Otherwise, SPELLFILE searches for the file on the directory list DRLST before attempting any spelling correction.

If NOPRINTFLG is NIL, SPELLFILE asks you to confirm any spelling correction done, and prints out any files found, even if spelling correction is not done. If NOPRINTFLG = T, SPELLFILE does not do any printing, nor ask for approval.

If NSFLG = T (or NOSPELLFLG = T, see Chapter 20), no spelling correction is attempted, though searching through DRLST still occurs.

DRLST is the list of directories searched if FILE does not have a directory field. If DRLST is NIL, the value of the variable DIRECTORIES is used.

Note: If DRLST is NIL, and FILE is not found by searching the directories on DIRECTORIES, but the root name of FILE has a FILEDATES property (Chapter 17) indicating that a file by that name has been loaded, then the directory indicated in the FILEDATES property is searched, too. This additional search is not done if DRLST is non-NIL.

ERRORTYPELST (Chapter 14) initially contains the entry ((23 (SPELLFILE (CADR ERRORMESS) NIL NOFILESPELLFLG))), which causes SPELLFILE to be called in case of a FILE NOT FOUND error. If the variable NOFILESPELLFLG is T (its initial value), then spelling correction is not done on the file name, but DIRECTORIES is still searched. If SPELLFILE is successful, the operation will be reexecuted with the new (corrected) file name.

(FINDFILE FILE NSFLG DRLST)

[Function]

Uses SPELLFILE to search for a file named FILE. If it finds one, returns its full name, with no user interaction. Specifically, it calls (SPELLFILE FILE T NSFLG DRLST), after first performing two simple checks: If FILE has an explicit directory, it checks to see if a file so named exists, and if so returns that file. If DRLST is NIL, it looks for FILE on the connected directory before calling SPELLFILE.
Listing File Directories

The function DIRECTORY allows you to conveniently specify and/or program a variety of directory operations:

(DIRECTORY FILES COMMANDS DEFAULTTEXT DEFAULTVERS)  [Function]

Returns, lists, or performs arbitrary operations on all files specified by the "file group" FILES. A file group has the form of a regular file name, except that the character * can be used to match any number of characters, including zero, in the file name. For example, the file group A*B matches all file names beginning with the character A and ending with the character B. The file group *.DCOM matches all files with an extension of DCOM.

If FILES does not contain an explicit extension, it is defaulted to DEFAULTTEXT; if FILES does not contain an explicit version, it is defaulted to DEFAULTVERS. DEFAULTTEXT and DEFAULTVERS themselves default to *. If the period or semicolon preceding the omitted extension or version, respectively, is present, the field is explicitly empty and no default is used. All other unspecified fields default to *. Null version is interpreted as "highest". Thus FILES = * or *. or *. then enumerates all files on the connected directory; FILES = *. or *.;* enumerates all versions of files with null extension; FILES = *.; enumerates the highest version of files with null extension; and FILES = *.*; enumerates the highest version of all files. If FILES is NIL, it defaults to *.*.

Note: Some hosts/devices are not capable of supporting "highest version" in enumeration. Such hosts instead enumerate all versions.

For each file that matches the file group FILES, the "file commands" in COMMANDS are executed in order. Some of the file commands allow aborting the command processing for a given file, effectively filtering the list of files. The interpretation of the different file commands is described below. If COMMANDS is NIL, it defaults to (COLLECT), which collects the matching file names in a list and returns it as the value of DIRECTORY.

The "file commands" in COMMANDS are interpreted as follows:

P  Prints the file’s name. For readability, DIRECTORY strips the directory from the name, printing it once as a header in front of each set of consecutive files on the same directory.

PP Prints the file’s name without a version number.

a string Prints the string.

READDATE, WRITEDATE CREATIONDATE, SIZE LENGTH, BYTESIZE PROTECTION, AUTHOR TYPE Prints the appropriate information returned by GETFILEINFO (see above).
COLLECT Adds the full name of this file to an accumulating list, which will be returned as the value of DIRECTORY.

COUNTSIZE Adds the size of this file to an accumulating sum, which will be returned as the value of DIRECTORY.

DELETE Deletes the file.

DELVER If this file is not the highest version of files by its name, delete it.

PAUSE Waits until you type any character before proceeding with the rest of the commands (good for display if you want to ponder).

The following commands are predicates to filter the list. If the predicate is not satisfied, then processing for this file is aborted and no further commands (such as those above) are executed for this file.

Note: if the P and PP commands appear in COMMANDS ahead of any of the filtering commands below except PROMPT, they are postponed until after the filters. Thus, assuming the caller has placed the attribute options after the filters as well, no printing occurs for a file that is filtered out. This is principally so that functions like DIR (below) can both request printing and pass arbitrary commands through to DIRECTORY, and have the printing happen in the appropriate place.

PROMPT MESS Prompts with the yes/no question MESS; if user responds with No, abort command processing for this file.

OLDERTHAN N Continue command processing if the file hasn’t been referenced (read or written) in N days. N can also be a string naming an explicit date and time since which the file must not have been referenced.

NEWERTHAN N Continue command processing if the file has been written within the last N days. N can also be a string naming an explicit date and time. Note that this is not quite the complement of OLDERTHAN, since it ignores the read date.

BY USER Continue command processing if the file was last written by the given user, i.e., its AUTHOR attribute matches (case insensitively) USER.

@ X X is either a function of one argument (FILENAME), or an arbitrary expression which uses the variable FILENAME freely. If X returns NIL, abort command processing for this file.
STREAMS & FILES

The following two commands apply not to any particular file, but globally to the manner in which directory information is printed.

**OUT FILE**  Directs output to *FILE*.

**COLUMNS N**  Attempts to format output in *N* columns (rather than just 1).

DIRECTORY uses the variable DIRCOMMANDS as a spelling list to correct spelling and define abbreviations and synonyms (see Chapter 20). Currently the following abbreviations are recognized:

- **AU** => AUTHOR
- **-** => PAUSE
- **COLLECT?** => PROMPT " ? " COLLECT
- **DA**
- **DATE** => CREATIONDATE
- **TI** => WRITEDATE
- **DEL** => DELETE
- **DEL?**
- **DELETE?** => PROMPT " delete? " DELETE
- **OLD** => OLDERTHAN 90
- **PR** => PROTECTION
- **SI** => SIZE
- **VERBOSE** => AUTHOR CREATIONDATE SIZE READDATE WRITEDATE

((FILDIR FILEGROUP)  [Function])

Obsolete synonym of (DIRECTORY FILEGROUP).

((DIR FILEGROUP COM₁ ... COMₙ)  [NLambda NoSpread Function])

Convenient form of DIRECTORY for use in type-in at the executive. Performs (DIRECTORY 'FILEGROUP ' (P COM₁ ... COMₙ)).

((NDIR FILEGROUP COM₂ ... COMₙ)  [NLambda NoSpread Function])

Version of DIR that lists the file names in a multi-column format. Also, by default only lists the most recent version of files (unless FILEGROUP contains an explicit version).

---

**File Servers**

A file server is a shared resource on a local communications network which provides large amounts of file storage. Different file servers honor a variety of access protocols. Medley supports the following
protocols: PUP-FTP, PUP-Leaf, and NS Filing. In addition, there are library packages available that support other communications protocols, such as TCP/IP and RS232.

With the exception of the RS232-based protocols, which exist only for file transfer, these network protocols are integrated into the Medley file system to allow files on a file server to be treated in much the same way files are accessed on local devices, such as the disk. Thus, it is possible to call OPENSTREAM on the file \{ERIS\}<LISP>FOO.DCOM;3 and read from it or write to it just as if the file had been on the local disk \{{DSK}\}<LISP>FOO.DCOM;3, rather than on a remote server named ERIS. However, the protocols vary in how much control they give the workstation over file system operations. Hence, some restrictions apply, as described in the following sections.

**PUP File Server Protocols**

There are two file server protocols in the family of PUP protocols: Leaf and FTP. Some servers support both, while others support only one of them. Medley uses whichever protocol is more appropriate for the requested operation.

Leaf is a random access protocol, so files opened using these protocols are RANDACCESSP, and thus most normal I/O operations can be performed. However, Leaf does not support directory enumeration. Hence, DIRECTORY cannot be used on a Leaf file server unless the server also supports FTP. In addition, Leaf does not supply easy access to a file’s attributes. INFILEP and GETFILEINFO have to open the file for input in order to obtain their information, and hence the file’s read date will change, even though the semantics of these functions do not imply it.

FTP is a file transfer protocol that only permits sequential access to files. However, most implementations of it are considerably more efficient than Leaf. Medley uses FTP in preference to Leaf whenever the call to OPENSTREAM requests sequential access only. In particular, the functions SYSOUT and COPYFILE open their files for sequential access. If a file server supports FTP but for some reason it is undesirable for Lisp to use it, one can set the internal variable \FTPAVAILABLE to NIL.

The system normally maintains a Leaf connection to a host in the background. This connection can be broken by calling (BREAKCONNECTION HOST). Any subsequent reference to files on that host will re-establish the connection. The principal use for this function arises when you interrupt a file operation in such a way that the file server thinks the file is open but Lisp thinks it is closed (or not yet open). As a result, the next time Lisp tries to open the file, it gets a file busy error.

**Xerox NS File Server Protocols**

Interlisp supports file access to Xerox 803x file servers, using the Filing Protocol built on Xerox Network Systems protocols. Medley determines that a host is an NS File Server by the presence of a colon in its name, e.g., \{PHLEX:\}. The general format of NS fileserver device names is \{SERVERNAME:DOMAIN:ORGANIZATION\}; the device specification for an 8000-series product in general includes the ClearingHouse domain and organization. If domain and organization are not supplied directly, then they are obtained from the defaults, which themselves are found by consulting
the nearest ClearingHouse if you have not defined them in an init file. However, note that the server name must still have a colon in it to distinguish it from other types of host names (e.g., PUP server names).

NS file servers in general permit arbitrary characters in file names. You should be cognizant of file name quoting conventions, and the fact that any file name presented as a symbol needs to have characters of significance to the reader, such as space, escaped with a %. Of course, one can always present the file name as a string, in which case only the quoting conventions are important.

NS file servers support a true hierarchical file system, where subdirectories are just another kind of file, which needs to be explicitly created. In Interlisp, subdirectories are created automatically as needed: A call to OPENFILE to create a file in a non-existent subdirectory automatically creates the subdirectory. CONN to a non-existent subdirectory asks you whether to create the directory. For those using Star software, a directory corresponds to a "File Drawer," while a subdirectory corresponds to a "File Folder."

Because of their hierarchical structure, NS directories can be enumerated to arbitrary levels. The default is to enumerate all the files (the leaves of the tree), omitting the subdirectory nodes themselves. This default can be changed by the following variable:

\texttt{FILING.\textsc{enumeration.\textsc{depth}}} \\
\hspace{1cm} \texttt{[\texttt{Variable}]}

This variable is either a number, specifying the number of levels deep to enumerate, or \texttt{T}, meaning enumerate to all levels. In the former case, when the enumeration reaches the specified depth, only the subdirectory name rooted at that level is listed, and none of its descendants is listed. When \texttt{FILING.\textsc{enumeration.\textsc{depth}}} is \texttt{T}, all files are listed, and no subdirectory names are listed. \texttt{FILING.\textsc{enumeration.\textsc{depth}}} is initially \texttt{T}.

Independent of \texttt{FILING.\textsc{enumeration.\textsc{depth}}}, a request to enumerate the top-level of a file server’s hierarchy lists only the top level, i.e., assumes a depth of 1. For example, \texttt{(DIRECTORY ‘(\textsc{phylex}::))} lists exactly the top-level directories of the server \texttt{\textsc{phylex}::}.

NS file servers do not currently support random access. Therefore, \texttt{SETFILEPTR} of an NS file generally causes an error. However, \texttt{GETFILEPTR} returns the correct character position for open files on NS file servers. In addition, \texttt{SETFILEPTR} works in the special case where the file is open for input, and the file pointer is being set forward. In this case, the intervening characters are automatically read.

Even while Interlisp has no file open on an NS Server, the system maintains a "session" with the server for a while in order to improve the speed of subsequent requests to the server. While this session is open, it is possible for some nodes of the server’s file system to appear "busy" or inaccessible to certain clients on other workstations (such as Star). If this happens, the following function can be used to terminate any open sessions immediately.

\texttt{(BREAK.NSFILING.CONNECTION \textit{HOST})} \\
\hspace{1cm} \texttt{[\texttt{Function}]}

Closes any open connections to NS file server \textit{HOST}.
Operating System Designations

Some of the network server protocols are implemented on more than one kind of foreign host. Such hosts vary in their conventions for logging in, naming files, representing end-of-line, etc. In order for Interlisp to communicate gracefully with all these hosts, it is necessary that the variable NETWORKOSTYPES be set correctly. The following functions are now considered obsolete, but are provided for backwards compatibility:

NETWORKOSTYPES [Variable]

An association-list that associates a host name with its operating system type. Elements in this list are of the form (HOSTNAME . TYPE). For example, (MAXC2 . TENEX). The operating system types currently known to Lisp are TENEX, TOPS20, UNIX, and VMS. The host names in this list should be the "canonical" host name, represented as an uppercase atom. For PUP and NS hosts, the function CANONICAL.HOSTNAME (below) can be used to determine which of several aliases of a server is the canonical name.

(CANONICAL.HOSTNAME HOSTNAME) [Function]

Returns the "canonical" name of the server HOSTNAME, or NIL if HOSTNAME is not the name of a server.

Logging In

Most file servers require a user name and password for access. Medley maintains an ephemeral database of user names and passwords for each host accessed recently. The database vanishes when LOGOUT, SAVEVM, SYSOUT, or MAKESYS is executed, so that the passwords remain secure from any subsequent user of the same virtual memory image. Medley also maintains a notion of the "default" user name and password, which are generally those with which you initially log in.

When a file server for which the system does not yet have an entry in its password database requests a name and password, the system first tries the default user name and password. If the file server does not recognize that name/password, the system prompts you for a name and password to use for that host. It suggests a default name:

{ERIS} Login: Green

which you can accept by pressing [Return], or replace the name by typing a new name or backspacing over it. Following the name, you are prompted for a password:

{ERIS} Login: Verdi (password)

which is not echoed, terminated by another [Return]. This information is stored in the password database so that you are prompted only once, until the database is again cleared.
Medley also prompts for password information when a protection violation occurs on accessing a directory on certain kinds of servers that support password-protected directories. Some such servers allow one to protect a file in a way that is inaccessible to even its owner until the file’s protection is changed. In such cases, no password would help, and the system causes the normal PROTECTION VIOLATION error.

You can abort a password interaction by typing the ERROR interrupt, initially Cosntrol-E. This generally either causes a PROTECTION VIOLATION error, if the password was requested in order to gain access to a protected file on an otherwise accessible server; or to act as though the server did not exist, in the case where the password was needed to gain any access to the server.

**(LOGIN HOSTNAME FLG DIRECTORY MSG)**

Forces Medley to ask for your name and password to be used when accessing host HOSTNAME. Any previous login information for HOSTNAME is overridden. If HOSTNAME is NIL, it overrides login information for all hosts and resets the default user name and password to be those typed in by you. The special value HOSTNAME = NS:: is used to obtain the default user name and password for all logins for NS Servers. If FLG is the atom QUIET, only prompts you if there is no cached information for HOSTNAME.

If DIRECTORY is specified, it is the name of a directory on HOSTNAME. In this case, the information requested is the "connect" password for that directory. Connect passwords for any number of different directories on a host can be maintained.

If MSG is non-NIL, it is a message (a string) to be printed before the name and password information is requested.

LOGIN returns the user name with which you completed the login.

**(SETPASSWORD HOST USER PASSWORD DIRECTORY)**

Sets the values in the internal password database exactly as if the strings USER and PASSWORD were typed in via (LOGIN HOST NIL DIRECTORY).

**(SETUSERNAME NAME)**

Sets the default user name to NAME.

**(USERNAME FLG STRPTR PRESERVECASE)**

If FLG = NIL, returns the default user name. This is the only value of FLG that is meaningful in Medley.

USERNAME returns the value as a string, unless STRPTR is T, in which case USERNAME returns the value as an atom. The name is returned in uppercase, unless PRESERVECASE is true.
Abnormal Conditions

If Medley tries to access a file and does not get a response from the file server in a reasonable period of time, it prints a message that the file server is not responding, and keeps trying. If the file server has actually crashed, this may continue indefinitely. A Control-E or similar interrupt aborts out of this state.

If the file server crashes but is restarted before you attempt to do anything, file operations will usually proceed normally, except for a brief pause while Medley tries to re-establish any connections it had open before the crash. However, this is not always possible. For example, when a file is open for sequential output and the server crashes, there is no way to recover the output already written, since it vanished with the crash. In such cases, the system will cause an error such as Connection Lost.

LOGOUT closes any file server connections that are currently open. On return, it attempts to re-establish connections for any files that were open before logging out. If a file has disappeared or been modified, Medley reports this fact. Files that were open for sequential access generally cannot be reopened after LOGOUT.

Interlisp supports simultaneous access to the same server from different processes and permits overlapping of Lisp computation with file server operations, allowing for improved performance. However, as a corollary of this, a file is not closed the instant that CLOSEF returns; Interlisp closes the file "in the background". It is therefore very important that you exit Interlisp via (LOGOUT) or (LOGOUT T), rather than boot the machine.

On rare occasions, the Ethernet may appear completely unresponsive, due to Interlisp having gotten into a bad state. Type (RESTART.ETHER) to reinitialize Lisp’s Ethernet driver(s), just as when the Lisp system is started up following a LOGOUT, SYSOUT, etc.
This chapter describes the standard I/O functions used for reading and printing characters and Interlisp expressions on files and other streams. First, the primitive input functions are presented, then the output functions, then functions for random-access operations (such as searching a file for a given stream, or changing the "next-character" pointer to a position in a file). Next, the PRINTOUT statement is documented (see below), which provides an easy way to write complex output operations. Finally, read tables, used to parse characters as Interlisp expressions, are documented.

Specifying Streams for Input/Output Functions

Most of the input/output functions in Interlisp-D have an argument named STREAM or FILE, specifying on which open stream the function's action should occur (the name FILE is used in older functions that predate the concept of stream; the two should, however, be treated synonymously). The value of this argument should be one of the following:

- **a stream** An object of type STREAM, as returned by OPENSTREAM (Chapter 23) or other stream-producing functions, is always the most precise and efficient way to designate a stream argument.
- **T** The litatom T designates the terminal input or output stream of the currently running process, controlling input from the keyboard and output to the display screen. For functions where the direction (input or output) is ambiguous, T is taken to designate the terminal output stream. The T streams are always open; they cannot be closed.
  
  The terminal output stream can be set to a given window or display stream by using TTYDISPLAYSTREAM (Chapter 28). The terminal input stream cannot be changed. For more information on terminal I/O, see Chapter 30.
- **NIL** The litatom NIL designates the "primary" input or output stream. These streams are initially the same as the terminal input/output streams, but they can be changed by using the functions INPUT and OUTPUT.
  
  For functions where the direction (input or output) is ambiguous, e.g., GETFILEPTR, the argument NIL is taken to mean the primary input stream, if that stream is not identical to the terminal input stream, else the primary output stream.
- **a window** Uses the display stream of the window. Valid for output only.
- **a file name** As of this writing, the name of an open file (as a litatom) can be used as a stream argument. However, there are inefficiencies and possible future incompatibilities associated with doing so. See Chapter 24 for details.
INTERLISP-D REFERENCE MANUAL

(GETSTREAM FILE ACCESS) [Function]

Coerces the argument FILE to a stream by the above rules. If ACCESS is INPUT, OUTPUT, or BOTH, produces the stream designated by FILE that is open for ACCESS. If ACCESS=NIL, returns a stream for FILE open for any kind of input/output (see the list above for the ambiguous cases). If FILE does not designate a stream open in the specified mode, causes an error, FILE NOT OPEN.

(STREAMP X) [Function]

Returns X if X is a STREAM, otherwise NIL.

Input Functions

While the functions described below can take input from any stream, some special actions occur when the input is from the terminal (the T input stream, see above). When reading from the terminal, the input is buffered a line at a time, unless buffering has been inhibited by CONTROL (Chapter 30) or the input is being read by READC or PEEKC. Using specified editing characters, you can erase a character at a time, a word at a time, or the whole line. The keys that perform these editing functions are assignable via SETSYNTAX, with the initial settings chosen to be those most natural for the given operating system. In Interlisp-D, the initial settings are as follows: characters are deleted one at a time by Backspace; words are erased by control-W; the whole line is erased by Control-Q.

On the Interlisp-D display, deleting a character or a line causes the characters to be physically erased from the screen. In Interlisp-10, the deleting action can be modified for various types of display terminals by using DELETECONTROL (Chapter 30).

Unless otherwise indicated, when the end of file is encountered while reading from a file, all input functions generate an error, END OF FILE. Note that this does not close the input file. The ENDOFSTREAMOP stream attribute (Chapter 24) is useful for changing the behavior at end of file.

Most input functions have a RDTBL argument, which specifies the read table to be used for input. Unless otherwise specified, if RDTBL is NIL, the primary read table is used.

If the FILE or STREAM argument to an input function is NIL, the primary input stream is used.

(INPUT FILE) [Function]

Sets FILE as the primary input stream; returns the old primary input stream. FILE must be open for input.

(INPUT) returns the current primary input stream, which is not changed.

Note: If the primary input stream is set to a file, the file's full name, rather than the stream itself, is returned. See discussion in Chapter 24.
I/O FUNCTIONS

(READ FILE RDTBL FLG) [Function]

Reads one expression from FILE. Atoms are delimited by the break and separator characters as defined in RDTBL. To include a break or separator character in an atom, the character must be preceded by the character %, e.g., AB%C is the atom AB(C, % is the atom %, %control-K is the atom Control-K. For input from the terminal, an atom containing an interrupt character can be input by typing instead the corresponding alphabetic character preceded by Control-V, e.g., ^VD for Control-D.

Strings are delimited by double quotes. To input a string containing a double quote or a %, precede it by %, e.g., "AB%C" is the string AB*C. Note that % can always be typed even if next character is not "special", e.g., %A%B%C is read as ABC.

If an atom is interpretable as a number, READ creates a number, e.g., 1E3 reads as a floating point number, 1D3 as a literal atom, 1.0 as a number, 1,0 as a literal atom, etc. An integer can be input in a non-decimal radix by using syntax such as 123Q, |b10101, |5r1234 (see Chapter 7). The function RADIX, sets the radix used to print integers.

When reading from the terminal, all input is line-buffered to enable the action of the backspacing control characters, unless inhibited by CONTROL (Chapter 30). Thus no characters are actually seen by the program until a carriage-return (actually the character with terminal syntax class EOL, see Chapter 30), is typed. However, for reading by READ, when a matching right parenthesis is encountered, the effect is the same as though a carriage-return were typed, i.e., the characters are transmitted. To indicate this, Interlisp also prints a carriage-return line-feed on the terminal. The line buffer is also transmitted to READ whenever an IMMEDIATE read macro character is typed (see below).

FLG=T suppresses the carriage-return normally typed by READ following a matching right parenthesis. (However, the characters are still given to READ; i.e., you do not have to type the carriage-return.)

(RATOM FILE RDTBL) [Function]

Reads in one atom from FILE. Separation of atoms is defined by RDTBL. % is also defined for RATOM, and the remarks concerning line-buffering and editing control characters also apply.

If the characters comprising the atom would normally be interpreted as a number by READ, that number is returned by RATOM. Note however that RATOM takes no special action for " whether or not it is a break character, i.e., RATOM never makes a string.

(RSTRING FILE RDTBL) [Function]

Reads characters from FILE up to, but not including, the next break or separator character, and returns them as a string. Backspace, Control-W, Control-Q, Control-V, and % have the same effect as with READ.

Note that the break or separator character that terminates a call to RATOM or RSTRING is not read by that call, but remains in the buffer to become the first character seen by the next reading function that
is called. If that function is RSTRING, it will return the null string. This is a common source of program bugs.

(RATOMS A FILE RDTBL)  [Function]
  Calls RATOM repeatedly until the atom A is read. Returns a list of the atoms read, not including A.

(RATEST FLG)       [Function]
  If FLG = T, RATEST returns T if a separator was encountered immediately prior to the atom returned by the last RATOM or READ, NIL otherwise.
  If FLG = NIL, RATEST returns T if last atom read by RATOM or READ was a break character, NIL otherwise.
  If FLG = 1, RATEST returns T if last atom read (by READ or RATOM) contained a % used to quote the next character (as in % [ or %A%B%C), NIL otherwise.

(READC FILE RDTBL)  [Function]
  Reads and returns the next character, including %, ", etc, i.e., is not affected by break or separator characters. The action of READC is subject to line-buffering, i.e., READC does not return a value until the line has been terminated even if a character has been typed. Thus, the editing control characters have their usual effect. RDTBL does not directly affect the value returned, but is used as usual in line-buffering, e.g., determining when input has been terminated. If (CONTROL T) has been executed (Chapter 30), defeating line-buffering, the RDTBL argument is irrelevant, and READC returns a value as soon as a character is typed (even if the character typed is one of the editing characters, which ordinarily would never be seen in the input buffer).

(PEEKC FILE)       [Function]
  Returns the next character, but does not actually read it and remove it from the buffer. If reading from the terminal, the character is echoed as soon as PEEKC reads it, even though it is then "put back" into the system buffer, where Backspace, Control-W, etc. could change it. Thus it is possible for the value returned by PEEKC to "disagree" in the first character with a subsequent READ.

(LASTC FILE)      [Function]
  Returns the last character read from FILE. LASTC can return an incorrect result when called immediately following a PEEKC on a file that contains run-coded NS characters.

(READCCODE FILE RDTBL)  [Function]
  Returns the next character code from STREAM; thus, this operation is equivalent to, but more efficient than, (CHCON1 (READC FILE RDTBL) ).
I/O FUNCTIONS

(PEEKCCODE FILE)  
[Function]
Returns, without consuming, the next character code from STREAM; thus, this operation is equivalent to, but more efficient than, (CHCON1 (PEEKC FILE)).

(BIN STREAM)  
[Function]
Returns the next byte from STREAM. This operation is useful for reading streams of binary, rather than character, data.

Note: BIN is similar to READCCODE, except that BIN always reads a single byte, whereas READCCODE reads a "character" that can consist of more than one byte, depending on the character and its encoding.

READ, RATOM, RATOMS, PEEKC, READC all wait for input if there is none. The only way to test whether or not there is input is to use READP:

(READP FILE FLG)  
[Function]
Returns T if there is anything in the input buffer of FILE, NIL otherwise. This operation is only interesting for streams whose source of data is dynamic, e.g., the terminal or a byte stream over a network; for other streams, such as to files, (READP FILE) is equivalent to (NOT (EOFP FILE)).

Note that because of line-buffering, READP may return T, indicating there is input in the buffer, but READ may still have to wait.

Frequently, the terminal’s input buffer contains a single EOL character left over from a previous input. For most applications, this situation wants to be treated as though the buffer were empty, and so READP returns NIL in this case. However, if FLG=T, READP returns T if there is any character in the input buffer, including a single EOL. FLG is ignored for streams other than the terminal.

(EOFP FILE)  
[Function]
Returns true if FILE is at "end of file", i.e., the next call to an input function would cause an END OF FILE error; NIL otherwise. For randomly accessible files, this can also be thought of as the file pointer pointing beyond the last byte of the file. FILE must be open for (at least) input, or an error is generated, FILE NOT OPEN.

Note that EOFP can return NIL and yet the next call to READ might still cause an END OF FILE error, because the only characters remaining in the input were separators or otherwise constituted an incomplete expression. The function SKIPSEPRS is sometimes more useful as a way of detecting end of file when it is known that all the expressions in the file are well formed.

(WAITFORINPUT FILE)  
[Function]
 Waits until input is available from FILE or from the terminal, i.e. from T. WAITFORINPUT is functionally equivalent to (until (OR (READP T) (READP FILE)) do NIL),
except that it does not use up machine cycles while waiting. Returns the device for which input is now available, i.e. FILE or T.

FILE can also be an integer, in which case WAITFORINPUT waits until there is input available from the terminal, or until FILE milliseconds have elapsed. Value is T if input is now available, NIL in the case that WAITFORINPUT timed out.

(SKREAD FILE REREADSTRING RDTBL) [Function]

"Skip Read". SKREAD consumes characters from FILE as if one call to READ had been performed, without paying the storage and compute cost to really read in the structure. REREADSTRING is for the case where the caller has already performed some READC's and RATOM's before deciding to skip this expression. In this case, REREADSTRING should be the material already read (as a string), and SKREAD operates as though it had seen that material first, thus setting up its parenthesis count, double-quote count, etc.

The read table RDTBL is used for reading from FILE. If RDTBL is NIL, it defaults to the value of FILEDRTBL. SKREAD may have difficulties if unusual read macros are defined in RDTBL. SKREAD does not recognize read macro characters in REREADSTRING, nor SPLICE or INFIX read macros. This is only a problem if the read macros are defined to parse subsequent input in the stream that does not follow the normal parenthesis and string-quote conventions.

SKREAD returns %) if the read terminated on an unbalanced closing parenthesis; %] if the read terminated on an unbalanced %], i.e., one which also would have closed any extant open left parentheses; otherwise NIL.

(SKIPSEPRS FILE RDTBL) [Function]

Consumes characters from FILE until it encounters a non-separator character (as defined by RDTBL). SKIPSEPRS returns, but does not consume, the terminating character, so that the next call to READC would return the same character. If no non-separator character is found before the end of file is reached, SKIPSEPRS returns NIL and leaves the stream at end of file. This function is useful for skipping over "white space" when scanning a stream character by character, or for detecting end of file when reading expressions from a stream with no pre-arranged terminating expression.

Output Functions

Unless otherwise specified by DEFPART, pointers other than lists, strings, atoms, or numbers, are printed in the form {DATATYPE} followed by the octal representation of the address of the pointer (regardless of radix). For example, an array pointer might print as {ARRAYP}#43,2760. This printed representation is for compactness of display on your terminal, and will not read back in correctly; if the form above is read, it will produce the litatom {ARRAYP}#43,2760.

Note: The term "end-of-line" appearing in the description of an output function means the character or characters used to terminate a line in the file system being used.
by the given implementation of Interlisp. For example, in Interlisp-D end-of-line
is indicated by the character carriage-return.

Some of the functions described below have a \textit{RDTBL} argument, which specifies the read table to be
used for output. If \textit{RDTBL} is \textit{NIL}, the primary read table is used.

Most of the functions described below have an argument \textit{FILE}, which specifies the stream on which
the operation is to take place. If \textit{FILE} is \textit{NIL}, the primary output stream is used .

\texttt{(OUTPUT \textit{FILE})} \hfill \textbf{[Function]}

Sets \textit{FILE} as the primary output stream; returns the old primary output stream. \textit{FILE}
must be open for output.

\texttt{(OUTPUT) returns the current primary output stream, which is not changed.}

\textbf{Note:} If the primary output stream is set to a file, the file’s full name, rather
than the stream itself, is returned. See the discussion in Chapter 24.

\texttt{(PRIN1 \textit{X\ FILE})} \hfill \textbf{[Function]}

Prints \textit{X} on \textit{FILE}.

\texttt{(PRIN2 \textit{X\ FILE\ RDTBL})} \hfill \textbf{[Function]}

Prints \textit{X} on \textit{FILE} with %’s and ”’s inserted where required for it to read back in properly
by \texttt{READ}, using \textit{RDTBL}.

Both \texttt{PRIN1} and \texttt{PRIN2} print any kind of Lisp expression, including lists, atoms, numbers, and
strings. \texttt{PRIN1} is generally used for printing expressions where human readability, rather than
machine readability, is important, e.g., when printing text rather than program fragments. \texttt{PRIN1}
does not print double quotes around strings, or % in front of special characters. \texttt{PRIN2} is used for
printing Interlisp expressions which can then be read back into Interlisp with \texttt{READ}; i.e., break and
separator characters in atoms will be preceded by %’s. For example, the atom ”((())” is printed as % (%)
by \texttt{PRIN2}. If the integer output radix (as set by \texttt{RADIX}) is not 10, \texttt{PRIN2} prints the integer using the
input syntax for non-decimal integers (see Chapter 7) but \texttt{PRIN1} does not (but both print the integer
in the output radix).

\texttt{(PRIN3 \textit{X\ FILE})} \hfill \textbf{[Function]}

\texttt{(PRIN4 \textit{X\ FILE\ RDTBL})} \hfill \textbf{[Function]}

\texttt{PRIN3 and PRIN4 are the same as PRIN1 and PRIN2 respectively, except that they do not
increment the horizontal position counter nor perform any linelength checks. They are
useful primarily for printing control characters.}

\texttt{(PRINT \textit{X\ FILE\ RDTBL})} \hfill \textbf{[Function]}

Prints the expression \textit{X} using \texttt{PRIN2} followed by an end-of-line. Returns \textit{X}. 
(PRINTCCODE CHARCODE FILE)  [Function]
Outputs a single character whose code is CHARCODE to FILE. This is similar to (PRIN1 (CHARACTER CHARCODE)), except that numeric characters are guaranteed to print "correctly"; e.g., (PRINTCCODE (CHARCODE 9)) always prints "9", independent of the setting of RADIX.

PRINTCCODE may actually print more than one byte on FILE, due to character encoding and end of line conventions; thus, no assumptions should be made about the relative motion of the file pointer (see GETFILEPTR) during this operation.

(BOUT STREAM BYTE)  [Function]
Outputs a single 8-bit byte to STREAM. This is similar to PRINTCCODE, but for binary streams the character position in STREAM is not updated (as with PRIN3), and end of line conventions are ignored.

Note: BOUT is similar to PRINTCCODE, except that BOUT always writes a single byte, whereas PRINTCCODE writes a "character" that can consist of more than one byte, depending on the character and its encoding.

(Spaces N FILE)  [Function]
Prints N spaces. Returns NIL.

(TERPRI FILE)  [Function]
Prints an end-of-line character. Returns NIL.

(FRESHLINE STREAM)  [Function]
Equivalent to TERPRI, except it does nothing if it is already at the beginning of the line. Returns T if it prints an end-of-line, NIL otherwise.

(TAB POS MINSPACES FILE)  [Function]
Prints the appropriate number of spaces to move to position POS. MINSPACES indicates how many spaces must be printed (if NIL, 1 is used). If the current position plus MINSPACES is greater than POS, TAB does a TERPRI and then (SPACES POS). If MINSPACES is T, and the current position is greater than POS, then TAB does nothing.

Note: A sequence of PRINT, PRIN2, SPACES, and TERPRI expressions can often be more conveniently coded with a single PRINTOUT statement.

(SHOWPRIN2 X FILE RDTBL)  [Function]
Like PRIN2 except if SYSPRETTYFLG=T, prettyprints X instead. Returns X.
I/O FUNCTIONS

(SHOWPRINT X FILE RDTBL) [Function]
Like PRINT except if SYSPRETTYFLG=T, prettyprints X instead, followed by an end-of-line. Returns X.

SHOWPRINT and SHOWPRIN2 are used by the programmer's assistant (Chapter 13) for printing the values of expressions and for printing the history list, by various commands of the break package (Chapter 14), e.g. ?= and BT commands, and various other system packages. The idea is that by simply setting or binding SYSPRETTYFLG to T (initially NIL), you instruct the system when interacting with you to PRETTYPRINT expressions (Chapter 26) instead of printing them.

(PRINTBELLS ) [Function]
Used by DWIM (Chapter 19) to print a sequence of bells to alert you to stop typing. Can be advised or redefined for special applications, e.g., to flash the screen on a display terminal.

(FORCEOUTPUT STREAM WAITFORFINISH) [Function]
Forces any buffered output data in STREAM to be transmitted.
If WAITFORFINISH is non-NIL, this doesn't return until the data has been forced out.

(POSITION FILE N) [Function]
Returns the column number at which the next character will be read or printed. After a end of line, the column number is 0. If N is non-NIL, resets the column number to be N.
Note that resetting POSITION only changes Lisp's belief about the current column number; it does not cause any horizontal motion. Also note that (POSITION FILE) is not the same as (GETFILEPTR FILE) which gives the position in the file, not on the line.

(LINELENGTH N FILE) [Function]
Sets the length of the print line for the output file FILE to N; returns the former setting of the line length. FILE defaults to the primary output stream. (LINELENGTH NIL FILE) returns the current setting for FILE. When a file is first opened, its line length is set to the value of the variable FILELINELENGTH.
Whenever printing an atom or string would increase a file's position beyond the line length of the file, an end of line is automatically inserted first. This action can be defeated by using PRIN3 and PRIN4.

(SETLINELENGTH N) [Function]
Sets the line length for the terminal by doing (LINELENGTH N T). If N is NIL, it determines N by consulting the operating system's belief about the terminal's characteristics. In Interlisp-D, this is a no-op.
PRINTLEVEL

When using Interlisp one often has to handle large, complicated lists, which are difficult to understand when printed out. PRINTLEVEL allows you to specify in how much detail lists should be printed. The print functions PRINT, PRIN1, and PRIN2 are all affected by level parameters set by:

(PRINTLEVEL CARVAL CDRVAL)    [Function]

Sets the CAR print level to CARVAL, and the CDR print level to CDRVAL. Returns a list cell whose CAR and CDR are the old settings. PRINTLEVEL is initialized with the value (1000 . -1).

In order that PRINTLEVEL can be used with RESETFORM or RESCHEDULE, if CARVAL is a list cell it is equivalent to (PRINTLEVEL (CAR CARVAL) (CDR CARVAL)).

(PRINTLEVEL N NIL) changes the CAR print level without affecting the CDR print level.

(PRINTLEVEL NIL N) changes the CDR print level with affecting the CAR print level.

(PRINTLEVEL) gives the current setting without changing either.

Note: Control-P (Chapter 30) can be used to change the PRINTLEVEL setting dynamically, even while Interlisp is printing.

The CAR print level specifies how "deep" to print a list. Specifically, it is the number of unpaired left parentheses which will be printed. Below that level, all lists will be printed as &. If the CAR print level is negative, the action is similar except that an end-of-line is inserted after each right parentheses that would be immediately followed by a left parenthesis.

The CDR print level specifies how "long" to print a list. It is the number of top level list elements that will be printed before the printing is terminated with --. For example, if CDRVAL=2, (A B C D E) will print as (A B --). For sublists, the number of list elements printed is also affected by the depth of printing in the CAR direction: Whenever the sum of the depth of the sublist (i.e. the number of unmatched left parentheses) and the number of elements is greater than the CDR printlevel, -- is printed. This gives a "triangular" effect in that less is printed the farther one goes in either CAR or CDR direction. If the CDR printlevel is negative, then it is the same as if the CDR printlevel were infinite.

Examples:

After:  (A (B C (D (E F) G) H) K L) prints as:

(PRINTLEVEL 3 -1)   (A (B C (D & G) H) K L)
(PRINTLEVEL 2 -1)   (A (B C &) H) K L)
(PRINTLEVEL 1 -1)   (A & K L)
(PRINTLEVEL 0 -1)   &
(PRINTLEVEL 1000 2)  (A (B --) --)
(PRINTLEVEL 1000 3)  (A (B C --) K --)
I/O FUNCTIONS

(PRINTLEVEL 1 3) (A & K --)

PLVLFILEFLG [Variable]

Normally, PRINTLEVEL only affects terminal output. Output to all other files acts as though the print level is infinite. However, if PLVLFILEFLG is T (initially NIL), then PRINTLEVEL affects output to files as well.

The following three functions are useful for printing isolated expressions at a specified print level without going to the overhead of resetting the global print level.

(LVLPRINT X FILE CARLVL CDRLVL TAIL) [Function]

Performs PRINT of X to FILE, using as CAR and CDR print levels the values CARLVL and CDRLVL, respectively. Uses the T read table. If TAIL is specified, and X is a tail of it, then begins its printing with "...", rather than on open parenthesis.

(LVLPRIN2 X FILE CARLVL CDRLVL TAIL) [Function]

Similar to LVLPRIN2, but performs a PRIN2.

(LVLPRIN1 X FILE CARLVL CDRLVL TAIL) [Function]

Similar to LVLPRIN1, but performs a PRIN1.

Printing Numbers

How the ordinary printing functions (PRIN1, PRIN2, etc.) print numbers can be affected in several ways. RADIX influences the printing of integers, and FLTFRMT influences the printing of floating point numbers. The setting of the variable PRXFLG determines how the symbol-manipulation functions handle numbers. The PRINTNUM package permits greater controls on the printed appearance of numbers, allowing such things as left-justification, suppression of trailing decimals, etc.

(RADIX N) [Function]

Resets the output radix for integers to the absolute value of N. The value of RADIX is its previous setting. (RADIX) gives the current setting without changing it. The initial setting is 10.

Note that RADIX affects output only. There is no input radix; on input, numbers are interpreted as decimal unless they are entered in a non-decimal radix with syntax such as 123Q, |b10101|, |5r1234| (see Chapter 7). RADIX does not affect the behavior of UNPACK, etc., unless the value of PRXFLG (below) is T. For example, if PRXFLG is NIL and the radix is set to 8 with (RADIX 8), the value of (UNPACK 9) is (9), not (1 1).

Using PRINTNUM (below) or the PRINTOUT command .I (below) is often a more convenient and appropriate way to print a single number in a specified radix than to globally change RADIX.
(FLTFMT FORMAT)  [Function]

Resets the output format for floating point numbers to the FLOAT format FORMAT (see PRINTNUM below for a description of FLOAT formats). FORMAT=T specifies the default "free" formatting: some number of significant digits (a function of the implementation) are printed, with trailing zeros suppressed; numbers with sufficiently large or small exponents are instead printed in exponent notation.

FLTFMT returns its current setting. (FLTFMT) returns the current setting without changing it. The initial setting is T.

Note: In Interlisp-D, FLTFMT ignores the WIDTH and PAD fields of the format (they are implemented only by PRINTNUM).

Whether print name manipulation functions (UNPACK, NCHARS, etc.) use the values of RADIX and FLTFMT is determined by the variable PRXFLG:

PRXFLG  [Variable]

If PRXFLG=NIL (the initial setting), then the "PRIN1" name used by PACK, UNPACK, MKSTRING, etc., is computed using base 10 for integers and the system default floating format for floating point numbers, independent of the current setting of RADIX or FLTFMT. If PRXFLG=T, then RADIX and FLTFMT do dictate the "PRIN1" name of numbers. Note that in this case, PACK and UNPACK are not inverses.

Examples with (RADIX 8), (FLTFMT '(FLOAT 4 2)):

With PRXFLG=NIL,

(UNPACK 13) => (1 3)  
(PACK '(A 9)) => A9  
(UNPACK 1.2345) => (1 . 2 3 4 5)

With PRXFLG=T,

(UNPACK 13) => (1 5)  
(PACK '(A 9)) => A11  
(UNPACK 1.2345) => (1 . 2 3)

Note that PRXFLG does not effect the radix of "PRIN2" names, so with (RADIX 8), (NCHARS 9 T), which uses PRIN2 names, would return 3, (since 9 would print as 11Q) for either setting of PRXFLG.

Warning: Some system functions will not work correctly if PRXFLG is not NIL. Therefore, resetting the global value of PRXFLG is not recommended. It is much better to rebind PRXFLG as a SPECVAR for that part of a program where it needs to be non-NIL.

The basic function for printing numbers under format control is PRINTNUM. Its utility is considerably enhanced when used in conjunction with the PRINTOUT package, which implements a compact language for specifying complicated sequences of elementary printing operations, and makes fancy output formats easy to design and simple to program.
(PRINTNUM FORMAT NUMBER FILE) [Function]

Prints NUMBER on FILE according to the format FORMAT. FORMAT is a list structure with one of the forms described below.

If FORMAT is a list of the form (FIX WIDTH RADIX PAD0 LEFTFLUSH), this specifies a FIX format. NUMBER is rounded to the nearest integer, and then printed in a field WIDTH characters long with radix set to RADIX (or 10 if RADIX=NIL; note that the setting from the function RADIX is not used as the default). If PAD0 and LEFTFLUSH are both NIL, the number is right-justified in the field, and the padding characters to the left of the leading digit are spaces. If PAD0 is T, the character "0" is used for padding. If LEFTFLUSH is T, then the number is left-justified in the field, with trailing spaces to fill out WIDTH characters.

The following examples illustrate the effects of the FIX format options on the number 9 (the vertical bars indicate the field width):

<table>
<thead>
<tr>
<th>FORMAT:</th>
<th>(PRINTNUM FORMAT 9) prints:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(FIX 2)</td>
<td>9</td>
</tr>
<tr>
<td>(FIX 2 NIL T)</td>
<td>09</td>
</tr>
<tr>
<td>(FIX 12 8 T)</td>
<td>000000000011</td>
</tr>
<tr>
<td>(FIX 5 NIL NIL T)</td>
<td>9</td>
</tr>
</tbody>
</table>

If FORMAT is a list of the form (FLOAT WIDTH DECPART EXPPART PAD0 ROUND), this specifies a FLOAT format. NUMBER is printed as a decimal number in a field WIDTH characters wide, with DECPART digits to the right of the decimal point. If EXPPART is not 0 (or NIL), the number is printed in exponent notation, with the exponent occupying EXPPART characters in the field. EXPPART should allow for the character E and an optional sign to be printed before the exponent digits. As with FIX format, padding on the left is with spaces, unless PAD0 is T. If ROUND is given, it indicates the digit position at which rounding is to take place, counting from the leading digit of the number.

Interlisp-D interprets WIDTH=NIL to mean no padding, i.e., to use however much space the number needs, and interprets DECPART=NIL to mean as many decimal places as needed.

The following examples illustrate the effects of the FLOAT format options on the number 27.689 (the vertical bars indicate the field width):

<table>
<thead>
<tr>
<th>FORMAT:</th>
<th>(PRINTNUM FORMAT 27.689) prints:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(FLOAT 7 2)</td>
<td>27.69</td>
</tr>
<tr>
<td>(FLOAT 7 2 NIL 0)</td>
<td>0027.69</td>
</tr>
<tr>
<td>(FLOAT 7 2 2)</td>
<td>2.77E1</td>
</tr>
<tr>
<td>(FLOAT 11 2 4)</td>
<td>2.77E+01</td>
</tr>
<tr>
<td>(FLOAT 7 2 NIL NIL 1)</td>
<td>30.00</td>
</tr>
<tr>
<td>(FLOAT 7 2 NIL NIL 2)</td>
<td>28.00</td>
</tr>
</tbody>
</table>
NILNUMPRINTFLG

If PRINTNUM’s NUMBER argument is not a number and not NIL, a NON-NUMERIC ARG error is generated. If NUMBER is NIL, the effect depends on the setting of the variable NILNUMPRINTFLG. If NILNUMPRINTFLG is NIL, then the error occurs as usual. If it is non-NIL, then no error occurs, and the value of NILNUMPRINTFLG is printed right-justified in the field described by FORMAT. This option facilitates the printing of numbers in aggregates with missing values coded as NIL.

User Defined Printing

Initially, Interlisp only knows how to print in an interesting way objects of type litatom, number, string, list and stackp. All other types of objects are printed in the form {datatype} followed by the octal representation of the address of the pointer, a format that cannot be read back in to produce an equivalent object. When defining user data types (using the DATATYPE record type, Chapter 8), it is often desirable to specify as well how objects of that type should be printed, so as to make their contents readable, or at least more informative to the viewer. The function DEFPRTN is used to specify the printing format of a data type.

(DEFPRINT TYPE FN)

TYPE is a type name. Whenever a printing function (PRINT, PRIN1, PRIN2, etc.) or a function requiring a print name (CHCON, NCHARS, etc.) encounters an object of the indicated type, FN is called with two arguments: the item to be printed and the name of the stream, if any, to which the object is to be printed. The second argument is NIL on calls that request the print name of an object without actually printing it.

If FN returns a list of the form (ITEM1 . ITEM2), ITEM1 is printed using PRIN1 (unless it is NIL), and then ITEM2 is printed using PRIN2 (unless it is NIL). No spaces are printed between the two items. Typically, ITEM1 is a read macro character.

If FN returns NIL, the datum is printed in the system default manner.

If FN returns T, nothing further is printed; FN is assumed to have printed the object to the stream itself. Note that this case if permitted only when the second argument passed to FN is non-NIL; otherwise, there is no destination for FN to do its printing, so it must return as in one of the other two cases.

Printing Unusual Data Structures

HPRINT (for ‘Horrible Print’) and HREAD provide a mechanism for printing and reading back in general data structures that cannot normally be dumped and loaded easily, such as (possibly re-entrant or circular) structures containing user datatypes, arrays, hash tables, as well as list structures. HPRINT will correctly print and read back in any structure containing any or all of the above, chasing all pointers down to the level of literal atoms, numbers or strings. HPRINT currently cannot handle compiled code arrays, stack positions, or arbitrary unboxed numbers.
I/O FUNCTIONS

HPRINT operates by simulating the Interlisp PRINT routine for normal list structures. When it encounters a user datatype (see Chapter 8), or an array or hash array, it prints the data contained therein, surrounded by special characters defined as read macro characters. While chasing the pointers of a structure, it also keeps a hash table of those items it encounters, and if any item is encountered a second time, another read macro character is inserted before the first occurrence (by resetting the file pointer with SETFILEPTR) and all subsequent occurrences are printed as a back reference using an appropriate macro character. Thus the inverse function, HREAD merely calls the Interlisp READ routine with the appropriate read table.

(HPRINT EXPR FILE UNCIRCULAR DATATYPESEEN) [Function]

Prints EXPR on FILE. If UNCIRCULAR is non-NIL, HPRINT does no checking for any circularities in EXPR (but is still useful for dumping arbitrary structures of arrays, hash arrays, lists, user data types, etc., that do not contain circularities). Specifying UNCIRCULAR as non-NIL results in a large speed and internal-storage advantage.

Normally, when HPRINT encounters a user data type for the first time, it outputs a summary of the data type’s declaration. When this is read in, the data type is redeclared. If DATATYPESEEN is non-NIL, HPRINT assumes that the same data type declarations will be in force at read time as were at HPRINT time, and not output declarations.

HPRINT is intended primarily for output to random access files, since the algorithm depends on being able to reset the file pointer. If FILE is not a random access file (and UNCIRCULAR = NIL), a temporary file, HPRINT.SCRATCH, is opened, EXPR is HPRINTed on it, and then that file is copied to the final output file and the temporary file is deleted.

You can not use HPRINT to save things that contains pointers to raw storage. Fontdescriptors contain pointers to raw storage and windows contain pointers to fontdescriptors. Neither can therefor be saved with HPRINT.

(HREAD FILE) [Function]

Reads and returns an HPRINT-ed expression from FILE.

(HCOPYALL X) [Function]

Copies data structure X. X may contain circular pointers as well as arbitrary structures.

Note: HORRIBLEVARS and UGLYVARS (Chapter 17) are two file package commands for dumping and reloading circular and re-entrant data structures. They provide a convenient interface to HPRINT and HREAD.

When HPRINT is dumping a data structure that contains an instance of an Interlisp datatype, the datatype declaration is also printed onto the file. Reading such a data structure with HREAD can cause problems if it redefines a system datatype. Redefining a system datatype will almost definitely cause serious errors. The Interlisp system datatypes do not change very often, but there is always a possibility when loading in old files created under an old Interlisp release.

To prevent accidental system crashes, HREAD will not redefine datatypes. Instead, it will cause an error "attempt to read DATATYPE with different field
specification than currently defined". Continuing from this error will redefine the datatype.

Random Access File Operations

For most applications, files are read starting at their beginning and proceeding sequentially, i.e., the next character read is the one immediately following the last character read. Similarly, files are written sequentially. However, for files on some devices, it is also possible to read/write characters at arbitrary positions in a file, essentially treating the file as a large block of auxiliary storage. For example, one application might involve writing an expression at the beginning of the file, and then reading an expression from a specified point in its middle. This particular example requires the file be open for both input and output. However, random file input or output can also be performed on files that have been opened for only input or only output.

Associated with each file is a "file pointer" that points to the location where the next character is to be read from or written to. The file position of a byte is the number of bytes that precede it in the file, i.e., 0 is the position of the beginning of the file. The file pointer to a file is automatically advanced after each input or output operation. This section describes functions which can be used to reposition the file pointer on those files that can be randomly accessed. A file used in this fashion is much like an array in that it has a certain number of addressable locations that characters can be put into or taken from. However, unlike arrays, files can be enlarged. For example, if the file pointer is positioned at the end of a file and anything is written, the file "grows." It is also possible to position the file pointer beyond the end of file and then to write. (If the program attempts to read beyond the end of file, an END OF FILE error occurs.) In this case, the file is enlarged, and a "hole" is created, which can later be written into. Note that this enlargement only takes place at the end of a file; it is not possible to make more room in the middle of a file. In other words, if expression A begins at position 1000, and expression B at 1100, and the program attempts to overwrite A with expression C, whose printed representation is 200 bytes long, part of B will be altered.

Warning: File positions are always in terms of bytes, not characters. You should thus be very careful about computing the space needed for an expression. In particular, NS characters may take multiple bytes (see below). Also, the end-of-line character (see Chapter 24) may be represented by a different number of characters in different implementations. Output functions may also introduce end-of-line’s as a result of LINELENGTH considerations. Therefore NCHARS (see Chapter 2) does not specify how many bytes an expression takes to print, even ignoring line length considerations.

\begin{description}
\item[GETFILEPTR FILE] \textbf{[Function]} \begin{itemize}
\item Returns the current position of the file pointer for \textit{FILE}, i.e., the byte address at which the next input/output operation will commence.
\end{itemize}
\item[SETFILEPTR FILE ADR] \textbf{[Function]} \begin{itemize}
\item Sets the file pointer for \textit{FILE} to the position \textit{ADR}; returns \textit{ADR}. The special value \textit{ADR}=-1 is interpreted to mean the address of the end of file.
\end{itemize}
\end{description}
I/O FUNCTIONS

Note: If a file is opened for output only, the end of file is initially zero, even if an old file by the same name had existed (see OPENSTREAM, Chapter 24). If a file is opened for both input and output, the initial file pointer is the beginning of the file, but (SETFILEPTR FILE -1) sets it to the end of the file. If the file had been opened in append mode by (OPENSTREAM FILE ’APPEND), the file pointer right after opening would be set to the end of the existing file, in which case a SETFILEPTR to position the file at the end would be unnecessary.

(GETEOFPTR FILE) [Function]
Returns the byte address of the end of file, i.e., the number of bytes in the file. Equivalent to performing (SETFILEPTR FILE -1) and returning (GETFILEPTR FILE) except that it does not change the current file pointer.

(RANDACCESSP FILE) [Function]
Returns FILE if FILE is randomly accessible, NIL otherwise. The file T is not randomly accessible, nor are certain network file connections in Interlisp-D. FILE must be open or an error is generated, FILE NOT OPEN.

(COPYBYTES SRCFIL DSTFIL START END) [Function]
Copies bytes from SRCFIL to DSTFIL, starting from position START and up to but not including position END. Both SRCFIL and DSTFIL must be open. Returns T.
If END=NIL, START is interpreted as the number of bytes to copy (starting at the current position). If START is also NIL, bytes are copied until the end of the file is reached.
Warning: COPYBYTES does not take any account of multi-byte NS characters (see Chapter 2). COPYCHARS (below) should be used whenever copying information that might include NS characters.

(COPYCHARS SRCFIL DSTFIL START END) [Function]
Like COPYBYTES except that it copies NS characters (see Chapter 2), and performs the proper conversion if the end-of-line conventions of SRCFIL and DSTFIL are not the same (see Chapter 24). START and END are interpreted the same as with COPYBYTES, i.e., as byte (not character) specifications in SRCFIL. The number of bytes actually output to DSTFIL might be more or less than the number of bytes specified by START and END, depending on what the end-of-line conventions are. In the case where the end-of-line conventions happen to be the same, COPYCHARS simply calls COPYBYTES.

(FILEPOS STR FILE START END SKIP TAIL CASEARRAY) [Function]
Analogous to STRPOS (see Chapter 4), but searches a file rather than a string. FILEPOS searches FILE for the string STR. Search begins at START (or the current position of the file pointer, if START=NIL), and goes to END (or the end of FILE, if END=NIL). Returns the address of the start of the match, or NIL if not found.
SKIP can be used to specify a character which matches any character in the file. If TAIL is T, and the search is successful, the value is the address of the first character after the sequence of characters corresponding to STR, instead of the starting address of the sequence. In either case, the file is left so that the next i/o operation begins at the address returned as the value of FILEPOS.

CASEARRAY should be a "case array" that specifies that certain characters should be transformed to other characters before matching. Case arrays are returned by CASEARRAY or SEPRCASE below. CASEARRAY=NIL means no transformation will be performed.

A case array is an implementation-dependent object that is logically an array of character codes with one entry for each possible character. FILEPOS maps each character in the file "through" CASEARRAY in the sense that each character code is transformed into the corresponding character code from CASEARRAY before matching. Thus if two characters map into the same value, they are treated as equivalent by FILEPOS. CASEARRAY and SETCASEARRAY provide an implementation-independent interface to case arrays.

For example, to search without regard to upper and lower case differences, CASEARRAY would be a case array where all characters map to themselves, except for lower case characters, whose corresponding elements would be the upper case characters. To search for a delimited atom, one could use "ATOM" as the pattern, and specify a case array in which all of the break and separator characters mapped into the same code as space.

For applications calling for extensive file searches, the function FFILEPOS is often faster than FILEPOS.

\[
(\text{FILEPOS \ PATTERN \ FILE \ START \ END \ SKIP \ TAIL \ CASEARRAY}) \quad \text{[Function]}
\]
Like FILEPOS, except much faster in most applications. FFILEPOS is an implementation of the Boyer-Moore fast string searching algorithm. This algorithm preprocesses the string being searched for and then scans through the file in steps usually equal to the length of the string. Thus, FFILEPOS speeds up roughly in proportion to the length of the string, e.g., a string of length 10 will be found twice as fast as a string of length 5 in the same position.

Because of certain fixed overheads, it is generally better to use FILEPOS for short searches or short strings.

\[
(\text{CASEARRAY \ OLDARRAY}) \quad \text{[Function]}
\]
Creates and returns a new case array, with all elements set to themselves, to indicate the identity mapping. If OLDARRAY is given, it is reused.

\[
(\text{SETCASEARRAY \ CASEARRAY \ FROMCODE \ TOCODE}) \quad \text{[Function]}
\]
Modifies the case array CASEARRAY so that character code FROMCODE is mapped to character code TOCODE.
I/O FUNCTIONS

(GETCASEARRAY CASEARRAY FROMCODE) [Function]

Returns the character code that FROMCODE is mapped to in CASEARRAY.

(SEPRCASE CLFLG) [Function]

Returns a new case array suitable for use by FILEPOS or FFILEPOS in which all of the break/separators of FILERDTBL are mapped into character code zero. If CLFLG is non-NIL, then all CLISP characters are mapped into this character as well. This is useful for finding a delimited atom in a file. For example, if PATTERN is " FOO ", and (SEPRCASE T) is used for CASEARRAY, then FILEPOS will find " (FOO_ ".

UPPERCASEARRAY [Variable]

Value is a case array in which every lowercase character is mapped into the corresponding uppercase character. Useful for searching text files.

Input/Output Operations with Characters and Bytes

Interlisp-D supports the 16-bit NS character set (see Chapter 2). All of the standard string and print name functions accept litatoms and strings containing NS characters. In almost all cases, a program does not have to distinguish between NS characters or 8-bit characters. The exception to this rule is the handling of input/output operations.

Interlisp-D uses two ways of writing 16-bit NS characters on files. One way is to write the full 16-bits (two bytes) every time a character is output. The other way is to use "run-encoding." Each 16 NS character can be decoded into a character set (an integer from 0 to 254 inclusive) and a character number (also an integer from 0 to 254 inclusive). In run-encoding, the byte 255 (illegal as either a character set number or a character number) is used to signal a change to a given character set, and the following bytes are all assumed to come from the same character set (until the next change-character set sequence). Run-encoding can reduce the number of bytes required to encode a string of NS characters, as long as there are long sequences of characters from the same character set (usually the case).

Note that characters are not the same as bytes. A single character can take anywhere from one to four bytes bytes, depending on whether it is in the same character set as the preceding character, and whether run-encoding is enabled. Programs which assume that characters are equal to bytes must be changed to work with NS characters.

The functions BIN and BOUT (see above) should only be used to read and write single eight-bit bytes. The functions READCCODE and PRINTCCODE (see above) should be used to read and write single character codes, interpreting run-encoded NS characters. COPYBYTES should only be used to copy blocks of 8-bit data; COPYCHARS should be used to copy characters. Most I/O functions (READC, PRIN1, etc.) read or write 16-bit NS characters.
The use of NS characters has serious consequences for any program that uses file pointers to access a file in a random access manner. At any point when a file is being read or written, it has a "current character set." If the file pointer is changed with SETFILEPTR to a part of the file with a different character set, any characters read or written may have the wrong character set. The current character set can be accessed with the following function:

\[(\text{CHARSET STREAM CHARACTERSET})\]  
\[\text{[Function]}\]

Returns the current character set of the stream \text{STREAM}. If \text{CHARACTERSET} is non-NIL, the current character set for \text{STREAM} is set. Note that for output streams this may cause bytes to be written to the stream.

If \text{CHARACTERSET} is T, run encoding for \text{STREAM} is disabled: both the character set and the character number (two bytes total) will be written to the stream for each character printed.

\text{PRINTOUT}

Interlisp provides many facilities for controlling the format of printed output. By executing various sequences of \text{PRIN1}, \text{PRIN2}, \text{TAB}, \text{TERPRI}, \text{SPACES}, \text{PRINTNUM}, and \text{PRINTDEF}, almost any effect can be achieved. \text{PRINTOUT} implements a compact language for specifying complicated sequences of these elementary printing functions. It makes fancy output formats easy to design and simple to program.

\text{PRINTOUT} is a CLISP word (like \text{FOR} and \text{IF}) for interpreting a special printing language in which you can describe the kinds of printing desired. The description is translated by \text{DWIMIFY} to the appropriate sequence of \text{PRIN1}, \text{TAB}, etc., before it is evaluated or compiled. \text{PRINTOUT} printing descriptions have the following general form:

\[(\text{PRINTOUT STREAM PRINTCOM}_1 \ldots \text{PRINTCOM}_N)\]

\text{STREAM} is evaluated to obtain the stream to which the output from this specification is directed. The \text{PRINTOUT} commands are strung together, one after the other without punctuation, after \text{STREAM}. Some commands occupy a single position in this list, but many commands expect to find arguments following the command name in the list. The commands fall into several logical groups: one set deals with horizontal and vertical spacing, another group provides controls for certain formatting capabilities (font changes and subscripting), while a third set is concerned with various ways of actually printing items. Finally, there is a command that permits escaping to a simple Lisp evaluation in the middle of a \text{PRINTOUT} form. The various commands are described below. The following examples give a general flavor of how \text{PRINTOUT} is used:

\textbf{Example 1:} Suppose you want to print out on the terminal the values of three variables, \textit{X}, \textit{Y}, and \textit{Z}, separated by spaces and followed by a carriage return. This could be done by:
I/O FUNCTIONS

(PRIN1 X T)
  (SPACES 1 T)
  (PRIN1 Y T)
  (SPACES 1 T)
  (PRIN1 Z T)
  (TERPRI T)

or by the more concise PRINTOUT form:

(PRINTOUT T X , Y , Z T)

Here the first T specifies output to the terminal, the commas cause single spaces to be printed, and the final T specifies a TERPRI. The variable names are not recognized as special PRINTOUT commands, so they are printed using PRIN1 by default.

Example 2: Suppose the values of X and Y are to be pretty-printed lined up at position 10, preceded by identifying strings. If the output is to go to the primary output stream, you could write either:

(PRIN1 "X =")
  (PRINTDEF X 10 T)
  (TERPRI )
  (PRIN1 "Y =")
  (PRINTDEF Y 10 T)
  (TERPRI)

or the equivalent:

(PRINTOUT NIL "X =" 10 .PPV X T
  "Y =" 10 .PPV Y T)

Since strings are not recognized as special commands, "X =" is also printed with PRIN1 by default. The positive integer means TAB to position 10, where the .PPV command causes the value of X to be prettyprinted as a variable. By convention, special atoms used as PRINTOUT commands are prefixed with a period. The T causes a carriage return, so the Y information is printed on the next line.

Example 3. As a final example, suppose that the value of X is an integer and the value of Y is a floating-point number. X is to be printed right-flushed in a field of width 5 beginning at position 15, and Y is to be printed in a field of width 10 also starting at position 15 with 2 places to the right of the decimal point. Furthermore, suppose that the variable names are to appear in the font class named BOLDFONT and the values in font class SMALLFONT. The program in ordinary Interlisp that would accomplish these effects is too complicated to include here. With PRINTOUT, one could write:

(PRINTOUT NIL
  .FONT BOLDFONT "X =" 15
The .FONT commands do whatever is necessary to change the font on a multi-font output device. The .I5 command sets up a FIX format for a call to the function PRINTNUM (see above) to print X in the desired format. The .F10.2 specifies a FLOAT format for PRINTNUM.

Horizontal Spacing Commands

The horizontal spacing commands provide convenient ways of calling TAB and SPACES. In the following descriptions, N stands for a literal positive integer (not for a variable or expression whose value is an integer).

N (N a number) [PRINTOUT Command]

Used for absolute spacing. It results in a TAB to position N (literally, a (TAB N)). If the line is currently at position N or beyond, the file will be positioned at position N on the next line.

.TAB POS [PRINTOUT Command]

Specifies TAB to position (the value of) POS. This is one of several commands whose effect could be achieved by simply escaping to Lisp, and executing the corresponding form. It is provided as a separate command so that the PRINTOUT form is more concise and is prettyprinted more compactly. Note that .TAB N and N, where N is an integer, are equivalent.

.TAB0 POS [PRINTOUT Command]

Like .TAB except that it can result in zero spaces (i.e. the call to TAB specifies MINSPACES=0).

-N (N a number) [PRINTOUT Command]

Negative integers indicate relative (as opposed to absolute) spacing. Translates as (SPACES |N|).

,, [PRINTOUT Command]

,, [PRINTOUT Command]

,, [PRINTOUT Command]

(1, 2 or 3 commas) Provides a short-hand way of specifying 1, 2 or 3 spaces, i.e., these commands are equivalent to -1, -2, and -3, respectively.

.SP DISTANCE [PRINTOUT Command]

Translates as (SPACES DISTANCE). Note that .SP N and -N, where N is an integer, are equivalent.
I/O FUNCTIONS

Vertical Spacing Commands

Vertical spacing is obtained by calling TERPRI or printing form-feeds. The relevant commands are:

\textbf{T} \hspace{1cm} \text{[PRINTOUT Command]}

Translates as (TERPRI), i.e., move to position 0 (the first column) of the next line. To print the letter T, use the string "T".

\textbf{.SKIP LINES} \hspace{1cm} \text{[PRINTOUT Command]}

Equivalent to a sequence of LINES (TERPRI)'s. The .SKIP command allows for skipping large constant distances and for computing the distance to be skipped.

\textbf{.PAGE} \hspace{1cm} \text{[PRINTOUT Command]}

Puts a form-feed (Control-L) out on the file. Care is taken to make sure that Interlisp's view of the current line position is correctly updated.

Special Formatting Controls

There are a small number of commands for invoking some of the formatting capabilities of multi-font output devices. The available commands are:

\textbf{.FONT FONTSPEC} \hspace{1cm} \text{[PRINTOUT Command]}

Changes printing to the font FONTSPEC, which can be a font descriptor, a "font list" such as `\text{(MODERN 10)}", an image stream (coerced to its current font), or a windows (coerced to the current font of its display stream). The DSPFONT is changed permanently. See fonts (Chapter 27) for more information.

FONTSPEC may also be a positive integer \textit{N}, which is taken as an abbreviated reference to the font class named FONT\textit{N} (e.g. 1 => FONT1).

\textbf{.SUP} \hspace{1cm} \text{[PRINTOUT Command]}

Specifies superscripting. All subsequent characters are printed above the base of the current line. Note that this is absolute, not relative: a .SUP following a .SUP is a no-op.

\textbf{.SUB} \hspace{1cm} \text{[PRINTOUT Command]}

Specifies subscripting. Subsequent printing is below the base of the current line. As with superscripting, the effect is absolute.

\textbf{.BASE} \hspace{1cm} \text{[PRINTOUT Command]}

Moves printing back to the base of the current line. Un-does a previous .SUP or .SUB; a no-op, if printing is currently at the base.
Printing Specifications

The value of any expression in a PRINTOUT form that is not recognized as a command itself or as a command argument is printed using PRIN1 by default. For example, title strings can be printed by simply including the string as a separate PRINTOUT command, and the values of variables and forms can be printed in much the same way. Note that a literal integer, say 51, cannot be printed by including it as a command, since it would be interpreted as a TAB; the desired effect can be obtained by using instead the string specification "51", or the form (QUOTE 51).

For those instances when PRIN1 is not appropriate, e.g., PRIN2 is required, or a list structures must be prettyprinted, the following commands are available:

. P2 THING  [PRINTOUT Command]
Causes THING to be printed using PRIN2; translates as (PRIN2 THING).

. PPF THING  [PRINTOUT Command]
Causes THING to be prettyprinted at the current line position via PRINTDEF (see Chapter 26). The call to PRINTDEF specifies that THING is to be printed as if it were part of a function definition. That is, SELECTQ, PROG, etc., receive special treatment.

. PPV THING  [PRINTOUT Command]
Prettyprints THING as a variable; no special interpretation is given to SELECTQ, PROG, etc.

. PPFTL THING  [PRINTOUT Command]
Like .PPF, but prettyprints THING as a tail, that is, without the initial and final parentheses if it is a list. Useful for prettyprinting sub-lists of a list whose other elements are formatted with other commands.

. PPVTL THING  [PRINTOUT Command]
Like .PPV, but prettyprints THING as a tail.

Paragraph Format

Interlisp’s prettyprint routines are designed to display the structure of expressions, but they are not really suitable for formatting unstructured text. If a list is to be printed as a textual paragraph, its internal structure is less important than controlling its left and right margins, and the indentation of its first line. The . PARA and . PARA2 commands allow these parameters to be conveniently specified.

. PARA LMarg RMArg LIST  [PRINTOUT Command]
Prints LIST in paragraph format, using PRIN1. Translates as (PRINTPARA LMarg RMArg LIST) (see below).
I/O FUNCTIONS

Example: (PRINTOUT T 10 .PARA 5 -5 LST) will print the elements of LST as a paragraph with left margin at 5, right margin at (LINELENGTH)-5, and the first line indented to 10.

.PROGRAM NAME

Print as paragraph using PRIN2 instead of PRIN1. Translates as (PRINTPARA LMARG RMARG LIST T).

Right-Flushing

Two commands are provided for printing simple expressions flushed-right against a specified line position, using the function FLUSHRIGHT (see below). They take into account the current position, the number of characters in the print-name of the expression, and the position the expression is to be flush against, and then print the appropriate number of spaces to achieve the desired effect. Note that this might entail going to a new line before printing. Note also that right-flushing of expressions longer than a line (e.g. a large list) makes little sense, and the appearance of the output is not guaranteed.

.FR POS EXPR

Flush-right using PRIN1. The value of POS determines the position that the right end of EXPR will line up at. As with the horizontal spacing commands, a negative position number means |POS| columns from the current position, a positive number specifies the position absolutely. POS=0 specifies the right-margin, i.e. is interpreted as (LINELENGTH).

.FR2 POS EXPR

Flush-right using PRIN2 instead of PRIN1.

Centering

Commands for centering simple expressions between the current line position and another specified position are also available. As with right flushing, centering of large expressions is not guaranteed.

.CENTER POS EXPR

Centers EXPR between the current line position and the position specified by the value of POS. A positive POS is an absolute position number, a negative POS specifies a position relative to the current position, and 0 indicates the right-margin. Uses PRIN1 for printing.

.CENTER2 POS EXPR

Centers using PRIN2 instead of PRIN1.
Numbering

The following commands provide FORTRAN-like formatting capabilities for integer and floating-point numbers. Each command specifies a printing format and a number to be printed. The format specification translates into a format-list for the function PRINTNUM.

`.I FORMAT NUMBER' [PRINTOUT Command]

Specifies integer printing. Translates as a call to the function PRINTNUM with a FIX format-list constructed from FORMAT. The atomic format is broken apart at internal periods to form the format-list. For example, `.I5.8.T' yields the format-list (FIX 5 8 T), and the command sequence (PRINTOUT T `.I.8.T FOO) translates as (PRINTNUM '(FIX 5 8 T) FOO). This expression causes the value of FOO to be printed in radix 8 right-flushed in a field of width 5, with 0's used for padding on the left. Internal NIL's in the format specification may be omitted, e.g., the commands `.I5..T' and `.I5.NIL.T' are equivalent.

The format specification `.11' is often useful for forcing a number to be printed in radix 10 (but not otherwise specially formatted), independent of the current setting of RADIX.

`.F FORMAT NUMBER' [PRINTOUT Command]

Specifies floating-number printing. Like the `.I' format command, except translates with a FLOAT format-list.

`.N FORMAT NUMBER' [PRINTOUT Command]

The `.I' and `.F' commands specify calls to PRINTNUM with quoted format specifications. The `.N' command translates as (PRINTNUM FORMAT NUMBER), i.e., it permits the format to be the value of some expression. Note that, unlike the `.I' and `.F' commands, FORMAT is a separate element in the command list, not part of an atom beginning with `.N'.

Escaping to Lisp

There are many reasons for taking control away from PRINTOUT in the middle of a long printing expression. Common situations involve temporary changes to system printing parameters (e.g. LINELENGTH), conditional printing (e.g. print FOO only if FIE is T), or lower-level iterative printing within a higher-level print specification.

`# FORM' [PRINTOUT Command]

The escape command. FORM is an arbitrary Lisp expression that is evaluated within the context established by the PRINTOUT form, i.e., FORM can assume that the primary output stream has been set to be the FILE argument to PRINTOUT. Note that nothing is done with the value of FORM; any printing desired is accomplished by FORM itself, and the value is discarded.

Note: Although PRINTOUT logically encloses its translation in a RESETFORM (Chapter 14) to change the primary output file to the FILE argument (if non-NIL), in most
cases it can actually pass FILE (or a locally bound variable if FILE is a non-trivial expression) to each printing function. Thus, the RESETFORM is only generated when the # command is used, or user-defined commands (below) are used. If many such occur in repeated PRINTOUT forms, it may be more efficient to embed them all in a single RESETFORM which changes the primary output file, and then specify FILE=NIL in the PRINTOUT expressions themselves.

**User-Defined Commands**

The collection of commands and options outlined above is aimed at fulfilling all common printing needs. However, certain applications might have other, more specialized printing idioms, so a facility is provided whereby you can define new commands. This is done by adding entries to the global list PRINTOUTMACROS to define how the new commands are to be translated.

**PRINTOUTMACROS**

PRINTOUTMACROS is an association-list whose elements are of the form (COMM FN). Whenever COMM appears in command position in the sequence of PRINTOUT commands (as opposed to an argument position of another command), FN is applied to the tail of the command-list (including the command).

After inspecting as much of the tail as necessary, the function must return a list whose CAR is the translation of the user-defined command and its arguments, and whose CDR is the list of commands still remaining to be translated in the normal way.

For example, suppose you want to define a command "?", which will cause its single argument to be printed with PRIN1 only if it is not NIL. This can be done by entering (? ?TRAN) on PRINTOUTMACROS, and defining the function ?TRAN as follows:

```lisp
(DEFINEQ (?TRAN (COMS)
            (CONS
              (SUBST (CADR COMS) 'ARG
                     '(PROG ((TEMP ARG))
                         (COND (TEMP (PRIN1 TEMP))))
              (CDDR COMS))]
```

Note that ?TRAN does not do any printing itself; it returns a form which, when evaluated in the proper context, will perform the desired action. This form should direct all printing to the primary output file.

**Special Printing Functions**

The paragraph printing commands are translated into calls on the function PRINTPARA, which may also be called directly:

```
(PRINTPARA LMARG RMARG LIST P2FLAG PARENFLAG FILE) [Function]
```

Prints LIST on FILE in line-filled paragraph format with its first element beginning at the current line position and ending at or before RMARG, and with subsequent lines appearing
between \texttt{LMARG} and \texttt{RMARG}. If \texttt{P2FLAG} is non-nil, prints elements using \texttt{PRIN2}, otherwise \texttt{PRIN1}. If \texttt{PARENFLAG} is non-nil, then parentheses will be printed around the elements of \texttt{LIST}.

If \texttt{LMARG} is zero or positive, it is interpreted as an absolute column position. If it is negative, then the left margin will be at \(|\text{LMARG}| + (\text{POSITION})\). If \texttt{LMARG}=nil, the left margin will be at (POSITION), and the paragraph will appear in block format.

If \texttt{RMARG} is positive, it also is an absolute column position (which may be greater than the current (LINELENGTH)). Otherwise, it is interpreted as relative to (LINELENGTH), i.e., the right margin will be at (LINELENGTH)+|RMARG|. Example: \((\text{TAB 10})\) \((\text{PRINTPARA 5 -5 LST T})\) will \texttt{PRIN2} the elements of \texttt{LST} in a paragraph with the first line beginning at column 10, subsequent lines beginning at column 5, and all lines ending at or before (LINELENGTH)-5.

The current (LINELENGTH) is unaffected by \texttt{PRINTPARA}, and upon completion, \texttt{FILE} will be positioned immediately after the last character of the last item of \texttt{LIST}. \texttt{PRINTPARA} is a no-op if \texttt{LIST} is not a list.

The right-flushing and centering commands translate as calls to the function \texttt{FLUSHRIGHT}:

\begin{verbatim}
(FLUSHRIGHT POS X MIN P2FLAG CENTERFLAG FILE)  [Function]
  If CENTERFLAG=Nil, prints X right-flushed against position POS on FILE; otherwise, centers X between the current line position and POS. Makes sure that it spaces over at least MIN spaces before printing by doing a \texttt{TERPRI} if necessary; MIN=Nil is equivalent to MIN=1. A positive POS indicates an absolute position, while a negative POS signifies the position which is \(|POS|\) to the right of the current line position. POS=0 is interpreted as (LINELENGTH), the right margin.
\end{verbatim}

\section*{READFILE and WRITEFILE}

For those applications where you simply want to simply read all of the expressions on a file, and not evaluate them, the function \texttt{READFILE} is available:

\begin{verbatim}
(READFILE FILE RDTBL ENDTOKEN)  [NoSpread Function]
  Reads successive expressions from file using \texttt{READ} (with read table \texttt{RDTBL}) until the single litatom \texttt{ENDTOKEN} is read, or an end of file encountered. Returns a list of these expressions.

  If \texttt{RDTBL} is not specified, it defaults to \texttt{FILERDTBL}. If \texttt{ENDTOKEN} is not specified, it defaults to the litatom \texttt{STOP}.
\end{verbatim}

\begin{verbatim}
(WRITEFILE X FILE)  [Function]
  Writes a date expression onto \texttt{FILE}, followed by successive expressions from \texttt{X}, using \texttt{FILERDTBL} as a read table. If \texttt{X} is atomic, its value is used. If \texttt{FILE} is not open, it is
\end{verbatim}
(ENDFILE FILE)

Prints STOP on FILE and closes it.

Read Tables

Many Interlisp input functions treat certain characters in special ways. For example, READ recognizes that the right and left parenthesis characters are used to specify list structures, and that the quote character is used to delimit text strings. The Interlisp input and (to a certain extent) output routines are table driven by read tables. Read tables are objects that specify the syntactic properties of characters for input routines. Since the input routines parse character sequences into objects, the read table in use determines which sequences are recognized as literal atoms, strings, list structures, etc.

Most Interlisp input functions take an optional read table argument, which specifies the read table to use when reading an expression. If NIL is given as the read table, the "primary read table" is used. If T is specified, the system terminal read table is used. Some functions will also accept the atom ORIG (not the value of ORIG) as indicating the "original" system read table. Some output functions also take a read table argument. For example, PRIN2 prints an expression so that it would be read in correctly using a given read table.

The Interlisp-D system uses the following read tables: T for input/output from terminals, the value of FILERDTBL for input/output from files, the value of EDITRDTBL for input from terminals while in the tty-based editor, the value of DEDITRDTBL for input from terminals while in the display-based editor, and the value of CODERDTBL for input/output from compiled files. These five read tables are initially copies of the ORIG read table, with changes made to some of them to provide read macros that are specific to terminal input or file input. Using the functions described below, you may further change, reset, or copy these tables. However, in the case of FILERDTBL and CODERDTBL, you are cautioned that changing these tables may prevent the system from being able to read files made with the original tables, or prevent users possessing only the standard tables from reading files made using the modified tables.

You can also create new read tables, and either explicitly pass them to input/output functions as arguments, or install them as the primary read table, via SETREADTABLE, and then not specify a RDTBL argument, i.e., use NIL.

Read Table Functions

(READTABLEP RDTBL)

[Function]

Returns RDTBL if RDTBL is a real read table (not T or ORIG), otherwise NIL.
(GETREADTABLE RDTBL) [Function]
If RDTBL=NIL, returns the primary read table. If RDTBL=T, returns the system terminal read table. If RDTBL is a real read table, returns RDTBL. Otherwise, generates an ILLEGAL READTABLE error.

(SETREADTABLE RDTBL FLG) [Function]
Sets the primary read table to RDTBL. If FLG=T, SETREADTABLE sets the system terminal read table, T. Note that you can reset the other system read tables with SETQ, e.g., (SETQ FILERD T (GETREADTABLE)).
Generates an ILLEGAL READTABLE error if RDTBL is not NIL, T, or a real read table. Returns the previous setting of the primary read table, so SETREADTABLE is suitable for use with RESETFORM (Chapter 14).

(COPYREADTABLE RDTBL) [Function]
Returns a copy of RDTBL. RDTBL can be a real read table, NIL, T, or ORIG (in which case COPYREADTABLE returns a copy of the original system read table), otherwise COPYREADTABLE generates an ILLEGAL READTABLE error.
Note that COPYREADTABLE is the only function that creates a read table.

(RESETREADTABLE RDTBL FROM) [Function]
Copies (smashes) FROM into RDTBL. FROM and RDTBL can be NIL, T, or a real read table. In addition, FROM can be ORIG, meaning use the system’s original read table.

Syntax Classes
A read table is an object that contains information about the “syntax class” of each character. There are nine basic syntax classes: LEFTPAREN, RIGHTPAREN, LEFTBRACKET, RIGHTBRACKET, STRINGDELM, ESCAPE, BREAKCHAR, SEPRCHAR, and OTHER, each associated with a primitive syntactic property. In addition, there is an unlimited assortment of user-defined syntax classes, known as “read macros”. The basic syntax classes are interpreted as follows:

- LEFTPAREN (normally left parenthesis) Begins list structure.
- RIGHTPAREN (normally right parenthesis) Ends list structure.
- LEFTBRACKET (normally left bracket) Begins list structure. Also matches RIGHTBRACKET characters.
- RIGHTBRACKET (normally left bracket) Ends list structure. Can close an arbitrary numbers of LEFTPAREN lists, back to the last LEFTBRACKET.
- STRINGDELM (normally double quote) Begins and ends text strings. Within the string, all characters except for the one(s) with class ESCAPE are treated as ordinary, i.e., interpreted as if they were of syntax class OTHER. To include the string delimiter inside a string, prefix it with the ESCAPE character.
I/O FUNCTIONS

ESCAPE  (normally percent sign)  Inhibits any special interpretation of the next
character, i.e., the next character is interpreted to be of class OTHER,
independent of its normal syntax class.

BREAKCHAR  (None initially)  Is a break character, i.e., delimits atoms, but is otherwise an
ordinary character.

SEPRCHAR  (space, carriage return, etc.)  Delimits atoms, and is otherwise ignored.

OTHER  Characters that are not otherwise special belong to the class OTHER.

Characters of syntax class LEFTPAREN, RIGHTPAREN, LEFTBRACKET, RIGHTBRACKET, and
STRINGDELIM are all break characters. That is, in addition to their interpretation as delimiting list or
string structures, they also terminate the reading of an atom. Characters of class BREAKCHAR serve
only to terminate atoms, with no other special meaning. In addition, if a break character is the first
non-separator encountered by RATOM, it is read as a one-character atom. In order for a break character
to be included in an atom, it must be preceded by the ESCAPE character.

Characters of class SEPRCHAR also terminate atoms, but are otherwise completely ignored; they can be
thought of as logically spaces. As with break characters, they must be preceded by the ESCAPE
character in order to appear in an atom.

For example, if $ were a break character and * a separator character, the input stream
ABC**DEF$GH*$ would be read by six calls to RATOM returning respectively ABC, DEF, $, GH, $, $.

Although normally there is only one character in a read table having each of the list- and string-
delimiting syntax classes (such as LEFTPAREN), it is perfectly acceptable for any character to have any
syntax class, and for more than one to have the same class.

Note that a "syntax class" is an abstraction: there is no object referencing a collection of characters
called a syntax class. Instead, a read table provides the association between a character and its syntax
class, and the input/output routines enforce the abstraction by using read tables to drive the parsing.

The functions below are used to obtain and set the syntax class of a character in a read table. CH can
either be a character code (a integer), or a character (a single-character atom). Single-digit integers are
interpreted as character codes, rather than as characters. For example, 1 indicates Control-A, and 49
indicates the character 1. Note that CH can be a full sixteen-bit NS character (see Chapter 2).

Note:  Terminal tables, described in Chapter 30, also associate characters with syntax
classes, and they can also be manipulated with the functions below. The set of
read table and terminal table syntax classes are disjoint, so there is never any
ambiguity about which type of table is being referred to.

(GETSYNTAX CH TABLE)  [Function]

Returns the syntax class of CH, a character or a character code, with respect to TABLE.
TABLE can be NIL, T, ORIG, or a real read table or terminal table.
CH can also be a syntax class, in which case GETSYNTAX returns a list of the character codes in TABLE that have that syntax class.

\[(SETSYYNTAX CH CLASS TABLE)\]  [Function]

Sets the syntax class of \(CH\), a character or character code, in TABLE. TABLE can be either NIL, T, or a real read table or terminal table. SETSYNTAX returns the previous syntax class of \(CH\). 

CLASS can be any one of the following:

- The name of one of the basic syntax classes.
- A list, which is interpreted as a read macro (see below).
- NIL, T, ORIG, or a real read table or terminal table, which means to give \(CH\) the syntax class it has in the table indicated by \(CLASS\). For example, \(\text{(SETSYYNTAX '(% ORIG TABLE)}\) gives the left parenthesis character in TABLE the same syntax class that it has in the original system read table.
- A character code or character, which means to give \(CH\) the same syntax class as the character \(CH\) in TABLE. For example, \(\text{(SETSYYNTAX '{' [TABLE]}\) gives the left brace character the same syntax class as the left bracket.

\[(SYNTAXP CODE CLASS TABLE)\]  [Function]

CODE is a character code; TABLE is NIL, T, or a real read table or terminal table. Returns T if CODE has the syntax class CLASS in TABLE; NIL otherwise.

CLASS can also be a read macro type (MACRO, SPLICE, INFIX), or a read macro option (FIRST, IMMEDIATE, etc.), in which case SYNTAXP returns T if the syntax class is a read macro with the specified property.

SYNTAXP will not accept a character as an argument, only a character code.

For convenience in use with SYNTAXP, the atom BREAK may be used to refer to all break characters, i.e., it is the union of LEFTPAREN, RIGHTPAREN, LEFTBRACKET, RIGHTBRACKET, STRINGDELIM, and BREAKCHAR. For purely symmetrical reasons, the atom SEPR corresponds to all separator characters. However, since the only separator characters are those that also appear in SEPRCHAR, SEPR and SEPRCHAR are equivalent.

Note that GETSYNTAX never returns BREAK or SEPR as a value although SETSYNTAX and SYNTAXP accept them as arguments. Instead, GETSYNTAX returns one of the disjoint basic syntax classes that comprise BREAK. BREAK as an argument to SETSYNTAX is interpreted to mean BREAKCHAR if the character is not already one of the BREAK classes. Thus, if \% is of class LEFTPAREN, then \(\text{(SETSYYNTAX '(% BREAK)}\) doesn’t do anything, since \% is already a break character, but \(\text{(SETSYYNTAX '(% BREAKCHAR)}\) means make \% be just a break character, and therefore disables the LEFTPAREN function of \%. Similarly, if one of the format characters is disabled completely, e.g., by \(\text{(SETSYYNTAX '(% OTHER)}\), then \(\text{(SETSYYNTAX '(% BREAK)}\) would make \% be only a break character; it would not restore \% as LEFTPAREN.
I/O FUNCTIONS

The following functions provide a way of collectively accessing and setting the separator and break characters in a read table:

**(GETSEPR RDTBL)**  
[Function]  
Returns a list of separator character codes in RDTBL. Equivalent to (GETSYNTAX 'SEPR RDTBL).

**(GETBRK RDTBL)**  
[Function]  
Returns a list of break character codes in RDTBL. Equivalent to (GETSYNTAX 'BREAK RDTBL).

**(SETSEPR LST FLG RDTBL)**  
[Function]  
Sets or removes the separator characters for RDTBL. **LST** is a list of characters or character codes. **FLG** determines the action of **SETSEPR** as follows: If **FLG=NIL**, makes RDTBL have exactly the elements of **LST** as separators, discarding from RDTBL any old separator characters not in **LST**. If **FLG=0**, removes from RDTBL as separator characters all elements of **LST**. This provides an "UNSETSEPR". If **FLG=1**, makes each of the characters in **LST** be a separator in RDTBL.

If **LST=T**, the separator characters are reset to be those in the system's read table for terminals, regardless of the value of **FLG**, i.e., (SETSEPR T) is equivalent to (SETSEPR (GETSEPR T)). If **RDTBL** is **T**, then the characters are reset to those in the original system table.

Returns NIL.

**(SETBRK LST FLG RDTBL)**  
[Function]  
Sets the break characters for RDTBL. Similar to **SETSEPR**.

As with **SETSYNTAX** to the **BREAK** class, if any of the list- or string-delimiting break characters are disabled by an appropriate **SETBRK** (or by making it be a separator character), its special action for **READ** will not be restored by simply making it be a break character again with **SETBRK**. However, making these characters be break characters when they already are will have no effect.

The action of the **ESCAPE** character (normally %) is not affected by **SETSEPR** or **SETBRK**. It can be disabled by setting its syntax to the class **OTHER**, and other characters can be used for escape on input by assigning them the class **ESCAPE**. As of this writing, however, there is no way to change the output escape character; it is "hardwired" as %.

That is, on output, characters of special syntax that need to be preceded by the **ESCAPE** character will always be preceded by %, independent of the syntax of % or which, if any, characters, have syntax **ESCAPE**.

The following function can be used for defeating the action of the **ESCAPE** character or characters:
(ESCAPE FLG RDTBL)  

[Function]  

If FLG=NIL, makes characters of class ESCAPE behave like characters of class OTHER on input. Normal setting is (ESCAPE T). ESCAPE returns the previous setting.

Read Macros

This is a description of the OLD-INTERLISP-T read macros. Read macros are user-defined syntax classes that can cause complex operations when certain characters are read. Read macro characters are defined by specifying as a syntax class an expression of the form:

\[
(Type \ Option_1 \ldots \ Option_n \ FN)
\]

where Type is one of MACRO, SPLICE, or INFIX, and FN is the name of a function or a lambda expression. Whenever READ encounters a read macro character, it calls the associated function, giving it as arguments the input stream and read table being used for that call to READ. The interpretation of the value returned depends on the type of read macro:

MACRO  This is the simplest type of read macro. The result returned from the macro is treated as the expression to be read, instead of the read macro character. Often the macro reads more input itself. For example, in order to cause ~EXPR to be read as (NOT EXPR), one could define ~ as the read macro:

\[
\begin{align*}
\text{[MACRO (LAMBDA (FL RDTBL)} \\
\text{\quad (LIST 'NOT (READ FL RDTBL))}
\end{align*}
\]

SPLICE  The result (which should be a list or NIL) is spliced into the input using NCONC. For example, if $ is defined by the read macro:

\[
\text{(SPLICE (LAMBDA NIL (APPEND FOO))} \}
\]

and the value of FOO is (A B C), then when you input (X $ Y), the result will be (X A B C Y).

INFIX  The associated function is called with a third argument, which is a list, in TCONC format (Chapter 3), of what has been read at the current level of list nesting. The function’s value is taken as a new TCONC list which replaces the old one. For example, the infix operator + could be defined by the read macro:

\[
\begin{align*}
\text{(INFIX (LAMBDA (FL RDTBL Z)} \\
\text{\quad (RPLACA (CDR Z))} \\
\text{\quad (LIST (QUOTE IPLUS)} \\
\text{\quad \quad \quad (CADR Z)} \\
\text{\quad \quad \quad (READ FL RDTBL)))} \\
\text{\quad Z))}
\end{align*}
\]

If an INFIX read macro character is encountered not in a list, the third argument to its associated function is NIL. If the function returns NIL, the read macro character is essentially ignored and reading continues. Otherwise, if the function returns a TCONC list of one element, that element is the value of
the \texttt{READ}. If it returns a \texttt{TCONC} list of more than one element, the list is the value of the \texttt{READ}.

The specification for a read macro character can be augmented to specify various options \texttt{OPTION}_1 \ldots \texttt{OPTION}_n, e.g., \texttt{(MACRO FIRST IMMEDIATE FN)}. The following three disjoint options specify when the read macro character is to be effective:

- \texttt{ALWAYS} The default. The read macro character is always effective (except when preceded by the \% character), and is a break character, i.e., a member of \texttt{(GETSYNTAX 'BREAK RDTBL)}.

- \texttt{FIRST} The character is interpreted as a read macro character only when it is the first character seen after a break or separator character; in all other situations, the character is treated as having class \texttt{OTHER}. The read macro character is \textit{not} a break character. For example, the quote character is a \texttt{FIRST} read macro character, so that \texttt{DON'T} is read as the single atom \texttt{DON'T}, rather than as \texttt{DON} followed by \texttt{(QUOTE T)}.

- \texttt{ALONE} The read macro character is \textit{not} a break character, and is interpreted as a read macro character only when the character would have been read as a separate atom if it were not a read macro character, i.e., when its immediate neighbors are both break or separator characters.

Making a \texttt{FIRST} or \texttt{ALONE} read macro character be a break character (with \texttt{SETBRK}) disables the read macro interpretation, i.e., converts it to syntax class \texttt{BREAKCHAR}. Making an \texttt{ALWAYS} read macro character be a break character is a no-op.

The following two disjoint options control whether the read macro character is to be protected by the \texttt{ESCAPE} character on output when a litatom containing the character is printed:

- \texttt{ESQUOTE} or \texttt{ESC} The default. When printed with \texttt{PRIN2}, the read macro character will be preceded by the output escape character (\%) as needed to permit the atom containing it to be read correctly. Note that for \texttt{FIRST} macros, this means that the character need be quoted only when it is the first character of the atom.

- \texttt{NOESQUOTE} or \texttt{NOESC} The read macro character will always be printed without an escape. For example, the \texttt{?} read macro in the \texttt{T} read table is a \texttt{NOESQUOTE} character. Unless you are very careful what you are doing, read macro characters in \texttt{FILERDTBL} should never be \texttt{NOESQUOTE}, since symbols that happen to contain the read macro character will not read back in correctly.

The following two disjoint options control when the macro's function is actually executed:

- \texttt{IMMEDIATE} or \texttt{IMMED} The read macro character is immediately activated, i.e., the current line is terminated, as if an \texttt{EOL} had been typed, a carriage-return line-feed is printed,
and the entire line (including the macro character) is passed to the input function.

IMMEDIATE read macro characters enable you to specify a character that will take effect immediately, as soon as it is encountered in the input, rather than waiting for the line to be terminated. Note that this is not necessarily as soon as the character is typed. Characters that cause action as soon as they are typed are interrupt characters (see Chapter 30).

Note that since an IMMEDIATE macro causes any input before it to be sent to the reader, characters typed before an IMMEDIATE read macro character cannot be erased by Control-A or Control-Q once the IMMEDIATE character has been typed, since they have already passed through the line buffer. However, an INFIX read macro can still alter some of what has been typed earlier, via its third argument.

NONIMMEDIATE or NONIMMED The default. The read macro character is a normal character with respect to the line buffering, and so will not be activated until a carriage-return or matching right parenthesis or bracket is seen.

Making a read macro character be both ALONE and IMMEDIATE is a contradiction, since ALONE requires that the next character be input in order to see if it is a break or separator character. Thus, ALONE read macros are always NONIMMEDIATE, regardless of whether or not IMMEDIATE is specified.

Read macro characters can be "nested". For example, if = is defined by

```
(MACRO (LAMBDA (FL RDTBL)
  (EVAL (READ FL RDTBL))))
```

and ! is defined by

```
(SPLICE (LAMBDA (FL RDTBL)
  (READ FL RDTBL)))
```

then if the value of FOO is (A B C), and (X =FOO Y) is input, (X (A B C) Y) will be returned. If (X !=FOO Y) is input, (X A B C Y) will be returned.

Note: If a read macro’s function calls READ, and the READ returns NIL, the function cannot distinguish the case where a RIGHTPAREN or RIGHTBRACKET followed the read macro character, (e.g. "'(A B ')"), from the case where the atom NIL (or "()") actually appeared. In Interlisp-D, a READ inside of a read macro when the next input character is a RIGHTPAREN or RIGHTBRACKET reads the character and returns NIL, just as if the READ had not occurred inside a read macro.
If a call to READ from within a read macro encounters an unmatched RIGHTBRACKET within a list, the bracket is simply put back into the buffer to be read (again) at the higher level. Thus, inputting an expression such as \((A \ B \ ' (C \ D])\) works correctly.

(INREADMACROP) [Function]

Returns NIL if currently not under a read macro function, otherwise the number of unmatched left parentheses or brackets.

(READMACROS FLG RDTBL) [Function]

If FLG=NIL, turns off action of read macros in read table RDTBL. If FLG=T, turns them on. Returns previous setting.

The following read macros are standardly defined in Interlisp in the T and EDITRDTBL read tables:

• (single-quote) Returns the next expression, wrapped in a call to QUOTE; e.g., ‘FOO reads as (QUOTE FOO). The macro is defined as a FIRST read macro, so that the quote character has no effect in the middle of a symbol. The macro is also ignored if the quote character is immediately followed by a separator character.

Control-Y Defined in T and EDITRDTBL. Returns the result of evaluating the next expression. For example, if the value of FOO is \((A \ B)\), then \((LIST 1 control-YFOO 2)\) is read as \((LIST 1 (A \ B) 2)\). Note that no structure is copied; the third element of that input expression is still EQ to the value of FOO. Control-Y can thus be used to read structures that ordinarily have no read syntax. For example, the value returned from reading \((KEY1 control-Y (ARRAY 10))\) has an array as its second element. Control-Y can be thought of as an "un-quote" character. The choice of character to perform this function is changeable with SETTERMCHARS (see Chapter 16).

• (backquote) Backquote makes it easier to write programs to construct complex data structures. Backquote is like quote, except that within the backquoted expression, forms can be evaluated. The general idea is that the backquoted expression is a "template" containing some constant parts (as with a quoted form) and some parts to be filled in by evaluating something. Unlike with control-Y, however, the evaluation occurs not at the time the form is read, but at the time the backquoted expression is evaluated. That is, the backquote macro returns an expression which, when evaluated, produces the desired structure.

Within the backquoted expression, the character ",@" (comma) introduces a form to be evaluated. The value of a form preceded by ",@" is to be spliced in, using APPEND. If it is permissible to destroy the list being spliced in (i.e., NCONC may be used in the translation), then ",." can be used instead of ",@".

For example, if the value of FOO is \((1 \ 2 \ 3 \ 4)\), then the form
`'(A , (CAR FOO) ,@(CDDR FOO) D E)\n\nevaluates to (A 1 3 4 D E); it is logically equivalent to writing\n\n(CONS 'A\n  (CONS (CAR FOO)\n       (APPEND (CDDR FOO) '(D E)))))\n\nBackquote is particularly useful for writing macros. For example, the body of a macro that refers to X as the macro’s argument list might be\n\n`'(COND\n  ((FIXP , (CAR X))\n   ,(CADR X))\n  (T ,,(CDDR X))))\n\nwhich is equivalent to writing\n\n(LIST 'COND\n  (LIST (LIST 'FIXP (CAR X))\n       (CADR X))\n  (CONS 'T (CDDR X))))\n\nNote that comma does not have any special meaning outside of a backquote context.
\nFor users without a backquote character on their keyboards, backquote can also be written as | (vertical-bar, quote).
\n? Implements the ?= command for on-line help regarding the function currently being "called" in the typein (see Chapter 26).
\n| (vertical bar) When followed by an end of line, tab or space, | is ignored, i.e., treated as a separator character, enabling the editor’s CHANGECHAR feature (see Chapter 26). Otherwise it is a "dispatching" read macro whose meaning depends on the character(s) following it. The following are currently defined:
\n' (quote) -- A synonym for backquote.

. (period) -- Returns the evaluation of the next expression, i.e., this is a synonym for Control-Y.

, (comma) -- Returns the evaluation of the next expression at load time, i.e., the following expression is quoted in such a manner that the compiler treats it as a literal whose value is not determined until the compiled expression is loaded.

O or o (the letter O) -- Treats the next number as octal, i.e., reads it in radix 8. For example, |o12 = 10 (decimal).

B or b -- Treats the next number as binary, i.e., reads it in radix 2. For example, |b101 = 5 (decimal).
X or x -- Treats the next number as hexadecimal, i.e., reads it in radix 16. The uppercase letters A though F are used as the digits after 9. For example, |x1A = 26 (decimal).

R or r -- Reads the next number in the radix specified by the (decimal) number that appears between the | and the R. When inputting a number in a radix above ten, the upper-case letters A through Z can be used as the digits after 9 (but there is no digit above Z, so it is not possible to type all base-99 digits). For example, 3r120 reads 120 in radix 3, returning 15.

(, {, ^ -- Used internally by HPRINT and HREAD (see above) to print and read unusual expressions.

The dispatching characters that are letters can appear in either upper- or lowercase.
25. USER/INPUT/OUTPUT PACKAGES

Interlisp-D can perform input/output operations on a large variety of physical devices.

This chapter presents a number of packages that have been developed for displaying and allowing the user to enter information. These packages are used to implement the user interface of many system facilities.

INSPECT (see the INSPECT section below) provides a window-based facility for displaying and changing the fields of a data object.

PROMPTFORWORD (see the PROMPTFORWORD section below) is a function used for entering a simple string of characters. Basic editing and prompting facilities are provided.

ASKUSER (see the ASKUSER section below) provides a more complicated prompting and answering facility, allowing a series of questions to be printed. Prompts and argument completion are supported.

TTYIN (see the TTYIN Display Typein Editor section below) is a display typein editor, that provides complex text editing facilities when entering an input line.

PRETTYPRINT (see the Prettyprint section below) is used for printing function definitions and other list structures, using multiple fonts and indenting lines to show the structure of the list.

Inspector

The Inspector provides a display-oriented facility for looking at and changing arbitrary Interlisp-D data structures. The inspector can be used to inspect all user datatypes and many system datatypes (although some objects such as numbers have no inspectable structure). The inspector displays the field names and values of an arbitrary object in a window that allows setting of the properties and further inspection of the values. This latter feature makes it possible to "walk" around all of the data structures in the system at the touch of a button. In addition, the inspector is integrated with the break package to allow inspection of any object on the stack and with the display and teletype structural editors to allow the editors to be used to "inspect" list structures and the inspector to "edit" datatypes.

The underlying mechanisms of the data inspector have been designed to allow their use as specialized editors in user applications. This functionality is described at the end of this section.

Note: Currently, the inspector does not have UNDOing. Also, variables whose values are changed will not be marked as such.

Calling the Inspector
There are several ways to open an inspect window onto an object. In addition to calling \texttt{INSPECT} directly (below), the inspector can also be called by buttoning an Inspect command inside an existing inspector window. Finally, if a non-list is edited with \texttt{EDITDEF} (see Chapter 17), the inspector is called. This also causes the inspector to be called by the Dedit command from the display editor or the \texttt{EV} command from the teletype editor if the selected piece of structure is a non-list.

\begin{verbatim}
(INSPECT OBJECT ASTYPE WHERE) [Function]

Creates an inspect window onto \texttt{OBJECT}. If \texttt{ASTYPE} is given, it will be taken as the record type of \texttt{OBJECT}. This allows records to be inspected with their property names. If \texttt{ASTYPE} is \texttt{NIL}, the data type of \texttt{OBJECT} will be used to determine its property names in the inspect window.

\texttt{WHERE} specifies the location of the inspect window. If \texttt{WHERE} is \texttt{NIL}, the user will be prompted for a location. If \texttt{WHERE} is a window, it will be used as the inspect window. If \texttt{WHERE} is a region, the inspect window will be created in that region of the screen. If \texttt{WHERE} is a position, the inspect window will have its lower left corner at that position on the screen.

\texttt{INSPECT} returns the inspect window onto \texttt{OBJECT}, or \texttt{NIL} if no inspection took place.
\end{verbatim}

\begin{verbatim}
(INSPECTCODE FN WHERE — — — —) [Function]

Opens a window and displays the compiled code of the function \texttt{FN} using \texttt{PRINTCODE}. The window is scrollable.

\texttt{WHERE} determines where the window should appear. It can be a position, a region, or a window. If \texttt{NIL}, the user is prompted to specify the position of the window.

Note: If the Tedit library package is loaded, \texttt{INSPECTCODE} uses it to create the code inspector window. Also, if \texttt{INSPECTCODE} is called to inspect the frame name in a break window (see Chapter 14), the location in the code that the frame's PC indicates it was executing at the time is highlighted.
\end{verbatim}

\textbf{Multiple Ways of Inspecting}

For some datatypes there is more than one aspect that is of interest or more than one method of inspecting the object. In these cases, the inspector will bring up a menu of the possibilities and wait for the user to select one.

If the object is a litatom, the commands are the types for which the litatom has definitions as determined by \texttt{HASDEF}. Some typical commands are:

\begin{verbatim}
FNS Edit the definition of the selected litatom.

VARS Inspect the value.

PROPS Inspect the property list.
\end{verbatim}

If the object is a list, there will be choice of how to inspect the list:
Inspect  Opens an inspect window in which the properties are numbers and the values are the elements of the list.

TtyEdit  Calls the teletype list structure editor on the list (see Chapter 16).

DisplayEdit  Calls the DEdit display editor on the list (see Chapter 16).

As a PLIST  Inspects the list as a property list, if the list is in property list form: \(((\text{PROP}_1 \ \text{VAL}_1) \ldots (\text{PROP}_N \ \text{VAL}_N))\).

As an ALIST  Inspects the list as an association-list, if the list is in ASSOC list form: \((\text{PROP}_1 \ \text{VAL}_1 \ldots \ \text{PROP}_N \ \text{VAL}_N)\).

As a record  Brings up a submenu with all of the RECORDs in the system and inspect the list with the one chosen.

As a "record type"  Inspects the list as the record of the type named in its CAR, if the CAR of the list is the name of a TYPERECORD (see Chapter 8).

If the object is a bitmap, the choice is between inspecting the bitmap’s contents with the bitmap editor (EDITBM) or inspecting the bitmap’s fields.

Other datatypes may include multiple methods for inspecting objects of that type.

Inspect Windows

An inspect window displays two columns of values. The lefthand column lists the property names of the structure being inspected. The righthand column contains the values of the properties named on the left. For variable length data such as lists and arrays, the "property names" are numbers from 1 to the length of the inspected item and the values are the corresponding elements. For arrays, the property names are the array element numbers and the values are the corresponding elements of the array.

For large lists or arrays, or datatypes with many fields, the initial window may be too small to contain all of them. In these cases, the unseen elements can be scrolled into view (from the bottom) or the window can be reshaped to increase its size.

In an inspect window, the LEFT button is used to select things, the MIDDLE button to invoke commands that apply to the selected item. Any property or value can be selected by pointing the cursor directly at the text representing it, and clicking the LEFT button. There is one selected item per window and it is marked by having its surrounding box inverted.

The options offered by the MIDDLE button depend on whether the selection is a property or a value. If the selected item is a value, the options provide different ways of inspecting the selected structure. The exact commands that are given depend on the type of the value. An example of the menu you may see is:
If the selected item is a property name, the command \texttt{SET} will appear. If selected, the user will be asked to type in an expression, and the selected property will be set to the result of evaluating the read form. The evaluation of the read form and the replacement of the selected item property will appear as their own history events and are individually undoable. Properties of system datatypes cannot be set. (There are often consistency requirements which can be inadvertently violated in ways that crash the system. This may be true of some user datatypes as well, however the system doesn’t know which ones. Users are advised to exercise caution.)

It is possible to copy-select property names or values out of an inspect window. Litatoms, numbers and strings are copied as they are displayed. Unprintable objects (such as bitmaps, etc.) come out as an appropriate system expression, such that if is evaluated, the object is re-created.

\textbf{Inspect Window Commands}

By pressing the \texttt{MIDDLE} button in the title of the inspect window, a menu of commands that apply to the inspect window is brought up:

\begin{center}
\begin{tabular}{|c|}
\hline
\texttt{ReFetch} \tab \texttt{IT=datum} \tab \texttt{IT=selection} \\
\hline
\end{tabular}
\end{center}

\texttt{ReFetch} \tab \texttt{[Inspect Window Command]}

An inspect window is not automatically updated when the structure it is inspecting is changed. The \texttt{ReFetch} command will refetch and redisplay all of the fields of the object being inspected in the inspect window.

\texttt{IT=datum} \tab \texttt{[Inspect Window Command]}

Sets the variable \texttt{IT} to object being inspected in the inspect window.

\texttt{IT=selection} \tab \texttt{[Inspect Window Command]}

Sets the variable \texttt{IT} to the property name or value currently selected in the inspect window.

\textbf{Interaction With Break Windows}

The break window facility (see Chapter 14) knows about the inspector in the sense that the backtrace frame window is an inspect window onto the frame selected from the back trace menu during a break. Thus you can call the inspector on an object that is bound on the stack by selecting its frame in the back trace menu, selecting its value with the \texttt{LEFT} button in the back trace frame window, and
selecting the inspect command with the MIDDLE button in the back trace frame window. The values of variables in frames can be set by selecting the variable name with the LEFT button and then the "Set" command with the MIDDLE button.

Note: The inspector will only allow the setting of named variables. Even with this restriction it is still possible to crash the system by setting variables inside system frames. Exercise caution in setting variables in other than your own code.

Controlling the Amount Displayed During Inspection

The amount of information displayed during inspection can be controlled using the following variables:

**MAXINSPECTCDRLEVEL** [Variable]

The inspector prints only the first MAXINSPECTCDRLEVEL elements of a long list, and will make the tail containing the unprinted elements the last item. The last item can be inspected to see further elements. Initially 50.

**MAXINSPECTARRAYLEVEL** [Variable]

The inspector prints only the first MAXINSPECTARRAYLEVEL elements of an array. The remaining elements can be inspected by calling the function (INSPECT/ARRAY ARRAY BEGINOFFSET) which inspects the BEGINOFFSET through the BEGINOFFSET + MAXINSPECTARRAYLEVEL elements of ARRAY. Initially 300.

**INSPECTPRINTLEVEL** [Variable]

When printing the values, the inspector resets PRINTLEVEL (see Chapter 25) to the value of INSPECTPRINTLEVEL. Initially (2 . 5).

**INSPECTALLFIELDSFLG** [Variable]

If INSPECTALLFIELDSFLG is T, the inspector will show computed fields (ACCESSFNS, Chapter 8) as well as regular fields for structures that have a record definition. Initially T.

Inspect Macros

The Inspector can be extended to inspect new structures and datatypes by adding entries to the list INSPECTMACROS. An entry should be of the form (OBJECTTYPE . INSPECTINFO). OBJECTTYPE is used to determine the types of objects that are inspected with this macro. If OBJECTTYPE is a litatom, the INSPECTINFO will be used to inspect items whose type name is OBJECTTYPE. If OBJECTTYPE is a list of the form (FUNCTION DATUM-PREDICATE), DATUM-PREDICATE will be APPLIED to the item and if it returns non-NIL, the INSPECTINFO will be used to inspect the item.

INSPECTINFO can be one of two forms. If INSPECTINFO is a litatom, it should be a function that will be applied to three arguments (the item being inspected, OBJECTTYPE, and the value of WHERE passed to INSPECT) that should do the inspection. If INSPECTINFO is not a litatom, it should be a list
of (PROPERTIES FETCHFN STOREFN PROPCOMMANDFN VALUECOMMANDFN TITLECOMMANDFN TITLE SELECTIONFN WHERE PROPPRINTFN) where the elements of this list are the arguments for INSPECTW.CREATE, described below. From this list, the WHERE argument will be evaluated; the others will not. If WHERE is NIL, the value of WHERE that was passed to INSPECT will be used.

Examples:

The entry ((FUNCTION MYATOMP) PROPNAME GETPROP PUTPROP) on INSPECTMACROS would cause all objects satisfying the predicate MYATOMP to have their properties inspected with GETPROP and PUTPROP. In this example, MYATOMP should make sure the object is a litatom.

The entry (MYDATATYPE . MYINSPECTFN) on INSPECTMACROS would cause all datatypes of type MYDATATYPE to be passed to the function MYINSPECTFN.

INSPECTWs

The inspector is built on the abstraction of an INSPECTW. An INSPECTW is a window with certain window properties that display an object and respond to selections of the object’s parts. It is characterized by an object and its list of properties. An INSPECTW displays the object in two columns with the property names on the left and the values of those properties on the right. An INSPECTW supports the protocol that the LEFT mouse button can be used to select any property name or property value and the MIDDLE button calls a user provided function on the selected value or property. For the Inspector application, this function puts up a menu of the alternative ways of inspecting values or of the ways of setting properties. INSPECTWs are created with the following function:

(INСПЕCTW.CREATE DATUM PROPERTIES FETCHFN STOREFN PROPCOMMANDFN VALUECOMMANDFN TITLECOMMANDFN TITLE SELECTIONFN WHERE PROPPRINTFN)  

[Function]

Creates an INSPECTW that views the object DATUM. If PROPERTIES is a list, it is taken as the list of properties of DATUM to display. If PROPERTIES is a litatom, it is APPLIED to DATUM and the result is used as the list of properties to display.

FETCHFN is a function of two arguments (OBJECT PROPERTY) that should return the value of the PROPERTY property of OBJECT. The result of this function will be printed (with PRIN2) in the INSPECTW as the value.

STOREFN is a function of three arguments (OBJECT PROPERTY NEWVALUE) that changes the PROPERTY property of OBJECT to NEWVALUE. It is used by the default PROPCOMMANDFN and VALUECOMMANDFN to change the value of a property and also by the function INSPECTW.REPLACE (described below). This can be NIL if the user provides command functions which do not call INSPECTW.REPLACE. Each replace action will be a separate event on the history list. Users are encouraged to provide UNDOable STOREFNs.

PROPCOMMANDFN is a function of three arguments (PROPERTY OBJECT INSPECTW) which gets called when the user presses the MIDDLE button and the selected item in the
**USER I/O PACKAGES**

INSPECTW is a property name. PROPERTY will be the name of the selected property, OBJECT will be the datum being viewed, and INSPECTW will be the window. If PROPCOMMANDFN is a string, it will get printed in the PROMPTWINDOW when the MIDDLE button is pressed. This provides a convenient way to notify the user about disabled commands on the properties. DEFAULT.INSPECTW.PROPCOMMANDFN, the default PROPCOMMANDFN, will present a menu with the single command Set on it. If selected, the Set command will read a value from the user and set the selected property to the result of EVALuating this read value.

VALUECOMMANDFN is a function of four arguments (VALUE PROPERTY OBJECT INSPECTW) that gets called when the user presses the MIDDLE button and the selected item in the INSPECTW is a property value. VALUE will be the selected value (as returned by FETCHFN), PROPERTY will be the name of the property VALUE is the value of, OBJECT will be the datum being viewed, and INSPECTW will be the INSPECTW window.

DEFAULT.INSPECTW.VALUECOMMANDFN, the default VALUECOMMANDFN, will present a menu of possible ways of inspecting the value and create a new Inspect window if one of the menu items is selected.

TITLECOMMANDFN is a function of two arguments (INSPECTW OBJECT) which gets called when the user presses the MIDDLE button and the cursor is in the title or border of the inspect window INSPECTW. This command function is provided so that users can implement commands that apply to the entire object. The default TITLECOMMANDFN (DEFAULT.INSPECTW.TITLECOMMANDFN) presents a menu with the commands ReFetch, IT←datum, and IT←election.

TITLE specifies the title of the window. If TITLE is NIL, the title of the window will be the printed form of DATUM followed by the string “Inspector”. If TITLE is the litatom DON’T, the inspect window will not have a title. If TITLE is any other litatom, it will be applied to the DATUM and the potential inspect window (if it is known). If this result is the litatom DON’T, the inspect window will not have a title; otherwise the result will be used as a title. If TITLE is not a litatom, it will be used as the title.

SELECTIONFN is a function of three arguments (PROPERTY VALUEFLG INSPECTW) which gets called when the user releases the left button and the cursor is on one of the items. The SELECTIONFN allows a program to take action on the user’s selection of an item in the inspect window. At the time this function is called, the selected item has been "selected". The function INSPECTW.SELECTITEM (described below) can be used to turn off this selection. PROPERTY will be the name of the property of the selected item. VALUEFLG will be NIL if the selected item is the property name; T if the selected item is the property value.

WHERE indicates where the inspect window should go. Its interpretation is described in INSPECT (see above).

PROPPRINTFN is a function of two arguments (PROPERTY DATUM) which gets called to determine what to print in the property place for the property PROPERTY. If PROPPRINTFN returns NIL, no property name will be printed and the value will be printed to the left of the other values.
An inspect window uses the following window property names to hold information: DATUM, FETCHFN, STOREFN, PROPCOMMANDFN, VALUECOMMANDFN, SELECTIONFN, PROPRINTFN, INSPECTWTITLE, PROPERTIES, CURRENTITEM and SELECTABLEITEMS.

**INSPECTW.REDISPLAY INSPECTW PROPS —)** [Function]
Updates the display of the objects being inspected in INSPECTW. If PROPS is a property name or a list of property names, only those properties are updated. If PROPS is NIL, all properties are redisplayed. This function is provided because inspect windows do not automatically update their display when the object they are showing changes.

This function is called by the ReFetch command in the title command menu of an INSPECTW (see above).

**INSPECTW.REPLACE INSPECTW PROPERTY NEWVALUE)** [Function]
Calls the STOREFN of the inspect window INSPECTW to change the property named PROPERTY to the value NEWVALUE and updates the display of PROPERTY's value in the display. This provides a functional interface for user PROPCOMMANDFNs.

**INSPECTW.SELECTITEM INSPECTW PROPERTY VALUEFLG)** [Function]
Sets the selected item in an inspect window. The item is inverted on the display and put on the window property CURRENTITEM of INSPECTW. If INSPECTW has a CURRENTITEM, it is deselected. PROPERTY is the name of the property of the selected item. VALUEFLG is NIL if the selected item is the property name; T if the selected item is the property value. If PROPERTY is NIL, no item will be selected. This provides a way of deselecting all items.

**PROMPTFORWORD**

PROMPTFORWORD is a function that reads in a sequence of characters, generally from the keyboard, without involving READ-like syntax. A user can supply a prompting string, as well as a “candidate” string, which is printed and used if the user types only a word terminator character (or doesn’t type anything before a given time limit). As soon as any characters are typed the “candidate” string is erased and the new input takes its place.

PROMPTFORWORD accepts user type-in until one of the “word terminator” characters is typed. Normally, the word terminator characters are EOL, ESCAPE, LF, SPACE, or TAB. This list can be changed using the TERMINCHAR.LST argument to PROMPTFORWORD, for example if it is desirable to allow the user to input lines including spaces.

PROMPTFORWORD also recognizes the following special characters:

- **Control-A**
- **BACKSPACE**
- **DELETE** Any of these characters deletes the last character typed and appropriately erases it from the echo stream if it is a display stream.
Control-Q Erases all the type-in so far.

Control-R Reprints the accumulated string.

Control-V 'Quotes' the next character: after typing Control-V, the next character typed is added to the accumulated string, regardless of any special meaning it has. Allows the user to include editing characters and word terminator characters in the accumulated string.

Control-W Erases the last word.

? Calls up a "help" facility. The action taken is defined by the GENERATE?LIST.FN argument to PROMPTFORWORD (see below). Normally, this prints a list of possible candidates.

(PROMPTFORWORD PROMPT.STR CANDIDATE.STR GENERATE?LIST.FN ECHO.CHANNEL DONTECHOTYPEIN.FLG URGENCY.OPTION TERMINCHARS.LST KEYBD.CHANNEL)

[Prompt]

PROMPTFORWORD has a multiplicity of features, which are specified through a rather large number of input arguments, but the default settings for them (i.e., when they aren't given, or are given as NIL) is such to minimize the number needed in the average case, and an attempt has been made to order the more frequently non-defaulted arguments at the beginning of the argument list. The default input and echo are both to the terminal; the terminal table in effect during input allows most control characters to be INDICATE’d.

PROMPTFORWORD returns NIL if a null string is typed; this would occur when no candidate is given and only a terminator is typed, or when the candidate is erased and a terminator is typed with no other input still un-erased. In all other cases, PROMPTFORWORD returns a string.

PROMPTFORWORD is controlled through the following arguments:

PROMPT.STR If non-NIL, this is coerced to a string and used for prompting; an additional space is output after this string.

CANDIDATE.STR If non-NIL, this is coerced to a string and offered as initial contents of the input buffer.

GENERATE?LIST.FN If non-NIL, this is either a string to be printed out for help, or a function to be applied to PROMPT.STR and CANDIDATE.STR (after both have been coerced to strings), and which should return a list of potential candidates. The help string or list of potential candidates will then be printed on a separate line, the prompt will be restarted, and any type-in will be re-echoed.

Note: If GENERATE?LIST.FN is a function, its value list will be cached so that it will be run at most once per call to PROMPTFORWORD.

ECHO.CHANNEL Coerced to an output stream; NIL defaults to T, the "terminal output stream", normally (TTYDISPLAYSTREAM). To achieve echoing to the "current output stream", use (GETSTREAM NIL ‘OUTPUT). If echo is to a display stream, it will have a flashing caret showing where the next input is to be echoed.

DONTECHOTYPEIN.FLG If T, there is no echoing of the input characters. If the value of DONTECHOTYPEIN.FLG is a single-character atom or string, that character is
echoed instead of the actual input. For example, LOGIN prompts for a password with DONTECHOTYPEIN.FLG being "]*".

**URGENCY.OPTION**  If NIL, PROMPTFORWORD quietly wait for input, as READ does; if a number, this is the number of seconds to wait for the user to respond (if timeout is reached, then CANDIDATE.WORD is returned, regardless of any other type-in activity); if T, this means to wait forever, but periodically flash the window to alert the user; if TTY, then PROMPTFORWORD grabs the TTY immediately. When URGENCY.OPTION = TTY, the cursor is temporarily changed to a different shape to indicate the urgent nature of the request.

**TERMINCHARS.LST**  This is list of “word terminator” character codes; it defaults to `(CHARCODE (EOL ESCAPE LF SPACE TAB))`. This may also be a single character code.

**KEYBD.CHANNEL**  If non-NIL, this is coerced to a stream, and the input bytes are taken from that stream. NIL defaults to the keyboard input stream. Note that this is not the same as the terminal input stream T, which is a buffered keyboard input stream, not suitable for use with PROMPTFORWORD.

**Examples:**

```lisp
(PROMPTFORWORD "What is your FOO word?" 'Mumble
 (FUNCTION (LAMBDA () '(Grumble Bletch)))
PROMPTWINDOW NIL 30)
```

This first prompts the user for input by printing the first argument as a prompt into PROMPTWINDOW; then the proffered default answer, Mumble, is printed out and the caret starts flashing just after it to indicate that the upcoming input will be echoed there. If the user fails to complete a word within 30 seconds, then the result will be the string Mumble.

```lisp
(FRESHLINE T)
(LIST
 (PROMPTFORWORD
   (CONCAT "{" HOST "} Login:")
   (USERNAME NIL NIL T))
 (PROMPTFORWORD
   " (password)" NIL NIL NIL "]*"))
```

This first prompts in whatever window is currently (TTYDISPLAYSTREAM), and then takes in a username; the second call prompts with (password) and takes in another word (the password) without proffering a candidate, echoing the typed-in characters as "]*".

**ASKUSER**

DWIM, the compiler, the editor, and many other system packages all use ASKUSER, an extremely general user interaction package, for their interactions with the user at the terminal. ASKUSER takes as its principal argument KEYLST which is used to drive the interaction. KEYLST specifies what the user can type at any given point, how ASKUSER should respond to the various inputs, what value should be returned by ASKUSER, and is also used to present the user at any given point with a list of the
possible responses. ASKUSER also takes other arguments which permit specifying a wait time, a
default value, a message to be printed on entry, a flag indicating whether or not typeahead is to be
permitted, a flag indicating whether the transaction is to be stored on the history list (see Chapter 13),
a default set of options, and an (optional) input file/string.

(ASKUSER WAIT DEFAULT MESS KEYLST TYPEAHEAD LISPXRNTFLG OPTIONSLST
FILE) [Function]

WAIT is either NIL or a number (of seconds). DEFAULT is a single character or a sequence
(list) of characters to be used as the default inputs for the case when WAIT is not NIL and
more than WAIT seconds elapse without any input. In this case, the character(s) from
DEFAULT are processed exactly as though they had been typed, except that ASKUSER first
types "...".

MESS is the initial message to be printed by ASKUSER, if any, and can be a string, or a list.
In the latter case, each element of the list is printed, separated by spaces, and terminated
with a "?". KEYLST and OPTIONSLST are described. TYPEAHEAD is T if the user is
permitted to typeahead a response to ASKUSER. NIL means any typeahead should be
cleared and saved. LISPXRNTFLG determines whether or not the interaction is to be
recorded on the history list. FILE can be either NIL (in which case it defaults to the
terminal input stream, T) or a stream.

All input operations take place from FILE until an unacceptable input is encountered, i.e.,
one that does not conform to the protocol defined by KEYLST. At that point, FILE is set
to T, DEFAULT is set to NIL, the input buffer is cleared, and a bell is rung. Unacceptable
inputs are not echoed.

The value of ASKUSER is the result of packing all the keys that were matched, unless the
RETURN option is specified (see the Options section below).

(MAKEKEYLST LST DEFAULTKEY LCASEFLG AUTOCOMPLETEFLG) [Function]

LST is a list of atoms or strings. MAKEKEYLST returns an ASKUSER KEYLST which will
permit the user to specify one of the elements on LST by either typing enough characters
to make the choice unambiguous, or else typing a number between 1 and N, where N is
the length of LST.

For example, if ASKUSER is called with KEYLST = (MAKEKEYLST ' (CONNECT
SUPPORT COMPIL)), then the user can type C-O-N, S, C-O-M, 1, 2, or 3 to indicate one
of the three choices.

If LCASEFLG = T, then echoing of upper case elements will be in lower case (but the
value returned will still be one of the elements of LST). If DEFAULTKEY is non-NIL, it will
be the last key on the KEYLST. Otherwise, a key which permits the user to indicate "No
none of the above" choices, in which case the value returned by ASKUSER will be NIL.

AUTOCOMPLETEFLG is used as the value of the AUTOCOMPLETEFLG option of the resulting
key list.
Format of KEYLST

KEYLST is a list of elements of the form (KEY PROMPTSTRING . OPTIONS), where KEY is an atom or a string (equivalent), PROMPTSTRING is an atom or a string, and OPTIONS a list of options in property list format. The options are explained below. If an option is specified in OPTIONS, the value of the option is the next element. Otherwise, if the option is specified in the OPTIONSLIST argument to ASKUSER, its value is the next element on OPTIONSLIST. Thus, OPTIONSLIST can be used to provide default options for an entire KEYLST, rather than having to include the option at each level. If an option does not appear on either OPTIONS or OPTIONSLIST, its value is NIL.

For convenience, an entry on KEYLST of the form (KEY . ATOM/STRING), can be used as an abbreviation for (KEY ATOM/STRING CONFIRMFLG T), and an entry of just the form KEY, i.e., a non-list, as an abbreviation for (KEY NIL CONFIRMFLG T).

As each character is read, it is matched against the currently active keys. A character matches a key if it is the same character as that in the corresponding position in the key, or, if the character is an alphabetic character, if the characters are the same without regard for upper/lower case differences, i.e. "A" matches "a" and vice versa (unless the NOCASEFLG option is T, see the Options section below). In other words, if two characters have already been input and matched, the third character is matched with each active key by comparing it with the third character of that key. If the character matches with one or more of the keys, the entries on KEYLST corresponding to the remaining keys are discarded. If the character does not match with any of the keys, the character is not echoed, and a bell is rung instead.

When a key is complete, PROMPTSTRING is printed (NIL is equivalent to "", the empty string, i.e., nothing will be printed). Then, if the value of the CONFIRMFLG option is T, ASKUSER waits for confirmation of the key by a carriage return or space. Otherwise, the key does not require confirmation.

Then, if the value of the KEYLST option is not NIL, its value becomes the new KEYLST, and the process recurses. Otherwise, the key is a "leaf," i.e., it terminates a particular path through the original, top-level KEYLST, and ASKUSER returns the result of packing all the keys that have been matched and completed along the way (unless the RETURN option is used to specify some other value, as described below).

For example, when ASKUSER is called with KEYLST = NIL, the following KEYLST is used as the default:

\[
((Y \text{"escr"}) (N \text{"ocr"}))
\]

This KEYLST specifies that if (as soon as) the user types Y (or y), ASKUSER echoes with Y, prompts with escr, and returns Y as its value. Similarly, if the user types N, ASKUSER echoes the N, prompts with ocr, and returns N. If the user types ?, ASKUSER prints:

Yes
No
to indicate his possible responses. All other inputs are unacceptable, and ASKUSER will ring the bell and not echo or print anything.

For a more complicated example, the following is the KEYLST used for the compiler questions:

```lisp
((ST "ore and redefine" KEYLST ("" (F . "orget
exprs")
(S . "ame as last time")
(F . "ile only")
(T . "o terminal")
1
2
(Y . "es")
(N . "o"))
```

When ASKUSER is called with this KEYLST, and the user types an S, two keys are matched: ST and S. The user can then type a T, which matches only the ST key, or confirm the S key by typing a CR or space. If the user confirms the S key, ASKUSER prompts with "ame as last time", and returns S as its value. (Note that the confirming character is not included in the value.) If the user types a T, ASKUSER prompts with "ore and redefine", and makes ("" (F . "orget exprs");) be the new KEYLST, and waits for more input. The user can then type an F, or confirm the "" (which essentially starts out with all of its characters matched). If he confirms the "", ASKUSER returns ST as its value the result of packing ST and ". If he types F, ASKUSER prompts with "orget exprs", and waits for confirmation again. If the user then confirms, ASKUSER returns STF, the result of packing ST and F.

At any point the user can type a ? and be prompted with the possible responses. For example, if the user types S and then ?, ASKUSER will type:

```
STore and redefine Forget exprs
STore and redefine
Same as last time
```

### Options

- **KEYLST**
  - When a key is complete, if the value of the KEYLST option is not NIL, this value becomes the new KEYLST and the process recurses. Otherwise, the key terminates a path through the original, top-level KEYLST, and ASKUSER returns the indicated value.

- **CONFIRMFLG**
  - If T, the key must be confirmed with either a carriage return or a space. If the value of CONFIRMFLG is a list, the confirming character may be any member of the list.

- **PROMPTCONFIRMFLG**
  - If T, whenever confirmation is required, the user is prompted with the string [confirm].

- **NOCASEFLG**
  - If T, says do not perform case independent matching on alphabetic characters. If NIL, do perform case independent matching, i.e. "A" matches with "a" and vice versa.
RETURN  If non-NIL, EVAL of the value of the RETURN option is returned as the value of ASKUSER. Note that different RETURN options can be specified for different keys. The variable ANSWER is bound in ASKUSER to the list of keys that have been matched. In other words, RETURN (PACK ANSWER) would be equivalent to what ASKUSER normally does.

NOECHOFLG  If non-NIL, characters that are matched (or automatically supplied as a result of typing $ (escape) or confirming) are not echoed, nor is the confirming character, if any. The value of NOECHOFLG is automatically NIL when ASKUSER is reading from a file or string. The decision about whether or not to echo a character that matches several keys is determined by the value of the NOECHOFLG option for the first key.

EXPLAINSTRING  If the value of the EXPLAINSTRING option is non-NIL, its value is printed when the user types a ?, rather than KEY + PROMPTSTRING. EXPLAINSTRING enables more elaborate explanations in response to a ? than what the user sees when he is prompted as a result of simply completing keys. For example: One of the entries on the KEYLST used by ADDTOFILES is:

\[
(\text{\small NOWHEREcrNOECHOFLG T EXPLAINSTRING "\text{\small ] - nowhere, item is marked as a dummycr"})}
\]

When the user types ], ASKUSER just prints Nowherecr, i.e., the ] is not echoed. If the user types ?, the explanation corresponding to this entry will be:

\[
\text{\small ] - nowhere, item is marked as a dummy}
\]

KEYSTRING  If non-NIL, characters that are matched are echoed as though the value of KEYSTRING were used in place of the key. KEYSTRING is also used for computing the value returned. The main reason for this feature is to enable echoing in lowercase.

PROMPTON  If non-NIL, PROMPTSTRING is printed only when the key is confirmed with a member of the value of PROMPTON.

COMPLETEON  When a confirming character is typed, the N characters that are automatically supplied, as specified in case (4), are echoed only when the key is confirmed with a member of the value of PROMPTON.

The PROMPTON and COMPLETEON options enable the user to construct a KEYLST which will cause ASKUSER to emulate the action of the TENEX exec. The protocol followed by the TENEX exec is that the user can type as many characters as he likes in specifying a command. The command can be completed with a carriage return or space, in which case no further output is forthcoming, or with a $ (escape), in which case the rest of the characters in the command are echoed, followed by some prompting information. The following KEYLST would handle the TENEX COPY and CONNECT commands:

\[
((\text{COPY } " \text{(FILE LIST)} " )
\text{PROMPTON } ($) )
\text{COMPLETEON } ($)
\text{CONFIRMFLG } ($))
\]

\[
(\text{CONNECT } " \text{(TO DIRECTORY)} " )
\]
PROMPTON ($)  
COMPLETEON ($)  
CONFIRMFLG ($))

AUTOCOMPLETEFLG  If the value of the AUTOCOMPLETEFLG option is not NIL, ASKUSER will automatically supply unambiguous characters whenever it can, i.e., ASKUSER acts as though $ (escape) were typed after each character (except that it does not ring the bell if there are no unambiguous characters).

MACROCHARS  value is a list of dotted pairs of form (CHARACTER . FORM). When CHARACTER is typed, and it does not match any of the current keys, FORM is evaluated and nothing else happens, i.e. the matching process stays where it is. For example, ? could have been implemented using this option. Essentially MACROCHARS provides a read macro facility while inside of ASKUSER (since ASKUSER does READC’s, read macros defined via the readtable are never invoked).

EXPLAINDELIMITER  value is what is printed to delimit explanation in response to ?. Initially a carriage return, but can be reset, e.g. to a comma, for more linear output.

Operation

All input operations are executed with the terminal table in the variable ASKUSERTTBL, in which the following is true:

*  (CONTROL T) has been executed (see the Line-Buffering section of Chapter 30), so that ASKUSER can interact with the user after each character is typed

*  (ECHOMODE NIL) has been executed (see the Terminal Control Functions section of Chapter 30), so that ASKUSER can decide after it reads a character whether or not the character should be echoed, and with what, e.g. unacceptable inputs are never echoed.

As each character is typed, it is matched against KEYLST, and appropriate echoing and/or prompting is performed. If the user types an unacceptable character, ASKUSER simply rings the bell and allows him to try again.

At any point, the user can type ? and receive a list of acceptable responses at that point (generated from KEYLST), or type a Control-A, Control-Q, Control-X, or delete, which causes ASKUSER to reinitialize, and start over.

Note that ?, Control-A, Control-Q, and Control-X will not work if they are acceptable inputs, i.e., they match one of the keys on KEYLST. Delete will not work if it is an interrupt character, in which case it is not seen by ASKUSER.

When an acceptable sequence is completed, ASKUSER returns the indicated value.
Completing a Key

The decision about when a key is complete is more complicated than simply whether or not all of its characters have been matched. In the compiler questions example above, all of the characters in the $S$ key are matched as soon as the $S$ has been typed, but until the next character is typed, ASKUSER does not know whether the $S$ completes the $S$ key, or is simply the first character in the $ST$ key. Therefore, a key is considered to be complete when:

1. All of its characters have been matched and it is the only key left, i.e., there are no other keys for which this key is a substring.
2. All of its characters have been matched and a confirming character is typed.
3. All of its characters have been matched, and the value of the CONFIRMFLG option is NIL, and the value of the KEYLST option is not NIL, and the next character matches one of the keys on the value of the KEYLST option.
4. There is only one key left and a confirming character is typed. Note that if the value of CONFIRMFLG is T, the key still has to be confirmed, regardless of whether or not it is complete. For example, if the first entry in the above example were instead

   \[ (ST \ "ore and redefine " CONFIRMFLG T KEYLST (" (F . "orget exprs")) \]

   and the user wanted to specify the STF path, he would have to type ST, then confirm before typing F, even though the ST completed the ST key by the rule in Case 1. However, he would be prompted with ore and redefine as soon as he typed the T, and completed the ST key.

Case 2 says that confirmation can be used to complete a key in the case where it is a substring of another key, even where the value of CONFIRMFLG is NIL. In this case, the confirming character doubles as both an indicator that the key is complete, and also to confirm it, if necessary. This situation corresponds to typing Scr in the above example.

Case 3 says that if there were another entry whose key was STX in the above example, so that after the user typed ST, two keys, ST and STX, were still active, then typing F would complete the ST key, because F matches the (F . "orget exprs") entry on the value of the KEYLST option of the ST entry. In this case, ore and redefine would be printed before the F was echoed.

Finally, Case 4 says that the user can use confirmation to specify completion when only one key is left, even when all of its characters have not been matched. For example, if the first key in the above example were STORE, the user could type ST and then confirm, and ORE would be echoed, followed by whatever prompting was specified. In this case, the confirming character also confirms the key if necessary, so that no further action is required, even when the value of CONFIRMFLG is T.

Case 4 permits the user not to have to type every character in a key when the key is the only one left. Even when there are several active keys, the user can type <escape> to specify the next $N>0$ common characters among the currently active keys. The effect is exactly the same as though these characters
had been typed. If there are no common characters in the active keys at that point, i.e. \( N = 0 \), the $ is treated as an incorrect input, and the bell is rung. For example, if \( \text{KEYLST} \) is \((\text{CLISPFLG} \ \text{CLISPIFYPACKFLG} \ \text{CLISPIFYTRANFLG})\), and the user types C followed by $, \text{ASKUSER} will supply the L, I, S, and P. The user can then type F followed by a carriage return or space to complete and confirm CLISPFLG, as per Case 4, or type I, followed by $, and \text{ASKUSER} will supply the F, etc. Note that the characters supplied do not have to correspond to a terminal segment of any of the keys. Note also that the $ does not confirm the key, although it may complete it in the case that there is only one key active.

If the user types a confirming character when several keys are left, the next \( N>0 \) common characters are still supplied, the same as with $. However, \text{ASKUSER} assumes the intent was to complete a key, i.e., Case 4 is being invoked. Therefore, after supplying the next \( N \) characters, the bell is rung to indicate that the operation was not completed. In other words, typing a confirming character has the same effect as typing an $ in that the next \( N \) common characters are supplied. Then, if there is only one key left, the key is complete (Case 4) and confirmation is not required. If the key is not the only key left, the bell is rung.

**Special Keys**

\& This can be used as a key to match with any single character, provided the character does not match with some other key at that level. For the purposes of echoing and returning a value, the effect is the same as though the character that were matched actually appeared as the key.

\(<\text{escape}>\) This can be used as a key to match with the result of a single call to \text{READ}. For example, if the \( \text{KEYLST} \) were:

\[
((\text{COPY } " (\text{FILE LIST}) "
    \text{PROMPTON } ($)
    \text{COMPLETEON } ($)
    \text{CONFIRMFLG } ($)
    \text{KEYLST } ((\$ \text{NIL \ RETURN \ ANSWER}))))
\]

then if the user typed \( \text{COPY} \ \text{FOOcr} \), \((\text{COPY} \ \text{FOO})\) would be returned as the value of \text{ASKUSER}. One advantage of using $, rather than having the calling program perform the \text{READ}, is that the call to \text{READ} from inside \text{ASKUSER} is \text{ERRORSET} protected, so that the user can back out of this path and reinitialize \text{ASKUSER}, e.g. to change from a \text{COPY} command to a \text{CONNECT} command, simply by typing Control-E.

\text{Escape Escape} This can be used as a key to match with the result of a single call to \text{READLINE}.

\text{A list} A list can be used as a key, in which case the list/form is evaluated and its value "matches" the key. This feature is provided primarily as an escape hatch for including arbitrary input operations as part of an \text{ASKUSER} sequence. For example, the effect of $$ (\text{escape}, \text{escape}) \) could be achieved simply by using \( (\text{READLINE} \ T) \) as a key.
The empty string can be used as a key. Since it has no characters, all of its characters are automatically matched. "" essentially functions as a place marker. For example, one of the entries on the KEYLST used by ADDTOFILES? is:

```
("" "File/list:  "
  EXPLAINSTRING "a file name or name of a function list"

```

KEYLST ($))

Thus, if the user types a character that does not match any of the other keys on the KEYLST, then the character completes the "" key, by virtue of case (4), since the character will match with the $ in the inner KEYLST. ASKUSER then prints File/list: before echoing the character, then calls READ. The character will be read as part of the READ. The value returned by ASKUSER will be the value of the READ.

Note: For Escape, Escape Escape, or a list, if the last character read by the input operation is a separator, the character is treated as a confirming character for the key. However, if the last character is a break character, it will be matched against the next key.

**Startup Protocol and Typeahead**

Interlispermitssandencouragesthusertypeofehead; in actual practice, the user frequently does this. This presents a problem for ASKUSER. When ASKUSER is entered and there has been typeahead, was the input intended for ASKUSER, or was the interaction unanticipated, and the user simply typing ahead some other program, e.g. the programmer's assistant? Even where there was no typeahead, i.e., the user starts typing after the call to ASKUSER, the question remains of whether the user had time to see the message from ASKUSER and react to it, or simply began typing ahead at an inauspicious moment. Thus, what is needed is an interlock mechanism which warns the user to stop typing, gives him a chance to respond to the warning, and then allows him to begin typing to ASKUSER.

Therefore, when ASKUSER is first entered, and the interaction is to take place with a terminal, and typeahead to ASKUSER is not permitted, the following protocol is observed:
1. If there is typeahead, \texttt{ASKUSER} clears and saves the input buffers and rings the bell to warn the user to stop typing. The buffers will be restored when \texttt{ASKUSER} completes operation and returns.

2. If \texttt{MESS}, the message to be printed on entry, is not \texttt{NIL} (the typical case), \texttt{ASKUSER} then prints \texttt{MESS} if it is a string, otherwise \texttt{CAR} of \texttt{MESS}, if \texttt{MESS} is a list.

3. After printing \texttt{MESS} or \texttt{CAR} of \texttt{MESS}, \texttt{ASKUSER} waits until the output has actually been printed on the terminal to make sure that the user has actually had a chance to see the output. This also give the user a chance to react. \texttt{ASKUSER} then checks to see if anything additional has been typed in the intervening period since it first warned the user in (1). If something has been typed, \texttt{ASKUSER} clears it out and again rings the bell. This latter material, i.e., that typed between the entry to \texttt{ASKUSER} and this point, is discarded and will not be restored since it is not certain whether the user simply reacted quickly to the first warning (bell) and this input is intended for \texttt{ASKUSER}, or whether the user was in the process of typing ahead when the call to \texttt{ASKUSER} occurred, and did not stop typing at the first warning, and therefore this input is a continuation of input intended for another program.

Anything typed after (3) is considered to be intended for \texttt{ASKUSER}, i.e., once the user sees \texttt{MESS} or \texttt{CAR} of \texttt{MESS}, he is free to respond. For example, \texttt{UNDO} (see Chapter 13) calls \texttt{ASKUSER} when the number of undosaves are exceeded for an event with \texttt{MESS} = \texttt{(LIST NUMBER-UNDOSAVES "undosaves, continue saving")}. Thus, the user can type a response as soon as \texttt{NUMBER-UNDOSAVES} is typed.

4. \texttt{ASKUSER} then types the rest of \texttt{MESS}, if any.

5. Then \texttt{ASKUSER} goes into a wait loop until something is typed. If \texttt{WAIT}, the wait time, is not \texttt{NIL}, and nothing is typed in \texttt{WAIT} seconds, \texttt{ASKUSER} will type "..." and treat the elements of \texttt{DEFAULT}, the default value, as a list of characters, and begin processing them exactly as though they had been typed. If the user does not type anything within \texttt{WAIT} seconds, he can then wait as long as he likes, i.e., once something has been typed, \texttt{ASKUSER} will not use the default value specified in \texttt{DEFAULT}.

If the user wants to consider his response for more than \texttt{WAIT} seconds, and does not want \texttt{ASKUSER} to default, he can type a carriage return or a space, which are ignored if they are not specified as acceptable inputs by \texttt{KEYLST} (see below) and they are the first thing typed.

If the calling program knows that the user is expecting an interaction with \texttt{ASKUSER}, e.g., another interaction preceded this one, it can specify in the call to \texttt{ASKUSER} that typeahead is permitted. In this case, \texttt{ASKUSER} simply notes whether there is any typeahead, then prints \texttt{MESS} and goes into a wait loop as described above.

If there is typeahead that contains unacceptable input, \texttt{ASKUSER} will assume that the typeahead was not intended for \texttt{ASKUSER}, and will restore the typeahead when it completes operation and returns.

6. Finally, if the interaction is not with the terminal, i.e., the optional input file/string is specified, \texttt{ASKUSER} simply prints \texttt{MESS} and begins reading from the file/string.
TTYIN is an Interlisp function for reading input from the terminal. It features altmode completion, spelling correction, help facility, and fancy editing, and can also serve as a glorified free text input function. This document is divided into two major sections: how to use TTYIN from the user’s point of view, and from the programmer’s.

TTYIN exists in implementations for Interlisp-10 and Interlisp-D. The two are substantially compatible, but the capabilities of the two systems differ (Interlisp-D has a more powerful display and allows greater access to the system primitives needed to control it effectively; it also has a mouse, greatly reducing the need for keyboard-oriented editing commands). Descriptions of both are included in this document for completeness, but Interlisp-D users may find large sections irrelevant.

Entering Input With TTYIN

There are two major ways of using TTYIN: set LISPXREADFN to TTYIN, so the LISPX executive uses it to obtain input; and call TTYIN from within a program to gather text input. Mostly the same rules apply to both; places where it makes a difference are mentioned below.

The following characters may be used to edit your input, independent of what kind of terminal you are on. The more TTYIN knows about your terminal, of course, the nicer some of these will behave. Some functions are performed by one of several characters; any character that you happen to have assigned as an interrupt character will, of course, not be read by TTYIN. There is a (somewhat inelegant) way of changing which characters perform which functions, described under TTYINREADMACROS later on.

Control-A
BACKSPACE
DELETE Deletes a character. At the start of the second or subsequent lines of your input, deletes the last character of the previous line.

Control-W
DEletes a "word". Generally this means back to the last space or parenthesis.

Control-Q
DELETEs the current line, or if the current line is blank, deletes the previous line.

Control-R
REFRESHes the current line. Two in a row refreshes the whole buffer (when doing multi-line input).

ESCAPE
Tries to complete the current word from the spelling list provided to TTYIN, if any. In the case of ambiguity, completes as far as is uniquely determined, or rings the bell. For LISPX input, the spelling list may be USERWORDS (see discussion of TTYINCOMPLETEFLG).

Interlisp-10 only: If no spelling list was provided, but the word begins with a "<", tries directory name completion (or filename completion if there is already a matching ">").
If typed in the middle of a word will supply alternative completions from the SPLST argument to TTYIN (if any). ?ACTIVATEFLG (see the Assorted Flags section below) must be true to enable this feature.

**Control-Y** Escapes to a Lisp user exec, from which you may return by the command OK. However, when in READ mode and the buffer is non-empty, Control-Y is treated as Lisp’s unquote macro instead, so you have to use meta-Control-Y (below) to invoke the user exec.

**LF in Interlisp-10** Retrieves characters from the previous non-empty buffer when it is able to; e.g., when typed at the beginning of the line this command restores the previous line you typed at TTYIN; when typed in the middle of a line fills in the remaining text from the old line; when typed following ↑Q or ↑W restores what those commands erased.

; If typed as the first character of the line means the line is a comment; it is ignored, and TTYIN loops back for more input.

Note: The exact behaviour of this character is determined by the value of TTYINCOMMENTCHAR (see the Assorted Flags section below).

**Control-X** Goes to the end of your input (or end of expression if there is an excess right parenthesis) and returns if parentheses are balanced, beeps if not.

During most kinds of input, TTYIN is in "autofill" mode: if a space is typed near the right margin, a carriage return is simulated to start a new line. In fact, on cursor-addressable displays, lines are always broken, if possible, so that no word straddles the end of the line. The "pseudo-carriage return" ending the line is still read as a space, however; i.e., the program keeps track of whether a line ends in a carriage return or is merely broken at some convenient point. You won’t get carriage returns in your strings unless you explicitly type them.

**Mouse Commands**

The mouse buttons are interpreted as follows during TTYIN input:

- **LEFT** Moves the caret to where the cursor is pointing. As you hold down LEFT, the caret moves around with the cursor; after you let up, any typein will be inserted at the new position.
- **MIDDLE** Like LEFT, but moves only to word boundaries.
- **RIGHT** Deletes text from the caret to the cursor, either forward or backward. While you hold down RIGHT, the text to be deleted is complemented; when you let up, the text actually goes away. If you let up outside the scope of the text, nothing is killed (this is how to “cancel” the command). This is roughly the same as CTRL-RIGHT with no initial selection (below).

If you hold down CTRL and/or SHIFT while pressing the mouse buttons, you instead get secondary selection, move selection or delete selection. You make a selection by bugging LEFT (to select a character) or MIDDLE (to select a word), and optionally extend the selection either left or right using RIGHT. While you are doing this, the caret does not move, but your selected text is highlighted in a manner indicating what is about to happen. When you have made your selection (all mouse buttons up now), lift up on CTRL and/or SHIFT and the action you have selected will occur, which is:
SHIFT  The selected text as typein at the caret. The text is highlighted with a broken underline during selection.

CTRL  Delete the selected text. The text is complemented during selection.

CTRL-SHIFT  Combines the above: delete the selected text and insert it at the caret. This is how you move text about.

You can cancel a selection in progress by pressing LEFT or MIDDLE as if to select, and moving outside the range of the text.

The most recent text deleted by mouse command can be inserted at the caret by typing Middle-blank key (on the Xerox 1132) or the Open key (on the Xerox 1108). This is the same key that retrieves the previous buffer when issued at the end of a line.

Display Editing Commands

On terminals with a meta key: In Interlisp-10, TTYIN reads from the terminal in binary mode, allowing many more editing commands via the meta key, in the style of TVEDIT commands. Note that due to Tenex's unfortunate way of handling typeahead, it is not possible to type ahead edit commands before TTYIN has started (i.e., before its prompt appears), because the meta bit will be thrown away. Also, since Escape has numerous other meanings in Lisp and even in TTYIN (for completion), this is not used as a substitute for the meta key.

In Interlisp-D: Users will probably have little use for most of these commands, as cursor positioning can often be done more conveniently, and certainly more obviously, with the mouse. Nevertheless, some commands, such as the case changing commands, can be useful. The <bottom-blank> key can be used as an meta key if you perform (METASHIFT T) (see Chapter 30). Alternatively, you can use the variable EDITPREFIXCHAR as described in the next paragraph.

On display terminals without a meta key: If you want to type any of these commands, you need to prefix them with the "edit prefix" character. Set the variable EDITPREFIXCHAR to the character code of the desired prefix char. Type the edit prefix twice to give an "meta-escape" command. Some users of the TENEX TVEDIT program like to make escape (33Q) be the edit prefix, but this makes it somewhat awkward to ever use escape completion. EDITPREFIXCHAR is initially NIL.

On hardcopy terminals without a meta key: You probably want to ignore this section, since you won’t be able to see what’s going on when you issue edit commands; there is no attempt made to echo anything reasonable.

In the descriptions below, "current word" means the word the cursor is under, or if under a space, the previous word. Currently parentheses are treated as spaces, which is usually what you want, but can occasionally cause confusion in the word deletion commands. Most commands can be preceded by numbers or escape (means infinity), only the first of which requires the meta key (or the edit prefix). Some commands also accept negative arguments, but some only look at the magnitude of the arg.
Most of these commands are taken from the display editors TVEDIT and/or E, and are confined to work within one line of text unless otherwise noted.

Cursor Movement Commands:

- **Meta-DELETE**
  - Meta-BS
    - Meta-< Back up one (or n) characters.
  - Meta-SPACE
    - Meta-> Moves forward one (or n) characters.
    - Meta-^ Moves up one (or n) lines.
    - Meta-lf Moves down one (or n) lines.
    - Meta-( Moves back one (or n) words.
    - Meta-) Moves ahead one (or n) words.
  - Meta-TAB Moves to end of line; with an argument moves to nth end of line; **Meta-ESC-TAB** goes to end of buffer.
  - Control-Meta-L Moves to start of line (or nth previous, or start of buffer).
    - Meta-{ Go to start and end of buffer, respectively.
    - Meta-} Moves to beginning of the current list, where cursor is currently under an element of that list or its closing paren. (See also the auto-parenthesis-matching feature below under "Flags").
    - Meta-[ Moves to end of current list.
    - Meta-Sx Skips ahead to next (or nth) occurrence of character x, or rings the bell.
    - Meta-Bx Backward search.

Buffer Modification Commands:

- **Meta-Zx** Zaps characters from cursor to next (or nth) occurrence of x. There is no unzap command yet.
- **Meta-A**
  - Meta-R Repeat the last S, B or Z command, regardless of any intervening input (note this differs from TEdit’s A command).
- **Meta-K** Kills the character under the cursor, or n chars starting at the cursor.
- **Meta-CR** When the buffer is empty is the same as LF, i.e. restores buffer’s previous contents. Otherwise is just like a CR (except that it also terminates an insert). Thus, **Meta-CR CR** will repeat the previous input (as will LF CR without the meta key).
**Meta-O** Does "Open line", inserting a crlf after the cursor, i.e., it breaks the line but leaves the cursor where it is.

**Meta-T** Transposes the characters before and after the cursor. When typed at the end of a line, transposes the previous two characters. Refuses to handle funny cases, such as tabs.

**Meta-G** Grabs the contents of the previous line from the cursor position onward. **Meta-nG** grabs the nth previous line.

**Meta-L** Lowercases current word, or n words on line. **Meta-ESC-L** lowercases the rest of the line, or if given at the end of line lowercases the entire line.

**Meta-U** Uppercases analogously.

**Meta-C** Capitalize. If you give it an argument, only the first word is capitalized; the rest are just lowercased.

**Control-Meta-Q** Deletes the current line. **Control-Meta-ESC-Q** deletes from the current cursor position to the end of the buffer. No other arguments are handled.

**Control-Meta-W** Deletes the current word, or the previous word if sitting on a space.

**Meta-J** "Justify" this line. This will break it if it is too long, or move words up from the next line if too short. Will not join to an empty line, or one starting with a tab (both of which are interpreted as paragraph breaks). Any new line breaks it introduces are considered spaces, not carriage returns. **Meta-nJ** justifies n lines.

The linelength is defined as **TTYJUSTLENGTH**, ignoring any prompt characters at the margin. If **TTYJUSTLENGTH** is negative, it is interpreted as relative to the right margin. **TTYJUSTLENGTH** is initially -8 in Interlisp-D, 72 in Interlisp-10.

**Meta-ESC-F** "Finishes" the input, regardless of where the cursor is. Specifically, it goes to the end of the input and enters a **CR**, **control-Z** or "", depending on whether normal, **REPEAT** or **READ** input is happening. Note that a "" won’t necessarily end a **READ**, but it seems likely to in most cases where you would be inclined to use this command, and makes for more predictable behavior.

**Miscellaneous Commands:**

**Meta-P** Interlisp-D: Prettyprint buffer. Clears the buffer and reprints it using prettyprint. If there are not enough right parentheses, it will supply more; if there are too many, any excess remains unprettyprinted at the end of the buffer. May refuse to do anything if there is an unclosed string or other error trying to read the buffer.

**Meta-N** Refresh line. Same as **Control-R**. **Meta-ESC-N** refreshes the whole buffer; **Meta-nN** refreshes n lines. Cursor movement in **TTYIN** depends on **TTYIN** being the only source of output to the screen; if you do a **Control-T**, or a system message appears, or line noise occurs, you may need to refresh the line for best results. In Interlisp-10, if for some reason your terminal falls out of binary mode (e.g. can happen when returning to a Lisp running in a lower fork), **Meta-<anything>** is unreadable, so you’d have to type **Control-R** instead.

**Control-Meta-Y** Gets user exec. Thus, this is like regular **Control-Y**, except when doing a **READ** (when **control-Y** is a read macro and hence does not invoke this function).
USER I/O PACKAGES

Control-Meta-ESC-Y Gets a user exec, but first unreads the contents of the buffer from the cursor onward. Thus if you typed at TTYIN something destined for the Lisp executive, you can do Control-Meta-L-ESC-Control-Y and give it to Lisp.

Meta← Adds the current word to the spelling list USERWORDS. With zero arg, removes word. See TTYINCOMPLETEFLG (see the Assorted Flags section below).

Note to Datamedia, Heath users: In addition to simple cursor movement commands and insert/delete, TTYIN uses the display’s cursor-addressing capability to optimize cursor movements longer than a few characters, e.g. Meta-TAB to go to the end of the line. In order to be able to address the cursor, TTYIN has to know where it is to begin with. Lisp keeps track of the current print position within the line, but does not keep track of the line on the screen (in fact, it knows precious little about displays, much like Tenex). Thus, TTYIN establishes where it is by forcing the cursor to appear on the last line of the screen. Ordinarily this is the case anyway (except possibly on startup), but if the cursor happens to be only halfway down the screen at the time, there is a possibly unsettling leap of the cursor when TTYIN starts.

Using TTYIN for Lisp Input

When TTYIN is loaded, or a sysout containing TTYIN is started up, the function SETREADFN is called. If the terminal is a display, it sets LISPXREADFN (see Chapter 13) to be TTYINREAD. If the terminal is not a display terminal, SETREADFN will set the variable to READ. (SETREADFN ’READ) will also set it to READ.

There are two principal differences between TTYINREAD and READ: (1) parenthesis balancing. The input does not activate on an exactly balancing right paren/bracket unless the input started with a paren/bracket, e.g., USE (FOO) FOR (FIE) will all be on one line, terminated by CR; and (2) read macros.

In Interlisp-10, TTYIN does not use a read table (TTYIN behaves as though using the default initial Lisp terminal input readtable), so read macros and redefinition of syntax characters are not supported; however, " ’ ” (QUOTE) and “Control-Y” (EVAL) are built in, and a simple implementation of ? and ?= is supplied. Also, the TTYINREADMACROS facility described below can supply some of the functionality of immediate read macros in the editor.

In Interlisp-D, read macros are (mostly) supported. Immediate read macros take effect only if typed at the end of the input (it’s not clear what their semantics should be elsewhere).

Useful Macros

There are two useful edit macros that allow you to use TTYIN as a character editor: (1) ED loads the current expression into the ttyin buffer to be edited (this is good for editing comments and strings). Input is terminated in the usual way (by typing a balancing right programmer’s assistant command FIX will load the buffer with the event’s input, rather than calling the editor. If you really wanted the
Interlisp editor for your fix, you can say FIX EVENT - TTY: once you got TTYIN's version to force you into the editor.

Programming With TTYIN

TTYIN PROMPT SPLST HELP OPTIONS ECHOTOFILE TABS UNREADBUF RDTBL)

[Function]

TTYIN prints PROMPT, then waits for input. The value returned in the normal case is a list of all atoms on the line, with comma and parens returned as individual atoms; OPTIONS may be used to get a different kind of value back.

PROMPT is an atom or string (anything else is converted to a string). If NIL, the value of DEFAULTPROMPT, initially "**", will be used. If PROMPT is T, no prompt will be given. PROMPT may also be a dotted pair (PROMPT1 . PROMPT2), giving the prompt for the first and subsequent (or overflow) lines, each prompt being a string/atom or NIL to denote absence of prompt. The default prompt for overflow lines is ". . .". Note that rebinding DEFAULTPROMPT gives a convenient way to affect all the "ordinary" prompts in some program module.

SPLST is a spelling list, i.e., a list of atoms or dotted pairs (SYNONYM . ROOT). If supplied, it is used to check and correct user responses, and to provide completion if the user types escape. If SPLST is one of the Lisp system spelling lists (e.g., USERWORDS or SPELLINGS3), words that are escape-completed get moved to the front, just as if a FIXSPELL had found them. Autocompletion is also performed when user types a break character (cr, space, paren, etc), unless one of the "nofixspell" options below is selected; i.e., if the word just typed would uniquely complete by escape, TTYIN behaves as though escape had been typed.

HELP, if non-NIL, determines what happens when the user types ? or HELP. If HELP = T, program prints back SPLST in suitable form. If HELP is any other litatom, or a string containing no spaces, it performs (DISPLAYHELP HELP). Anything else is printed as is. If HELP is NIL, ? and HELP are treated as any other atoms the user types. [DISPLAYHELP is a user-supplied function, initially a noop; systems with a suitable HASH package, for example, have defined it to display a piece of text from a hashfile associated with the key HELP.]

OPTIONS is an atom or list of atoms chosen from among the following:

NOFIXSPELL Uses SPLST for HELP and Escape completion, but does not attempt any FIXSPELLing. Mainly useful if SPLST is incomplete and the caller wants to handle corrections in a more flexible way than a straight FIXSPELL.

MUSTAPPROVE Does spelling correction, but requires confirmation.

CRCOMPLETE Requires confirmation on spelling correction, but also does autocompletion on <cr> (i.e. if what user has typed so far uniquely identifies a member of SPLST, completes it). This allows you to have the benefits of autocompletion and still allow new words to be typed.
USER I/O PACKAGES

DIRECTORY  (only if SPLST = NIL) Interprets Escape to mean directory name completion [Interlisp-10 only].

USER    Like DIRECTORY, but does username completion. This is identical to DIRECTORY under Tenex [Interlisp-10 only].

FILE    (only if SPLST = NIL) Interprets Escape to mean filename completion [Sumex and Tops20 only].

FIX If response is not on, or does not correct to, SPLST, interacts with user until an acceptable response is entered. A blank line (returning NIL) is always accepted. Note that if you are willing to accept responses that are not on SPLST, you probably should specify one of the options NOFIXSPELL, MUSTAPPROVE or CRCOMPLETE, lest the user's new response get FIXSPELLed away without their approval.

STRING Line is read as a string, rather than list of atoms. Good for free text.

NORAISE Does not convert lower case letters to upper case.

NOVALUE For use principally with the ECHOTOFILE arg (below). Does not compute a value, but returns T if user typed anything, NIL if just a blank line.

REPEAT For multi-line input. Repeatedly prompts until user types Control-Z (as in Tenex sndmsg). Returns one long list; with STRING option returns a single string of everything typed, with carriage returns (EOL) included in the string.

TEXT Implies REPEAT, NORAISE, and NOVALUE. Additionally, input may be terminated with Control-V, in which case the global flag CTRLVFLG will be set true (it is set to NIL on any other termination). This flag may be utilized in any way the caller desires.

COMMAND Only the first word on the line is treated as belonging to SPLST, the remainder of the line being arbitrary text; i.e., "command format". If other options are supplied, COMMAND still applies to the first word typed. Basically, it always returns (CMD . REST-OF-INPUT), where REST-OF-INPUT is whatever the other options dictate for the remainder. E.g. COMMAND NOVALUE returns (CMD) or (CMD . T), depending on whether there was further input; COMMAND STRING returns (CMD . "REST-OF-INPUT"). When used with REPEAT, COMMAND is only in effect for the first line typed; furthermore, if the first line consists solely of a command, the REPEAT is ignored, i.e., the entire input is taken to be just the command.

READ Paren, brackets, and quotes are treated a la READ, rather than being returned as individual atoms. Control characters may be input via the Control-Vx notation. Input is terminated roughly along the lines of READ conventions: a balancing or over-balancing right paren/bracket will activate the input, or <cr> when no parenthesis remains unbalanced. READ overrides all other options (except NORAISE).
**INTERLISP-D REFERENCE MANUAL**

**LISPXREAD** Like READ, but implies that TTYIN should behave even more like READ, i.e., do NORAISE, not be errorset-protected, etc.

**NOPROMPT** Interlisp-D only: The prompt argument is treated as usual, except that TTYIN assumes that the prompt for the first line has already been printed by the caller; the prompt for the first line is thus used only when redisplaying the line.

**ECHOTOFILE** if specified, user's input is copied to this file, i.e., TTYIN can be used as a simple text-to-file routine if NOVALUE is used. If ECHOTOFILE is a list, copies to all files in the list. PROMPT is not included on the file.

**TABS** is a special addition for tabular input. It is a list of tabstops (numbers). When user types a tab, TTYIN automatically spaces over to the next tabstop (thus the first tabstop is actually the second "column" of input). Also treats specially the characters * and "; they echo normally, and then automatically tab over.

**UNREADBUF** allows the caller to "preload" the TTYIN buffer with a line of input. UNREADBUF is a list, the elements of which are unread into the buffer (i.e., "the outer parentheses are stripped off") to be edited further as desired; a simple carriage return (or Control-Z for REPEAT input) will thus cause the buffer's contents to be returned unchanged. If doing READ input, the "PRIN2 names" of the input list are used, i.e., quotes and %'s will appear as needed; otherwise the buffer will look as though UNREADBUF had been PRIN1'ed. UNREADBUF is treated somewhat like READBUF, so that if it contains a pseudo-carriage return (the value of HISTSTR0), the input line terminates there.

Input can also be unread from a file, using the HISTSTR1 format: UNREADBUF = (&lt;value of HISTSTR1&gt; (FILE START . END)), where START and END are file byte pointers. This makes TTYIN a miniature text file editor.

**RDTBL** [Interlisp-D only] is the read table to use for READing the input when one of the READ options is given. A lot of character interpretations are hardwired into TTYIN, so currently the only effect this has is in the actual READ, and in deciding whether a character typed at the end of the input is an immediate read macro, for purposes of termination.

If the global variable TYPEAHEADFLG is T, or option LISPXREAD is given, TTYIN permits type-ahead; otherwise it clears the buffer before prompting the user.

**Using TTYIN as a General Editor**

The following may be useful as a way of outsiders to call TTYIN as an editor. These functions are currently only in Interlisp-D.
USER I/O PACKAGES

TTYINEDIT EXPRS WINDOW PRINTFN PROMPT) [Function]

This is the body of the edit macro EE. Switches the tty to WINDOW, clears it, prettyprints EXPRS, a list of expressions, into it, and leaves you in TTYIN to edit it as Lisp input. Returns a new list of expressions.

If PRINTFN is non-NIL, it is a function of two arguments, EXPRS and FILE, which is called instead of PRETTYPRINT to print the expressions to the window (actually to a scratch file). Note that EXPRS is a list, so normally the outer parentheses should not be printed. PRINTFN = T is shorthand for "unpretty"; use PRIN2 instead of PRETTYPRINT.

PROMPT determines what prompt is printed, if any. If T, no prompt is printed. If NIL, it defaults to the value of TTYINEDITPROMPT.

TTYINAUTOCLOSEFLG [Variable]

If TTYINAUTOCLOSEFLG is true, TTYINEDIT closes the window on exit.

TTYINEDITWINDOW [Variable]

If the WINDOW arg to TTYINEDIT is NIL, it uses the value of TTYINEDITWINDOW, creating it if it does not yet exist.

TTYINPRINTFN [Variable]

The default value for PRINTFN in EE’s call to TTYINEDIT.

(SET.TTYINEDIT.WINDOW WINDOW) [Function]

Called under a RESETLST. Switches the tty to WINDOW (defaulted as in TTYINEDIT) and clears it. The window’s position is left so that TTYIN will be happy with it if you now call TTYIN yourself. Specifically, this means positioning an integral number of lines from the bottom of the window, the way the top-level tty window normally is.

(TTYIN.SCRATCHFILE) [Function]

Returns, possibly creating, the scratchfile that TTYIN uses for prettyprinting its input. The file pointer is set to zero. Since TTYIN does use this file, beware of multiple simultaneous use of the file.

?= Handler

In Interlisp, the ?= read macro displays the arguments to the function currently "in progress" in the typein. Since TTYIN wants you to be able to continue editing the buffer after a ?=, it processes this macro specially on its own, printing the arguments below your typein and then putting the cursor back where it was when ?= was typed. For users who want special treatment of ?=, the following hook exists:
TTYIN?=FN

[Variable]

The value of this variable, if non-NIL, is a user function of one argument that is called when ?= is typed. The argument is the function that ?= thinks it is inside of. The user function should return one of the following:

- NIL: Normal ?= processing is performed.
- T: Nothing is done. Presumably the user function has done something privately, perhaps diddled some other window, or called TTYIN.PRINTARGS (below).

- a list (ARGS . STUFF): Treats STUFF as the argument list of the function in question, and performs the normal ?= processing using it.

- anything else: The value is printed in lieu of what ?= normally prints.

At the time that ?= is typed, nothing has been "read" yet, so you don’t have the normal context you might expect inside a conventional readmacro. If the user function wants to examine the typed-in arguments being passed to the fn, however, it can call the function TTYIN.READ?=ARGS:

TTYIN.READ?=ARGS

[Function]

When called inside TTYIN?=FN user function, returns everything between the function and the typing of ?= as a list (like an arglist). Returns NIL if ?= was typed immediately after the function name.

TTYIN.PRINTARGS FN ARGS ACTUALS ARGTYPE

[Function]

Does the function/argument printing for ?=. ARGS is an argument list, ACTUALS is a list of actual parameters (from the typein) to match up with args. ARGTYPE is a value of the function ARGTYPE; it defaults to (ARGTYPE FN).

Read Macros

When doing READ input in Interlisp-10, no Lisp-style read macros are available (but the ’ and control-Y macros are built in). Principally because of the usefulness of the editor read macros (set by SETTERMCHARS), and the desire for a way of changing the meanings of the display editing commands, the following exists as a hack:

TTYINREADMACROS

[Variable]

Value is a set of shorthand inputs useable during READ input. It is an alist of entries (CHARCODE . SYNONYM). If the user types the indicated character (the meta bit is denoted by the 200Q bit in the char code), TTYIN behaves as though the synonym character had been typed.

Special cases: 0 - the character is ignored; 200Q - pure meta bit; means to read another char and turn on its meta bit; 400Q - macro quote: read another char and use its original meaning. For example, if you have macros ((33Q . 200Q) (30Q . 33Q)), then Escape (33Q) will behave as an edit prefix, and control-X (30Q) will behave like Escape.
Note: currently, synonyms for meta commands are not well-supported, working only when the command is typed with no argument.

Slightly more powerful macros also can be supplied; they are recognized when a character is typed on an empty line, i.e., as the first thing after the prompt. In this case, the 
TTYINREADMACROS entry is of the form (CHARCODE T . RESPONSE) or (CHARCODE
CONDITION . RESPONSE), where CONDITION is a list that evaluates true. If RESPONSE
is a list, it is EVALed; otherwise it is left unevaluated. The result of this evaluation (or
RESPONSE itself) is treated as follows:

NIL The macro is ignored and the character reads normally, i.e., as though
TTYINREADMACROS had never existed.

An integer A character code, treated as above. Special case: -1 is treated like 0, but says
that the display may have been altered in the evaluation of the macro, so
TTYIN should reset itself appropriately.

Anything else This TTYIN input is terminated (with a crlf) and returns the value of
"response" (turned into a list if necessary). This is the principal use of this
facility. The macro character thus stands for the (possibly computed) reponse,
terminated if necessary with a crlf. The original character is not echoed.

Interrupt characters, of course, cannot be read macros, as TTYIN never sees them, but any
other characters, even non-control chars, are allowed. The ability to return NIL allows
you to have conditional macros that only apply in specified situations (e.g., the macro
might check the prompt (LISPXID) or other contextual variables). To use this specifically
to do immediate editor read macros, do the following for each edit command and
character you want to invoke it with:

(ADDTOVAR TTYINREADMACROS (CHARCODE 'CHARMACRO? EDITCOM))

For example, (ADDTOVAR TTYINREADMACROS (12Q CHARMACRO? !NX)) will make
linefeed do the !NX command. Note that this will only activate linefeed at the beginning
of a line, not anywhere in the line. There will probably be a user function to do this in the
next release.

Note that putting (12Q T . !NX) on TTYINREADMACROS would also have the effect of
returning !NX from the READ call so that the editor would do an !NX. However, TTYIN
would also return !NX outside the editor (probably resulting in a u.b.a. error, or
convincing DWIM to enter the editor), and also the clearing of the output buffer (performed
by CHARMACRO?) would not happen.

Assorted Flags

These flags control aspects of TTYIN's behavior. Some have already been mentioned. In Interlisp-D,
the flags are all initially set to T.
INTERLISP-D REFERENCE MANUAL

TYPEAHEADFLG [Variable]

If true, TTYIN always permits typeahead; otherwise it clears the buffer for any but LISPXREAD input.

?ACTIVATEFLG [Variable]

If true, enables the feature whereby ? lists alternative completions from the current spelling list.

SHOWPARENFLG [Variable]

If true, then whenever you are typing Lisp input and type a right parenthesis/bracket, TTYIN will briefly move the cursor to the matching parenthesis/bracket, assuming it is still on the screen. The cursor stays there for about 1 second, or until you type another character (i.e., if you type fast you’ll never notice it). This feature was inspired by a similar EMACS feature, and turned out to be pretty easy to implement.

TTYINBSFLG [Variable]

Causes TTYIN to always physically backspace, even if you’re running on a non-display (not a DM or Heath), rather than print \deletedtext\ (this assumes your hardcopy terminal or glass tty is capable of backspacing). If TTYINBSFLG is LF, then in addition to backspacing, TTYIN x’s out the deleted characters as it backs up, and when you stop deleting, it outputs a linefeed to drop to a new, clean line before resuming. To save paper, this linefeed operation is not done when only a single character is deleted, on the grounds that you can probably figure out what you typed anyway.

TTYINRESPONSES [Variable]

An association list of special responses that will be handled by routines designated by the programmer. See "Special Responses", below.

TTYINERRORSETFLG [Variable]

[Interlisp-D only] If true, non-LISPXREAD inputs are errorset-protected (Control-E traps back to the prompt), otherwise errors propagate upwards. Initially NIL.

TTYINCOMMENTCHAR [Variable]

This variable affects the treatment of lines beginning with the comment character (usually ";"). If TTYINCOMMENTCHAR is a character code, and the first character on a line of typein is equal to TTYINCOMMENTCHAR, then the line is erased from the screen and no input function will see it. If TTYINCOMMENTCHAR is NIL, this feature is disabled. TTYINCOMMENTCHAR is initially NIL.

TTYINCOMPLETEFLG [Variable]

If true, enables Escape completion from USERWORDS during READ inputs. Details below.
USER I/O PACKAGES

USERWORDS (see Chapter 20) contains words you mentioned recently: functions you have defined or edited, variables you have set or evaluated at the executive level, etc. This happens to be a very convenient list for context-free escape completion; if you have recently edited a function, chances are good you may want to edit it again (typing "EF xx$") or type a call to it. If there is no completion for the current word from USERWORDS, the escape echoes as "$", i.e. nothing special happens; if there is more than one possible completion, you get beeped. If typed when not inside a word, Escape completes to the value of LASTWORD, i.e., the last thing you typed that the p.a. "noticed" (setting TTYINCORECOMPLETEFLG to 0 disables this latter feature), except that Escape at the beginning of the line is left alone (it is a p.a. command).

If you really wanted to enter an escape, you can, of course, just quote it with a control-V, like you can other control chars.

You may explicitly add words to USERWORDS yourself that wouldn’t get there otherwise. To make this convenient online the edit command [←] means "add the current atom to USERWORDS" (you might think of the command as "pointing out this atom"). For example, you might be entering a function definition and want to "point to" one or more of its arguments or prog variables. Giving an argument of zero to this command will instead remove the indicated atom from USERWORDS.

Note that this feature loses some of its value if the spelling list is too long, for then the completion takes too long computationally and, more important, there are too many alternative completions for you to get by with typing a few characters followed by escape. Lisp’s maintenance of the spelling list USERWORDS keeps the "temporary" section (which is where everything goes initially unless you say otherwise) limited to #USERWORDS atoms, initially 100. Words fall off the end if they haven’t been used (they are "used" if FIXSPELL corrects to one, or you use <escape> to complete one).

Special Responses

There is a facility for handling "special responses" during any non-READ TTYIN input. This action is independent of the particular call to TTYIN, and exists to allow you to effectively "advise" TTYIN to intercept certain commands. After the command is processed, control returns to the original TTYIN call. The facility is implemented via the list TTYINRESPONSES.

TTYINRESPONSES

TTYINRESPONSES is a list of elements, each of the form:

(COMMANDS RESPONSE-FORM OPTION)

COMMANDS is a single atom or list of commands to be recognized; RESPONSE-FORM is EVALed (if a list), or APPLYed (if an atom) to the command and the rest of the line. Within this form one can reference the free variables COMMAND (the command the user typed) and LINE (the rest of the line). If OPTION is the atom LINE, this means to pass the rest of line as a list; if it is STRING, this means to pass it as a string; otherwise, the command is only valid if there is nothing else on the line. If RESPONSE-FORM returns the atom IGNORE, it is not treated as a special response (i.e. the input is returned normally as the result of TTYIN).
Suggested use: global commands or options can be added to the toplevel value of TTYINRESPONSES. For more specialized commands, rebind TTYINRESPONSES to (APPEND NEWENTRIES TTYINRESPONSES) inside any module where you want to do this sort of special processing.

Special responses are not checked for during READ-style input.

**Display Types**

[This is not relevant in Interlisp-D]

TTYIN determines the type of display by calling DISPLAYTERMP, which is initially defined to test the value of the GTTYP jsys. It returns either NIL (for printing terminals) or a small number giving TTYIN's internal code for the terminal type. The types TTYIN currently knows about:

- 0 = glass tty (capable of deleting chars by backspacing, but little else)
- 1 = Datamedia
- 2 = Heath

Only the Datamedia has full editing power. DISPLAYTERMP has built into it the correct terminal types for Sumex and Stanford campus 20's: Datamedia = 11 on tenex, 5 on tops20; Heath = 18 on Tenex, 25 on tops20. You can override those values by setting the variable DISPLAYTYPES to be an association list associating the GTTYP value with one of these internal codes. For example, Sumex displays correspond to DISPLAYTYPES = ((11 . 1) (18 . 2)) [although this is actually compiled into DISPLAYTERMP for speed]. Any display terminal other than Datamedia and Heath can probably safely be assigned to '0' for glass tty.

To add new terminal types, you have to choose a number for it, add new code to TTYIN for it and recompile. The TTYIN code specifies what the capabilities of the terminal are, and how to do the primitive operations: up, down, left, right, address cursor, erase screen, erase to end of line, insert character, etc.

For terminals lacking a meta key (currently only Datamedias have it), set the variable EDITPREFIXCHAR to the ascii code of an edit "prefix" (i.e., anything typed preceded by the prefix is considered to have the meta bit on). If your EDITPREFIXCHAR is 33Q (Escape), you can type a real Escape by typing 3 of them (2 won’t do, since that means "Meta-Escape", a legitimate argument to another command). You could also define an Escape synonym with TTYINREADMACROS if you wanted (but currently it doesn’t work in filename completion). Setting EDITPREFIXCHAR for a terminal that is not equipped to handle the full range of editing functions (only the Heath and Datamedia are currently so equipped) is not guaranteed to work, i.e. the display will not always be up to date; but if you can keep track of what you’re doing, together with an occasional control-R to help out, go right ahead.
Prettyprint

The standard way of printing out function definitions (on the terminal or into files) is to use PRETTYPRINT.

\[(\text{PRETTYPRINT } FNS \text{ PRETTYDEFLG } \to)\]  

\[\text{FNS is a list of functions. If FNS is atomic, its value is used}.\] The definitions of the functions are printed in a pretty format on the primary output file using the primary readtable. For example, if FACTORIAL were defined by typing

\[
(\text{DEFINEQ} \ (\text{FACTORIAL} \ (\text{LAMBDA} \ (N) \ (\text{COND} \ ((\text{ZEROP} \ N) \ 1) \ (\text{T} \ (\text{ITIMES} \ N \ (\text{FACTORIAL} \ (\text{SUB1} \ N)) \text{PP} \ (\text{FACTORIAL})) \text{would print out}) \text{FACTIORAL} \ (\text{LAMBDA} \ (N) \ (\text{COND} \ ((\text{ZEROP} \ N) \ 1) \ (\text{T} \ (\text{ITIMES} \ N \ (\text{FACTORIAL} \ (\text{SUB1} \ N))}))\]

PRETTYDEFLG is T when called from PRETTYDEF (and hence MAKEFILE). Among other actions taken when this argument is true, PRETTYPRINT indicates its progress in writing the current output file: whenever it starts a new function, it prints on the terminal the name of that function if more than 30 seconds (real time) have elapsed since the last time it printed the name of a function.

PRETTYPRINT operates correctly on functions that are BROKEN, BROKEN-IN, ADVISED, or have been compiled with their definitions saved on their property lists: it prints the original, pristine definition, but does not change the current state of the function. If a function is not defined but is known to be on one of the files noticed by the file package, PRETTYPRINT loads in the definition (using LOADFNS) and prints it (except when called from PRETTYDEF). If PRETTYPRINT is given an atom which is not the name of a function, but has a value, it prettyprints the value. Otherwise, PRETTYPRINT attempts spelling correction. If all fails, PRETTYPRINT returns (FN NOT PRINTABLE). Note that PRETTYPRINT will return (FN NOT PRINTABLE) if FN does not have an accessible expr definition, or if it doesn’t have any definition at all.

\[(\text{PP } FN_1 \ \ldots \ FN_N)\]  

[ NLambda NoSpread Function ]

For prettyprinting functions to the terminal. \(\text{PP}\) calls \(\text{PRETTYPRINT}\) with the primary output file set to T and the primary read table set to T. The primary output file and primary readtable are restored after printing.

\((\text{PP} \ FOO)\) is equivalent to \((\text{PRETTYPRINT} \ '(\text{FOO}))\); \((\text{PP} \ FOO \ PIE)\) is equivalent to \((\text{PRETTYPRINT} \ '(\text{FOO \ PIE}))\).
As described above, when PRETTYPRINT, and hence PP, is called with the name of a function that is not defined, but whose definition is on a file known to the file package, the definition is automatically read in and then prettyprinted. However, if the user does not intend on editing or running the definition, but simply wants to see the definition, the function PF described below can be used to simply copy the corresponding characters from the file to the terminal. This results in a savings in both space and time, since it is not necessary to allocate storage to actually read in the definition, and it is not necessary to re-prettyprint it (since the function is already in prettyprint format on the file).

(PF FN FROMFILES TOFILE)  
[ NLambda NoSpread Function ]

Copies the definition of FN found on each of the files in FROMFILES to TOFILE. If TOFILE = NIL, defaults to T. If FROMFILES = NIL, defaults to (WHEREIS FN NIL T) (see Chapter 17). The typical usage of PF is simply to type "PF FN".

PF prints a message if it can’t find a file on FROMFILES, or it can’t find the function FN on a file.

When printing to the terminal, PF performs several transformations on the characters in the file that comprise the definition for FN:

1. Font information is stripped out (except in Interlisp-D, whose display supports multiple fonts)
2. Occurrences of the CHANGECHAR (see the Special Prettyprint Controls section below) are not printed
3. Since functions typically tend to be printed to a file with a larger linelength than when printing to a terminal, the number of leading spaces on each line is cut in half (unless PFDEFAULT is T; initially NIL)
4. Comments are elided, if **COMMENT**FLG is non-NIL (see the Comment Feature section below).

(SEE FROMFILE TOFILE)  
[ NLambda NoSpread Function ]

Copies all of the text from FROMFILE to TOFILE (defaults to T), processing all text as PF does. Used to display the contents of files on the terminal.

(PP* X)  
[ NLambda NoSpread Function ]

(PP* FN FROMFILES TOFILE)  
[ NLambda NoSpread Function ]

(SEE* FROMFILE TOFILE)  
[ NLambda NoSpread Function ]

These functions operate exactly like PP, PF, and SEE, except that they bind **COMMENT**FLG to NIL, so comments are printed in full.

While the function PRETTYPRINT prints entire function definitions, the function PRINTDEF can be used to print parts of functions, or arbitrary Interlisp structures:
(PRINTDEF EXPR LEFT DEF TAILFLG FNSLST FILE)

[Function]

Prints the expression \textit{EXPR} in a pretty format on \textit{FILE} using the primary readtable. \textit{LEFT} is the left hand margin (LINELENGTH determines the right hand margin). PRINTDEF initially performs (TAB LEFT T), which means to space to position \textit{LEFT}, unless already beyond this position, in which case it does nothing.

\textit{DEF} = T means \textit{EXPR} is a function definition, or a piece of one. If \textit{DEF} = NIL, no special action is taken for LAMBDA's, PROG's, COND's, comments, CLISP, etc. \textit{DEF} is NIL when PRETTYDEF calls PRETTYPRINT to print variables and property lists, and when PRINTDEF is called from the editor via the command PPV.

\textit{TAILFLG} = T means \textit{EXPR} is interpreted as a tail of a list, to be printed without parentheses.

\textit{FNSLST} is for use for printing with multiple fonts (see Chapter 27). PRINTDEF prints occurrences of any function in the list \textit{FNSLST} in a different font, for emphasis. MAKEFILE passes as \textit{FNSLST} the list of all functions on the file being made.

\textbf{Comment Feature}

A facility for annotating Interlisp functions is provided in PRETTYPRINT. Any expression beginning with the atom * is interpreted as a comment and printed in the right margin. Example:

\begin{verbatim}
(FACTORIAL
  [LAMBDA (N) (* COMPUTES N!)]
(COND
  ((ZEROP N) (* 0! = 1) 1)
  (T (* RECURSIVE DEFINITION:
      N! = N*N-1!)
    (ITIMES N (FACTORIAL (SUB1 N)))
)

These comments actually form a part of the function definition. Accordingly, * is defined as an nlambda nospread function that returns its argument, similar to \textit{QUOTE}. When running an interpreted function, * is entered the same as any other Interlisp function. Therefore, comments should only be placed where they will not harm the computation, i.e., where a quoted expression could be placed. For example, writing

\begin{verbatim}
(ITIMES N (FACTORIAL (SUB1 N)) (* RECURSIVE DEFINITION))
\end{verbatim}

in the above function would cause an error when ITIMES attempted to multiply \textit{N}, N-1!, and RECURSIVE.

For compilation purposes, * is defined as a macro which compiles into no instructions (unless the comment has been placed where it has been used for value, in which case the compiler prints an appropriate error message and compiles * as \textit{QUOTE}). Thus, the compiled form of a function with
comments does not use the extra atom and list structure storage required by the comments in the source (interpreted) code. This is the way the comment feature is intended to be used.

A comment of the form \((\ast \text{ E } X)\) causes \(X\) to be evaluated at prettyprint time, as well as printed as a comment in the usual way. For example, \((\ast \text{ E (RADIX 8)})\) as a comment in a function containing octal numbers can be used to change the radix to produce more readable printout.

The comment character \(\ast\) is stored in the variable \texttt{COMMENTFLG}. The user can set it to some other value, e.g. \(\text{";"}\), and use this to indicate comments.

\texttt{COMMENTFLG} \hfill [Variable]

If \texttt{CAR} of an expression is \texttt{EQ} to \texttt{COMMENTFLG}, the expression is treated as a comment by \texttt{PRETTYPRINT}. \texttt{COMMENTFLG} is initialized to \(\ast\). Note that whatever atom is chosen for \texttt{COMMENTFLG} should also have an appropriate function definition and compiler macro, for example, by copying those of \(\ast\).

Comments are designed mainly for documenting listings. Therefore, when prettyprinting to the terminal, comments are suppressed and printed as the string \texttt{**COMMENT**}. The value of \texttt{**COMMENT**FLG} determines the action.

\texttt{**COMMENT**FLG} \hfill [Variable]

If \texttt{**COMMENT**FLG} is \texttt{NIL}, comments are printed. Otherwise, the value of \texttt{**COMMENT**FLG} is printed. Initially \texttt{"**COMMENT**"}.

\texttt{(COMMENT1 L \(-\))} \hfill [Function]

Prints the comment \(L\). \texttt{COMMENT1} is a separate function to permit the user to write prettyprint macros that use the regular comment printer. For example, to cause comments to be printed at a larger than normal linelength, one could put an entry for \(\ast\) on \texttt{PRETTYPRINTMACROS}:

\[
\begin{align*}
\ast \text{ LAMBDA (X) (RESETFORM (LINELENGTH 100)} \\
\text{(COMMENT1 X))}
\end{align*}
\]

This macro resets the line length, prints the comment, and then restores the line length.

\texttt{COMMENT1} expects to be called from within the environment established by \texttt{PRINTDEF}, so ordinarily the user should call it only from within prettyprint macros.

**Comment Pointers**

For a well-commented collection of programs, the list structure, atom, and print name storage required to represent the comments in core can be significant. If the comments already appear on a file and are not needed for editing, a significant savings in storage can be achieved by simply leaving the text of the comment on the file when the file is loaded, and instead retaining in core only a pointer to the comment. When this feature is enabled, \(\ast\) is defined as a read macro (see Chapter 25) in
FILERDTBL which, instead of reading in the entire text of the comment, constructs an expression containing

- The name of the file in which the text of the comment is contained
- The address of the first character of the comment
- The number of characters in the comment
- A flag indicating whether the comment appeared at the right hand margin or centered on the page

For output purposes, * is defined on PRETTYPRINTMACROS (see the Prettyprint Control Functions section below) so that it prints the comments represented by such pointers by simply copying the corresponding characters from one file to another, or to the terminal. Normal comments are processed the same as before, and can be intermixed freely with comment pointers.

The comment pointer feature is controlled by the function NORMALCOMMENTS.

\( \text{(NORMALCOMMENTS FLG)} \) \[\text{Function}\]

If FLG is NIL, the comment pointer feature is enabled. If FLG is T, the comment pointer feature is disabled (the default).

NORMALCOMMENTS can be changed as often as desired. Thus, some files can be loaded normally, and others with their comments converted to comment pointers.

For convenience of editing selected comments, an edit macro, GET*, is included, which loads in the text of the corresponding comment. The editor’s PP* command, in contrast, prints the comment without reading it by simply copying the corresponding characters to the terminal. GET* is defined in terms of GETCOMMENT:

\( \text{(GETCOMMENT X DESTFL --)} \) \[\text{Function}\]

If X is a comment pointer, replaces X with the actual text of the comment, which it reads from its file. Returns X in all cases. If DESTFL is non-NIL, it is the name of an open file, to which GETCOMMENT copies the comment; in this case, X remains a comment pointer, but it has been changed to point to the new file (unless NORMALCOMMENTS has been set to DONTUPDATE).

\( \text{(PRINTCOMMENT X)} \) \[\text{Function}\]

Defined as the prettyprint macro for *: copies the comment to the primary output file by using GETCOMMENT.

\( \text{(READCOMMENT FL RDTBL LST)} \) \[\text{Function}\]

Defined as the read macro for * in FILERDTBL: if NORMALCOMMENTSFLG is NIL, it constructs a comment pointer, unless it believes the expression beginning with * is not actually a comment, e.g., if the next atom is "." or E.
INTERLISP-D REFERENCE MANUAL

Note that a certain amount of care is required in using the comment pointer feature. Since the text of
the comment resides on the file pointed to by the comment pointer, that file must remain in existence
as long as the comment is needed. GETCOMMENT helps out by changing the comment pointer to
always point at the most recent file that the comment lives on. However, if the user has been
performing repeated MAKEFILE’s (see Chapter 17) in which differing functions have changed at each
invocation of MAKEFILE, it is possible for the comment pointers in memory to be pointing at several
versions of the same file, since a comment pointer is only updated when the function it lives in is
prettyprinted, not when the function has been copied verbatim to the new file. This can be a problem
for file systems that have a built-in limit on the number of versions of a given file that will be made
before old versions are expunged. In such a case, the user should set the version retention count of
any directories involved to be infinite. GETCOMMENT prints an error message if the file that the
comment pointer points at has disappeared.

Similarly, one should be cognizant of comment pointers in sysouts, and be sure to retain any files thus
pointed to.

When using comment pointers, the user should also not set PRETTYFLG to NIL or call MAKEFILE
with option FAST, since this will prevent functions from being prettyprinted, and hence not get the
text of the comment copied into the new file.

If the user changes the value of COMMENTFLG but still wishes to use the comment pointer feature, the
new COMMENTFLG should be given the same read-macro definition in FILERDTBL as * has, and the
same entry be put on PRETTYPRINTMACROS. For example, if COMMENTFLG is reset to be ";", then
(SBTSYNTAX '; '; * FILERDTBL) should be performed, and (;; . PRINTCOMMENT) added to
PRETTYPRINTMACROS.

Converting Comments to Lower Case

This section is for users using terminals without lower case, who nevertheless would like their
comments to be converted to lower case for more readable listings. If the second atom in a comment
is %%, the text of the comment is converted to lower case so that it looks like English instead of Lisp.
Note that comments are converted only when they are actually written to a file by PRETTYPRINT.

The algorithm for conversion to lower case is the following: If the first character in an atom is \^, do
not change the atom (but remove the \^). If the first character is %, convert the atom to lower case.
Note that the user must type %% as % is the escape character. If the atom (minus any trailing
punctuation marks) is an Interlisp word (i.e., is a bound or free variable for the function containing the
comment, or has a top level value, or is a defined function, or has a non-NIL property list), do not
change it. Otherwise, convert the atom to lower case. Conversion only affects the upper case
alphabet, i.e., atoms already converted to lower case are not changed if the comment is converted
again. When converting, the first character in the comment and the first character following each
period are left capitalized. After conversion, the comment is physically modified to be the lower case
text minus the % flag, so that conversion is thus only performed once (unless the user edits the
comment inserting additional upper case text and another % flag).
LCASELST

Words on LCASELST will always be converted to lower case. LCASELST is initialized to contain words which are Interlisp functions but also appear frequently in comments as English words (AND, EVERY, GET, GO, LAST, LENGTH, LIST, etc.). Therefore, if one wished to type a comment including the Lisp function GO, it would be necessary to type ↑GO in order that it might be left in upper case.

UCASELST

Words on UCASELST (that do not appear on LCASELST) will be left in upper case. UCASELST is initialized to NIL.

ABBREVLST

ABBREVLST is used to distinguish between abbreviations and words that end in periods. Normally, words that end in periods and occur more than halfway to the right margin cause carriage-returns. Furthermore, during conversion to lowercase, words ending in periods, except for those on ABBREVLST, cause the first character in the next word to be capitalized. ABBREVLST is initialized to the upper and lower case forms of ETC, I.E., and E.G..

Special Prettyprint Controls

PRETTYTABFLG

In order to save space on files, tabs are used instead of spaces for the initial spaces on each line, assuming that each tab corresponds to 8 spaces. This results in a reduction of file size by about 30%. Tabs are not used if PRETTYTABFLG is set to NIL (initially T).

#RPARS

Controls the number of right parentheses necessary for square bracketing to occur. If #RPARS = NIL, no brackets are used. #RPARS is initialized to 4.

FIRSTCOL

The starting column for comments. Comments run between FIRSTCOL and the line length set by LINELENGTH (see Chapter 25). If a word in a comment ends with a "." and is not on the list ABBREVLST, and the position is greater than halfway between FIRSTCOL and LINELENGTH, the next word in the comment begins on a new line. Also, if a list is encountered in a comment, and the position is greater than halfway, the list begins on a new line.

PRETTYLCOM

If a comment has more than PRETTYLCOM elements (using COUNT), it is printed starting at column 10, instead of FIRSTCOL. Comments are also printed starting at column 10 if their second element is also a *, i.e., comments of the form (* * --).
#CAREFULCOLUMNS

In the interests of efficiency, PRETTYPRINT approximates the number of characters in each atom, rather than calling NCHARS, when computing how much will fit on a line. This procedure works satisfactorily in most cases. However, users with unusually long atoms in their programs, e.g., such as produced by CLISPIFY, may occasionally encounter some glitches in the output produced by PRETTYPRINT. The value of #CAREFULCOLUMNS tells PRETTYPRINT how many columns (counting from the right hand margin) in which to actually compute NCHARS instead of approximating. Setting #CAREFULCOLUMNS to 20 or 30 will eliminate the glitches, although it will slow down PRETTYPRINT slightly. #CAREFULCOLUMNS is initially 0.

(WIDEPAPER FLG)

(WIDEPAPER T) sets FILELINELENGTH (see Chapter 25), FIRSTCOL, and PRETTYLCOM to large values appropriate for pretty printing files to be listed on wide paper. (WIDEPAPER) restores these parameters to their initial values. WIDEPAPER returns the previous setting of FLG.

PRETTYFLG

If PRETTYFLG is NIL, PRINTDEF uses PRIN2 instead of prettyprinting. This is useful for producing a fast symbolic dump (see the FAST option of MAKEFILE in Chapter 17). Note that the file loads the same as if it were prettyprinted. PRETTYFLG is initially set to T. PRETTYFLG should not be set to NIL if comment pointers are being used.

CLISPIFYPRETTYFLG

Used to inform PRETTYPRINT to call CLISPIFY on selected function definitions before printing them (see Chapter 21).

PRETTYPRINTMACROS

An association-list that enables the user to control the formatting of selected expressions. CAR of each expression being PRETTYPRINTed is looked up on PRETTYPRINTMACROS, and if found, CDR of the corresponding entry is applied to the expression. If the result of this application is NIL, PRETTYPRINT ignores the expression; i.e., it prints nothing, assuming that the prettyprintmacro has done any desired printing. If the result of applying the prettyprint macro is non-NIL, the result is prettyprinted in the normal fashion. This gives the user the option of computing some other expression to be prettyprinted in its place.

Note: "prettyprinted in the normal fashion" includes processing prettyprint macros, unless the prettyprint macro returns a structure EQ to the one it was handed, in which case the potential recursion is broken.

PRETTYPRINTYPEMACROS

A list of elements of the form (TYPENAME . FN). For types other than lists and atoms, the type name of each datum to be prettyprinted is looked up on
PRETTYPRINTYPEMACROS, and if found, the corresponding function is applied to the
datum about to be printed, instead of simply printing it with PRIN2.

PRETTYEQUIVLST [Variable]
An association-list that tells PRETTYPRINT to treat a CAR-of-form the same as some other
CAR-of-form. For example, if (QLAMBDA . LAMBDA) appears on PRETTYEQUIVLST,
then expressions beginning with QLAMBDA are prettyprinted the same as LAMBDA.
Currently, PRETTYEQUIVLST only allows (i.e., supports in an interesting way) equivalence to forms for
which the user has specified a prettyprint macro should be made by adding further
entries to PRETTYPRINTYPEMACROS

CHANGECHAR [Variable]
If non-NIL, and PRETTYPRINT is printing to a file or display terminal, PRETTYPRINT
prints CHANGECHAR in the right hand margin while printing those expressions marked by
the editor as having been changed (see Chapter 16). CHANGECHAR is initially |.
Streams are used as the basis for all I/O operations. Files are implemented as streams that can support character printing and reading operations, and file pointer manipulation. An image stream is a type of stream that also provides an interface for graphical operations. All of the operations that can applied to streams can be applied to image streams. For example, an image stream can be passed as the argument to PRINT, to print something on an image stream. In addition, special functions are provided to draw lines and curves and perform other graphical operations. Calling these functions on a stream that is not an image stream will generate an error.

Primitive Graphics Concepts

The Interlisp-D graphics system is based on manipulating bitmaps (rectangular arrays of pixels), positions, regions, and textures. These objects are used by all of the graphics functions.

Positions

A position denotes a point in an X, Y coordinate system. A POSITION is an instance of a record with fields XCOORD and YCOORD and is manipulated with the standard record package facilities. For example, (create POSITION XCOORD ← 10 YCOORD ← 20) creates a position representing the point (10, 20).

(POSITIONP X) [Function]

Returns X if X is a position; NIL otherwise.

Regions

A Region denotes a rectangular area in a coordinate system. Regions are characterized by the coordinates of their bottom left corner and their width and height. A REGION is a record with fields LEFT, BOTTOM, WIDTH, and HEIGHT. It can be manipulated with the standard record package facilities. There are access functions for the REGION record that return the TOP and RIGHT of the region.

The following functions are provided for manipulating regions:

(CREATEREGION LEFT BOTTOM WIDTH HEIGHT) [Function]

Returns an instance of the REGION record which has LEFT, BOTTOM, WIDTH and HEIGHT as respectively its LEFT, BOTTOM, WIDTH, and HEIGHT fields.
Example: (CREATEREGION 10 -20 100 200) will create a region that denotes a rectangle whose width is 100, whose height is 200, and whose lower left corner is at the position (10,-20).

**REGIONP X**

[Function]

Returns T if X is a region, NIL otherwise.

**INTERSECTREGIONS REGION₁ REGION₂ ... REGIONₙ**

[NoSpread Function]

Returns a region which is the intersection of a number of regions. Returns NIL if the intersection is empty.

**UNIONREGIONS REGION₁ REGION₂ ... REGIONₙ**

[NoSpread Function]

Returns a region which is the union of a number of regions, i.e. the smallest region that contains all of them. Returns NIL if there are no regions given.

**REGIONSINTERSECTP REGION₁ REGION₂**

[Function]

Returns T if REGION₁ intersects REGION₂. Returns NIL if they do not intersect.

**SUBREGIONP LARGEREGION SMALLREGION**

[Function]

Returns T if SMALLREGION is a subregion (is equal to or entirely contained in) LARGEREGION; otherwise returns NIL.

**EXTENDREGION REGION INCLUDEREGION**

[Function]

Changes (destructively modifies) the region REGION so that it includes the region INCLUDEREGION. It returns REGION.

**MAKEWITHINREGION REGION LIMITREGION**

[Function]

Changes (destructively modifies) the left and bottom of the region REGION so that it is within the region LIMITREGION, if possible. If the dimension of REGION are larger than LIMITREGION, REGION is moved to the lower left of LIMITREGION. If LIMITREGION is NIL, the value of the variable WHOLEDISPLAY (the screen region) is used. MAKEWITHINREGION returns the modified REGION.

**INSIDEPOS REGION POSORX Y**

[Function]

If POSORX and Y are numbers, it returns T if the point (POSORX, Y) is inside of REGION. If POSORX is a POSITION, it returns T if POSORX is inside of REGION. If REGION is a WINDOW, the window’s interior region in window coordinates is used. Otherwise, it returns NIL.
Bitmaps

The display primitives manipulate graphical images in the form of bitmaps. A bitmap is a rectangular array of “pixels,” each of which is an integer representing the color of one point in the bitmap image. A bitmap is created with a specific number of bits allocated for each pixel. Most bitmaps used for the display screen use one bit per pixel, so that at most two colors can be represented. If a pixel is 0, the corresponding location on the image is white. If a pixel is 1, its location is black. This interpretation can be changed for the display screen with the function VIDEOCOLOR. Bitmaps with more than one bit per pixel are used to represent color or grey scale images. Bitmaps use a positive integer coordinate system with the lower left corner pixel at coordinate (0,0). Bitmaps are represented as instances of the datatype BITMAP. Bitmaps can be saved on files with the VARS file package command.

(BITMAPCREATE WIDTH HEIGHT BITSPERPIXEL) [Function]
Creates and returns a new bitmap which is WIDTH pixels wide by HEIGHT pixels high, with BITSPERPIXEL bits per pixel. If BITSPERPIXEL is NIL, it defaults to 1.

(BITMAP X) [Function]
Returns X if X is a bitmap, NIL otherwise.

(BITMAPWIDTH BITMAP) [Function]
Returns the width of BITMAP in pixels.

(BITMAPHEIGHT BITMAP) [Function]
Returns the height of BITMAP in pixels.

(BITSPERPIXEL BITMAP) [Function]
Returns the number of bits per pixel of BITMAP.

(BITMAPBIT BITMAP X Y NEWVALUE) [Function]
If NEWVALUE is between 0 and the maximum value for a pixel in BITMAP, the pixel (X, Y) is changed to NEWVALUE and the old value is returned. If NEWVALUE is NIL, BITMAP is not changed but the value of the pixel is returned. If NEWVALUE is anything else, an error is generated. If (X, Y) is outside the limits of BITMAP, 0 is returned and no pixels are changed. BITMAP can also be a window or display stream. Note: non-window image streams are "write-only"; the NEWVALUE argument must be non-NIL.

(BITMAPCOPY BITMAP) [Function]
Returns a new bitmap which is a copy of BITMAP (same dimensions, bits per pixel, and contents).

(EXPANDBITMAP BITMAP WIDTHFACTOR HEIGHTFACTOR) [Function]
Returns a new bitmap that is WIDTHFACTOR times as wide as BITMAP a
and HEIGHTFACTOR times as high. Each pixel of BITMAP is copied into a WIDTHFACTOR times HEIGHTFACTOR block of pixels. If NIL, WIDTHFACTOR defaults to 4, HEIGHTFACTOR to 1.

(RotateBitmap BITMAP) [Function]

Given an m-high by n-wide bitmap, this function returns an n-high by m-wide bitmap. The returned bitmap is the image of the original bitmap, rotated 90 degrees clockwise.

(ShrinkBitmap BITMAP WIDTHFACTOR HEIGHTFACTOR DESTINATIONBITMAP) [Function]

Returns a copy of BITMAP that has been shrunken by WIDTHFACTOR and HEIGHTFACTOR in the width and height, respectively. If NIL, WIDTHFACTOR defaults to 4, HEIGHTFACTOR to 1. If DESTINATIONBITMAP is not provided, a bitmap that is 1/WIDTHFACTOR by 1/HEIGHTFACTOR the size of BITMAP is created and returned. WIDTHFACTOR and HEIGHTFACTOR must be positive integers.

(PrintBitmap BITMAP FILE) [Function]

Prints the bitmap BITMAP on the file FILE in a format that can be read back in by READBITMAP.

(ReadBitmap FILE) [Function]

Creates a bitmap by reading an expression (written by PRINTBITMAP) from the file FILE.

(EditBm BMSPEC) [Function]

EDITBM provides an easy-to-use interactive editing facility for various types of bitmaps. If BMSPEC is a bitmap, it is edited. If BMSPEC is an atom whose value is a bitmap, its value is edited. If BMSPEC is NIL, EDITBM asks for dimensions and creates a bitmap. If BMSPEC is a region, that portion of the screen bitmap is used. If BMSPEC is a window, it is brought to the top and its contents edited.

EDITBM sets up the bitmap being edited in an editing window. The editing window has two major areas: a gridded edit area in the lower part of the window and a display area in the upper left part. In the edit area, the left button will add points, the middle button will erase points. The right button provides access to the normal window commands to reposition and reshape the window. The actual size bitmap is shown in the display area. For example, the following is a picture of the bitmap editing window editing a eight-high by eighteen-wide bitmap:
If the bitmap is too large to fit in the edit area, only a portion will be editable. This portion can be changed by scrolling both up and down in the left margin and left and right in the bottom margin. Pressing the middle button while in the display area will bring up a menu that allows global placement of the portion of the bitmap being edited. To allow more of the bitmap to be editing at once, the window can be reshaped to make it larger or the GridSize→ command described below can be used to reduce the size of a bit in the edit area.

The bitmap editing window can be reshaped to provide more or less room for editing. When this happens, the space allocated to the editing area will be changed to fit in the new region.

Whenever the left or middle button is down and the cursor is not in the edit area, the section of the display of the bitmap that is currently in the edit area is complemented. Pressing the left button while not in the edit region will put the lower left 16 x 16 section of the bitmap into the cursor for as long as the left button is held down.

Pressing the middle button while not in either the edit area or the display area (i.e., while in the grey area in the upper right or in the title) will bring up a command menu.

There are commands to stop editing, to restore the bitmap to its initial state and to clear the bitmap. Holding the middle button down over a command will result in an explanatory message being printed in the prompt window. The commands are described below:

- **Paint**: Puts the current bitmap into a window and call the window PAINT command on it. The PAINT command implements drawing with various brush sizes and shapes but only on an actual sized bitmap. The PAINT mode is left by pressing the RIGHT button and selecting the QUIT command from
the menu. At this point, you will be given a choice of whether or not the changes you made while in PAINT mode should be made to the current bitmap.

**ShowAsTile**  Tesselates the current bitmap in the upper part of the window. This is useful for determining how a bitmap will look if it were made the display background (using the function CHANGEBACKGROUND). Note: The tiled display will not automatically change as the bitmap changes; to update it, use the ShowAsTile command again.

**Grid, On/Off**  Turns the editing grid display on or off.

**GridSize**←  Allows specification of the size of the editing grid. Another menu will appear giving a choice of several sizes. If one is selected, the editing portion of the bitmap editor will be redrawn using the selected grid size, allowing more or less of the bitmap to be edited without scrolling. The original size is chosen heuristically and is typically about 8. It is particularly useful when editing large bitmaps to set the edit grid size smaller than the original.

**Reset**  Sets all or part of the bitmap to the contents it had when EDITBM was called. Another menu will appear giving a choice between resetting the entire bitmap or just the portion that is in the edit area. The second menu also acts as a confirmation, since not selecting one of the choices on this menu results in no action being taken.

**Clear**  Sets all or part of the bitmap to 0. As with the Reset command, another menu gives a choice between clearing the entire bitmap or just the portion that is in the edit area.

**Cursor**←  Sets the cursor to the lower left part of the bitmap. This prompts the user to specify the cursor "hot spot" by clicking in the lower left corner of the grid.

**OK**  Copies the changed image into the original bitmap, stops the bitmap editor and closes the edit windows. The changes the bitmap editor makes during the interaction occur on a copy of the original bitmap. Unless the bitmap editor is exited via OK, no changes are made in the original.

**Stop**  Stops the bitmap editor without making any changes to the original bitmap.

**Textures**

A Texture denotes a pattern of gray which can be used to (conceptually) tessellate the plane to form an infinite sheet of gray. It is currently either a 4 by 4 pattern or a 16 by N (N <= 16) pattern. Textures are created from bitmaps using the following function:

(CREATETEXTUREFROMBITMAP BITMAP)  [Function]

Returns a texture object that will produce the texture of BITMAP. If BITMAP is too large, its lower left portion is used. If BITMAP is too small, it is repeated to fill out the texture.
GRAPHICS OUTPUT OPERATIONS

(TEXTUREP OBJECT) [Function]

Returns OBJECT if it is a texture; NIL otherwise.

The functions which accept textures (TEXTUREP, BITBLT, DSPTEXTURE, etc.) also accept bitmaps up to 16 bits wide by 16 bits high as textures. When a region is being filled with a bitmap texture, the texture is treated as if it were 16 bits wide (if less, the rest is filled with white space).

The common textures white and black are available as system constants WHITESHADE and BLACKSHADE. The global variable GRAYSHADE is used by many system facilities as a background gray shade and can be set by the user.

(EDITSHADE SHADE) [Function]

Opens a window that allows the user to edit textures. Textures can be either small (4 by 4) patterns or large (16 by 16). In the edit area, the left button adds bits to the shade and the middle button erases bits from the shade. The top part of the window is painted with the current texture whenever all mouse keys are released. Thus it is possible to directly compare two textures that differ by more than one pixel by holding a mouse key down until all changes are made. When the "quit" button is selected, the texture being edited is returned.

If SHADE is a texture object, EDITSHADE starts with it. If SHADE is T, it starts with a large (16 by 16) white texture. Otherwise, it starts with WHITESHADE.

The following is a picture of the texture editor, editing a large (16 by 16) pattern:

Opening Image Streams

An image stream is an output stream which "knows" how to process graphic commands to a graphics output device. Besides accepting the normal character-output functions (PRINT, etc.), an image
stream can also be passed as an argument to functions to draw curves, to print characters in multiple fonts, and other graphics operations.

Each image stream has an “image stream type,” a litatom that specifies the type of graphic output device that the image stream is processing graphics commands for. Currently, the built-in image stream types are DISPLAY (for the display screen), INTERPRESS (for Interpress format printers), and PRESS (for Press format printers). There are also library packages available that define image stream types for the IRIS display, 4045 printer, FX-80 printer, C150 printer, etc.

Image streams to the display (display streams) interpret graphics commands by immediately executing the appropriate operations to cause the desired image to appear on the display screen. Image streams for hardcopy devices such as Interpress printers interpret the graphic commands by saving information in a file, which can later be sent to the printer.

Note: Not all graphics operations can be properly executed for all image stream types. For example, BITBLT may not be supported to all printers. This functionality is still being developed, but even in the long run some operations may be beyond the physical or logical capabilities of some devices or image file formats. In these cases, the stream will approximate the specified image as best it can.

**(OPENIMAGESTREAM FILE IMAGETYPE OPTIONS)**

[Function]

Opens and returns an image stream of type IMAGETYPE on a destination specified by FILE. If FILE is a file name on a normal file storage device, the image stream will store graphics commands on the specified file, which can be transmitted to a printer by explicit calls to LISTFILES and SEND.FILE.TO.PRINTER. If IMAGETYPE is DISPLAY, then the user is prompted for a window to open. FILE in this case will be used as the title of the window.

If FILE is a file name on the LPT device, this indicates that the graphics commands should be stored in a temporary file, and automatically sent to the printer when the image stream is closed by CLOSEF. FILE = NIL is equivalent to FILE = {LPT}. File names on the LPT device are of the form {LPT}PRINTERNAME.TYPE, where PRINTERNAME, TYPE, or both may be omitted. PRINTERNAME is the name of the particular printer to which the file will be transmitted on closing; it defaults to the first printer on DEFAULTPRINTINGHOST that can print IMAGETYPE files. The TYPE extension supplies the value of IMAGETYPE when it is defaulted (see below). OPENIMAGESTREAM will generate an error if the specified printer does not accept the kind of file specified by IMAGETYPE.

If IMAGETYPE is NIL, the image type is inferred from the extension field of FILE and the EXTENSIONS properties in the list PRINTFILETYPES. Thus, the extensions IP, IPR, and INTERPRESS indicate Interpress format, and the extension PRESS indicates Press format. If FILE is a printer file with no extension (of the form {LPT}PRINTERNAME), then IMAGETYPE will be the type that the indicated printer can print. If FILE has no extension but is not on the printer device {LPT}, then IMAGETYPE will default to the type accepted by the first printer on DEFAULTPRINTINGHOST.
OPTIONS is a list in property list format, (PROP1 VAL1 PROP2 VAL2 —), used to specify certain attributes of the image stream; not all attributes are meaningful or interpreted by all types of image streams. Acceptable properties are:

REGION  Value is the region on the page (in stream scale units, 0,0 being the lower-left corner of the page) that text will fill up. It establishes the initial values for DSPLEFTMARGIN, DSPIIGHTMARGIN, DSPBOTTOMMARGIN (the point at which carriage returns cause page advancement) and DSPTOPMARGIN (where the stream is positioned at the beginning of a new page).

If this property is not given, the value of the variable DEFAULTPAGEREGION, is used.

FONTS  Value is a list of fonts that are expected to be used in the image stream. Some image streams (e.g. Interpress) are more efficient if the expected fonts are specified in advance, but this is not necessary. The first font in this list will be the initial font of the stream, otherwise the default font for that image stream type will be used.

HEADING  Value is the heading to be placed automatically on each page. NIL means no heading.

Examples: Suppose that Tremor: is an Interpress printer, Quake is a Press printer, and DEFAULTPRINTINGHOST is (Tremor: Quake):

(OPENIMAGESTREAM)  returns an Interpress image stream on printer Tremor:.

(OPENIMAGESTREAM NIL 'PRESS)  returns a Press stream on Quake.

(OPENIMAGESTREAM '{LPT}.INTERPRESS)  returns an Interpress stream on Tremor:.

(OPENIMAGESTREAM '{CORE}FOO.PRESS)  returns a Press stream on the file {CORE}FOO.PRESS.

(IMAGESTREAMP X IMAGETYPE)  [NoSpread Function]

Returns X (possibly coerced to a stream) if it is an output image stream of type IMAGETYPE (or of any type if IMAGETYPE = NIL), otherwise NIL.

(IMAGESTREAMTYPE STREAM)  [Function]

Returns the image stream type of STREAM.

(IMAGESTREAMTYPEP STREAM TYPE)  [Function]

Returns T if STREAM is an image stream of type TYPE.
Accessing Image Stream Fields

The following functions manipulate the fields of an image stream. These functions return the old value (the one being replaced). A value of NIL for the new value will return the current setting without changing it. These functions do not change any of the bits drawn on the image stream; they just affect future operations done on the image stream.

(DSPCLIPPINGREGION REGION STREAM)  [Function]

The clipping region is a region that limits the extent of characters printed and lines drawn (in the image stream’s coordinate system). Initially set so that no clipping occurs.

Warning: For display streams, the window system maintains the clipping region during window operations. Users should be very careful about changing this field.

(DSPFONT FONT STREAM)  [Function]

The font field specifies the font used when printing characters to the image stream.

Note: DSPFONT determines its new font descriptor from FONT by the same coercion rules that FONTPROP and FONTCREATE use, with one additional possibility: If FONT is a list of the form (PROP1 VAL1 PROP2 VAL2 ...) where PROP1 is acceptable as a font-property to FONTCOPY, then the new font is obtained by (FONTCOPY (DSPFONT NIL STREAM) PROP1 VAL1 PROP2 VAL2 ...).

For example, (DSPFONT '(SIZE 12) STREAM) would change the font to the 12 point version of the current font, leaving all other font properties the same.

(DSPTOPMARGIN YPOSITION STREAM)  [Function]

The top margin is an integer that is the Y position after a new page (in the image stream’s coordinate system). This function has no effect on windows.

(DSPBOTTOMMARGIN YPOSITION STREAM)  [Function]

The bottom margin is an integer that is the minimum Y position that characters will be printed by PRIN1 (in the image stream’s coordinate system). This function has no effect on windows.

(DSPLEFTMARGIN XPOSITION STREAM)  [Function]

The left margin is an integer that is the X position after an end-of-line (in the image stream’s coordinate system). Initially the left edge of the clipping region.

(DSPRIGHTMARGIN XPOSITION STREAM)  [Function]

The right margin is an integer that is the maximum X position that characters will be printed by PRIN1 (in the image stream’s coordinate system). This is initially the position of the right edge of the window or page.
The line length of a window or image stream (as returned by LINELENGTH) is computed by dividing
the distance between the left and right margins by the width of an uppercase “A” in the current font.
The line length is changed whenever the font, left margin, or right margin are changed or whenever
the window is reshaped.

(DSPOPERATION OPERATION STREAM)  [Function]

The operation is the default BITBLT operation used when printing or drawing on the
image stream. One of REPLACE, PAINT, INVERT, or ERASE. Initially REPLACE.
This is a meaningless operation for most printers which support the model that once dots
are deposited on a page they cannot be removed.

(DSPLINEFEED DELTAY STREAM)  [Function]

The linefeed is an integer that specifies the Y increment for each linefeed, normally
negative. Initially minus the height of the initial font.

(DSPCLEOL DSPSTREAM XPOS YPOS HEIGHT)  [Function]

"Clear to end of line". Clears a region from (XPOS, YPOS) to the right margin of the
display, with a height of HEIGHT. If XPOS and YPOS are NIL, clears the remainder of the
current display line, using the height of the current font.

(DSPRUBOUTCHAR DSPSTREAM CHAR X Y TTBL)  [Function]

Backs up over character code CHAR in the DSPSTREAM, erasing it. If X, Y are supplied, the
rubbing out starts from the position specified. DSPRUBOUTCHAR assumes CHAR was
printed with the terminal table TTBL, so it knows to handle control characters, etc. TTBL
defaults to the primary terminal table.

(DSPSCALE SCALE STREAM)  [Function]

Returns the scale of the image stream STREAM, a number indicating how many units in
the streams coordinate system correspond to one printer’s point (1/72 of an inch). For
example, DSPSCALE returns 1 for display streams, and 35.27778 for Interpress and Press
streams (the number of micas per printer’s point). In order to be device-independent, user
graphics programs must either not specify position values absolutely, or must multiply
absolute point quantities by the DSPSCALE of the destination stream. For example, to set
the left margin of the Interpress stream XX to one inch, do

(DSPLLEFTMARGIN (TIMES 72 (DSPSCALE NIL XX)) XX)

The SCALE argument to DSPSCALE is currently ignored. In a future release it will
enable the scale of the stream to be changed under user control, so that the necessary
multiplication will be done internal to the image stream interface. In this case, it would be
possible to set the left margin of the Interpress stream XX to one inch by doing

(DSPSCALE 1 XX)
(DSPLLEFTMARGIN 72 XX)
DSPSPACEFACTOR

The space factor is the amount by which to multiply the natural width of all following space characters on STREAM; this can be used for the justification of text. The default value is 1. For example, if the natural width of a space in STREAM’s current font is 12 units, and the space factor is set to two, spaces appear 24 units wide. The values returned by STRINGWIDTH and CHARWIDTH are also affected.

The following two functions only have meaning for image streams that can display color:

DSPCOLOR

Sets the default foreground color of STREAM. Returns the previous foreground color. If COLOR is NIL, it returns the current foreground color without changing anything. The default color is white.

DSPBACKCOLOR

Sets the background color of STREAM. Returns the previous background color. If COLOR is NIL, it returns the current background color without changing anything. The default background color is black.

Current Position of an Image Stream

Each image stream has a “current position,” which is a position (in the image stream’s coordinate system) where the next printing operation will start from. The functions which print characters or draw on an image stream update these values appropriately. The following functions are used to explicitly access the current position of an image stream:

DSPXPOSITION

Returns the X coordinate of the current position of STREAM. If XPOSITION is non-NIL, the X coordinate is set to it (without changing the Y coordinate).

DSPYPOSITION

Returns the Y coordinate of the current position of STREAM. If YPOSITION is non-NIL, the Y coordinate is set to it (without changing the X coordinate).

MOVETO

Changes the current position of STREAM to the point (X, Y).

RELMOVETO

Changes the current position to the point (DX, DY) coordinates away from current position of STREAM.
MOVETOUPPERLEFT STREAM REGION

Moves the current position to the beginning position of the top line of text. If REGION is non-NIL, it must be a REGION and the X position is changed to the left edge of REGION and the Y position changed to the top of REGION less the font ascent of STREAM. If REGION is NIL, the X coordinate is changed to the left margin of STREAM and the Y coordinate is changed to the top of the clipping region of STREAM less the font ascent of STREAM.

Moving Bits Between Bitmaps With BITBLT

BITBLT is the primitive function for moving bits from one bitmap to another, or from a bitmap to an image stream.

BITBLT SOURCE SOURCELEFT SOURCEBOTTOM DESTINATION DESTINATIONLEFT DESTINATIONBOTTOM WIDTH HEIGHT SOURCETYPE OPERATION TEXTURE CLIPPINGREGION

Transfers a rectangular array of bits from SOURCE to DESTINATION. SOURCE can be a bitmap, or a display stream or window, in which case its associated bitmap is used. DESTINATION can be a bitmap or an arbitrary image stream.

WIDTH and HEIGHT define a pair of rectangles, one in each of the SOURCE and DESTINATION whose left, bottom corners are at, respectively, (SOURCELEFT, SOURCEBOTTOM) and (DESTINATIONLEFT, DESTINATIONBOTTOM). If these rectangles overlap the boundaries of either source or destination they are both reduced in size (without translation) so that they fit within their respective boundaries. If CLIPPINGREGION is non-NIL it should be a REGION and is interpreted as a clipping region within DESTINATION; clipping to this region may further reduce the defining rectangles. These (possibly reduced) rectangles define the source and destination rectangles for BITBLT.

The mode of transferring bits is defined by SOURCETYPE and OPERATION. SOURCETYPE and OPERATION specify whether the source bits should come from SOURCE or TEXTURE, and how these bits are combined with those of DESTINATION. SOURCETYPE and OPERATION are described further below.

TEXTURE is a texture. BITBLT aligns the texture so that the upper-left pixel of the texture coincides with the upper-left pixel of the destination bitmap.

SOURCELEFT, SOURCEBOTTOM, DESTINATIONLEFT, and DESTINATIONBOTTOM default to 0. WIDTH and HEIGHT default to the width and height of the SOURCE. TEXTURE defaults to white. SOURCETYPE defaults to INPUT. OPERATION defaults to REPLACE. If CLIPPINGREGION is not provided, no additional clipping is done. BITBLT returns T if any bits were moved; NIL otherwise.

Note: If SOURCE or DESTINATION is a window or image stream, the remaining arguments are interpreted as values in the coordinate system of the window or image.
stream and the operation of BITBLT is translated and clipped accordingly. Also, if a window or image stream is used as the destination to BITBLT, its clipping region further limits the region involved.

SOURCETYPE specifies whether the source bits should come from the bitmap SOURCE, or from the texture TEXTURE. SOURCETYPE is interpreted as follows:

- **INPUT** The source bits come from SOURCE. TEXTURE is ignored.
- **INVERT** The source bits are the inverse of the bits from SOURCE. TEXTURE is ignored.
- **TEXTURE** The source bits come from TEXTURE. SOURCE, SOURCELEFT, and SOURCETEXTURE are ignored.

OPERATION specifies how the source bits (as specified by SOURCETYPE) are combined with the bits in DESTINATION and stored back into DESTINATION. DESTINATION is one of the following:

- **REPLACE** All source bits (on or off) replace destination bits.
- **PAINT** Any source bits that are on replace the corresponding destination bits. Source bits that are off have no effect. Does a logical OR between the source bits and the destination bits.
- **INVERT** Any source bits that are on invert the corresponding destination bits. Does a logical XOR between the source bits and the destination bits.
- **ERASE** Any source bits that are on erase the corresponding destination bits. Does a logical AND operation between the inverse of the source bits and the destination bits.

Different combinations of SOURCETYPE and OPERATION can be specified to achieve many different effects. Given the following bitmaps as the values of SOURCE, TEXTURE, and DESTINATION:

BITBLT would produce the results given below for the difference combinations of SOURCETYPE and OPERATION (assuming CLIPPINGREGION, SOURCELEFT, etc. are set correctly, of course):
BLTSHADE is the SOURCETYPE = TEXTURE case of BITBLT. It fills the specified region of the destination bitmap DESTINATION with the texture TEXTURE. DESTINATION can be a bitmap or image stream.

(BITMAPIMAGESIZE BITMAP DIMENSION STREAM) [Function]

Returns the size that BITMAP will be when BITBLTed to STREAM, in STREAM's units. DIMENSION can be one of WIDTH, HEIGHT, or NIL, in which case the dotted pair (WIDTH, HEIGHT) will be returned.

Drawing Lines

Interlisp-D provides several functions for drawing lines and curves on image streams. The line drawing functions are intended for interactive applications where efficiency is important. They do not allow the use of "brush" patterns, like the curve drawing functions, but (for display streams) they support drawing a line in INVERT mode, so redrawing the line will erase it. DRAWCURVE can be used to draw lines using a brush.

(DRAWLINE X1 Y1 X2 Y2 WIDTH OPERATION STREAM COLOR DASHING) [Function]

Draws a straight line from the point \((X_1,Y_1)\) to the point \((X_2,Y_2)\) on the image stream STREAM. The position of STREAM is set to \((X_2,Y_2)\). If \(X_1\) equals \(X_2\) and \(Y_1\) equals \(Y_2\), a point is drawn at \((X_1,Y_1)\).

WIDTH is the width of the line, in the units of the device. If WIDTH is NIL, the default is 1.

OPERATION is the BITBLT operation used to draw the line. If OPERATION is NIL, the value of DSPOPERATION for the image stream is used.

COLOR is a color specification that determines the color used to draw the line for image streams that support color. If COLOR is NIL, the DSPCOLOR of STREAM is used.
DASHING is a list of positive integers that determines the dashing characteristics of the line. The line is drawn for the number of points indicated by the first element of the dashing list, is not drawn for the number of points indicated by the second element. The third element indicates how long it will be on again, and so forth. The dashing sequence is repeated from the beginning when the list is exhausted. A brush LINEWITHBRUSH-by-LINEWITHBRUSH is used.

If DASHING is NIL, the line is not dashed.

(DRAWBETWEEN POSITION1 POSITION2 WIDTH OPERATION STREAM COLOR DASHING)
[Function]
Draws a line from the point POSITION1 to the point POSITION2 onto the destination bitmap of STREAM. The position of STREAM is set to POSITION2.

In the Medley release, when using the color argument, Interpress DRAWLINE treats 16x16 bitmaps or negative numbers as shades/textures. Positive numbers continue to refer to color maps, and so cannot be used as textures. To convert an integer shade into a negative number use NEGSHADE (e.g. (NEGSHADE 42495) is -23041).

(DRAWTO X Y WIDTH OPERATION STREAM COLOR DASHING)
[Function]
Draws a line from the current position to the point \((X, Y)\) onto the destination bitmap of STREAM. The position of STREAM is set to \((X, Y)\).

(RELDRAWTO DX DY WIDTH OPERATION STREAM COLOR DASHING)
[Function]
Draws a line from the current position to the point \((DX, DY)\) coordinates away onto the destination bitmap of STREAM. The position of STREAM is set to the end of the line. If \(DX\) and \(DY\) are both 0, nothing is drawn.

### Drawing Curves

A curve is drawn by placing a brush pattern centered at each point along the curve's trajectory. A brush pattern is defined by its shape, size, and color. The predefined brush shapes are ROUND, SQUARE, HORIZONTAL, VERTICAL, and DIAGONAL; new brush shapes can be created using the INSTALLBRUSH function, described below. A brush size is an integer specifying the width of the brush in the units of the device. The color is a color specification, which is only used if the curve is drawn to an image stream that supports colors.

A brush is specified to the various drawing functions as a list of the form \((SHAPE\ WIDTH\ COLOR)\), for example \((\text{SQUARE} \ 2)\) or \((\text{VERTICAL} \ 4 \ \text{RED})\). A brush can also be specified as a positive integer, which is interpreted as a ROUND brush of that width. If a brush is a litatom, it is assumed to be a function which is called at each point of the curve's trajectory (with three arguments: the X-
coordinate of the point, the Y-coordinate, and the image stream), and should do whatever image stream operations are necessary to draw each point. Finally, if a brush is specified as NIL, a (ROUND 1) brush is used as default.

The appearance of a curve is also determined by its dashing characteristics. Dashing is specified by a list of positive integers. If a curve is dashed, the brush is placed along the trajectory for the number of units indicated by the first element of the dashing list. The brush is off, not placed in the bitmap, for a number of units indicated by the second element. The third element indicates how long it will be on again, and so forth. The dashing sequence is repeated from the beginning when the list is exhausted. The units used to measure dashing are the units of the brush. For example, specifying the dashing as (1 1) with a brush of (ROUND 16) would put the brush on the trajectory, skip 16 points, and put down another brush. A curve is not dashed if the dashing argument to the drawing function is NIL.

The curve functions use the image stream’s clipping region and operation. Most types of image streams only support the PAINT operation when drawing curves. When drawing to a display stream, the curve-drawing functions accept the operation INVERT if the brush argument is 1. For brushes larger than 1, these functions will use the ERASE operation instead of INVERT. For display streams, the curve-drawing functions treat the REPLACE operation the same as PAINT.

(DRAWCURVE KNOTS CLOSED BRUSH DASHING STREAM)  [Function]

Draws a “parametric cubic spline curve” on the image stream STREAM. KNOTS is a list of positions to which the curve will be fitted. If CLOSED is non-NIL, the curve will be closed; otherwise it ends at the first and last positions in KNOTS. BRUSH and DASHING are interpreted as described above.

For example,

(DRAWCURVE '((10 . 10)(50 . 50)(100 . 10)(150 . 50))
NIL '(ROUND 5) '(1 1 1 2) XX)

would draw a curve like the following on the display stream XX:

![Spline Curve Diagram]

(DRAWCIRCLE CENTERX CENTERY RADIUS BRUSH DASHING STREAM)  [Function]

Draws a circle of radius RADIUS about the point (CENTERX, CENTERY) onto the image stream STREAM. STREAM’s position is left at (CENTERX, CENTERY). The other arguments are interpreted as described above.
**DRAWARC CENTERX CENTERY RADIUS STARTANGLE NDEGREES BRUSH DASHINGSTREAM)**

[Function]

Draws an arc of the circle whose center point is (CENTERX CENTERY) and whose radius is RADIUS from the position at STARTANGLE degrees for NDEGREES number of degrees. If STARTANGLE is 0, the starting point will be (CENTERX (CENTERY + RADIUS)). If NDEGREES is positive, the arc will be counterclockwise. If NDEGREES is negative, the arc will be clockwise. The other arguments are interpreted as described in DRAWCIRCLE.

**DRAWELLIPSE CENTERX CENTERY SEMIMINORRADIUS SEMIMAJORRADIUS ORIENTATION BRUSH DASHING STREAM)**

[Function]

Draws an ellipse with a minor radius of SEMIMINORRADIUS and a major radius of SEMIMAJORRADIUS about the point (CENTERX, CENTERY) onto the image stream STREAM. ORIENTATION is the angle of the major axis in degrees, positive in the counterclockwise direction. STREAM’s position is left at (CENTERX, CENTERY). The other arguments are interpreted as described above.

New brush shapes can be defined using the following function:

**INSTALLBRUSH BRUSHNAME BRUSHFN BRUSHARRAY)**

[Function]

Installs a new brush called BRUSHNAME with creation-function BRUSHFN and optional array BRUSHARRAY. BRUSHFN should be a function of one argument (a width), which returns a bitmap of the brush for that width. BRUSHFN will be called to create new instances of BRUSHNAME-type brushes; the sixteen smallest instances will be pre-computed and cached. "Hand-crafted" brushes can be supplied as the BRUSHARRAY argument. Changing an existing brush can be done by calling INSTALLBRUSH with new BRUSHFN and/or BRUSHARRAY.

**DRAWPOINT X Y BRUSH STREAM OPERATION)**

[Function]

Draws BRUSH centered around point (X, Y) on STREAM, using the operation OPERATION. BRUSH may be a bitmap or a brush.

**Miscellaneous Drawing and Printing Operations**

**DSPFILL REGION TEXTURE OPERATION STREAM)**

[Function]

Fills REGION of the image stream STREAM (within the clipping region) with the texture TEXTURE. If REGION is NIL, the whole clipping region of STREAM is used. If TEXTURE or OPERATION is NIL, the values for STREAM are used.
(DRAWPOLYGON POINTS CLOSED BRUSH DASHING STREAM)  [Function]

Draws a polygon on the image stream STREAM. POINTS is a list of positions to which the figure will be fitted (the vertices of the polygon). If CLOSED is non-NIL, then the starting position is specified only once in POINTS. If CLOSED is NIL, then the starting vertex must be specified twice in POINTS. BRUSH and DASHING are interpreted as described in Chapter 27 of the Interlisp-D Reference Manual.

For example,

```
(DRAWPOLYGON '(((100 . 100) (50 . 125) (150 . 175) (200 . 100) (150 . 50))
    T 'ROUND 3) '(4 2) XX)
```

will draw a polygon like the following on the display stream XX.

(FILLPOLYGON POINTS TEXTURE OPERATION WINDNUMBER STREAM)  [Function]

OPERATION is the BITBLT operation (see page 27.15 in the Interlisp-D Reference Manual) used to fill the polygon. If the OPERATION is NIL, the OPERATION defaults to the STREAM default OPERATION.

WINDNUMBER is the number for the winding rule convention. This number is either 0 or 1; 0 indicates the “zero” winding rule, 1 indicates the “odd” winding rule.

When filling a polygon, there is more than one way of dealing with the situation where two polygon sides intersect, or one polygon is fully inside the other. Currently, FILLPOLYGON to a display stream uses the “odd” winding rule, which means that intersecting polygon sides define areas that are filled or not filled somewhat like a checkerboard. For example,

```
(FILLPOLYGON
 '(((110 . 110) (150 . 200) (190 . 110))
   ((135 . 125) (160 . 125) (160 . 150) (150 . 150)))
  GRAYSHADE WINDOW)
```

will produce a display something like this:
This fill convention also takes into account all polygons in POINTS, if it specifies multiple polygons.

(FILLCIRCLE CENTERX CENTERY RADIUS TEXTURE STREAM)  [Function]
Fills in a circular area of radius RADIUS about the point (CENTERX, CENTERY) in STREAM with TEXTURE. STREAM's position is left at (CENTERX, CENTERY).

(DSPRESET STREAM)  [Function]
Sets the X coordinate of STREAM to its left margin, sets its Y coordinate to the top of the clipping region minus the font ascent. For a display stream, this also fills its destination bitmap with its background texture.

(DSPNEWPAGE STREAM)  [Function]
Starts a new page. The X coordinate is set to the left margin, and the Y coordinate is set to the top margin plus the linefeed.

(CENTERPRINTINREGION EXP REGION STREAM)  [Function]
Prints EXP so that it is centered within REGION of the STREAM. If REGION is NIL, EXP will be centered in the clipping region of STREAM.

### Drawing and Shading Grids

A grid is a partitioning of an arbitrary coordinate system (hereafter referred to as the "source system") into rectangles. This section describes functions that operate on grids. It includes functions to draw the outline of a grid, to translate between positions in a source system and grid coordinates (the coordinates of the rectangle which contains a given position), and to shade grid rectangles. A grid is defined by its "unit grid," a region (called a grid specification) which is the origin rectangle of the grid in terms of the source system. Its LEFT field is interpreted as the X-coordinate of the left edge of the origin rectangle, its BOTTOM field is the Y-coordinate of the bottom edge of the origin rectangle, its WIDTH is the width of the grid rectangles, and its HEIGHT is the height of the grid rectangles.

(GRID GRIDSPEC WIDTH HEIGHT BORDER STREAM GRIDSHADE)  [Function]
Outlines the grid defined by GRIDSPEC which is WIDTH rectangles wide and HEIGHT rectangles high on STREAM. Each box in the grid has a border within it that is BORDER points on each side; so the resulting lines in the grid are 2*BORDER thick. If BORDER is the atom POINT, instead of a border the lower left point of each grid rectangle will be turned
GRAPHICS OUTPUT OPERATIONS

on. If GRIDSHADE is non-NIL, it should be a texture and the border lines will be drawn using that texture.

\[(\text{SHADEGRIDBOX} \ X \ Y \ \text{SHADE} \ \text{OPERATION} \ \text{GRIDSPEC} \ \text{GRIDBORDER} \ \text{STREAM})\]  

[Function]

Shades the grid rectangle \((X, Y)\) of \text{GRIDSPEC} with texture \text{SHADE} using \text{OPERATION} on \text{STREAM}. \text{GRIDBORDER} is interpreted the same as for \text{GRID}.

The following two functions map from the \(X,Y\) coordinates of the source system into the grid \(X,Y\) coordinates:

\[(\text{GRIDXCOORD} \ \text{XCOORD} \ \text{GRIDSPEC})\]  

[Function]

Returns the grid \(X\)-coordinate (in the grid specified by \text{GRIDSPEC}) that contains the source system \(X\)-coordinate \text{XCOORD}.

\[(\text{GRIDYCOORD} \ \text{YCOORD} \ \text{GRIDSPEC})\]  

[Function]

Returns the grid \(Y\)-coordinate (in the grid specified by \text{GRIDSPEC}) that contains the source system \(Y\)-coordinate \text{YCOORD}.

The following two functions map from the grid \(X,Y\) coordinates into the \(X,Y\) coordinates of the source system:

\[(\text{LEFTOFGRIDCOORD} \ \text{GRIDX} \ \text{GRIDSPEC})\]  

[Function]

Returns the source system \(X\)-coordinate of the left edge of a grid rectangle at grid \(X\)-coordinate \text{GRIDX} (in the grid specified by \text{GRIDSPEC}).

\[(\text{BOTTOMOFGRIDCOORD} \ \text{GRIDY} \ \text{GRIDSPEC})\]  

[Function]

Returns the source system \(Y\)-coordinate of the bottom edge of a grid rectangle at grid \(Y\)-coordinate \text{GRIDY} (in the grid specified by \text{GRIDSPEC}).

Display Streams

Display streams (image streams of type \text{DISPLAY}) are used to control graphic output operations to a bitmap, known as the “destination” bitmap of the display stream. For each window on the screen, there is an associated display stream which controls graphics operations to a specific part of the screen bitmap. Any of the functions that take a display stream will also take a window, and use the associated display stream. Display streams can also have a destination bitmap that is not connected to any window or display device.
(DSPCREATE DESTINATION)  [Function]

Creates and returns a display stream. If DESTINATION is specified, it is used as the destination bitmap, otherwise the screen bitmap is used.

(DSPDESTINATION DESTINATION DISPLAYSTREAM)  [Function]

Returns the current destination bitmap for DISPLAYSTREAM, setting it to DESTINATION if non-NIL. DESTINATION can be either the screen bitmap, or an auxiliary bitmap in order to construct figures, possibly save them, and then display them in a single operation.

Warning: The window system maintains the destination of a window’s display stream. Users should be very careful about changing this field.

(DSPXOFFSET XOFFSET DISPLAYSTREAM)  [Function]

(DSPYOFFSET YOFFSET DISPLAYSTREAM)  [Function]

Each display stream has its own coordinate system, separate from the coordinate system of its destination bitmap. Having the coordinate system local to the display stream allows objects to be displayed at different places by translating the display stream’s coordinate system relative to its destination bitmap. This local coordinate system is defined by the X offset and Y offset.

DSPXOFFSET returns the current X offset for DISPLAYSTREAM, the X origin of the display stream’s coordinate system in the destination bitmap’s coordinate system. It is set to XOFFSET if non-NIL.

DSPYOFFSET returns the current Y offset for DISPLAYSTREAM, the Y origin of the display stream’s coordinate system in the destination bitmap’s coordinate system. It is set to YOFFSET if non-NIL.

The X offset and Y offset for a display stream are both initially 0 (no X or Y-coordinate translation).

Warning: The window system maintains the X and Y offset of a window’s display stream. Users should be very careful about changing these fields.

(DSPTEXTURE TEXTURE DISPLAYSTREAM)  [Function]

Returns the current texture used as the background pattern for DISPLAYSTREAM. It is set to TEXTURE if non-NIL. Initially the value of WHITETEXTURE.

(DSPSOURCETYPE SOURCETYPE DISPLAYSTREAM)  [Function]

Returns the current BITBLT sourcetype used when printing characters to the display stream. It is set to SOURCETYPE, if non-NIL. Must be either INPUT or INVERT. Initially INPUT.
(DSPSCROLL SWITCHSETTING DISPLAYSTREAM)  
[Function]

Returns the current value of the "scroll flag," a flag that determines the scrolling behavior of the display stream; either ON or OFF. If ON, the bits in the display stream's destination bitmap are moved after any linefeed that moves the current position out of the destination bitmap. Any bits moved out of the current clipping region are lost. Does not adjust the X offset, Y offset, or clipping region of the display stream. Initially OFF.

Sets the scroll flag to SWITCHSETTING, if non-NIL.

Note: The word "scrolling" also describes the use of "scroll bars" on the left and bottom of a window to move an object displayed in a window.

Each window has an associated display stream. To get the window of a particular display stream, use WFROMDS:

(WFROMDS DISPLAYSTREAM DONTCREATE)  
[Function]

Returns the window associated with DISPLAYSTREAM, creating a window if one does not exist (and DONTCREATE is NIL). Returns NIL if the destination of DISPLAYSTREAM is not a screen bitmap that supports a window system.

If DONTCREATE is non-NIL, WFROMDS will never create a window, and returns NIL if DISPLAYSTREAM does not have an associated window.

TTYDISPLAYSTREAM calls WFROMDS with DONTCREATE = T, so it will not create a window unnecessarily. Also, if WFROMDS does create a window, it calls CREATEW with NOOPENFLG = T.

(DSPBACKUP WIDTH DISPLAYSTREAM)  
[Function]

Backs up DISPLAYSTREAM over a character which is WIDTH screen points wide. DSPBACKUP fills the backed over area with the display stream’s background texture and decreases the X position by WIDTH. If this would put the X position less than DISPLAYSTREAM's left margin, its operation is stopped at the left margin. It returns T if any bits were written, NIL otherwise.

Fonts

A font is the collection of images that are printed or displayed when characters are output to a graphic output device. Some simple displays and printers can only print characters using one font. Bitmap displays and graphic printers can print characters using a large number of fonts.

Fonts are identified by a distinctive style or family (such as Modern or Classic), a size (such as 10 points), and a face (such as bold or italic). Fonts also have a rotation that indicates the orientation of characters on the screen or page. A normal horizontal font (also called a portrait font) has a rotation of 0; the rotation of a vertical (landscape) font is 90 degrees. While any combination can be specified, in
practice the user will find that only certain combinations of families, sizes, faces, and rotations are available for any graphic output device.

To specify a font to the functions described below, a FAMILY is represented by a literal atom, a SIZE by a positive integer, and a FACE by a three-element list of the form (WEIGHT SLOPE EXPANSION). WEIGHT, which indicates the thickness of the characters, can be BOLD, MEDIUM, or LIGHT; SLOPE can be ITALIC or REGULAR; and EXPANSION can be REGULAR, COMPRESSED, or EXPANDED, indicating how spread out the characters are. For convenience, faces may also be specified by three-character atoms, where each character is the first letter of the corresponding field. Thus, MRR is a synonym for (MEDIUM REGULAR REGULAR). In addition, certain common face combinations may be indicated by special literal atoms:

- STANDARD = (MEDIUM REGULAR REGULAR) = MRR
- ITALIC = (MEDIUM ITALIC REGULAR) = MIR
- BOLD = (BOLD REGULAR REGULAR) = BRR
- BOLDITALIC = (BOLD ITALIC REGULAR) = BIR

Interlisp represents all the information related to a font in an object called a font descriptor. Font descriptors contain the family, size, etc. properties used to represent the font. In addition, for each character in the font, the font descriptor contains width information for the character and (for display fonts) a bitmap containing the picture of the character.

The font functions can take fonts specified in a variety of different ways. DSPFONT, FONTCREATE, FONTCOPY, etc. can be applied to font descriptors, "font lists" such as '(MODERN 10), image streams (coerced to its current font), or windows (coerced to the current font of its display stream). The printout command ".FONT" will also accept fonts specified in any of these forms.

In general font files use the following format:

The family name (e.g., Modern); a two digit size (e.g., 08); a three letter Face (e.g., BIR, for Bold Italic Regular); the letter C followed by the font’s character set in base 8 (e.g., C41); and finally an extension (e.g., Displayfont).
(FONTCREATE FAMILY SIZE FACE ROTATION DEVICE NOERRORFLG CHARSET)

[Function]

Returns a font descriptor for the specified font. FAMILY is a litatom specifying the font family. SIZE is an integer indicating the size of the font in points. FACE specifies the face characteristics in one of the formats listed above; if FACE is NIL, STANDARD is used. ROTATION, which specifies the orientation of the font, is 0 (or NIL) for a portrait font and 90 for a landscape font. DEVICE indicates the output device for the font, and can be any image stream type, such as DISPLAY, INTERPRESS, etc. DEVICE may also be an image stream, in which case the type of the stream determines the font device. DEVICE defaults to DISPLAY.

The FAMILY argument to FONTCREATE may also be a list, in which case it is interpreted as a font-specification quintuple, a list of the form (FAMILY SIZE FACE ROTATION DEVICE). Thus, (FONTCREATE '(GACHA 10 BOLD)) is equivalent to (FONTCREATE 'GACHA 10 'BOLD). FAMILY may also be a font descriptor, in which case that descriptor is simply returned.

If a font descriptor has already been created for the specified font, FONTCREATE simply returns it. If it has not been created, FONTCREATE has to read the font information from a font file that contains the information for that font. The name of an appropriate font file, and the algorithm for searching depends on the device that the font is for, and is described in more detail below. If an appropriate font file is found, it is read into a font descriptor. If no file is found, for DISPLAY fonts FONTCREATE looks for fonts with less face information and fakes the remaining faces (such as by doubling the bit pattern of each character or slanting it). For hardcopy printer fonts, there is no acceptable faking algorithm.

If no acceptable font is found, the action of FONTCREATE is determined by NOERRORFLG. If NOERRORFLG is NIL, it generates a FONT NOT FOUND error with the offending font specification; otherwise, FONTCREATE returns NIL.

CHARSET is the character set which will be read to create the font. Defaults to 0. For more information on character sets, see NS Characters.

(FONTP X)

[Function]

Returns X if X is a font descriptor; NIL otherwise.

(FONTPROP FONT PROP)

[Function]

Returns the value of the PROP property of font FONT. The following font properties are recognized:

FAMILY The style of the font, represented as a literal atom, such as CLASSIC or MODERN.

SIZE A positive integer giving the size of the font, in printer’s points (1/72 of an inch).
WEIGHT  The thickness of the characters; one of BOLD, MEDIUM, or LIGHT.

SLOPE  The "slope" of the characters in the font; one of ITALIC or REGULAR.

EXPANSION  The extent to which the characters in the font are spread out; one of REGULAR, COMPRESSED, or EXPANDED. Most available fonts have EXPANSION = REGULAR.

FACE  A three-element list of the form (WEIGHT SLOPE EXPANSION), giving all of the typeface parameters.

ROTATION  An integer that gives the orientation of the font characters on the screen or page, in degrees. A normal horizontal font (also called a portrait font) has a rotation of 0; the rotation of a vertical (landscape) font is 90.

DEVICE  The device that the font can be printed on; one of DISPLAY, INTERPRESS, etc.

ASCENT  An integer giving the maximum height of any character in the font from its base line (the printing position). The top line will be at BASELINE + ASCENT - 1.

DESCENT  An integer giving the maximum extent of any character below the base line, such as the lower part of a "p". The bottom line of a character will be at BASELINE - DESCENT.

HEIGHT  Equal to ASCENT + DESCENT.

SPEC  The (FAMILY SIZE FACE ROTATION DEVICE) quintuple by which the font is known to Lisp.

DEVICESPEC  The (FAMILY SIZE FACE ROTATION DEVICE) quintuple that identifies what will be used to represent the font on the display or printer. It will differ from the SPEC property only if an implicit coercion is done to approximate the specified font with one that actually exists on the device.

SCALE  The units per printer’s point (1/72 of an inch) in which the font is measured. For example, this is 35.27778 (the number of micas per printer’s point) for Interpress fonts, which are measured in terms of micas.

(FONTCOPY OLDFONT PROP1 VAL1 PROP2 VAL2 ...)  [NoSpread Function]

Returns a font descriptor that is a copy of the font OLDFONT, but which differs from OLDFONT in that OLDFONT's properties are replaced by the specified properties and values. Thus, (FONTCOPY FONT 'WEIGHT 'BOLD 'DEVICE 'INTERPRESS) will return a bold Interpress font with all other properties the same as those of FONT. FONDCOPY accepts the properties FAMILY, SIZE, WEIGHT, SLOPE, EXPANSION, FACE, ROTATION, and DEVICE. If the first property is a list, it is taken to be the PROP1 VAL1 PROP2 VAL2 ... sequence. Thus, (FONTCOPY FONT '((WEIGHT BOLD DEVICE INTERPRESS)) is equivalent to the example above.
If the property NOERROR is specified with value non-NIL, FONTCOPY will return NIL rather than causing an error if the specified font cannot be created.

(FONTSAVAILABLE FAMILY SIZE FACE ROTATION DEVICE CHECKFILESTOO?) [Function]

Returns a list of available fonts that match the given specification. FAMILY, SIZE, FACE, ROTATION, and DEVICE are the same as for FONTCREATE. Additionally, any of them can be the atom *, in which case all values of that field are matched.

If CHECKFILESTOO? is NIL, only fonts already loaded into virtual memory will be considered. If CHECKFILESTOO? is non-NIL, the font directories for the specified device will be searched. When checking font files, the ROTATION is ignored.

Note: The search is conditional on the status of the server which holds the font. Thus a file server crash may prevent FONTCREATE from finding a file that an earlier FONTSAVAILABLE returned.

Each element of the list returned will be of the form (FAMILY SIZE FACE ROTATION DEVICE).

Examples:

(FONTSAVAILABLE 'MODERN 10 'MRR 0 'DISPLAY)

will return ((MODERN 10 (MEDIUM REGULAR REGULAR) 0 DISPLAY)) if the regular Modern 10 font for the display is in virtual memory; NIL otherwise.

(FONTSAVAILABLE '* 14 '* '* 'INTERPRESS T)

will return a list of all the size 14 Interpress fonts, whether they are in virtual memory or in font files.

(SETFONTDESCRIPTOR FAMILY SIZE FACE ROTATION DEVICE FONT) [Function]

Indicates to the system that FONT is the font that should be associated with the FAMILY SIZE FACE ROTATION DEVICE characteristics. If FONT is NIL, the font associated with these characteristics is cleared and will be recreated the next time it is needed. As with FONTPROP and FONTCOPY, FONT is coerced to a font descriptor if it is not one already.

This function is useful when it is desirable to simulate an unavailable font or to use a font with characteristics different from the interpretations provided by the system.

(DEFAULTFONT DEVICE FONT —) [Function]

Returns the font that would be used as the default (if NIL were specified as a font argument) for image stream type DEVICE. If FONT is a font descriptor, it is set to be the default font for DEVICE.
(CHARWIDTH CHARCODE FONT)  [Function]
CHARCODE is an integer that represents a valid character (as returned by CHCON1).
Returns the amount by which an image stream’s X-position will be incremented when
the character is printed.

(CHARWIDTHY CHARCODE FONT)  [Function]
Like CHARWIDTH, but returns the Y component of the character’s width, the amount by
which an image stream’s Y-position will be incremented when the character is printed.
This will be zero for most characters in normal portrait fonts, but may be non-zero for
landscape fonts or for vector-drawing fonts.

(STRINGWIDTH STR FONT FLG RDTBL)  [Function]
Returns the amount by which a stream’s X-position will be incremented if the printname
for the Interlisp-D object STR is printed in font FONT. If FONT is NIL, DEFAULTFONT is
used as FONT. If FONT is an image stream, its font is used. If FLG is non-NIL, the PRIN2-
pname of STR with respect to the readtable RDTBL is used.

(STRINGREGION STR STREAM PRIN2FLG RDTBL)  [Function]
Returns the region occupied by STR if it were printed at the current location in the image
stream STREAM. This is useful, for example, for determining where text is in a window to
allow the user to select it. The arguments PRIN2FLG and RDTBL are passed to
STRINGWIDTH.
Note: STRINGREGION does not take into account any carriage returns in the
string, or carriage returns that may be automatically printed if STR is
printed to STREAM. Therefore, the value returned is meaningless for multi-
line strings.

The following functions allow the user to access and change the bitmaps for individual characters in a
display font. Note: Character code 256 can be used to access the “dummy” character, used for
characters in the font with no bitmap defined.

(GETCHARBITMAP CHARCODE FONT)  [Function]
Returns a bitmap containing a copy of the image of the character CHARCODE in the font
FONT.

(PUTCHARBITMAP CHARCODE FONT NEWCHARBITMAP NEWCHARDESCENT)  [Function]
Changes the bitmap image of the character CHARCODE in the font FONT to the bitmap
NEWCHARBITMAP. If NEWCHARDESCENT is non-NIL, the descent of the character is
changed to the value of NEWCHARDESCENT.
(EDITCHAR CHARCODE FONT) [Function]

Calls the bitmap editor (EDITBM) on the bitmap image of the character CHARCODE in the font FONT. CHARCODE can be a character code (as returned by CHCON1) or an atom or string, in which case the first character of CHARCODE is used.

(WRITESTRIKEFONTFILE FONT CHARSET FILENAME) [Function]

Takes a display font font descriptor and a character set number, and writes that character set into a file suitable for reading in again. Note that the font descriptor’s current state is used (which was perhaps modified by INSPECTing the datum), so this provides a mechanism for creating/modifying new fonts.

For example:

(WRITESTRIKEFONTFILE (FONTCREATE ‘GACHA 10) 0 ‘{DSK}Magic10-MRR-C0.DISPLAYFONT)

If your DISPLAYFONTDIRECTORIES includes {DSK}, then a subsequent (FONTCREATE ‘MAGIC 10) will create a new font descriptor whose appearance is the same as the old Gacha font descriptor.

However, the new font is identical to the old one in appearance only. The individual datatype fields and bitmap may not be the same as those in the old font descriptor, due to peculiarities of different font file formats.

Font Files and Font Directories

If FONTCREATE is called to create a font that has not been loaded into Interlisp, FONTCREATE has to read the font information from a font file that contains the information for that font. For printer devices, the font files have to contain width information for each character in the font. For display fonts, the font files have to contain, in addition, bitmap images for each character in the fonts. The font file names, formats, and searching algorithms are different for each device. There are a set of variables for each device, that determine the directories that are searched for font files. All of these variables must be set before Interlisp can auto-load font files. These variables should be initialized in the site-specific INIT file.

DISPLAYFONTDIRECTORIES [Variable]

Value is a list of directories searched to find font bitmap files for display fonts.

DISPLAYFONTEXTENSIONS [Variable]

Value is a list of file extensions used when searching DISPLAYFONTDIRECTORIES for display fonts. Initially set to (DISPLAYFONT), but when using older font files it may be necessary to add STRIKE and AC to this list.
INTERPRESSFONTDIRECTORIES [Variable]

Value is a list of directories searched to find font widths files for Interpress fonts.

PRESSFONTWIDTHSFILES [Variable]

Value is a list of files (not directories) searched to find font widths files for Press fonts.
Press font widths are packed into large files (usually named FONTS.WIDTHS).

Font Profiles

PRETTYPRINT contains a facility for printing different elements (user functions, system functions, clisp words, comments, etc.) in different fonts to emphasize (or deemphasize) their importance, and in general to provide for a more pleasing appearance. Of course, in order to be useful, this facility requires that the user is printing on a device (such as a bitmapped display or a laser printer) which supports multiple fonts.

PRETTYPRINT signals font changes by inserting into the file a user-defined escape sequence (the value of the variable FONTESCAPECHAR) followed by the character code which specifies, by number, which font to use, i.e. ↑A for font number 1, etc. Thus, if FONTESCAPECHAR were the character ↑F, ↑F↑C would be output to change to font 3, ↑F↑A to change to font 1, etc. If FONTESCAPECHAR consists of characters which are separator characters in FILERDTBL, then a file with font changes in it can also be loaded back in.

Currently, PRETTYPRINT uses the following font classes. The user can specify separate fonts for each of these classes, or use the same font for several different classes.

- **LAMBDAFONT** The font for printing the name of the function being prettyprinted, before the actual definition (usually a large font).
- **CLISPFONT** If CLISPFLG is on, the font for printing any clisp words, i.e. atoms with property CLISPWORD.
- **COMMENTFONT** The font used for comments.
- **USERFONT** The font for the name of any function in the file, or any member of the list FONTFNS.
- **SYSTEMFONT** The font for any other (defined) function.
- **CHANGEFONT** The font for an expression marked by the editor as having been changed.
- **PRETTYCOMFONT** The font for the operand of a file package command.
- **DEFAULTFONT** The font for everything else.

Note that not all combinations of fonts will be aesthetically pleasing (or even readable!) and the user may have to experiment to find a compatible set.
Although in some implementations LAMBDAFONT et al. may be defined as variables, one should not set them directly, but should indicate what font is to be used for each class by calling the function FONTPROFILE:

\[
(\text{FONTPROFILE PROFILE}) \quad \text{[Function]}
\]

Sets up the font classes as determined by PROFILE, a list of elements which defines the correspondence between font classes and specific fonts. Each element of PROFILE is a list of the form:

\[
(\text{FONTCLASS FONT# DISPLAYFONT PRESSFONT INTERPRESSFONT})
\]

FONTCLASS is the font class name and FONT# is the font number for that class. For each font class name, the escape sequence will consist of FONTEscapeCHAR followed by the character code for the font number, e.g. ↑A for font number 1, etc.

If FONT# is NIL for any font class, the font class named DEFAULTFONT (which must always be specified) is used. Alternatively, if FONT# is the name of a previously defined font class, this font class will be equivalenced to the previously defined one.

DISPLAYFONT, PRESSFONT, and INTERPRESSFONT are font specifications (of the form accepted by FONTCREATE) for the fonts to use when printing to the display and to Press and Interpress printers respectively.

FONTPROFILE \quad \text{[Variable]}

This is the variable used to store the current font profile, in the form accepted by the function FONTPROFILE. Note that simply editing this value will not change the fonts used for the various font classes; it is necessary to execute (FONTPROFILE FONTPROFILE) to install the value of this variable.

The process of printing with multiple fonts is affected by a large number of variables: FONTPROFILE, FILELINELENGTH, PRETTYLCOM, etc. To facilitate switching back and forth between various sets of values for the font variables, Interlisp supports the idea of named "font configurations" encapsulating the values of all relevant variables.

To create a new font configuration, set all "relevant" variables to the values you want, and then call FONTNAME to save them (on the variable FONTDEFS) under a given name. To install a particular font configuration, call FONTSET giving it your name. To change the values in a saved font configuration, edit the value of the variable FONTDEFS.

Note: The list of variables saved by FONTNAME is stored in the variable FONTDEFSVARS. This can be changed by the user.
(FONTSET NAME)  [Function]

Installs font configuration for NAME. Also evaluates (FONTPROFILE FONTPROFILE) to install the font classes as specified in the new value of the variable FONTPROFILE. Generates an error if NAME not previously defined.

FONTDEFSVARS  [Variable]

The list of variables to be packaged by a FONTNAME. Initially FONTCHANGEFLG, FILELINELENGTH, COMMENTLINELENGTH, FIRSTCOL, PRETTYLCON, LISTFILESTR, and FONTPROFILE.

FONTDEFS  [Variable]

An association list of font configurations. FONTDEFS is a list of elements of form (NAME . PARAMETER-PAIRS). To save a configuration on a file after performing a FONTNAME to define it, the user could either save the entire value of FONTDEFS, or use the ALISTS file package command to dump out just the one configuration.

FONTESCAPECHAR  [Variable]

The character or string used to signal the start of a font escape sequence.

FONTCHANGEFLG  [Variable]

If T, enables fonts when prettyprinting. If NIL, disables fonts. ALL indicates that all calls to CHANGEFONT are executed.

LISTFILESTR  [Variable]

In Interlisp-10, passed to the operating system by LISTFILES. Can be used to specify subcommands to the LIST command, e.g. to establish correspondence between font number and font name.

COMMENTLINELENGTH  [Variable]

Since comments are usually printed in a smaller font, COMMENTLINELENGTH is provided to offset the fact that Interlisp does not know about font widths. When FONTCHANGEFLG = T, CAR of COMMENTLINELENGTH is the linelength used to print short comments, i.e. those printed in the right margin, and CDR is the linelength used when printing full width comments.

(CHANGEFONT FONT STREAM)  [Function]

Executes the operations on STREAM to change to the font FONT. For use in PRETTYPRINTMACROS.
Image Objects

An Image Object is an object that includes information about an image, such as how to display it, how to print it, and how to manipulate it when it is included in a collection of images (such as a document). More generally, it enables you to include one kind of image, with its own semantics, layout rules, and editing paradigms, inside another kind of image. Image Objects provide a general-purpose interface between image users who want to manipulate arbitrary images, and image producers, who create images for use, say, in documents.

Images are encapsulated inside a uniform barrier—the IMAGEOBJ data type. From the outside, you communicate to the image by calling a standard set of functions. For example, calling one function tells you how big the image is; calling another causes the image object to be displayed where you tell it, and so on. Anyone who wants to create images for general use can implement his own brand of IMAGEOBJ. IMAGEOBJs have been implemented (in library packages) for bitmaps, menus, annotations, graphs, and sketches.

Image Objects were originally implemented to support inserting images into TEdit text files, but the facility is available for use by any tools that manipulate images. The Image Object interface allows objects to exist in TEdit documents and be edited with their own editor. It also provides a facility in which objects can be shift-selected (or "copy-selected") between TEdit and non-TEdit windows. For example, the Image Objects interface allows you to copy-select graphs from a Grapher window into a TEdit window. The source window (where the object comes from) does not have to know what sort of window the destination window (where the object is inserted) is, and the destination does not have to know where the insertion comes from.

A new data type, IMAGEOBJ, contains the data and the procedures necessary to manipulate an object that is to be manipulated in this way. IMAGEOBJs are created with the function IMAGEOBJCREATE (below).

Another new data type, IMAGEFNS, is a vector of the procedures necessary to define the behavior of a type of IMAGEOBJ. Grouping the operations in a separate data type allows multiple instances of the same type of image object to share procedure vectors. The data and procedure fields of an IMAGEOBJ have a uniform interface through the function IMAGEOBJPROP. IMAGEFNS are created with the function IMAGEFNSCREATE:

(IMAGEFNSCREATE DISPLAYFN IMAGEBOXFN PUTFN GETFN COPYFN BUTTONEVENTINFN COPYBUTTONEVENTINFN WHENMOVEDFN WHENINSERTEDFN WHENDELETEDFN WHENCOPIEDFN WHENOPERATEDONFN PREPRINTFN — [Function])

Returns an IMAGEFNS object that contains the functions necessary to define the behavior of an IMAGEOBJ.

The arguments DISPLAYFN through PREPRINTFN should all be function names to be stored as the "methods" of the IMAGEFNS. The purpose of each IMAGEFNS method is described below.
Note: Image objects must be "registered" before they can be read by TEdit or HREAD. IMAGEFNSCREATE implicitly registers its GETFN argument.

\[\text{IMAGEOBJCREATE OBJECTDATUM IMAGEFNS} \]  
\[\text{[Function]}\]  
Returns an IMAGEOBJ that contains the object datum OBJECTDATUM and the operations vector IMAGEFNS. OBJECTDATUM can be arbitrary data.

\[\text{IMAGEOBJPROP IMAGEOBJECTOR PROPERTY NEWVALUE} \]  
\[\text{[NoSpread Function]}\]  
Accesses and sets the properties of an IMAGEOBJ. Returns the current value of the PROPERTY property of the image object IMAGEOBJECT. If NEWVALUE is given, the property is set to it.

IMAGEOBJPROP can be used on the system properties OBJECTDATUM, DISPLAYFN, IMAGEBOXFN, PUTFN, GETFN, COPYFN, BUTTONEVENTINFN, COPYBUTTONEVENTINFN, WHENOPERATEDONFN, and PREPRINTFN. Additionally, it can be used to save arbitrary properties on an IMAGEOBJ.

\[\text{IMAGEFNSP X} \]  
\[\text{[Function]}\]  
Returns X if X is an IMAGEFNS object, NIL otherwise.

\[\text{IMAGEOBJP X} \]  
\[\text{[Function]}\]  
Returns X if X is an IMAGEOBJ object, NIL otherwise.

**IMAGEFNS Methods**

Note: Many of the IMAGEFNS methods below are passed "host stream" arguments. The TEdit text editor passes the "text stream" (an object contain all of the information in the document being edited) as the "host stream" argument. Other editing programs that want to use image objects may want to pass the data structure being edited to the IMAGEFNS methods as the "host stream" argument.

\[\text{DISPLAYFN IMAGEOBJ IMAGESTREAM IMAGESTREAMTYPE HOSTSTREAM} \]  
\[\text{[IMAGEFNS Method]}\]  
The DISPLAYFN method is called to display the object IMAGEOBJ at the current position on IMAGESTREAM. The type of IMAGESTREAM indicates whether the device is the display or some other image stream.

Note: When the DISPLAYFN method is called, the offset and clipping regions for the stream are set so the object’s image is at \((0,0)\), and only that image area can be modified.

\[\text{IMAGEBOXFN IMAGEOBJ IMAGESTREAM CURRENTX RIGHTMARGIN} \]  
\[\text{[IMAGEFNS Method]}\]  
The IMAGEBOXFN method should return the size of the object as an IMAGEBOX, which is a data structure that describes the image laid down when an IMAGEOBJ is displayed in terms of width, height, and descender height. An IMAGEBOX has four fields: XSIZE,
YSIZE, YDESC, and XKERN. XSIZE and YSIZE are the width and height of the object image. YDESC and XKERN give the position of the baseline and the left edge of the image relative to where you want to position it. For characters, the YDESC is the descent (height of the descender) and the XKERN is the amount of left kerning (note: TEdit doesn’t support left kerning).

The IMAGEBOXFN looks at the type of the stream to determine the output device if the object’s size changes from device to device. (For example, a bit-map object may specify a scale factor that is ignored when the bit map is displayed on the screen.) CURRENTX and RIGHTMARGIN allow an object to take account of its environment when deciding how big it is. If these fields are not available, they are NIL.

Note: TEdit calls the IMAGEBOXFN only during line formatting, then caches the IMAGEBOX as the BOUNDBOX property of the IMAGEOBJ. This avoids the need to call the IMAGEBOXFN when incomplete position and margin information is available.

(PUTFN IMAGEOBJ FILESTREAM) [IMAGEFNS Method]

The PUTFN method is called to save the object on a file. It prints a description on FILESTREAM that, when read by the corresponding GETFN method (see below), regenerates the image object. (TEdit and HPRINT take care of writing out the name of the GETFN.)

(GETFN FILESTREAM) [IMAGEFNS Method]

The GETFN method is called when the object is encountered on the file during input. It reads the description that was written by the PUTFN method and returns an IMAGEOBJ.

(COPYFN IMAGEOBJ SOURCEHOSTSTREAM TARGETHOSTSTREAM) [IMAGEFNS Method]

The COPYFN method is called during a copy-select operation. It should return a copy of IMAGEOBJ. If it returns the litatom DON’T, copying is suppressed.

(BUTTONEVENTINFN IMAGEOBJ WINDOWSTREAM SELECTION RELX RELY WINDOW HOSTSTREAM BUTTON) [IMAGEFNS Method]

The BUTTONEVENTINFN method is called when you press a mouse button inside the object. The BUTTONEVENTINFN decides whether or not to handle the button, to track the cursor in parallel with mouse movement, and to invoke selections or edits supported by the object (but see the COPYBUTTONEVENTINFN method below). If the BUTTONEVENTINFN returns NIL, TEdit treats the button press as a selection at its level. Note that when this function is first called, a button is down. The BUTTONEVENTINFN should also support the button-down protocol to descend inside of any composite objects with in it. In most cases, the BUTTONEVENTINFN relinquishes control (i.e., returns) when the cursor leaves its object’s region.
When the BUTTONEVENTINFN is called, the window’s clipping region and offsets have been changed so that the lower-left corner of the object’s image is at \((0, 0)\), and only the object’s image can be changed. The selection is available for changing to fit your needs; the mouse button went down at \((\text{RELX}, \text{RELY})\) within the object’s image. You can affect how TEdit treats the selection by returning one of several values. If you return NIL, TEdit forgets that you selected an object; if you return the atom DON’T, TEdit doesn’t permit the selection; if you return the atom CHANGED, TEdit updates the screen. Use CHANGED to signal TEdit that the object has changed size or will have side effects on other parts of the screen image.

\[
\text{(COPYBUTTONEVENTINFN \text{IMAGEOBJ \text{WINDOWSTREAM}) \quad \text{[IMAGEFNS Method]}}}
\]

The COPYBUTTONEVENTINFN method is called when you button inside an object while holding down a copy key. Many of the comments about BUTTONEVENTINFN apply here too. Also, see the discussion below about copying image objects between windows.

\[
\text{(WHENMOVEDFN \text{IMAGEOBJ \text{TARGETWINDOWSTREAM \text{SOURCEHOSTSTREAM \text{TARGETHOSTSTREAM}) \quad \text{[IMAGEFNS Method]}}}}}
\]

The WHENMOVEDFN method provides hooks by which the object is notified when TEdit performs an operation (MOVEing) on the whole object. It allows objects to have side effects.

\[
\text{(WHENINSERTEDFN \text{IMAGEOBJ \text{TARGETWINDOWSTREAM \text{SOURCEHOSTSTREAM \text{TARGETHOSTSTREAM}) \quad \text{[IMAGEFNS Method]}}}}}
\]

The WHENINSERTEDFN method provides hooks by which the object is notified when TEdit performs an operation (INSERTing) on the whole object. It allows objects to have side effects.

\[
\text{(WHENDELETEDFN \text{IMAGEOBJ \text{TARGETWINDOWSTREAM}) \quad \text{[IMAGEFNS Method]}}}
\]

The WHENDELETEDFN method provides hooks by which the object is notified when TEdit performs an operation (DELETEing) on the whole object. It allows objects to have side effects.

\[
\text{(WHENCOPIEDFN \text{IMAGEOBJ \text{TARGETWINDOWSTREAM \text{SOURCEHOSTSTREAM \text{TARGETHOSTSTREAM}) \quad \text{[IMAGEFNS Method]}}}}}
\]

The WHENCOPIEDFN method provides hooks by which the object is notified when TEdit performs an operation (COPYing) on the whole object. The WHENCOPIEDFN method is called in addition to (and after) the COPYFN method above. It allows objects to have side effects.

\[
\text{(WHENOPERATEDONFN \text{IMAGEOBJ \text{WINDOWSTREAM \text{HOWOPERATEDON \text{SELECTION \text{HOSTSTREAM}) \quad \text{[IMAGEFNS Method]}}}}}}
\]

The WHENOPERATEDONFN method provides a hook for edit operations. HOWOPERATEDON should be one of SELECTED, DESELECTED, HIGHLIGHTED, and UNHIGHLIGHTED. The WHENOPERATEDONFN differs from the BUTTONEVENTINFN because it is called when you extend a selection through the object. That is, the object is
treated in toto as a TEdit character. HIGHLIGHTED refers to the selection being highlighted on the screen, and UNHIGHLIGHTED means that the highlighting is being turned off.

\begin{verbatim}
(PREPRINTFN IMAGEOBJ) [IMAGEFNS Method]
\end{verbatim}

The PREPRINTFN method is called to convert the object into something that can be printed for inclusion in documents. It returns an object that the receiving window can print (using either PRIN1 or PRIN2, its choice) to obtain a character representation of the object. If the PREPRINTFN method is NIL, the OBJECTDATUM field of IMAGEOBJ itself is used. TEdit uses this function when you indicate that you want to print the characters from an object rather than the object itself (presumably using PRIN1 case).

### Registering Image Objects

Each legitimate GETFN needs to be known to the system, to prevent various Trojan-horse problems and to allow the automatic loading of the supporting code for infrequently used IMAGEOBJs. To this end, there is a global list, IMAGEOBJGETFNS, that contains an entry for each GETFN. The existence of the entry marks the GETFN as legitimate; the entry itself is a property list, which can hold information about the GETFN.

No action needs to be taken for GETFNs that are currently in use: the function IMAGEFNSCREATE automatically adds its GETFN argument to the list. However, packages that support obsolete versions of objects may need to explicitly add the obsolete GETFNs. For example, TEdit supports bit-map IMAGEOBJs. Recently, a change was made in the format in which objects are stored; to retain compatibility with the old object format, there are now two GETFNs. The current GETFN is automatically on the list, courtesy of IMAGEFNSCREATE. However, the code file that supports the old bit-map objects contains the clause: \begin{verbatim}
(ADDVARS (IMAGEOBJGETFNS (OLDGETFNNAME)))
\end{verbatim}, which adds the old GETFN to IMAGEOBJGETFNS.

For a given GETFN, the entry on IMAGEOBJGETFNS may be a property list of information. Currently the only recognized property is FILE.

FILE is the name of the file that can be loaded if the GETFN isn’t defined. This file should define the GETFN, along with all the other functions needed to support that kind of IMAGEOBJ.

For example, the bit-map IMAGEOBJ implemented by TEdit use the GETFN BMajan.GETFN2. Its entry on IMAGEOBJGETFNS is \begin{verbatim}
(BMOBJ.GETFN2 FILE IMAGEOBJ)
\end{verbatim}, indicating that the support code for bit-map image objects resides on the file IMAGEOBJ, and that the GETFN for them is BMOBJ.GETFN2.

This makes it possible to have entries for GETFNs whose supporting code isn’t loaded—you might, for instance, have your init file add entries to IMAGEOBJGETFNS for the kinds of image objects you
commonly use. The system’s default reading method will automatically load the code when necessary.

Reading and Writing Image Objects on Files

Image Objects can be written out to files using HPRINT and read back using HREAD. The following functions can also be used:

(WRITEIMAGEOBJ IMAGEOBJ STREAM) [Function]
Prints (using PRIN2) a call to READIMAGEOBJ, then calls the PUTFN for IMAGEOBJ to write it onto STREAM. During input, then, the call to READIMAGEOBJ is read and evaluated; it in turn reads back the object’s description, using the appropriate GETFN.

(READIMAGEOBJ STREAM GETFN NOERROR) [Function]
Reads an IMAGEOBJ from STREAM, starting at the current file position. Uses the function GETFN after validating it (and loading support code, if necessary).

If the GETFN can’t be validated or isn’t defined, READIMAGEOBJ returns an "encapsulated image object", an IMAGEOBJ that safely encapsulates all of the information in the image object. An encapsulated image object displays as a rectangle that says, "Unknown IMAGEOBJ Type" and lists the GETFN’s name. Selecting an encapsulated image object with the mouse causes another attempt to read the object from the file; this is so you can load any necessary support code and then get to the object.

Warning: You cannot save an encapsulated image object on a file because there isn’t enough information to allow copying the description to the new file from the old one.

If NOERROR is non-NIL, READIMAGEOBJ returns NIL if it can’t successfully read the object.
Copying Image Objects Between Windows

Copying between windows is implemented as follows: If a button event occurs in a window when a copy key is down, the window’s COPYBUTTONEVENTFN window property is called. If this window supports copy-selection, it should track the mouse, indicating the item to be copied. When the button is released, the COPYBUTTONEVENTFN should create an image object out of the selected information, and call COPYINSERT to insert it in the current TTY window. COPYINSERT calls the COPYINSERTFN window property of the TTY window to insert this image object. Therefore, both the source and destination windows can determine how they handle copying image objects.

If the COPYBUTTONEVENTFN of a window is NIL, the BUTTONEVENTFN is called instead when a button event occurs in the window when a copy key is down, and copying from that window is not supported. If the COPYINSERTFN of the TTY window is NIL, COPYINSERT will turn the image object into a string (by calling the PREPRINTFN method of the image object) and insert it by calling BKSYSBUF.

COPYBUTTONEVENTFN [Window Property]
The COPYBUTTONEVENTFN of a window is called (if it exists) when a button event occurs in the window and a copy key is down. If no COPYBUTTONEVENTFN exists, the BUTTONEVENTFN is called.

COPYINSERTFN [Window Property]
The COPYINSERTFN of the "destination" window is called by COPYINSERT to insert something into the destination window. It is called with two arguments: the object to be inserted and the destination window. The object to be inserted can be a character string, an IMAGEOBJ, or a list of IMAGEOBJs and character strings. As a convention, the COPYINSERTFN should call BKSYSBUF if the object to be inserted insert is a character string.

COPYINSERT IMAGEOBJ [Function]
COPYINSERT inserts IMAGEOBJ into the window that currently has the TTY. If the current TTY window has a COPYINSERTFN, it is called, passing it IMAGEOBJ and the window as arguments.

If no COPYINSERTFN exists and if IMAGEOBJ is an image object, BKSYSBUF is called on the result of calling its PREPRINTFN on it. If IMAGEOBJ is not an image object, it is simply passed to BKSYSBUF. In this case, BKSYSBUF will call PRIN2 with a read table taken from the process associated with the TTY window. A window that wishes to use PRIN1 or a different read table must provide its own COPYINSERTFN to do this.
Implementation of Image Streams

Interlisp does all image creation through a set of functions and data structures for device-independent graphics, known popularly as DIG. DIG is implemented through the use of a special type of stream, known as an image stream.

An image stream, by convention, is any stream that has its IMAGEOPS field (described in detail below) set to a vector of meaningful graphical operations. Using image streams, you can write programs that draw and print on an output stream without regard to the underlying device, be it a window, a disk, or a printer.

To define a new image stream type, it is necessary to put information on the variable IMAGESTREAMTYPES:

\[
\text{IMAGESTREAMTYPES} \quad \text{[Variable]}
\]

This variable describes how to create a stream for a given image stream type. The value of IMAGESTREAMTYPES is an association list, indexed by the image stream type (e.g., DISPLAY, INTERPRESS, etc.). The format of a single association list item is:

\[
\text{(IMAGETYPE } \quad \text{(OPENSTREAM } \quad \text{OPENSTREAMFN)}) \quad \text{(FONTCREATE } \quad \text{FONTCREATEFN)}) \quad \text{(FONTAVAILABLE } \quad \text{FONTAVAILABLEFN)})
\]

OPENSTREAMFN, FONTCREATEFN, and FONTAVAILABLEFN are "image stream methods," device-dependent functions used to implement generic image stream operations. For Interpress image streams, the association list entry is:

\[
\text{(INTERPRESS } \quad \text{(OPENSTREAM } \quad \text{OPENIPSTREAM)}) \quad \text{(FONTCREATE } \quad \text{\CREATEINTERPRESSFONT)}) \quad \text{(FONTAVAILABLE } \quad \text{\SEARCHINTERPRESSFONTS)})
\]

\[
\text{(OPENSTREAMFN } \quad \text{FILE OPTIONS) } \quad \text{[Image Stream Method]}
\]

FILE is the file name as it was passed to OPENIMAGESTREAM, and OPTIONS is the OPTIONS property list passed to OPENIMAGESTREAM. The result must be a stream of the appropriate image type.

\[
\text{(FONTCREATEFN } \quad \text{FAMILY SIZE FACE ROTATION DEVICE) } \quad \text{[Image Stream Method]}
\]

FAMILY is the family name for the font, e.g., MODERN. SIZE is the body size of the font, in printer’s points. FACE is a three-element list describing the weight, slope, and expansion of the face desired, e.g., (MEDIUM ITALIC EXPANDED). ROTATION is how much the font is to be rotated from the normal orientation, in minutes of arc. For example, to print a landscape page, fonts have the rotation 5400 (90 degrees). The function’s result must be a FONTDESCRIPTOR with the fields filled in appropriately.
This function returns a list of all fonts agreeing with the FAMILY, SIZE, FACE, and ROTATION arguments; any of them may be wild-carded (i.e., equal to *, which means any value is acceptable). Each element of the list should be a quintuple of the form (FAMILY SIZE FACE ROTATION DEVICE).

Where the function looks is an implementation decision: the FONTAVAILABLEFN for the display device looks at DISPLAYFONTDIRECTORIES, the Interpress code looks on INTERPRESSFONTDIRECTORIES, and implementors of new devices should feel free to introduce new search path variables.

As indicated above, image streams use a field that no other stream uses: IMAGEOPS. IMAGEOPS is an instance of the IMAGEOPS data type and contains a vector of the stream’s graphical methods. The methods contained in the IMAGEOPS object can make arbitrary use of the stream’s IMAGEDATA field, which is provided for their use, and may contain any data needed.

IMAGETYPE [IMAGEOPS Field]
Value is the name of an image type. Monochrome display streams have an IMAGETYPE of DISPLAY; color display streams are identified as (COLOR DISPLAY). The IMAGETYPE field is informational and can be set to anything you choose.

IMFONTCREATE [IMAGEOPS Field]
Value is the device name to pass to FONTCREATE when fonts are created for the stream.

The remaining fields are all image stream methods, whose value should be a device-dependent function that implements the generic operation. Most methods are called by a similarly-named function, e.g. the function DRAWLINE calls the IMDRAWLINE method. All coordinates that refer to points in a display device’s space are measured in the device’s units. (The IMSCALE method provides access to a device’s scale.) For arguments that have defaults (such as the BRUSH argument of DRAWCURVE), the default is substituted for the NIL argument before it is passed to the image stream method. Therefore, image stream methods do not have to handle defaults.

IMCLOSEFN [IMAGEOPS Field]
Called before a stream is closed with CLOSEF. This method should flush buffers, write header or trailer information, etc.

IMDRAWLINE [IMAGEOPS Field]
Draws a line of width WIDTH from (X1, Y1) to (X2, Y2). See DRAWLINE.

IMDRAWCURVE [IMAGEOPS Field]
Draws a curve through KNOTS. See DRAWCURVE.
(IMDRAWCIRCLE STREAM CENTERX CENTERY RADIUS BRUSH DASHING)  [Image Stream Method]

Draws a circle of radius RADIUS around (CENTERX, CENTERY). See DRAWCIRCLE.

(IMDRAWELLIPSE STREAM CENTERX CENTERY SEMIMINORRADIUS SEMIMAJORRADIUS ORIENTATION BRUSH DASHING)  [Image Stream Method]

Draws an ellipse around (CENTERX, CENTERY). See DRAWELLIPSE.

(IMFILLPOLYGON STREAM POINTS TEXTURE)  [Image Stream Method]

Fills in the polygon outlined by POINTS on the image stream STREAM, using the texture TEXTURE. See FILLPOLYGON.

(IMFILLCIRCLE STREAM CENTERX CENTERY RADIUS TEXTURE)  [Image Stream Method]

Draws a circle filled with texture TEXTURE around (CENTERX, CENTERY). See FILLCIRCLE.

(IMBLTSHADE TEXTURE STREAM DESTINATIONLEFT DESTINATIONBOTTOM WIDTH HEIGHT OPERATION CLIPPINGREGION)  [Image Stream Method]

The texture-source case of BITBLT. DESTINATIONLEFT, DESTINATIONBOTTOM, WIDTH, HEIGHT, and CLIPPINGREGION are measured in STREAM's units. This method is invoked by the functions BITBLT and BLTSHADE.

(IMBITBLT SOURCEBITMAP SOURCELEFT SOURCEBOTTOM STREAM DESTINATIONLEFT DESTINATIONBOTTOM WIDTH HEIGHT SOURCETYPE OPERATION TEXTURE CLIPPINGREGION CLIPPEDSOURCELEFT CLIPPEDSOURCEBOTTOM ) SCALE[Image Stream Method]

Contains the bit-map-source cases of BITBLT. SOURCELEFT, SOURCEBOTTOM, CLIPPEDSOURCELEFT, CLIPPEDSOURCEBOTTOM, WIDTH, and HEIGHT are measured in pixels; DESTINATIONLEFT, DESTINATIONBOTTOM, and CLIPPINGREGION are in the units of the destination stream.

(IMSCALEDBITBLT SOURCEBITMAP SOURCELEFT SOURCEBOTTOM STREAM DESTINATIONLEFT DESTINATIONBOTTOM WIDTH HEIGHT SOURCETYPE OPERATION TEXTURE CLIPPINGREGION CLIPPEDSOURCELEFT CLIPPEDSOURCEBOTTOM SCALE) [Image Stream Method]

A scaled version of IMBITBLT. Each pixel in SOURCEBITMAP is replicated SCALE times in the X and Y directions; currently, SCALE must be an integer.

(IMMOVETO STREAM X Y)  [Image Stream Method]

Moves to (X, Y). This method is invoked by the function MOVETO. If IMMOVETO is not supplied, a default method composed of calls to the IMXPOSITION and IMYPOSITION methods is used.
(IMSTRINGWIDTH STREAM STR RDTBL) [Image Stream Method]

Returns the width of string STR in STREAM's units, using STREAM's current font. This is invoked when STRINGWIDTH is passed a stream as its FONT argument. If IMSTRINGWIDTH is not supplied, it defaults to calling STRINGWIDTH on the default font of STREAM.

(IMCHARWIDTH STREAM CHARCODE) [Image Stream Method]

Returns the width of character CHARCODE in STREAM's units, using STREAM's current font. This is invoked when CHARWIDTH is passed a stream as its FONT argument. If IMCHARWIDTH is not supplied, it defaults to calling CHARWIDTH on the default font of STREAM.

(IMCHARWIDTHY STREAM CHARCODE) [Image Stream Method]

Returns the Y component of the width of character CHARCODE in STREAM's units, using STREAM's current font. This is invoked when CHARWIDTHY is passed a stream as its FONT argument. If IMCHARWIDTHY is not supplied, it defaults to calling CHARWIDTHY on the default font of STREAM.

(IMBITMAPSIZE STREAM BITMAP DIMENSION) [Image Stream Method]

Returns the size that BITMAP will be when BITBLTed to STREAM, in STREAM's units. DIMENSION can be one of WIDTH, HEIGHT, or NIL, in which case the dotted pair (WIDTH . HEIGHT) will be returned.

This is invoked by BITMAPIMAGESIZE. If IMBITMAPSIZE is not supplied, it defaults to a method that multiplies the bitmap height and width by the scale of STREAM.

(IMNEWPAGE STREAM) [Image Stream Method]

Causes a new page to be started. The X position is set to the left margin, and the Y position is set to the top margin plus the linefeed. If not supplied, defaults to (\OUTCHAR STREAM (CHARCODE ^L)). Envoked by DSPNEWPAGE.

(IMTERPRI STREAM) [Image Stream Method]

Causes a new line to be started. The X position is set to the left margin, and the Y position is set to the current Y position plus the linefeed. If not supplied, defaults to (\OUTCHAR STREAM (CHARCODE EOL)). Envoked by TERPRI.

(IMRESET STREAM) [Image Stream Method]

Resets the X and Y position of STREAM. The X coordinate is set to its left margin; the Y coordinate is set to the top of the clipping region minus the font ascent. Envoked by DSPRESET.
The following methods all have corresponding DSPxx functions (e.g., IMYPOSITION corresponds to DSPYPOSITION) that invoke them. They also have the property of returning their previous value; when called with NIL they return the old value without changing it.

**(IMCLIPPINGREGION STREAM REGION)**  [Image Stream Method]
Sets a new clipping region on STREAM.

**(IMXPOSITION STREAM XPOSITION)**  [Image Stream Method]
Sets the X-position on STREAM.

**(IMYPOSITION STREAM YPOSITION)**  [Image Stream Method]
Sets a new Y-position on STREAM.

**(IMFONT STREAM FONT)**  [Image Stream Method]
Sets STREAM's font to be FONT.

**(IMLEFTMARGIN STREAM LEFTMARGIN)**  [Image Stream Method]
Sets STREAM's left margin to be LEFTMARGIN. The left margin is defined as the X-position set after the new line.

**(IMRIGHTMARGIN STREAM RIGHTMARGIN)**  [Image Stream Method]
Sets STREAM's right margin to be RIGHTMARGIN. The right margin is defined as the maximum X-position at which characters are printed; printing beyond it causes a new line.

**(IMTOPMARGIN STREAM YPOSITION)**  [Image Stream Method]
Sets STREAM's top margin (the Y-position of the tops of characters that is set after a new page) to be YPOSITION.

**(IMBOTTOMMARGIN STREAM YPOSITION)**  [Image Stream Method]
Sets STREAM's bottom margin (the Y-position beyond which any printing causes a new page) to be YPOSITION.

**(IMLINEFEED STREAM DELTA)**  [Image Stream Method]
Sets STREAM's line feed distance (distance to move vertically after a new line) to be DELTA.

**(IMSCALE STREAM SCALE)**  [Image Stream Method]
Returns the number of device points per screen point (a screen point being ~1/72 inch). SCALE is ignored.
GRAPHICS OUTPUT OPERATIONS

(IMSPACEFACTOR STREAM FACTOR) [Image Stream Method]
Sets the amount by which to multiply the natural width of all following space characters on STREAM; this can be used for the justification of text. The default value is 1. For example, if the natural width of a space in STREAM's current font is 12 units, and the space factor is set to two, spaces appear 24 units wide. The values returned by STRINGWIDTH and CHARWIDTH are also affected.

(IMOPERATION STREAM OPERATION) [Image Stream Method]
Sets the default BITBLT OPERATION argument.

(IMBACKCOLOR STREAM COLOR) [Image Stream Method]
Sets the background color of STREAM.

(IMCOLOR STREAM COLOR) [Image Stream Method]
Sets the default color of STREAM.

In addition to the IMAGEOPS methods described above, there are two other important methods, which are contained in the stream itself. These fields can be installed using a form like (replace (STREAM OUTCHARFN) of STREAM with (FUNCTION MYOUTCHARFN)). Note: You need to have loaded the Interlisp-D system declarations to manipulate the fields of STREAMs. The declarations can be loaded by loading the Lisp Library package SYSEDIT.

(STRMBOUTFN STREAM CHARCODE) [Stream Method]
The function called by BOUT.

(OUTCHARFN STREAM CHARCODE) [Stream Method]
The function that is called to output a single byte. This is like STRMBOUTFN, except for being one level higher: it is intended for text output. Hence, this function should convert (CHARCODE EOL) into the stream’s actual end-of-line sequence and should adjust the stream’s CHARPOSITION appropriately before invoking the stream’s STRMBOUTFN (by calling BOUT) to actually put the character.Defaults to \FILEOUTCHARFN, which is probably incorrect for an image stream.
27. WINDOWS AND MENUS

Windows provide a means by which different programs can share a single display harmoniously. Rather than having every program directly manipulating the screen bitmap, all display input/output operations are directed towards windows, which appear as rectangular regions of the screen, with borders and titles. The Interlisp-D window system provides both interactive and programmatic constructs for creating, moving, reshaping, overlapping, and destroying windows in such a way that a program can use a window in a relatively transparent fashion (see the Windows section below). This allows existing Interlisp programs to be used without change, while providing a base for experimentation with more complex windows in new applications.

Menus are a special type of window provided by the window system, used for displaying a set of items to the user, and having the user select one using the mouse and cursor. The window system uses menus to provide the interactive interface for manipulating windows. The menu facility also allows users to create and use menus in interactive programs (see the Menus section below).

Sometimes, a program needs to use a number of windows, displaying related information. The attached window facility (see the Attached Windows section below) makes it easy to manipulate a group of windows as a single unit, moving and reshaping them together.

This chapter documents the Interlisp-D window system. First, it describes the default windows and menus supplied by the window system. Then, the programmatic facilities for creating windows. Next, the functions for using menus. Finally, the attached window facility.

Warning: The window system assumes that all programs follow certain conventions concerning control of the screen. All user programs should use perform display operations using windows and menus. In particular, user programs should not perform operate directly on the screen bitmap; otherwise the window system will not work correctly. For specialized applications that require taking complete control of the display, the window system can be turned off (and back on again) with the following function:

\[
\text{(WINDOWWORLD \text{FLAG}) [NoSpread Function]}
\]

The window system is turned on if \text{FLAG} is T and off if \text{FLAG} is NIL. WINDOWWORLD returns the previous state of the window system (T or NIL). If WINDOWWORLD is given no arguments, it simply returns the current state without affecting the window system.

Using the Window System

When Medley is initially started, the display screen lights up, showing a number of windows, including the following:
This window is the "logo window," used to identify the system. The logo window is bound to the variable LOGOW until it is closed. The user can create other windows like this by calling the following function:

\[
\text{(LOGOW STRING WHERE TITLE ANGLEDELTA)}
\]

This window is formatted like the "logo window." STRING is the string to be printed in big type in the window; if NIL, "Medley" is used. WHERE is the position of the lower-left corner of the window; if NIL, the user is asked to specify a position. TITLE is the window title to use; if NIL, it defaults to the Xerox copyright notice and date. ANGLEDELTA specifies the angle (in degrees) between the boxes in the picture; if NIL, it defaults to 23 degrees.

This window is the "executive window," used for typing expressions and commands to the Interlisp-D executive, and for the executive to print any results (see Chapter 13). For example, in the above picture, the user typed in \((PLUS \ 3 \ 4)\), the executive evaluated it, and printed out the result, 7. The upward-pointing arrow (\(\uparrow\)) is the flashing caret, which indicates where the next keyboard typein will be printed (see the TTY Process and the Caret section in this chapter).

This window is the "prompt window," used for printing various system prompt messages. It is available to user programs through the following functions:

\[
\text{PROMPTWINDOW}
\]

Global variable containing the prompt window.

\[
\text{(PROMPTPRINT EXP_1 ... EXP_N)}
\]

Clears the prompt window, and prints \(EXP_1\) through \(EXP_N\) in the prompt window.
The Medley window system allows the user to interactively manipulate the windows on the screen, moving them around, changing their shape, etc. by selecting various operations from a menu.

For most windows, pressing the **RIGHT** mouse button when the cursor is inside a window during I/O wait will cause the window to come to the top and a menu of window operations to appear.

If a command is selected from this menu (by releasing the right mouse key while the cursor is over a command), the selected operation will be applied to the window in which the menu was brought up. It is possible for an applications program to redefine the action of the **RIGHT** mouse button. In these cases, there is a convention that the default command menu may be brought up by depressing the **RIGHT** button when the cursor is in the header or border of a window (see the Mouse Activity in Windows section in this chapter). The operations are:

- **Close**
  - [Window Menu Command]
  - Closes the window, i.e., removes it from the screen. (See `CLOSEW` in the Opening and Closing Windows section in this chapter.)

- **Snap**
  - [Window Menu Command]
  - Prompts for a region on the screen and makes a new window whose bits are a snapshot of the bits currently in that region. Useful for saving some particularly choice image before the window image changes.

- **Paint**
  - [Window Menu Command]
  - Switches to a mode in which the cursor can be used like a paint brush to draw in a window. This is useful for making notes on a window. While the **LEFT** button is down, bits are added. While the **MIDDLE** button is down, they are erased. The **RIGHT** button pops up a command menu that allows changing of the brush shape, size and shade, changing the mode of combining the brush with the existing bits, or stopping paint mode.

- **Clear**
  - [Window Menu Command]
  - Clears the window and repositions it to the left margin of the first line of text (below the upper left corner of the window by the amount of the font ascent).
INTERLISP-D REFERENCE MANUAL

Bury [Window Menu Command]

Puts the window on the bottom of the occlusion stack, thereby exposing any windows that it was hiding.

Redisplay [Window Menu Command]

Redisplays the window. (See REDISPLAYW in the Redisplaying Windows section in this chapter.)

Hardcopy [Window Menu Command]

Prints the contents of the window to the printer. If the window has a window property HARDCOPYFN, it is called with two arguments, the window and an image stream to print to, and the HARDCOPYFN must do the printing. In this way, special windows can be set up that know how to print their contents in a particular way. If the window does not have a HARDCOPYFN, the bitmap image of the window (including the border and title) are printed on the file or printer.

To save the image in a Press or Interpress-format file, or to send it to a non-default printer, use the submenu of the Hardcopy command, indicated by a gray triangle on the right edge of the Hardcopy menu item. If the mouse is moved off of the right of the menu item, another pop-up menu will appear giving the choices "To a file" or "To a printer." If "To a file" is selected, the user is prompted to supply a file name, and the format of the file (Press, Interpress, etc.), and the specified region will be stored in the file.

If "To a printer" is selected, the user is prompted to select a printer from the list of known printers, or to type the name of another printer. If the printer selected is not the first printer on DEFAULTPRINTINGHOST (see Chapter 29), the user will be asked whether to move or add the printer to the beginning of this list, so that future printing will go to the new printer.

Move [Window Menu Command]

Moves the window to a location specified by pressing and then releasing the LEFT button. During this time a ghost frame will indicate where the window will reappear when the key is released. (See GETBOXPOSITION in the Interactive Display Functions section below.)

Shape [Window Menu Command]

Allows the user to specify a new region for the existing window contents. If the LEFT button is used to specify the new region, the reshaped window can be placed anywhere. If the MIDDLE button is used, the cursor will start out tugging at the nearest corner of the existing window, which is useful for making small adjustments in a window that is already positioned correctly. This is done by calling the function SHAPEN (see the Reshaping Windows section below).

Occasionally, a user will have a number of large windows on the screen, making it difficult to access those windows being used. To help with the problem of screen space management, the Interlisp-D window system allows the creation of "icons." An icon is a small rectangle (containing text or a
bitmap) which is a "shrunken-down" form of a particular window. Using the Shrink and Expand commands, the user can shrink windows not currently being used into icons, and quickly restore the original windows at any time.

**Shrink** [Window Menu Command]

Removes the window from the screen and brings up its icon. (See `SHRINKW` in the Shrinking Windows into Icons section in this chapter) The window can be restored by selecting Expand from the window command menu of the icon.

If the **RIGHT** button is pressed while the cursor is in an icon, the window command menu will contain a slightly different set of commands. The Redisplay and Clear commands are removed, and the Shrink command is replaced with the Expand command:

**Expand** [Window Menu Command]

Restores the window associated with this icon and removes the icon. (See `EXPANDW` in the Shrinking Windows into Icons section in this chapter.)

If the **RIGHT** button is pressed while the cursor is not in any window, a "background menu" appears with the following operations:

**Idle** [Background Menu Command]

Enters "idle mode" (see Chapter 12), which blacks out the display screen to save the phosphor. Idle mode can be exited by pressing any key on the keyboard or mouse. This menu command has subitems that allow the user to interactively set idle options to erase the password cache (for security), to request a password before exiting idle mode, to change the timeout before idle mode is entered automatically, etc.

**SaveVM** [Background Menu Command]

Calls the function `SAVEVM` (see Chapter 12), which writes out all of the dirty pages of the virtual memory. After a `SAVEVM`, and until the pagefault handler is next forced to write out a dirty page, your virtual memory image will be continuable (as of the `SAVEVM`) should you experience a system crash or other disaster.

**Snap** [Background Menu Command]

The same as the window menu command Snap described above.

**Hardcopy** [Background Menu Command]

Prompts for a region on the screen, and sends the bitmap image to the printer by calling `HARDCOPYW` (see Chapter 29). Note that the region can cross window boundaries.

Like the Hardcopy window menu command (above), the user can print to a file or specify a printer by using a submenu.

**PSW** [Background Menu Command]

Prompts the user for a position on the screen, and creates a "process status window" that allows the user to examine and manipulate all of the existing processes (see Chapter 23).
Various system utilities (TEdit, SEdit, TTYIN) allow information to be "copy-inserted" at the current cursor position by selecting it with the "copy" key held down (Normally the shift keys are the "copy" key; this action can be changed in the key action table.) To "copy-insert" the bitmap of a snap into a Tedit document. If the right mouse button is pressed in the background with the copy key held down, a menu with the single item "SNAP" appears. If this item is selected, the user is prompted to select a region, and a bitmap containing the bits in that region of the screen is inserted into the current tty process, if that process is able to accept image objects.

Some built-in facilities and Lispusers packages add commands to the background menu, to provide an easy way of calling the different facilities. The user can determine what these new commands do by holding the RIGHT button down for a few seconds over the item in question; an explanatory message will be printed in the prompt window.

Changing the Window System

The following functions provide a functional interface to the interactive window operations so that user programs can call them directly.

\( \text{(DOWINDOWCOM \textit{WINDOW})} \)[Function]

If \textit{WINDOW} is a \textit{WINDOW} that has a DOWINDOWCOMFN window property, it \textsc{apply}s that property to \textit{WINDOW}. Shrunken windows have a DOWINDOWCOMFN property that presents a window command menu that contains "expand" instead of "shrink".

If \textit{WINDOW} is a \textit{WINDOW} that doesn’t have a DOWINDOWCOMFN window property, it brings up the window command menu. The initial items in these menus are described above. If the user selects one of the items from the provided menu, that item is \textsc{apply}ed to \textit{WINDOW}.

If \textit{WINDOW} is \texttt{NIL}, DOBACKGROUNDCOM (below) is called.

If \textit{WINDOW} is not a \textit{WINDOW} or \texttt{NIL}, DOWINDOWCOM simply returns without doing anything.

\( \text{(DOBACKGROUNDCOM)} \)[Function]

Brings up the background menu. The initial items in this menu are described above. If the user selects one of the items from the menu, that item is \textsc{eval}ed.

The window command menu for unshrunken windows is cached in the variable WindowMenu. To change the entries in this menu, the user should change the change the menu "command lists" in the variable WindowMenuCommands, and set the appropriate menu variable to a non-\textsc{menu}, so the menu will be recreated. This provides a way of adding commands to the menu, of changing its font or of restoring the menu if it gets clobbered. The window command menus for icons and the background have similar pairs of variables, documented below. The "command lists" are in the format of the \textsc{items} field of a menu (see the Menu Fields section below), except as specified below.

Note: Command menus are recreated using the current value of \textsc{menufont}.
The menu that is brought up in response to a right button in an unshrunken window is stored on the variable `WindowMenu`. If `WindowMenu` is set to a non-`MENU`, the menu will be recreated from the list of commands `WindowMenuCommands`. The `CADR` of each command added to `WindowMenuCommands` should be a function name that will be `APPLY`ed to the window.

If `WindowMenu` is `NIL`, it is recreated from the list of commands `WindowMenuCommands`. The `CADR` of each command added a function name that will be `APPLY`ed to the window.

The menu that is brought up in response to a right button in a shrunken window is stored on the variable `IconWindowMenu`. If it is `NIL`, it is recreated from the list of commands `IconWindowMenuCommands`. The `CADR` of each command added to `IconWindowMenuCommands` should be a function name that will be `APPLY`ed to the window.

The menu that is brought up in response to a right button in the background is stored on the variable `BackgroundMenu`. If it is `NIL`, it is recreated from the list of commands `BackgroundMenuCommands`. The `CADR` of each command added to `BackgroundMenuCommands` should be a form that will be `EVAL`ed.

The menu that is brought up in response to a right button in the background when the copy key is down is stored on the variable `BackgroundCopyMenu`. If it is `NIL`, it is recreated from the list of commands `BackgroundCopyMenuCommands`. The `CADR` of each command added to `BackgroundCopyMenuCommands` should be a form that will be `EVAL`ed.

**Interactive Display Functions**

The following functions can be used by programs to allow the user to interactively specify positions or regions on the display screen.

**(GETPOSITION WINDOW CURSOR)**

Returns a `POSITION` that is specified by the user. `GETPOSITION` waits for the user to press and release the left button of the mouse and returns the cursor position at the time of release. If `WINDOW` is a `WINDOW`, the position will be in the coordinate system of `WINDOW`'s display stream. If `WINDOW` is `NIL`, the position will be in screen coordinates. If `CURSOR` is a `CURSOR` (see Chapter 30), the cursor will be changed to it while `GETPOSITION` is running. If `CURSOR` is `NIL`, the value of the system variable `CROSSHAIRS` will be used as the cursor: 📊.
(GETBOXPOSITION BOXWIDTH BOXHEIGHT ORGX ORGY WINDOW PROMPTMSG)  [Function]

Allows the user to position a "ghost" region of size BOXWIDTH by BOXHEIGHT on the screen, and returns the POSITION of the lower left corner of the region. If PROMPTMSG is non-NIL, GETBOXPOSITION first prints it in the PROMPTWINDOW. GETBOXPOSITION then changes the cursor to a box (using the global variable BOXCURSOR). If ORGX and ORGY are numbers, they are taken to be the original position of the region, and the cursor is moved to the nearest corner of that region. A ghost region is locked to the cursor so that if the cursor is moved, the ghost region moves with it. If ORGX and ORGY are numbers, the corner of the region formed by (ORGX ORGY BOXWIDTH BOXHEIGHT) that is nearest the cursor position is locked, otherwise the lower left corner is locked. The user can change to another corner by holding down the right button. With the right button down, the cursor can be moved across the screen without effect on the ghost region frame. When the right button is released, the mouse will snap to the nearest corner, which will then become locked to the cursor. (The held corner can be changed after the left or middle button is down by holding both the original button and the right button down while the cursor is moved to the desired new corner, then letting up just the right button.) When the left or middle button is pressed and released, the lower left corner of the region at the time of release is returned. If WINDOW is a WINDOW, the returned position will be in WINDOW's coordinate system; otherwise it will be in screen coordinates.

Example:

(GETBOXPOSITION 100 200 NIL NIL NIL "Specify the position of the command area.")

prompts the user for a 100 wide by 200 high region and returns its lower left corner in screen coordinates.

(GETREGION MINWIDTH MINHEIGHT OLDREGION NEWREGIONFN NEWREGIONFNARG INITCORNERS) [Function]

Lets the user specify a new region and returns that region in screen coordinates. GETREGION prompts for a region by displaying a four-pronged box next to the cursor arrow at one corner of a "ghost" region. If the user presses the left button, the corner of a "ghost" region opposite the cursor is locked where it is. Once one corner has been fixed, the ghost region expands as the cursor moves.

To specify a region:

1. Move the ghost box so that the corner opposite the cursor is at one corner of the intended region.
2. Press the left button.
3. Move the cursor to the position of the opposite corner of the intended region while holding down the left button.
4. Release the left button.
Before one corner has been fixed, one can switch the cursor to another corner of the ghost region by holding down the right button. With the right button down, the cursor changes to a "forceps" and the cursor can be moved across the screen without effect on the ghost region frame. When the right button is released, the cursor will snap to the nearest corner of the ghost region.

After one corner has been fixed, one can still switch to another corner. To change to another corner, continue to hold down the left button and hold down the right button also. With both buttons down, the cursor can be moved across the screen without effect on the ghost region frame. When the right button is released, the cursor will snap to the nearest corner, which will become the moving corner. In this way, the region may be moved all over the screen, before its size and position is finalized.

The size of the initial ghost region is controlled by the MINWIDTH, MINHEIGHT, OLDREGION, and INITCORNERS arguments.

If INITCORNERS is non-NIL, it should be a list specifying the initial corners of a ghost region of the form (BASEX BASEY OPPX OPPY), where (BASEX, BASEY) describes the anchored corner of the box, and (OPPX, OPPY) describes the trackable corner (in screen coordinates). The cursor is moved to (OPPX, OPPY).

If INITCORNERS is NIL, the ghost region will be MINWIDTH wide and MINHEIGHT high. If MINWIDTH or MINHEIGHT is NIL, 0 is used. Thus, for a call to GETREGION with no arguments specified, there will be no initial ghost region. The cursor will be in the lower right corner of the region, if there is one.

If OLDREGION is a region and the user presses the middle button, the corner of OLDREGION farthest from the cursor position is fixed and the corner nearest the cursor is locked to the cursor.

MINWIDTH and MINHEIGHT, if given, are the smallest WIDTH and HEIGHT that the returned region will have. The ghost image will not get any smaller than MINWIDTH by MINHEIGHT.

If NEWREGIONFN is non-NIL, it will be called to determine values for the positions of the corners. This provides a way of "filtering" prospective regions; for instance, by restricting the region to lie on an arbitrary grid. When the user is specifying a region, the region is determined by two of its corners, one that is fixed and one that is tracking the cursor. Each time the cursor moves or a mouse button is pressed, NEWREGIONFN is called with three arguments: FIXEDPOINT, the position of the fixed corner of the prospective region; MOVINGPOINT, the position of the opposite corner of the prospective region; and NEWREGIONFNARG. NEWREGIONFNARG allows the caller of GETREGION to pass information to the NEWREGIONFN.

The first time a button is pressed and when the user changes the moving corner via right buttoning, MOVINGPOINT is NIL and FIXEDPOINT is the position the user selected for the fixed corner of the new region. In this case, the position returned by NEWREGIONFN will be used for the fixed corner instead of the one proposed by the user. For all other calls, FIXEDPOINT is the position of the fixed corner (as returned by the previous call) and...
MOVINGPOINT is the new position the user selected for the opposite corner. In these cases, the value of NEWREGIONFN is used for the opposite corner instead of the one proposed by the user. In all cases, the ghost region is drawn with the values returned by NEWREGIONFN. NEWREGIONFN can be a list of functions in which case they are called in order with each being passed the result of calling the previous and the value of the last one used as the point.

(GETBOXREGION WIDTH HEIGHT ORGX ORGY WINDOW PROMPTMSG) [Function]

Performs the same prompting as GETBOXPOSITION and returns the REGION specified by the user instead of the POSITION of its lower left corner.

(MOUSECONFIRM PROMPTSTRING HELPSTRING WINDOW DON’TTCLEARWINDOWFLG) [Function]

MOUSECONFIRM provides a simple way for the user to confirm or abort some action simply by using the mouse buttons. It prints the strings PROMPTSTRING and HELPSTRING in the window WINDOW, changes the cursor to a "little mouse" cursor: ☛ (stored in the variable MOUSECONFIRM_CURSOR), and waits for the user to press the left button to confirm, or any other button to abort. If the left button was the last button released, returns T, else NIL.

If PROMPTSTRING is NIL, it is not printed out. If HELPSTRING is NIL, the string "Click LEFT to confirm, RIGHT to abort." is used. If WINDOW is NIL, the prompt window is used.

Normally, MOUSECONFIRM clears WINDOW before returning. If DON’TTCLEARWINDOWFLG is non-NIL, the window is not cleared.

Windows

A window specifies a region of the screen, a display stream, functions that get called when the window undergoes certain actions, and various other items of information. The basic model is that a window is a passive collection of bits (on the screen). On top of this basic level, the system supports many different types of windows that are linked to the data structures displayed in them and provide selection and redisplaying routines. In addition, it is possible for the user to create new types of windows by providing selection and displaying functions for them.

Windows are ordered in depth from user to background. Windows in front of others obscure the latter. Operating on a window generally brings it to the top.

Windows are located at a certain position on the screen. Each window has a clipping region that confines all bits written to it to a region that allows a border around the window, and a title above it.

Each window has a display stream associated with it (see Chapter 27), and either a window or its display stream can be passed interchangeably to all system functions. There are dependencies
between the window and its display stream that the user should not disturb. For instance, the
destination bitmap of the display stream of a window must always be the screen bitmap. The \(X\) offset,
\(Y\) offset, and Clipping Region fields of the display stream should not be changed.

Windows can be created by the user interactively, under program control, or may be created
automatically by the system.

Windows are in one of two states: "open" or "closed". In an "open" state, a window is visible on the
screen (unless it is covered by other open windows or off the edge of the screen) and accessible to
mouse operations. In a "closed" state, a window is not visible and not accessible to mouse operations.
Any attempt to print or draw on a closed window will open it.

Window Properties

The behavior of a window is controlled by a set of "window properties." Some of these are used by
the system. However, any arbitrary property name may be used by a user program to associate
information with a window. For many applications the user will associate the structure being
displayed with its window using a property. The following functions provide for reading and setting
window properties:

\[
\begin{align*}
\text{(WINDOWPROP WINDOW PROP NEWVALUE)} & \quad \text{[NoSpread Function]} \\
\text{Returns the previous value of \textsc{window}'s \textit{prop} aspect. If \textsc{newvalue} is given, (even if} \\
\text{given as NIL), it is stored as the new \textit{prop} aspect. Some aspects cannot be set by the user} \\
\text{and will generate errors. Any \textit{prop} name that is not recognized is stored on a property} \\
\text{list associated with the window.}
\end{align*}
\]

\[
\begin{align*}
\text{(WINDOWADDPROP WINDOW PROP ITEMTODELETE FIRSTFLG)} & \quad \text{[Function]} \\
\text{WINDOWADDPROP adds a new item to a window property. If \textsc{itemtodelete} is \textsc{eq} to an} \\
\text{element of the \textit{prop} property of the window \textsc{window}, nothing is added. If the current} \\
\text{property is not a list, it is made a list before \textsc{itemtodelete} added. \textsc{windowaddprop} \text{returns the previous property. If \textsc{firstflg} is non-NIL, the new item goes on the front of} \\
\text{the list; otherwise, it goes on the end of the list. If \textsc{firstflg} is non-NIL and \textsc{itemtodelete} \text{is already on the list, it is moved to the front.} \\
\text{Many window properties (\textsc{openfn}, \textsc{closefn}, etc.) can be a list of functions.} \text{WINDOWADDPROP is useful for adding additional functions to a window property} \\
\text{without affecting any existing functions. Note that if the order of items in a window} \\
\text{property is important, the list can be modified using WINDOWPROP.}
\end{align*}
\]

\[
\begin{align*}
\text{(WINDOWDELPROP WINDOW PROP ITEMTODELETE)} & \quad \text{[Function]} \\
\text{WINDOWDELPROP deletes \textsc{itemtodelete} from the window property \textit{prop} of \textsc{window} \text{and returns the previous list if \textsc{itemtodelete} was an element. If \textsc{itemtodelete} was} \\
\text{not a member of window property \textit{prop}, NIL is returned.}
\end{align*}
\]

Creating Windows
(CREATEW REGION TITLE BORDERSIZE NOOPENFLG)  [Function]

Creates a new window. REGION indicates where and how large the window should be by specifying the exterior region of the window. The usable height and width of the resulting window will be smaller than the height and width of the region by twice the border size and further less the height of the title, if any. If REGION is NIL, GETREGION is called to prompt the user for a region.

If TITLE is non-NIL, it is printed in the border at the top of the window. The TITLE is printed using the global display stream WindowTitleDisplayStream. Thus the height of the title will be (FONTPROP WindowTitleDisplayStream 'HEIGHT).

If BORDERSIZE is a number, it is used as the border size. If BORDERSIZE is not a number, the window will have a border WBorder (initially 4) bits wide.

If NOOPENFLG is non-NIL, the window will not be opened, i.e. displayed on the screen.

The initial X and Y positions of the window are set to the upper left corner by calling MOVETOUPPERLEFT (see Chapter 27).

(DECODE.WINDOW.ARG WHERESPEC WIDTH HEIGHT TITLE BORDER NOOPENFLG)  [Function]

This is a useful function for creating windows. WHERESPEC can be a WINDOW, a REGION, a POSITION or NIL. If WHERESPEC is a WINDOW, it is returned. In all other cases, CREATEW is called with the arguments TITLE BORDER and NOOPENFLG. The REGION argument to CREATEW is determined from WHERESPEC as follows:

If WHERESPEC is a REGION, it is adjusted to be on the screen, then passed to CREATEW.

If WIDTH and HEIGHT are numbers and WHERESPEC is a POSITION, the region whose lower left corner is WHERESPEC, whose width is WIDTH and whose height is HEIGHT is adjusted to be on the screen, then passed to CREATEW.

If WIDTH and HEIGHT are numbers and WHERESPEC is not a POSITION, then GETBOXREGION is called to prompt the user for the position of a region that is WIDTH by HEIGHT.

If WIDTH and HEIGHT are not numbers, CREATEW is given NIL as a REGION argument.

If WIDTH and HEIGHT are used, they are used as interior dimensions for the window.

(WINDOWP X)  [Function]

Returns X if X is a window, NIL otherwise.

Opening and Closing Windows

(OPENWP WINDOW)  [Function]

Returns WINDOW, if WINDOW is an open window (has not been closed); NIL otherwise.
(OPENWINDOWS) [Function]

Returns a list of all open windows.

(OPENW WINDOW) [Function]

If WINDOW is a closed window, OPENW calls the function or functions on the window property OPENFN of WINDOW, if any. If one of the OPENFNs is the atom DON'T, the window will not be opened. Otherwise the window is placed on the occlusion stack of windows and its contents displayed on the screen. If WINDOW is an open window, it returns NIL.

(CLOSEW WINDOW) [Function]

CLOSEW calls the function or functions on the window property CLOSEFN of WINDOW, if any. If one of the CLOSEFNs is the atom DON’T or returns the atom DON’T as a value, CLOSEW returns without doing anything further. Otherwise, CLOSEW removes WINDOW from the window stack and restores the bits it is obscuring. If WINDOW was closed, WINDOW is returned as the value. If it was not closed, (for example because its CLOSEFN returned the atom DON’T), NIL is returned as the value.

WINDOW can be restored in the same place with the same contents (reopened) by calling OPENW or by using it as the source of a display operation.

OPENFN [Window Property]

The OPENFN window property can be a single function or a list of functions. If one of the OPENFNs is the atom DON’T, the window will not be opened. Otherwise, the OPENFNs are called after a window has been opened by OPENW, with the window as a single argument.

CLOSEFN [Window Property]

The CLOSEFN window property can be a single function or a list of functions that are called just before a window is closed by CLOSEW. The function(s) will be called with the window as a single argument. If any of the CLOSEFNs are the atom DON’T, or if the value returned by any of the CLOSEFNs is the atom DON’T, the window will not be closed.

Note: If the CAR of the CLOSEFN list is a LAMBDA word, it is treated as a single function.

Note: A CLOSEFN should not call CLOSEW on its argument.

Redisplaying Windows

(REDISPLAYW WINDOW REGION ALWAYSFLG) [Function]

Redisplay the region REGION of the window WINDOW. If REGION is NIL, the entire window is redisplayed.
If \textit{WINDOW} doesn’t have a \texttt{REPAINTFN}, the action depends on the value of \texttt{ALWAYSFLG}. If \texttt{ALWAYSFLG} is \texttt{NIL}, \textit{WINDOW} will not change and the message "Window has no \texttt{REPAINTFN}. Can’t redisplay." will be printed in the prompt window. If \texttt{ALWAYSFLG} is non-\texttt{NIL}, \texttt{REDISPLAYW} acts as if \texttt{REPAINTFN} was \texttt{NIL}.

\textbf{REPAINTFN} \hspace{1cm} \texttt{[Window Property]}

The \texttt{REPAINTFN} window property can be a single function or a list of functions that are called to repaint parts of the window by \texttt{REDISPLAYW}. The \texttt{REPAINTFN}s are called with two arguments: the window and the region in the coordinates of the window’s display stream of the area that should be repainted. Before the \texttt{REPAINTFN} is called, the clipping region of the window is set to clip all display operations to the area of interest so that the \texttt{REPAINTFN} can display the entire window contents and the results will be appropriately clipped.

Note: \texttt{CLEARW} (see the Miscellaneous Window Functions section below) should not be used in \texttt{REPAINTFN}s because it resets the window’s coordinate system. If a \texttt{REPAINTFN} wants to clear its region first, it should use \texttt{DSPFILL} (see Chapter 27).

\section*{Reshaping Windows}

\textbf{(SHAPEW \textit{WINDOW} \textit{NEWREGION})} \hspace{1cm} \texttt{[Function]}

Reshapes \textit{WINDOW}. If the window property \texttt{RESHAPFN} is the atom \texttt{DON’T} or a list that contains the atom \texttt{DON’T}, a message is printed in the prompt window, \textit{WINDOW} is not changed, and \texttt{NIL} is returned. Otherwise, \texttt{RESHAPFN} window property can be a single function or a list of functions that are called when a window is reshaped, to reformat or redisplay the window contents (see below). If the \texttt{RESHAPFN} window property is \texttt{NIL}, \texttt{RESHAPEBYREPAINTFN} is the default.

If the region \textit{NEWREGION} is \texttt{NIL}, it prompts for a region with \texttt{GETREGION}. When calling \texttt{GETREGION}, the function \texttt{MINIMUMWINDOWSIZE} is called to determine the minimum height and width of the window, the function \texttt{WINDOWREGION} is called to get the region passed as the \texttt{OLDREGION} argument, the window property \texttt{NEWREGIONFN} is used as the \texttt{NEWREGIONFN} argument and \texttt{WINDOW} as the \texttt{NEWREGIONFNARG} argument. If the window property \texttt{INITCORNERSFN} is non-\texttt{NIL}, it is applied to the window, and the value is passed as the \texttt{INITCORNERS} argument to \texttt{GETREGION}, to determine the initial size of the "ghost region." These window properties allow the window to specify the regions used for interactive calls to \texttt{SHAPEW}.

If the region \textit{NEWREGION} is a \texttt{REGION} and its \texttt{WIDTH} or \texttt{HEIGHT} less than the minimums returned by calling the function \texttt{MINIMUMWINDOWSIZE}, they will be increased to the minimums.

If \textit{WINDOW} has a window property \texttt{DOSHAPEFN}, it is called, passing it \texttt{WINDOW} and \texttt{NEWREGION} (or the region returned by \texttt{GETREGION}). If \textit{WINDOW} does not have a \texttt{DOSHAPEFN} window property, the function \texttt{SHAPEW1} is called to reshape the window.
DOSHAPEFNs are provided to implement window groups and few users should ever write them. They are tricky to write and must call SHAPEW eventually. The RESHAPEFN window property is a simpler hook into reshape operations.

\[(\text{SHAPEW} \text{ WINDOW} \text{ REGION})\]  

[Function]

Changes \text{WINDOW}'s size and position on the screen to be \text{REGION}. After clearing the region on the screen, it calls the window's RESHAPEFN, if any, passing it three arguments: \text{WINDOW}, a bitmap that contains \text{WINDOW}'s previous screen image; and the region of \text{WINDOW}'s old image within the bitmap.

**RESHAPEFN**  

[Window Property]

The RESHAPEFN window property can be a single function or a list of functions that are called when a window is reshaped by SHAPEW. If the RESHAPEFN is DON'T or a list containing DON'T, the window will not be reshaped. Otherwise, the function(s) are called after the window has been reshaped, its coordinate system readjusted to the new position, the title and border displayed, and the interior filled with texture. The RESHAPEFN should display any additional information needed to complete the window's image in the new position and shape. The RESHAPEFN is called with four arguments: (1) the window in its reshaped form, (2) a bitmap with the image of the old window in its old shape, and (3) the region within the bitmap that contains the window's old image, and (4) the region of the screen previously occupied by this window. This function is provided so that users can reformat window contents or whatever. RESHAPEBYREPAINTFN (below) is the default and should be useful for many windows.

**NEWREGIONFN**  

[Window Property]

If SHAPEW calls GETREGION to prompt the user for a region, the value of the NEWREGIONFN window property is passed as the NEWREGIONFN argument to GETREGION.

**INITCORNERSFN**  

[Window Property]

If this window property is non-NIL, it should be a function of one argument, a window, that returns a list specifying the initial corners of a "ghost region" of the form (BASEX BASEY OPPX OPPY), where (BASEX, BASEY) describes the anchored corner of the box, and (OPPX, OPPY) describes the trackable corner. If SHAPEW calls GETREGION to prompt the user for a region, this function is applied to the window, and the list returned is passed as the INITCORNERS argument to GETREGION, to specify the initial ghost region.

**DOSHAPEFN**  

[Window Property]

If this window property is non-NIL, it is called by SHAPEW to reshape the window (instead of SHAPEW1). It is called with two arguments: the window and the new region.

\[(\text{RESHAPEBYREPAINTFN} \text{ WINDOW} \text{ OLDIMAGE} \text{ IMAGEREGION} \text{ OLDSCREENREGION})\]  

[Function]
This the default window RESHAPEFN. WINDOW is a window that has been reshaped from the screen region OLDSCREENREGION to its new region (available via (WINDOWPROP WINDOW 'REGION)). OLDIMAGE is a bitmap that contains the image of the window from its previous location. IMAGEREGION is the region within OLDIMAGE that contains the old image.

RESHAPEBYREPAINTFN BITBLT’s the old region contents into the new region. If the new shape is larger in either or both dimensions, the newly exposed areas are redisplayed via calls WINDOW’s REPAINTFN window property. RESHAPEBYREPAINTFN may call the REPAINTFN up to four times during a single reshape.

The choice of which areas of the window to remove or extend is done as follows. If WINDOW’s new region shares an edge with OLDSCREENREGION, that edge of the window image will remain fixed and any addition or reduction in that dimension will be performed on the opposite side. If WINDOW has an EXTENT property and the newly exposed window area is outside of it, any extra will be added so as to show EXTENT that was previously not visible. An exception to these rules is that the current X,Y position is kept visible, if it was visible before the reshape.

Moving Windows

(MOVEW WINDOW POSorX Y) [Function]

Moves WINDOW to the position specified by POSorX and Y according to the following rules:

If POSorX is NIL, GETBOXPOSITION is called to read a position from the user. If WINDOW has a CALCULATEREGION window property, it will be called with WINDOW as an argument and should return a region which will be used to prompt the user with. If WINDOW does not have a CALCULATEREGION window property, the region of WINDOW is used to prompt with.

If POSorX is a POSITION, POSorX is used.

If POSorX and Y are both NUMBERP, a position is created using POSorX as the XCOORD and Y as the YCOORD.

If POSorX is a REGION, a position is created using its LEFT as the XCOORD and BOTTOM as the YCOORD.

If WINDOW is not open and POSorX is non-NIL, the window will be moved without being opened. Otherwise, it will be opened.

If WINDOW has the atom DON’T as a MOVEFN window property, the window will not be moved. If WINDOW has any other non-NIL value as a MOVEFN property, it should be a function or list of functions that will be called before the window is moved with the WINDOW and the new positon as its arguments. If it returns the atom DON’T, the window will not be moved. If it returns a position, the window will be moved to that position.
instead of the new one. If there are more than one MOVEFNS, the last one to return a value is the one that determines where the window is moved to.

If WINDOW is moved and WINDOW has an AFTERMOVEFN window property, it should be a function or a list of functions that will be called after the window is moved with WINDOW as an argument.

MOVEW returns the new position, or NIL if the window could not be moved.

Note: If MOVEW moves any part of the window from off-screen onto the screen, that part is redisplayed (by calling REDISPLAYW).

(RELMOVEW WINDOW POSITION) [Function]

Like MOVEW for moving windows but the POSITION is interpreted relative to the current position of WINDOW. Example: The following code moves WINDOW to the right one screen point.

(RELMOVEW WINDOW (create POSITION XCOORD ← 1 YCOORD ← 0))

CALCULATEREGION [Window Property]

If MOVEW calls GETBOXPOSITION to prompt the user for a region, the CALCULATEREGION window property is called (passing the window as an argument). The CALCULATEREGION should returns a region to be used to prompt the user with. If CALCULATEREGION is NIL, the region of the window is used to prompt with.

MOVEFN [Window Property]

If the MOVEFN is DON’T, the window will not be moved by MOVEW. Otherwise, if the MOVEFN is non-NIL, it should be a function or a list of functions that will be called before a window is moved with two arguments: the window being moved and the new position of the lower left corner in screen coordinates. If the MOVEFN returns DON’T, the window will not be moved. If the MOVEFN returns a POSITION, the window will be moved to that position. Otherwise, the window will be moved to the specified new position.

AFTERMOVEFN [Window Property]

If non-NIL, it should be a function or a list of functions that will be called after the window is moved (by MOVEW) with the window as an argument.

Exposing and Burying Windows

(TOTOPW WINDOW NOCALLTOTOPFNFLG) [Function]

Brings WINDOW to the top of the stack of overlapping windows, guaranteeing that it is entirely visible. If WINDOW is closed, it is opened. This is done automatically whenever a printing or drawing operation occurs to the window.
If `NOCALLTOTOPFNFLG` is `NIL`, the `TOTOPFN` of `WINDOW` is called. If `NOCALLTOTOPFNFLG` is `T`, it is not called, which allows a `TOTOPFN` to call `TOTOPW` without causing an infinite loop.

`BURYW WINDOW` [Function]

Puts `WINDOW` on the bottom of the stack by moving all the windows that it covers in front of it.

`TOTOPFN` [Window Property]

If non-`NIL`, whenever the window is brought to the top, the `TOTOPFN` is called (with the window as a single argument). This function may be used to bring a collection of windows to the top together.

If the `NOCALLTOPWFN` argument of `TOTOPW` is non-`NIL`, the `TOTOPFN` of the window is not called, which provides a way of avoiding infinite loops when using `TOTOPW` from within a `TOTOPFN`.

Shrinking Windows Into Icons

Occasionally, a user will have a number of large windows on the screen, making it difficult to access those windows being used. To help with the problem of screen space management, the Interlisp-D window system allows the creation of Icons. An icon is a small rectangle (containing text or a bitmap) which is a ‘shrunken-down’ form of a particular window. Using the Shrink and Expand window menu commands (see the beginning of this chapter), the user can shrink windows not currently being used into icons, and quickly restore the original windows at any time. This facility is controlled by the following functions and window properties:

`SHRINKW WINDOW TOWHAT ICONPOSITION EXPANDFN` [Function]

`SHRINKW` makes a small icon which represents `WINDOW` and removes `WINDOW` from the screen. Icons have a different window command menu that contains "EXPAND" instead of "SHRINK". The EXPAND command calls `EXPANDW` which returns the shrunken window to its original size and place. The icon can also be moved by pressing the LEFT button in it, or expanded by pressing the MIDDLE button in it.

The `SHRINKFN` property of the window `WINDOW` affects the operation of `SHRINKW`. If the `SHRINKFN` property of `WINDOW` is the atom `DON’T`, `SHRINKW` returns. Otherwise, the `SHRINKFN` property of the window is treated as a (list of) function(s) to apply to `WINDOW`; if any returns the atom `DON’T`, `SHRINKW` returns.

`TOWHAT`, if given, indicates the image the icon window will have. If `TOWHAT` is a string, atom or list, the icon’s image will be that string (currently implemented as a title-only window with `TOWHAT` as the title.) If `TOWHAT` is a `BITMAP`, the icon’s image will be a copy of the bitmap. If `TOWHAT` is a `WINDOW`, that window will be used as the icon.

If `TOWHAT` is not given (as is the case when invoked from the `SHRINK` window command), then the following apply in turn:
WINDOWS AND MENUS

1. If the window has an ICONFN property, it gets called with the two arguments WINDOW and OLDICON, where WINDOW is the window being shrunk and OLDICON is the previously created icon, if any. The ICONFN should return one of the TOWHAT entities described above or return the OLDICON if it does not want to change it.

2. If the window has an ICON property, it is used as the value of TOWHAT.

3. If the window has neither an ICONFN or ICON property, the icon will be WINDOW's title or, if WINDOW doesn't have a title, the date and time of the icon creation.

ICONPOSITION gives the position that the new icon will be on the screen. If it is NIL, the icon will be in the corner of the window furthest from the center of the screen.

In all but the default case, the icon is cached on the property ICONWINDOW of WINDOW so repeating SHRINKW reuses the same icon (unless overridden by the ICONFN described above). Thus to change the icon it is necessary to remove the ICONWINDOW property or call SHRINKW explicitly giving a TOWHAT argument.

( EXPANDW ICONW ) [Function]

Restores the window for which ICONW is an icon, and removes the icon from the screen. If the EXPANDFN window property of the main window is the atom DON'T, the window won't be expanded. Otherwise, the window will be restored to its original size and location and the EXPANDFN (or list of functions) will be applied to it.

SHRINKFN [Window Property]

The SHRINKFN window property can be a single function or a list of functions that are called just before a window is shrunk by SHRINKW, with the window as a single argument. If any of the SHRINKFNs are the atom DON'T, or if the value returned by any of the SHRINKFNs is the atom DON'T, the window will not be shrunk.

EXPANDREGIONFN [Window property]

EXPANDREGIONFN, if non-NIL, should be the function to be called (with the window as its argument) before the window is actually expanded.

The EXPANDREGIONFN must return NIL or a valid region, and must not do any window operations (e.g., redisplaying). If NIL is returned, the window is expanded normally, as if the EXPANDREGIONFN had not existed. The region returned specifies the new region for the main window only, not for the group including any of its attached windows. The window will be opened in its new shape, and any attached windows will be repositioned or rejustified appropriately. The main window must have a REPAINTFN which can repaint the entire window under these conditions.

As with expanding windows normally, the OPENFN for the main window is not called.
Also, the window is reshaped without checking for a special shape function (e.g., a DOSHAPEFN).

**ICONFN** [Window Property]

If SHRINKW is called without begin given a TOWHAT argument (as is the case when invoked from the SHRINK window command) and the window’s ICONFN property is non-NIL, then it gets called with two arguments, the window being shrunk and the previously created icon, if any. The ICONFN should return one of the TOWHAT entities described above or return the previously created icon if it does not want to change it.

**ICON** [Window Property]

If SHRINKW is called without being given a TOWHAT argument, the window’s ICONFN property is NIL, and the ICON property is non-NIL, then it is used as the value of TOWHAT.

**ICONWINDOW** [Window Property]

Whenever an icon is created, it is cached on the property ICONWINDOW of the window, so calling SHRINKW again will reuse the same icon (unless overridden by the ICONFN).

Thus, to change the icon it is necessary to remove the ICONWINDOW property or call SHRINKW explicitly giving a TOWHAT argument.

**DEFAULTICONFN** [Variable]

Changes how an icon is created when a window having no ICONFN is shrunk or when SHRINKW, with a TOWHAT argument of a string, is called. The value of DEFAULTICONFN is a function of two arguments (window text); text is either NIL or a string. DEFAULTICONFN returns an icon window.

The initial value of DEFAULTICONFN is MAKETITLEBARICON. It creates a window that is a title bar only; the title is either the text argument, the window’s title, or “Icon made <date>” for titleless windows. MAKETITLEBARICON places the title bar at some corner of the main window.

An alternative behavior is available by setting DEFAULTICONFN to be TEXTICON. TEXTICON creates a titled icon window from the text or window’s title.

You can now copy-select titled icons such as those used by FileBrowser, SEdit, TEdit, Sketch. The default behavior is that the icon’s title is unread (via BKSYSBUF), but if the icon window has a COPYFN property, that gets called instead, with the icon window as its argument. For example, if the name displayed in an icon is really a symbol, and you want copy selection to cause the name to be unread correctly with respect to the package and read table of the exec you are copying into, you could put the following COPYFN property on the icon window:

```
(LAMBDA (WINDOW)
  ...)
```
EXPANDFN

The EXPANDFN window property can be a single function or a list of functions. If one of the EXPANDFNs is the atom DON'T, the window will not be expanded. Otherwise, the EXPANDFNs are called after the window has been expanded by EXPANDW, with the window as a single argument.

Creating Icons with ICONW

ICONW is a group of functions available for building small windows of arbitrary shape. These windows are principally for use as icons for shrinking windows; i.e., these functions are likely to be invoked from within the ICONFN of a window. An icon is specified by supplying its image (a bitmap) and a mask that specifies its shape. The mask is a bitmap of the same dimensions as the image whose bits are on (black) in those positions considered to be in the image, and off (white) in those positions where the background should show through. By using the mask and appropriate window functions, ICONW maintains the illusion that the icon window is nonrectangular, even though the actual window itself is rectangular. The illusion is not complete, of course. For example, if you try to select what looks like the background (or an occluded window) around the icon but still within its rectangular perimeter, the icon window itself is selected. Also, if you move a window occluded by an icon, the icon never notices that the background changed behind it. Icons created with ICONW can also have titles; some part of the image can be filled with text computed at the time the icon is created, or text may be changed after creation.

Creating Icons

Two types of icons can be created with ICONW, a borderless window containing an image defined by a mask and a window with a title.

(ICONW IMAGE MASK POSITION NOOPENFLG) [Function]

Creates a window at POSITION, or prompts for a position if POSITION is NIL. The window is borderless, and filled with IMAGE, as cookie-cut by MASK. If MASK is NIL, the image is considered rectangular (i.e., MASK defaults to a black bitmap of the same dimensions as IMAGE). If NOOPENFLG is T, the window is returned unopened.

(TITLEDICONW ICON TITLE FONT POSITION NOOPENFLG JUST BREAKCHARS OPERATION) [Function]
Creates a titled icon at POSITION, or prompts for a position if POSITION is NIL. If NOOPENFLG is T, the window is returned unopened. The argument ICON is an instance of the record TITLEDICON, which specifies the icon image and mask, as with ICONW, and a region within the image to be used for displaying the title. Thus, the ICON argument is usually of the form

(creator TITLEDICON ICON ← someIconImage
  MASK ← iconMask
  TITLEREG ← someRegionWithinICON)

The title region is specified in coordinates relative to the icon, i.e., the lower-left corner of the image bitmap is (0, 0). The mask can be NIL if the icon is rectangular. The image should be white where it is covered by the title region. TITLEDICONW clears the region before printing on it. The title is printed into the specified region in the image, using FONT. If FONT is NIL it defaults to the value of DEFAULTICONFONT, initially Helvetica 10. The title is broken into multiple lines if necessary; TITLEDICONW attempts to place the breaks at characters that are in the list of character codes BREAKCHARS. BREAKCHARS defaults to (CHARCODE (SPACE ÿ )). In addition, line breaks are forced by any carriage returns in TITLE, independent of BREAKCHARS. BREAKCHARS is ignored if a long title would not otherwise fit in the specified region. For convenience, BREAKCHARS = FILE means the title is a file name, so break at file name field delimiters. The argument JUST indicates how the text should be justified relative to the region. It is an atom or list of atoms chosen from TOP, BOTTOM, LEFT, or RIGHT, which indicate the vertical positioning (flush to top or bottom) and/or horizontal positioning (flush to left edge or right). If JUST = NIL, the text is centered. The argument OPERATION is a display stream operation indicating how the title should be printed. If OPERATION is INVERT, then the title is printed white-on-black. The default OPERATION is REPLACE, meaning black-on-white. ERASE is the same as INVERT; PAINT is the same as REPLACE.

For convenience, TITLEDICONW can also be used to create icons that consist solely of a title, with no special image. If the argument ICON is NIL, TITLEDICONW creates a rectangular icon large enough to contain TITLE, with a border the same width as that on a regular window. The remaining arguments are as described above, except that a JUST of TOP or BOTTOM is not meaningful.

In the Medley release, TITLEDICONW can create icons with white text on a black background. To get this effect, your icon image must be black in the correct area, and you must specify the OPERATION argument as INVERT.

In Medley, you can copy-select the title of an icon.

**Modifying Icons**

(ICONW.TITLE ICON TITLE)
WINDOWS AND MENUS

Returns the current title of the window ICON, which must be a window returned by TITLEDICONW. In addition, if TITLE is non-NIL, makes TITLE the new title of the window and repaints it accordingly. To erase the current title, make TITLE a null string.

(iconw.shade window shade) [Function]
Returns the current shading of the window ICON, which must be a window returned by ICONW or TITLEDICONW. In addition, if SHADE is non-NIL, paints the texture SHADE on WINDOW. A typical use for this function is to communicate a change of state in a window that is shrunk, without reopening the window. To remove any shading, make SHADE be WHITESHADE.

Default Icons

When you shrink a window that has no ICONFN, the system currently creates an icon that looks like the window’s title bar. You can make the system instead create titled icons by setting the global variable DEFAULTICONFN to the value TEXTICON.

(texticon window text) [Function]
Creates a titled icon window for the main window WINDOW containing the text TEXT, or the window’s title if TEXT is NIL.

DEFAULTTEXTICON [Variable]
The value that TEXTICON passes to TITLEDICONW as its ICON argument. Initially it is NIL, which creates an unadorned rectangular window. However, you can set it to a TITLEDICON record of your choosing if you would like default icons to have a different appearance.

Coordinate Systems, Extents, And Scrolling

Note: The word “scrolling” has two distinct meanings when applied to Interlisp-D windows. This section documents the use of "scroll bars" on the left and bottom of a window to move an object displayed in the window. "Scrolling" also describes the feature where trying to print text off the bottom of a window will cause the contents to "scroll up." This second feature is controlled by the function DSPSCROLL (see Chapter 27).

One way of thinking of a window is as a "view" onto an object (e.g. a graph, a file, a picture, etc.) The object has its own natural coordinate system in terms of which its subparts are laid out. When the window is created, the X Offset and Y Offset of the window’s display stream are set to map the origin of the object’s coordinate system into the lower left point of the window’s interior region. At the same time, the Clipping Region of the display stream is set to correspond to the interior of the window. From then on, the display stream’s coordinate system is translated and its clipping region adjusted whenever the window is moved, scrolled or reshaped.
There are several distinct regions associated with a window viewing an object. First, there is a region in the window’s coordinate system that contains the complete image of the object. This region (which can only be determined by application programs with knowledge of the "semantics" of the object) is stored as the `EXTENT` property of the window (below). Second, the clipping region of the display stream (obtainable with the function `DSPCLIPPINGREGION`, see Chapter 27) specifies the portion of the object that is actually visible in the window. This is set so that it corresponds to the interior of the window (not including the border or title). Finally, there is the region on the screen that specifies the total area that the window occupies, including the border and title. This region (in screen coordinates) is stored as the `REGION` property of the window (see the Miscellaneous Window Properties section below).

The window system supports the idea of scrolling the contents of a window. Scrolling regions are on the left and the bottom edge of each window. The `LEFT` button is used to indicate upward or leftward scrolling by the amount necessary to move the selected position to the top or the left edge. The `RIGHT` button is used to indicate downward or rightward scrolling by the amount necessary to move the top or left edge to the selected position. The `MIDDLE` button is used to indicate global placement of the object within the window (similar to "thumbing" a book). In the scroll region, the part of the object that is being viewed by the window is marked with a gray shade. If the whole scroll bar is thought of as the entire object, the shaded portion is the portion currently being viewed. This will only occur when the window "knows" how big the object is (see window property `EXTENT`, below).

When the button is released in a scroll region, the function `SCROLLW` is called. `SCROLLW` calls the scrolling function associated with the window to do the actual scrolling and provides a programmable entry to the scrolling operation.

```
(SCROLLW WINDOW DELTAX DELTAY CONTINUOUSFLG)  [Function]
```

Calls the `SCROLLFN` window property of the window `WINDOW` with arguments `WINDOW`, `DELTAX`, `DELTAY` and `CONTINUOUSFLG`. See `SCROLLFN` window property below.

```
(SCROLL.HANDLER WINDOW)  [Function]
```

This is the function that tracks the mouse while it is in the scroll region. It is called when the cursor leaves a window in either the left or downward direction. If `N WINDOW` does not have a scroll region for this direction (e.g. the window has moved or reshaped since it was last scrolled), a scroll region is created that is `SCROLLBARWIDTH` wide. It then waits for `SCROLLWAITTIME` milliseconds and if the cursor is still inside the scroll region, it opens a window the size of the scroll region and changes the cursor to indicate the scrolling is taking place.

When a button is pressed, the cursor shape is changed to indicate the type of scrolling (up, down, left, right or thumb). After the button is held for `WAITBEFORESCROLLTIME` milliseconds, until the button is released `SCROLLW` is called each `WAITBETWEENSCROLLTIME` milliseconds. These calls are made with the `CONTINUOUSFLG` argument set to `T`. If the button is released before `WAITBEFORESCROLLTIME` milliseconds, `SCROLLW` is called with the `CONTINUOUSFLG` argument set to `NIL`. 
The arguments passed to SCROLLW depend on the mouse button. If the LEFT button is used in the vertical scroll region, DY is distance from cursor position at the time the button was released to the top of the window and DX is 0. If the RIGHT button is used, the inverse of this quantity is used for DY and 0 for DX. If the LEFT button is used in the horizontal scroll region, DX is distance from cursor position to left of the window and DY is 0. If the RIGHT button is used, the inverse of this quantity is used for DX and 0 for DY.

If the MIDDLE button is pressed, the distance argument to SCROLLW will be a FLOATP between 0.0 and 1.0 that indicates the proportion of the distance the cursor was from the left or top edge to the right or bottom edge.

Note: The scrolling regions will not come up if the window has a SCROLLFN window property of NIL, has a non-NIL NOSCROLLBARS window property, or if its SCROLLEXTENTUSE property has certain values and its EXTENT is fully visible.

(SCROLLBYREPAINTFN WINDOW DELTAX DELTAY CONTINUOUSFLG) [Function]

SCROLLBYREPAINTFN is the standard scrolling function which should be used as the SCROLLFN property for most scrolling windows.

This function, when used as a SCROLLFN, BITBLTs the bits that will remain visible after the scroll to their new location, fills the newly exposed area with texture, adjusts the window’s coordinates and then calls the window’s REPAINTFN on the newly exposed region. Thus this function will scroll any window that has a repaint function.

If WINDOW has an EXTENT property, SCROLLBYREPAINTFN will limit scrolling in the X and Y directions according to the value of the window property SCROLLEXTENTUSE.

If DELTAX or DELTAY is a FLOATP, SCROLLBYREPAINTFN will position the window so that its top or left edge will be positioned at that proportion of its EXTENT. If the window does not have an EXTENT, SCROLLBYREPAINTFN will do nothing.

If CONTINUOUSFLG is non-NIL, this indicates that the scrolling button is being held down. In this case, SCROLLBYREPAINTFN will scroll the distance of one linefeed height (as returned by DSPLINEFEED, see Chapter 27).

Scrolling is controlled by the following window properties:

EXTENT [Window Property]

Used to limit scrolling operations. Accesses the extent region of the window. If non-NIL, the EXTENT is a region in the window’s display stream that contains the complete image of the object being viewed by the window. User programs are responsible for updating the EXTENT. The functions UNIONREGIONS, EXTENDREGION, etc. (see Chapter 27) are useful for computing a new extent region.

In some situations, it is useful to define an EXTENT that only exists in one dimension. This may be done by specifying an EXTENT region with a width or height of -1.
SCROLLFN handling recognizes this situation as meaning that the negative EXTENT dimension is unknown.

**SCROLLFN**

[Window Property]

If the SCROLLFN property is NIL, the window will not scroll. Otherwise, it should be a function of four arguments: (1) the window being scrolled, (2) the distance to scroll in the horizontal direction (positive to right, negative to left), (3) the distance to scroll in the vertical direction (positive up, negative down), and (4) a flag which is T if the scrolling button is being held down. For more information, see SCROLLHANDLER. For most scrolling windows, the SCROLLFN function should be SCROLLBYREPAINTFN.

**NOSCROLLBARS**

[Window Property]

If the NOSCROLLBARS property is non-NIL, scroll bars will not be brought up for this window. This disables mouse-driven scrolling of a window. This window can still be scrolled using SCROLLW.

**SCROLLEXTENTUSE**

[Window Property]

SCROLLBYREPAINTFN uses the SCROLLEXTENTUSE window property to limit how far scrolling can go in the X and Y directions. The possible values for SCROLLEXTENTUSE and their interpretations are:

- **NIL** This will keep the extent region visible or near visible. It will not scroll the window so that the top of the extent is below the top of the window, the bottom of the extent is more than one point above the top of the window, the left of the extent is to the right of the window and the right of the extent is to the left of the window. The EXTENT can be scrolled to just above the window to provide a way of "hiding" the contents of a window. In this mode the extent is either in the window or just of the top of the window.

- **T** The extent is not used to control scrolling. The user can scroll the window to anywhere. Having the EXTENT window property does all thumb scrolling to be supported so that the user can get back to the EXTENT by thumb scrolling.

- **LIMIT** This will keep the extent region visible. The window is only allowed to view within the extent.

- **+** This will keep the extent region visible or just off in the positive direction in either X or Y (i.e., the image will be either be visible or just off to the top and/or right.)

- **-** This will keep the extent region visible or just off in the negative direction in either X or Y (i.e., the image will be either be visible or just off to the left and/or bottom.)
This will keep the extent region visible or just off in the window (i.e. the image will be either be visible or just off to the left, bottom, top or right).

(XBEHAVIOR . YBEHAVIOR) If the SCROLLEXTENTUSE is a list, the CAR is interpreted as the scrolling limit in the X behavior and the CDR as the scrolling limit in the Y behavior. XBEHAVIOR and YBEHAVIOR should each be one of the atoms (NIL T LIMIT + - ++ -+). The interpretations of the atoms is the same as above except that NIL is equivalent to LIMIT.

Note: The NIL value of SCROLLEXTENTUSE is equivalent to (LIMIT . +).

Example: If the SCROLLEXTENTUSE window property of a window (with an extent defined) is (LIMIT . T), the window will scroll uncontrolled in the Y dimension but be limited to the extent region in the X dimension.

Mouse Activity in Windows

The following window properties allow the user to control the response to mouse activity in a window. The value of these properties, if non-NIL, should be a function that will be called (with the window as argument) when the specified event occurs.

These functions should be "self-contained", communicating with the outside world solely via their window argument, e.g., by setting window properties. In particular, these functions should not expect to access variables bound on the stack, as the stack context is formally undefined at the time these functions are called. Since the functions are invoked asynchronously, they perform any terminal input/output operations from their own window.

WINDOWENTRYFN [Window Property]

Whenever a button goes down in the window and the process associated with the window is not the tty process, the WINDOWENTRYFN is called. The default is GIVE.TTY.PROCESS which gives the process associated with the window the tty and calls the BUTTONEVENTFN. WINDOWENTRYFN can be a list of functions and all will be called.

CURSORINFN [Window Property]

Whenever the mouse moves into the window, the CURSORINFN is called. If CURSORINFN is a list of functions, all will be called.

CURSOROUTFN [Window Property]

The CURSOROUTFN is called when the cursor leaves the window. If CURSOROUTFN is a list of functions, all will be called.

CURSORMOVEDFN [Window Property]
The CURSORMOVEDFN is called whenever the cursor has moved and is inside the window. CURSORMOVEDFN can be a list of functions and all will be called. This allows a window function to implement "active" regions within itself by having its CURSORMOVEDFN determine if the cursor is in a region of interest, and if so, perform some action.

**BUTTONEVENTFN** [Window Property]

The BUTTONEVENTFN is called whenever there is a change in the state (up or down) of the mouse buttons inside the window. Changes to the mouse state while the BUTTONEVENTFN is running will not be interpreted as new button events, and the BUTTONEVENTFN will not be re-invoked.

**RIGHTBUTTONFN** [Window Property]

The RIGHTBUTTONFN is called in lieu of the standard window menu operation (DOWINDOWCOM) when the RIGHT button is depressed in a window. More specifically, the RIGHTBUTTONFN is called instead of the BUTTONEVENTFN when (MOUSESTATE (ONLY RIGHT)). If the RIGHT button is to be treated like any other key in a window, supply RIGHTBUTTONFN and BUTTONEVENTFN with the same function.

When an application program defines its own RIGHTBUTTONFN, there is a convention that the default RIGHTBUTTONFN, DOWINDOWCOM, may be executed by pressing the RIGHT button when the cursor is in the header or border of a window. User RIGHTBUTTONFNs are encouraged to follow this convention, by calling DOWINDOWCOM if the cursor is not in the interior region of the window.

**BACKGROUNDBUTTONEVENTFN** [Variable]

**BACKGROUNDCURSORINFN** [Variable]

**BACKGROUNDCURSOROUTFN** [Variable]

**BACKGROUNDCURSORMOVEDFN** [Variable]

These variables provide a way of taking action when there is cursor action and the cursor is in the background. They are interpreted like the corresponding window properties. If set to the name of a function, that function will be called, respectively, whenever the cursor is in the background and a button changes, when the cursor moves into the background from a window, when the cursor moved from the background into a window and when the cursor moves from one place in the background to another.

**Terminal I/O and Page Holding**

Each process has its own terminal i/o stream (accessed as the stream T, see Chapter 25). The terminal i/o stream for the current process can be changed to point to a window by using the function TTYDISPLAYSTREAM, so that output and echoing of type-in is directed to a window.

(TTYDISPLAYSTREAM DISPLAYSTREAM) [Function]

Selects the display stream or window DISPLAYSTREAM to be the terminal output channel, and returns the previous terminal output display stream. TTYDISPLAYSTREAM puts
DISPLAYSTREAM into scrolling mode and calls PAGEHEIGHT with the number of lines that will fit into DISPLAYSTREAM given its current Font and Clipping Region. The line length of TTYDISPLAYSTREAM is computed (like any other display stream) from its Left Margin, Right Margin, and Font. If one of these fields is changed, its line length is recalculated. If one of the fields used to compute the number of lines (such as the Clipping Region or Font) changes, PAGEHEIGHT is not automatically recomputed. (TTYDISPLAYSTREAM (TTYDISPLAYSTREAM)) will cause it to be recomputed.

If the window system is active, the line buffer is saved in the old TTY window, and the line buffer is set to the one saved in the window of the new display stream, or to a newly created line buffer (if it does not have one). Caution: It is possible to move the TTYDISPLAYSTREAM to a nonvisible display stream or to a window whose current position is not in its clipping region.

(PAGEHEIGHT N) [Function]

If N is greater than 0, it is the number of lines of output that will be printed to TTYDISPLAYSTREAM before the page is held. A page is held before the N+1 line is printed to TTYDISPLAYSTREAM without intervening input if there is no terminal input waiting to be read. The output is held with the screen video reversed until a character is typed. Output holding is disabled if N is 0. PAGEHEIGHT returns the previous setting.

PAGEFULLFN [Window Property]

If the PAGEFULLFN window property is non-NIL, it will be called with the window as a single argument when the window is full (i.e., when enough has been printed since the last TTY interaction so that the next character printed will cause information to be scrolled off the top of the window.)

If the PAGEFULLFN window property is NIL, the system function PAGEFULLFN is called. PAGEFULLFN simply returns if there are characters in the type-in buffer for WINDOW, otherwise it inverts the window and waits for the user to type a character. PAGEFULLFN is user advisable.

Note: The PAGEFULLFN window property is only called on windows which are the TTYDISPLAYSTREAM of some process.

TTY Process and the Caret

At any time, one process is designated as the TTY process, which is used for accepting keyboard input. The TTY process can be changed to a given process by calling GIVE.TTY.PROCESS (see Chapter 23), or by clicking the mouse in a window associated with the process. The latter mechanism is implemented with the following window property:

PROCESS [Window Property]

If the PROCESS window property is non-NIL, it should be a PROCESS and will be made the TTY process by GIVE.TTY.PROCESS (see Chapter 23), the default
WINDOWENTRYFN property (see above). This implements the mechanism by which the keyboard is associated with different processes.

The window system uses a flashing caret (▲) to indicate the position of the next window typeout. There is only one caret visible at any one time. The caret in the current TTY process is always visible; if it is hidden by another window, its window is brought to the top. An exception to this rule is that the flashing caret’s window is not brought to the top if the user is buttoning or has a shift key down. This prevents the destination window (which has the tty and caret flashing) from interfering with the window one is trying to select text to copy from.

(CARET NEWCARET) [Function]
Sets the shape that blinks at the location of the next output to the current process. NEWCARET should be one of the following:

- a CURSOR object: If NEWCARET is a CURSOR object (see Chapter 30), it is used to give the new caret shape
- OFF: Turns the caret off
- NIL: The caret is not changed. CARET returns a CURSOR representing the current caret
- T: Reset the caret to the value of DEFAULTCARET. DEFAULTCARET can be set to change the initial caret for new processes.

The hotspot of NEWCARET indicates which point in the new caret bitmap should be located at the current output position. The previous caret is returned. Note: the bitmap for the caret is not limited to the dimensions CURSORWIDTH by CURSORHEIGHT.

(CARETRATE ONRATE OFFRATE) [Function]
Sets the rate at which the caret for the current process will flash. The caret will be visible for ONRATE milliseconds, then not visible for OFFRATE milliseconds. If OFFRATE is NIL then it is set to be the same as ONRATE. If ONRATE is T, both the "on" and "off" times are set to the value of the variable DEFAULTCARETRATE (initially 333). The previous value of CARETRATE is returned. If the caret is off, CARETRATE return NIL.

Miscellaneous Window Functions

(CLEARW WINDOW) [Function]
Fills WINDOW with its background texture, changes its coordinate system so that the origin is the lower left corner of the window, sets its X position to the left margin and sets its Y position to the base line of the uppermost line of text, i.e., the top of the window less the font ascent.

(INVERTW WINDOW SHADE) [Function]
Fills the window \textit{WINDOW} with the texture \textit{SHADE} in \textit{INVERT} mode. If \textit{SHADE} is NIL, \textit{BLACKSHADE} is used. \textit{INVERTW} returns \textit{WINDOW} so that it can be used inside \textit{RESETFORM}.

\textbf{(FLASHWINDOW \textit{WIN}}? \textit{N \textit{FLASHINTERVAL \textit{SHADE}}}) \hspace{1cm} \textbf{[Function]}

Flashes the window \textit{WIN}? by “inverting” it twice. \textit{N} is the number of times to flash the window (default is 1). \textit{FLASHINTERVAL} is the length of time in milliseconds to wait between flashes (default is 200). \textit{SHADE} is the shade that will be used to invert the window (default is \textit{BLACKSHADE}).

If \textit{WIN}? is NIL, the whole screen is flashed. In this case, the \textit{SHADE} argument is ignored (can only invert the screen).

\textbf{(WHICHW \textit{X Y})} \hspace{1cm} \textbf{[Function]}

Returns the window which contains the position in screen coordinates of \textit{X} if \textit{X} is a \textit{POSITION}, the position \textit{(X, Y)} if \textit{X} and \textit{Y} are numbers, or the position of the cursor if \textit{X} is NIL. Returns NIL if the coordinates are not in any window. If they are in more than one window, it returns the uppermost.

Example: (\textbf{WHICHW}) returns the window that the cursor is in.

\textbf{(DECODE/\textit{WINDOW}/\textit{OR}/DISPLAYSTREAM \textit{DSORW \textit{WINDOWVAR TITLE BORDER}})} \hspace{1cm} \textbf{[Function]}

Returns a display stream as determined by the \textit{DSORW} and \textit{WINDOWVAR} arguments. If \textit{DSORW} is a display stream, it is returned. If \textit{DSORW} is a window, its display stream is returned. If \textit{DSORW} is NIL, the litatom \textit{WINDOWVAR} is evaluated. If its value is a window, its display stream is returned. If its value is not a window, \textit{WINDOWVAR} is set to a newly created window (prompting user for region) whose display stream is then returned. If \textit{DSORW} is \textit{NEW}, the display stream of a newly created window is returned. If a window is involved in the decoding, it is opened and if \textit{TITLE} or \textit{BORDER} are given, the \textit{TITLE} or \textit{BORDER} property of the window are reset. The \textit{DSORW = NIL} case is most useful for programs that want to display their output in a window, but want to reuse the same window each time they are called. The non-NIL cases are good for decoding a display stream argument passed to a function.

\textbf{(WIDTHIFWINDOW \textit{INTERIORWIDTH BORDER})} \hspace{1cm} \textbf{[Function]}

Returns the width of the window necessary to have \textit{INTERIORWIDTH} points in its interior if the width of the border is \textit{BORDER}. If \textit{BORDER} is NIL, the default border size \textit{WBorder} is used.

\textbf{(HEIGHTIFWINDOW \textit{INTERIORHEIGHT TITLEFLG BORDER})} \hspace{1cm} \textbf{[Function]}

Returns the height of the window necessary to have \textit{INTERIORHEIGHT} points in its interior with a border of \textit{BORDER} and, if \textit{TITLEFLG} is non-NIL, a title. If \textit{BORDER} is NIL, the default border size \textit{WBorder} is used.
WIDTHIFWINDOW and HEIGHTIFWINDOW are useful for calculating the width and height for a call to GETBOXPOSITION for the purpose of positioning a prospective window.

\[ \text{(MINIMUMWINDOWSIZE \textit{WINDOW})} \] [Function]

Returns a dotted pair, the \textit{car} of which is the minimum width \textit{WINDOW} needs and the \textit{cdr} or which is the minimum height \textit{WINDOW} needs.

The minimum size is determined by the value of the window property MINSIZE of \textit{WINDOW}. If the value of the MINSIZE window property is \texttt{NIL}, the width is 26 and the height is the height \textit{WINDOW} needs to have its title, border and one line of text visible. If MINSIZE is a dotted pair, it is returned. If it is a litatom, it should be a function which is called with \textit{WINDOW} as its first argument, which should return a dotted pair.

**Miscellaneous Window Properties**

\textbf{TITLE} [Window Property]

Accesses the title of the window. If a title is added to a window whose title is \texttt{NIL} or the title is removed (set to \texttt{NIL}) from a window with a title, the window’s exterior (its region on the screen) is enlarged or reduced to accommodate the change without changing the window’s interior. For example, \texttt{(WINDOWPROP \textit{WINDOW} 'TITLE "Results")} changes the title of \textit{WINDOW} to be "Results". \texttt{(WINDOWPROP \textit{WINDOW} 'TITLE NIL)} removes the title of \textit{WINDOW}.

\textbf{BORDER} [Window Property]

Accesses the width of the border of the window. The border will have at most 2 point of white (but never more than half) and the rest black. The default border is the value of the global variable \texttt{WBorder} (initially 4).

\textbf{WINDOWTITLESHADE} [Window Property]

Accesses the window title shade of the window. If non-\texttt{NIL}, it should be a texture which is used as the "background texture" for the title bar on the top of the window. If it is \texttt{NIL}, the value of the global variable \texttt{WINDOWTITLESHADE} (initially \texttt{BLACKSHADE}) is used. Note that black is always used as the background of the title printed in the title bar, so that the letters can be read. The remaining space is painted with the "title shade".

\textbf{HARDCOPYFN} [Window Property]

If non-\texttt{NIL}, it should be a function that is called by the window menu command Hardcopy to print the contents of a window. The \texttt{HARDCOPYFN} property is called with two arguments, the window and an image stream to print to. If the window does not have a \texttt{HARDCOPYFN}, the bitmap image of the window (including the border and title) are printed on the file or printer.

\textbf{DSP} [Window Property]
Value is the display stream of the window. All system functions will operate on either the window or its display stream. This window property cannot be changed using WINDOWPROP.

**HEIGHT** [Window Property]

**WIDTH** [Window Property]

Value is the height and width of the interior of the window (the usable space not counting the border and title). These window properties cannot be changed using WINDOWPROP.

**REGION** [Window Property]

Value is a region (in screen coordinates) indicating where the window (counting the border and title) is located on the screen. This window property cannot be changed using WINDOWPROP.

### Example: A Scrollable Window

The following is a simple example showing how one might create a scrollable window.

CREATE.PPWINDOW creates a window that displays the pretty printed expression EXPR. The window properties PPEXPR, PPORIGX, and PPORIGY are used for saving this expression, and the initial window position. Using this information, REPAINT.PPWINDOW simply reinitializes the window position, and prettyprints the expression again. Note that the whole expression is reformatted every time, even if only a small part actually lies within the window. If this window was going to be used to display very large structures, it would be desirable to implement a more sophisticated REPAINTFN that only redisplays that part of the expression within the window. However, this scheme would be satisfactory if most of the items to be displayed are small.

RESHAPE.PPWINDOW resets the window (and stores the initial window position), calls REPAINT.PPWINDOW to display the window’s expression, and then sets the EXTENT property of the window so that SCROLLBYREPAINTFN will be able to handle scrolling and "thumbing" correctly.

```lisp
(defineq
(create.ppwindow
 [lambda (expr) (* rrb "4-oct-82 12:06")
 (* creates a window that displays a pretty printed expression.)]
 (prog (window)
 (* ask the user for a piece of the screen and make it into a window.)
 (setq window (createw nil "pp window")
 (* put the expression on the property list of the window so that the repaint and reshape functions can access it.)
 (windowprop window (quote ppepr) expr)
 (* set the repaint and reshape functions.)
```

27 - 33
* make the scroll function
  SCROLLBYREPAINTFN, a system
  function that uses the repaint
  function to do scrolling.

* call the reshape function to
  initially print the expression and
  calculate its extent.

(RESHAPE.PPWINDOW WINDOW)
(RETURN WINDOW]

(REPAINT.PPWINDOW

Menus

A menu is basically a means of selecting from a list of items. The system provides common layout and interactive user selection mechanisms, then calls a user-supplied function when a selection has been confirmed. The two major constituents of a menu are a list of items and a "when selected function." The label that appears for each item is the item itself for non-lists, or its CAR if the item is a list. In addition, there are a multitude of different formatting parameters for specifying font, size, and layout. When a menu is created, its unspecified fields are filled with defaults and its screen image is computed and saved.

Menus can be either pop up or fixed. If fixed menus are used, the menu must be included in a window.

(MENU MENU POSITION RELEASECONTROLFLG —) [Function]

This function provides menus that pop up when they are used. It displays MENU at POSITION (in screen coordinates) and waits for the user to select an item with a mouse key. Before any mouse key is pressed, the item the mouse is over is boxed. After any key is down, the selected menu item is video reversed. When all keys are released, MENU's WHENSELECTEDFN field is called with four arguments: (1) the item selected, (2) the menu, (3) the last mouse key released (LEFT, MIDDLE, or RIGHT), and (4) the reverse list of superitems rolled through when selecting the item and MENU returns its
value. If no item is selected, \texttt{MENU} returns \texttt{NIL}. If \texttt{POSITION} is \texttt{NIL}, the menu is brought up at the value from \texttt{MENU}'s \texttt{MENU\_POSITION} field, if it is a \texttt{POSITION}, or at the current cursor position. The orientation of \texttt{MENU} with respect to the specified position is determined by its \texttt{MENU\_OFFSET} field.

If \texttt{RELEASE\_CONTROL\_FLG} is \texttt{NIL}, this process will retain control of the mouse. In this case, if the user lets the mouse key up outside of the menu, \texttt{MENU} return \texttt{NIL}. (Note: this is the standard way of allowing the user to indicate that they do not want to make the offered choice.) If \texttt{RELEASE\_CONTROL\_FLG} is non-\texttt{NIL}, this process will give up control of the mouse when it is outside of the menu so that other processes can be run. In this case, clicking outside the menu has no effect on the call to \texttt{MENU}. If the menu is closed (for example, by right buttoning in it and selecting "Close" from the window menu), \texttt{MENU} returns \texttt{NIL}. Programmers are encouraged to provide a menu item such as "cancel" or "abort" which gives users a positive way of indicating "no choice".

Note: A "released" menu will stay visible (on top of the window stack) until it is closed or an item is selected.

\textbf{ADDMENU \texttt{MENU \texttt{WINDOW \texttt{POSITION \texttt{DONTOPENFLG})}} [Function]}

This function provides menus that remain active in windows. \texttt{ADDMENU} displays \texttt{MENU} at \texttt{POSITION} (in window coordinates) in \texttt{WINDOW}. If the window is too small to display the entire menu, the window is made scrollable. When an item is selected, the value of the \texttt{WHENSELECTED\_FN} field of \texttt{MENU} is called with three arguments: (1) the item selected, (2) the menu, and (3) the mouse button that the item was selected with (\texttt{LEFT}, \texttt{MIDDLE}, or \texttt{RIGHT}). More than one menu can be put in a window, but a menu can only be added to one window at a time. \texttt{ADDMENU} returns the window into which \texttt{MENU} is placed.

If \texttt{WINDOW} is \texttt{NIL}, a window is created at the position specified by \texttt{POSITION} (in screen coordinates) that is the size of \texttt{MENU}. If a window is created, it will be opened unless \texttt{DONTOPENFLG} is non-\texttt{NIL}. If \texttt{POSITION} is \texttt{NIL}, the menu is brought up at the value of \texttt{MENU}'s \texttt{MENU\_POSITION} field (in window coordinates), if it is a position, or else in the lower left corner of \texttt{WINDOW}. If both \texttt{WINDOW} and \texttt{POSITION} are \texttt{NIL}, a window is created at the current cursor position.

Warning: \texttt{ADDMENU} resets several of the window properties of \texttt{WINDOW}. The \texttt{CURSOR\_INFN}, \texttt{CURSOR\_MOVED\_FN}, and \texttt{BUTTONDOWN\_FN} window properties are replaced with \texttt{MENU\_BUTTON\_FN}, so that \texttt{MENU} will be active. \texttt{MENUREPAINT\_FN} is added to the \texttt{REPAINT\_FN} window property to update the menu image if the window is redisplayed. The \texttt{SCROLL\_FN} window property is changed to \texttt{SCROLL\_BY\_REPAINT\_FN} if the window is too small for the menu, to make the window scroll.

\textbf{DELETEmenu \texttt{MENU \texttt{CLOSEFLG \texttt{FROMWINDOW})} [Function]}

This function removes \texttt{MENU} from the window \texttt{FROMWINDOW}. If \texttt{MENU} is the only menu in the window and \texttt{CLOSEFLG} is non-\texttt{NIL}, its window will be closed (by \texttt{CLOSE\_W}).
If FROMWINDOW is NIL, the list of currently open windows is searched for one that contains MENU. If none is found, DELETEMENU does nothing.

**Menu Fields**

A menu is a datatype with the following fields:

**ITEMS**

[Menu Field]

The list of items to appear in the menu. If an item is a list, its CAR will appear in the menu. If the item (or its CAR) is a bitmap, the bitmap will be displayed in the menu. The default selection functions interpret each item as a list of three elements: a label, a form whose value is returned upon selection, and a help string that is printed in the prompt window when the user presses a mouse key with the cursor pointing to this item. The default subitem function interprets the fourth element of the list. If it is a list whose CAR is the litatom SUBITEMS, the CDR is taken as a list of subitems.

**SUBITEMFN**

[Menu Field]

A function to be called to determine if an item has any subitems. If an item has subitems and the user rolls the cursor out the right of that item, a submenu with that item’s subitems in it pops up. If the user selects one of the items from the submenu, the selected subitem is handled as if it were selected from the main menu. If the user rolls out of the submenu to the left, the submenu is taken down and selection resumes from the main menu.

An item with subitems is marked in the menu by a grey, right pointing triangle following the label.

The function is called with two arguments: (1) the menu and (2) the item. It should return a list of the subitems of this item if any. (It is called twice to compute the menu image and each time the user rolls out of the item box so it should be moderately efficient. The default SUBITEMFN, DEFAULTSUBITEMFN, checks to see if the item is a list whose fourth element is a list whose CAR is the litatom SUBITEMS and if so, returns the CDR of it.

For example:

```lisp
(create MENU
    ITEMS ← '(AAAA (BBBB 'BBBB "help string for BBBB"
            (SUBITEMS BBBB1 BBBB2 BBBB3)))
```

will create a menu with items A and B in which B will have subitems B1, B2 and B3. The following picture below shows this menu as it first appears:
The following picture shows the submenu, with the item BBBB3 selected by the cursor:

```
AAAA  BBBB1
BBBB2  BBBB3
```

WHENSELECTEDFN

A function to be called when an item is selected. The function is called with three arguments: (1) the item selected, (2) the menu, and (3) the mouse key that the item was selected with (LEFT, MIDDLE, or RIGHT). The default function DEFAULTWHENSELECTEDFN evaluates and returns the value of the second element of the item if the item is a list of at least length 2. If the item is not a list of at least length 2, DEFAULTWHENSELECTEDFN returns the item.

Note: If the menu is added to a window with ADDMENU, the default WHENSELECTEDFN is BACKGROUNDWHENSELECTEDFN, which is the same as DEFAULTWHENSELECTEDFN except that EVAL.AS.PROCESS is used to evaluate the second element of the item, instead of tying up the mouse process.

WHENHELDFN

The function which is called when the user has held a mouse key on an item for MENUHELDFWAIT milliseconds (initially 1200). The function is called with three arguments: (1) the item selected, (2) the menu, and (3) the mouse key that the item was selected with (LEFT, MIDDLE, or RIGHT). WHENHELDFN is intended for prompting users. The default is DEFAULTMENUHELDFN which prints (in the prompt window) the third element of the item or, if there is not a third element, the string "This item will be selected when the button is released."

WHENUNHELDFN

If WHENHELDFN was called, WHENUNHELDFN will be called: (1) when the cursor leaves the item, (2) when a mouse key is released, or (3) when another key is pressed. The function is called with the same three argument values used to call WHENHELDFN. The default WHENUNHELDFN is the function CLR.PROMPT, which just clears the prompt window.

MENUPOSITION

The position of the menu to be used if the call to MENU or ADDMENU does not specify a position. For popup menus, this is in screen coordinates. For fixed menus, it is in the coordinates of the window the menu is in. The point within the menu image that is placed at this position is determined by MENUOFFSET. If MENUPOSITION is NIL, the menu will be brought up at the cursor position.

MENUOFFSET

[Menu Field]

[Image 177x549 to 185x565]
[Image 306x489 to 397x539]
The position in the menu image that is to be located at MENUPOSITION. The default offset is (0,0). For example, to bring up a menu with the cursor over a particular menu item, set its MENUOFFSET to a position within that item and set its MENUPOSITION to NIL.

**MENUFONT**  
[Menu Field]  
The font in which the items will be appear in the menu. Default is the value of MENUFONT.

**TITLE**  
[Menu Field]  
If non-NIL, the value of this field will appear as a title in a line above the menu.

**MENUTITLEFONT**  
[Menu Field]  
The font in which the title of the menu will be appear. If this is NIL, the title will be in the same font as window titles. If it is T, it will be in the same font as the menu items.

**CENTERFLG**  
[Menu Field]  
If non-NIL, the menu items are centered; otherwise they are left-justified.

**MENUROWS**  
[Menu Field]  
**MENUCOLUMNS**  
[Menu Field]  
These fields control the shape of the menu in terms of rows and columns. If MENUROWS is given, the menu will have that number of rows. If MENUCOLUMNS is given, the menu will have that number of columns. If only one is given, the other one will be calculated to generate the minimal rectangular menu. (Normally only one of MENUROWS or MENUCOLUMNS is given.) If neither is given, the items will be in one column.

**ITEMHEIGHT**  
[Menu Field]  
The height of each item box in the menu. If not specified, it will be the maximum of the height of the MENUFONT and the heights of any bitmaps appearing as labels.

**ITEMWIDTH**  
[Menu Field]  
The width of each item box in the menu. If not specified, it will be the width of the largest item in the menu.

**MENUBORDERSIZE**  
[Menu Field]  
The size of the border around each item box. If not specified, 0 (no border) is used.

**MENUOUTLINESIZE**  
[Menu Field]  
The size of the outline around the entire menu. If not specified, a maximum of 1 and the MENUBORDERSIZE is used.

**CHANGEOFFSETFLG**  
[Menu Field]
If CHANGEOFFSETFLG is non-NIL, the position of the menu offset is set each time a selection is confirmed so that the menu will come up next time in the same position relative to the cursor. This will cause the menu to reappear in the same place on the screen if the cursor has not moved since the last selection. This is implemented by changing the MENUOFFSET field on each use. If CHANGEOFFSETFLG is the atom X or the atom Y, only the X or the Y coordinate of the MENUOFFSET field will be changed. For example, by setting the MENUOFFSET position to (-1,0) and setting CHANGEOFFSETFLG to Y, the menu will pop up so that the cursor is just to the left of the last item selected. This is the setting of the window command menus.

The following fields are read only.

**IMAGEHEIGHT**  
Returns the height of the entire menu.

**IMAGEWIDTH**  
Returns the width of the entire menu.

**Miscellaneous Menu Functions**

(\(
\text{MAXMENUITEMWIDTH \( \textit{MENU} \)}
\)

Returns the width of the largest menu item label in the menu \( \textit{MENU} \).

(\(
\text{MAXMENUITEMHEIGHT \( \textit{MENU} \)}
\)

Returns the height of the largest menu item label in the menu \( \textit{MENU} \).

(\(
\text{MENUREGION \( \textit{MENU} \)}
\)

Returns the region covered by the image of \( \textit{MENU} \) in its window.

(\(
\text{WFROMMENU \( \textit{MENU} \)}
\)

Returns the window \( \textit{MENU} \) is located in, if it is in one; NIL otherwise.

(\(
\text{DOSELECTEDITEM \( \textit{MENU} \ \textit{ITEM} \ \textit{BUTTON} \)}
\)

Calls \( \textit{MENU} \)'s WHENSELECTEDFN on \( \textit{ITEM} \) and \( \textit{BUTTON} \). It provides a programmatic way of making a selection. It does not change the display.

(\(
\text{MENUITEMREGION \( \textit{ITEM} \ \textit{MENU} \)}
\)

Returns the region occupied by \( \textit{ITEM} \) in \( \textit{MENU} \).

(\(
\text{SHADEITEM \( \textit{ITEM} \ \textit{MENU} \ \textit{SHADE} \ \textit{DS/W} \)}
\)

Shades the region occupied by \( \textit{ITEM} \) in \( \textit{MENU} \). If \( \textit{DS/W} \) is a display stream or a window, it is assumed to be where \( \textit{MENU} \) is displayed. Otherwise, WFROMMENU is called to locate the
window MENU is in. Shading is persistent, and is reapplied when the window the menu is in gets redisplayed. To unshade an item, call with a SHADE of 0.

(PUTMENUPROP MENU PROPERTY VALUE)  [Function]
Stores the property PROPERTY with the value VALUE on a property list in the menu MENU. The user can use this property list for associating arbitrary data with a menu object.

(GETMENUPROP MENU PROPERTY)  [Function]
Returns the value of the PROPERTY property of the menu MENU.

Examples of Menu Use

Example: A simple menu:

(MENU (create MENU ITEMS _ '((YES T) (NO (QUOTE NIL))) )

Creates a menu with items YES and NO in a single vertical column:

YES
NO

If YES is selected, T will be returned. Otherwise, NIL will be returned.

Example: A simple menu, with centering:

(MENU (create MENU TITLE ← "Foo?" ITEMS ← '((YES T "Adds the Foo feature.") (NO 'NO "Removes the Foo feature."))) CENTERFLG ← T))

Creates a menu with a title Foo? and items YES and NO centered in a single vertical column:

Foo?
YES
NO

The strings following the YES and NO are help strings and will be printed if the cursor remains over one of the items for a period of time. This menu differs from the one above in that it distinguishes the NO case from the case where the user clicked outside of the menu. If the user clicks outside of the menu, NIL is returned.

Example: A multi-column menu:

(create MENU ITEMS ← '(1 2 3 4 5 6 7 8 9 * 0 #) CENTERFLG ← T)
INTERLISP-D REFERENCE MANUAL

MENUCOLUMNS ← 3
MENUFONT ← (FONTCREATE 'MODERN 10 'BOLD)
ITEMHEIGHT ← 15
ITEMWIDTH ← 15
CHANGEOFFSETFLG ← T)

Creates a touch-tone-phone number pad with the items in 15 by 15 boxes printed in Modern 10 bold font:

```
   1 2 3
   4 5 6
   7 8 9
   * 0 #
```

If used in pop up mode, its first use will have the cursor in the middle. Subsequent use will have the cursor in the same relative location as the previous selection.

Example: A program using a previously-saved menu:

```lisp
(SELECTQ [MENU
  (COND ((type? MENU FOOMENU)
      (* use previously computed menu.)
      FOOMENU)
    (T (* create and save the menu)
     (SETQ FOOMENU
      (create MENU
       ITEMS ← '((A 'A-SELECTED "prompt string for A")
          (B 'B-SELECTED "prompt string for B")
          (A-SELECTED (* if A is selected) (DOATHING))
          (B-SELECTED (* if B is selected) (DOBTHING)))
     (PROGN (* user selected outside the menu) NIL)))
```

This expression displays a pop up menu with two items, A and B, and waits for the user to select one. If A is selected, DOATHING is called. If B is selected, DOBTHING is called. If neither of these is selected, the form returns NIL.

The purpose of this example is to show some good practices to follow when using menus. First, the menu is only created once, and saved in the variable FOOMENU. This is more efficient if the menu is used more than once. Second, all of the information about the menu is kept in one place, which makes it easy to understand and edit. Third, the forms evaluated as a result of selecting something from the menu are part of the code and hence will be known to masterscope (as opposed to the situation if the forms were stored as part of the items). Fourth, the items in the menu have help strings for the user. Finally, the code is commented (always worth the trouble).
Free Menus

Free Menus are powerful and flexible menus that are useful for applications needing menus with different types of items, including command items, state items, and items that can be edited. A Free Menu is part of a window. It can can be opened and closed as desired, or attached as a control menu to the application window.

Making a Free Menu

A Free Menu is built from a description of the contents and layout of the menu. As a Free Menu is simply a group of items, a Free Menu Description is simply a specification of a group of items. Each group has properties associated with it, as does each Free Menu Item. These properties specify the format of the items in the group, and the behavior of each item. The function FREEMENU takes a Free Menu Description, and returns a closed window with the Free Menu in it.

The easiest way to make a Free Menu is to define a specific function which calls FREEMENU with the Free Menu Description in the function. This function can then also set up the Free Menu window as required by the application. The Free Menu Description is saved as part of the specific function when the application is saved. Alternately, the Free Menu Description can be saved as a variable in your file; then just call FREEMENU with the name of the variable. This may be a more difficult alternative if the backquote facility is used to build the Free Menu Description.

Free Menu Formatting

A Free Menu can be formatted in one of four ways. The items in any group can be automatically laid out in rows, in columns, or in a table, or else the application can specify the exact location of each item in the group. Free Menu keeps track of the region that a group of items occupies, and items can be justified within that region. This way an item can be automatically positioned at one of the nine justification locations, top-left, top-center, top-right, middle-left, etc.

Free Menu Description

A Free Menu Description, specifying a group of items, is a list structure. The first entry in the list is an optional list of the properties for this group of items. This entry is in the form:

```
(PROPS  <PROP> <VALUE> <PROP> <VALUE> ...)
```

The keyword PROPS determines whether or not the optional group properties list is specified.

One important group property is FORMAT. The four types of formatting, ROW, TABLE, COLUMN, or EXPLICIT, determine the syntax of the rest of the Free Menu Description. When using EXPLICIT formatting, the rest of the description is any number of Item Descriptions which have LEFT and BOTTOM properties specifying the position of the item in the menu. The syntax is:
When using **ROW** or **TABLE** formatting, the rest of the description is any number of item groups, each group corresponding to a row in the menu. These groups are identical in syntax to an **EXPLICIT** group description. The groups have an optional **PROPS** list and any number of Item Descriptions. The items need not have **LEFT** and **BOTTOM** properties, as the location of each item is determined by the formatter. However, the order of the rows and items is important. The menu is laid out top to bottom by row, and left to right within each row. The syntax is:

```
((PROPS FORMAT ROW ...) ; props of this group
 (ITEM DESCRIPTION> ; items in first row
  (ITEM DESCRIPTION> ...))
 ((PROPS ...) ; props of second row
  (ITEM DESCRIPTION> ; items in second row
   (ITEM DESCRIPTION> ...)))
```

(The comments above only describe the syntax.)

For **COLUMN** formatting, the syntax is identical to that of **ROW** formatting. However, each group of items corresponds to a column in the menu, rather than a row. The menu is laid out left to right by column, top to bottom within each column.

Finally, a Free Menu Description can have recursively nested groups. Anywhere the description can take an Item Description, it can take a group, marked by the keyword **GROUP**. A nested group inherits all of the properties of its mother group, by default. However, any of these properties can be overridden in the nested groups **PROPS** list, including the **FORMAT**. The syntax is:

```
(() ; no PROPS list, default row format
 (ITEM DESCRIPTION> ; first in row
  (GROUP ; nested group, second in row
   (PROPS FORMAT COLUMN ...); optional props
    (ITEM DESCRIPTION> ...); first column
    (ITEM DESCRIPTION> ...))
  (ITEM DESCRIPTION> ...)) ; third in row
```

Here is an example of a simple Free Menu Description for a menu which might provide access to a simple data base:

```
(((LABEL LOOKUP SELECTEDFN MYLOOKUPFN)
  (LABEL EXIT SELECTEDFN MYEXITFN))
 ((LABEL Name: TYPE DISPLAY) (LABEL "" TYPE EDIT ID NAME))
 ((LABEL Address: TYPE DISPLAY) (LABEL "" TYPE EDIT ID ADDRESS))
 ((LABEL Phone: TYPE DISPLAY)
```

27-44
This menu has two command buttons, LOOKUP and EXIT, and three edit fields, with IDs NAME, PHONE, and ADDRESS. The Edit items are initialized to the empty string, as in this example they need no other initial value. The user could select the Name: prompt, type a person's name, and then press the LOOKUP button. The function MYLOOKUPFN would be called. That function would look at the NAME Edit item, look up that name in the data base, and fill in the rest of the fields appropriately. The PHONE item has MYPHONEP as a LIMITCHARS function. This function would be called when editing the phone number, in order to restrict input to a valid phone number. After looking up Perry, the Free Menu might look like:

Here is a more complicated example:

```lisp
((PROPS FONT (MODERN 10))
 ((LABEL Example FONT (MODERN 10 BOLD) HJUSTIFY CENTER))
 ((LABEL NORTH) (LABEL SOUTH) (LABEL EAST) (LABEL WEST))
 ((PROPS ID ROW3 BOX 1)
   (LABEL ONE) (LABEL TWO) (LABEL THREE))
 ((PROPS ID ROW4)
   (LABEL ONE ID ALPHA)
   (GROUP (PROPS FORMAT COLUMN BACKGROUND 23130 BOX 2 BOXSPACE 4)
     ((TYPE NWAY LABEL A BOX 1 COLLECTION COL1 NWAYPROPS (DESELECT T))
     (TYPE NWAY LABEL B BOX 1 COLLECTION COL1)
     (TYPE NWAY LABEL C BOX 1 COLLECTION COL1))
   ((TYPE STATE LABEL "Choose Me" BOX 1 MENUITEMS (BRAVO DELTA) INITSTATE DELTA LINKS (DISPLAY (GROUP ALPHA)))
   (TYPE DISPLAY ID ALPHA LABEL "" BOX 1 MAXWIDTH 35)))
 (LABEL THREE)))
```

which will produce the following Free Menu:
And if the Free Menu were formatted as a Table, instead of in Rows, it would look like:

The following breakdown of the example explains how each part contributes to the Free Menu shown above.

(PROPS FONT (MODERN 10))

This line specifies the properties of the group that is the entire Free Menu. These properties are described in Section 28.7.4, Free Menu Group Properties. In this example, all items in the Free Menu, unless otherwise specified, will be in Modern 10.

((LABEL Example FONT (MODERN 10 BOLD) HJUSTIFY CENTER))

This line of the Free Menu Description describes the first row of the menu. Since the FORMAT specification of a Free Menu is, by default, ROW formatting, this line sets the first row in the menu. If the menu were in COLUMN formatting, this position in the description would specify the first column in the menu.

In this example the first row contains only one item. The item is, by default, a type MOMENTARY item. It has its own Font declaration (FONT (MODERN 10 BOLD)), that overrides the font specified for the Free Menu as a whole, so the item appears bolded.

Finally, the item is justified, in this case centered. The HJUSTIFY Item Property indicates that the item is to be centered horizontally within its row.

((LABEL NORTH) (LABEL SOUTH) (LABEL EAST) (LABEL WEST))
This line specifies the second row of the menu. The second row has four very simple items, labeled NORTH, SOUTH, EAST, and WEST next to each other within the same row.

```
(PROPS ID ROW3 BOX 1)
(LABEL ONE) (LABEL TWO) (LABEL THREE)
```

The third row in the menu is similar to the second row, except that it has a box drawn around it. The box is specified in the PROPS declaration for this row. Rows (and columns) are just like Groups in that the first thing in the declaration can be a list of properties for that row. In this case the row is named by giving it an ID property of ROW3. It is useful to name your groups if you want to be able to access and modify their properties later (via the function FM.GROUPPROP). It is boxed by specifying the BOX property with a value of 1, meaning draw the box one dot wide.

```
(PROPS ID ROW4)
(LABEL ONE ID ALPHA)
(GROUP (PROPS FORMAT COLUMN BACKGROUND 23130 BOX 2 BOXSPACE 4)
 ((TYPE NWAY LABEL A BOX 1 COLLECTION COL1 NWAYPROPS (DESELECT T))
 (TYPE NWAY LABEL B BOX 1 COLLECTION COL1)
 (TYPE NWAY LABEL C BOX 1 COLLECTION COL1))
 ((TYPE STATE LABEL "Choose Me" BOX 1 MENUITEMS (BRAVO DELTA)
 INITSTATE DELTA LINKS (DISPLAY (GROUP ALPHA)))
 (TYPE DISPLAY ID ALPHA LABEL "" BOX 1 MAXWIDTH 35)))
(LABEL THREE)))
```

This part of the description specifies the fourth row in the menu. This row consists of: an item labelled ONE, a group of items, and an item labelled THREE. That is, Free Menu thinks of the group as an entry, and formats the rest of the row just as it it were a large item.

```
(GROUP (PROPS FORMAT COLUMN BACKGROUND 23130 BOX 2 BOXSPACE 4)
 ((TYPE NWAY LABEL A BOX 1 COLLECTION COL1 NWAYPROPS (DESELECT T))
 (TYPE NWAY LABEL B BOX 1 COLLECTION COL1)
 (TYPE NWAY LABEL C BOX 1 COLLECTION COL1))
 ((TYPE STATE LABEL "Choose Me" BOX 1 MENUITEMS (BRAVO DELTA)
 INITSTATE DELTA LINKS (DISPLAY (GROUP ALPHA)))
 (TYPE DISPLAY ID ALPHA LABEL "" BOX 1 MAXWIDTH 35)))
```

The second part of this row is a nested group of items. It is declared as a group by placing the keyword GROUP as the first word in the declaration. A group can be declared anywhere a Free Menu Description can take a Free Menu Item Description (as opposed to a row or column declaration).

The first thing in what would have been the second item declaration in this row is the keyword GROUP. Following this keyword comes a normal group description, starting with an optional list of properties, and followed by any number of things to go in the group (based on the format of the group).
This group’s Props declaration is:

\[
\text{PROPS FORMAT COLUMN BACKGROUND 23130 BOX 2 BOXSPACE 4) .}
\]

It specifies that the group is to be formatted as a number of columns (instead of rows, the default). The entire group will have a background shade of 23130, and a box of width 2 around it, as you can see in the sample menu. The BOXSPACE declaration tells Free Menu to leave an extra four dots of room between the edge of the group (ie the box around the group) and the items in the group.

The first column of this group is a Collection of NWAY items:

\[
\text{((TYPE NWAY LABEL A BOX 1 COLLECTION COL1 NWAYPROPS(DESELECT T))}
\]

The three items, labelled A, B, and C are all declared as NWAY items, and are also specified to belong to the same NWAY Collection, Col1. This is how a number of NWAY items are collected together. The property NWAYPROPS (DESELECT T) on the first NWAY item specifies that the Col1 Collection is to have the Deselect property enabled. This simply means that the NWAY collection can be put in the state where none of the items (A, B, or C) are selected (highlighted). Additionally, each item is declared with a box whose width is one dot (pixel) around it.

The second column in this nested group is specified by:

\[
\text{((TYPE STATE LABEL "Choose Me" BOX 1 MENUITEMS (BRAVO DELTA) INITSTATE DELTA LINKS (DISPLAY (GROUP ALPHA)))}
\]

Column two contains two items, a STATE item and a DISPLAY item. The STATE item is labelled "Choose Me." A Label can be a string or a bitmap, as well as an atom. Selecting the STATE item will cause a pop-up menu to appear with two choices for the state of the item, BRAVO and DELTA. The items to go in the pop-up menu are designated by the MENUITEMS property.

The pop-up menu would look like:

```
Choose Me
    BRAVO
    DELTA
```

The initial state of the "Choose Me" item is designated to be DELTA by the INITSTATE Item Property. The initial state can be anything; it does not have to be one of the items in the pop-up menu.

Next, the STATE item is Linked to a DISPLAY item, so that the current state of the item will be displayed in the Free Menu. The link’s name is DISPLAY (a special link name for
STATE items), and the item linked to is described by the Link Description, (GROUP ALPHA). Normally the linked item can just be described by its ID. But in this case, there is more than one item whose ID is ALPHA (for the sake of this example), specifically the first item in the fourth row and the display item in this nested group. The form (GROUP ALPHA) tells Free Menu to search for an item whose ID is ALPHA, limiting the search to the items that are within this lexical group. The lexical group is the smallest group that is declared with the GROUP keyword (i.e., not row and column groups) that contains this item declaration. So in this case, Free Menu will link the STATE item to the DISPLAY item, rather than the first item in the fourth row, since that item is outside of the nested group. For further discussion of linking items, see Section 28.7.12, Free Menu Item Links.

Now, establish the DISPLAY item:

(TYPE DISPLAY ID ALPHA LABEL "" BOX 1 MAXWIDTH 35)

We have given it the ID of Alpha that the above STATE item uses in finding the proper DISPLAY item to link to. This display item is used to display the current state of the item "Choose Me." Every item is required to have a Label property specified, but the label for this DISPLAY item will depend on the state of "Choose Me." That is, when the state of the "Choose Me" item is changed from DELTA to BRAVO, the label of the DISPLAY item will also change. The null string serves to hold the place for the changeable label.

A box is specified for this item. Since the label is the empty string, Free Menu would draw a very small box. Instead, the MAXWIDTH property indicates that the label, whatever it becomes, will be limited to a stringwidth of 35. The width restriction of 35 was chosen because it is big enough for each of the possible labels for this display item. So Free Menu draws the box big enough to enclose any item within this width restriction.

Finally we specify the final item in row four:

(LABEL THREE)

Free Menu Group Properties

Each group has properties. Most group properties are relevant and should be set in the group’s PROPS list in the Free Menu Description. User properties can be freely included in the PROPS list. A few other properties are set up by the formatter. The macros FM.GROUPPROP or FM.MENUPROP allow access to group properties after the Free Menu is created.

ID The identifier of this group. Setting the group ID is desirable, for example, if the application needs to get handles on items in particular groups, or access group properties.

FORMAT One of ROW, COLUMN, TABLE, or EXPLICIT. The default is ROW.

FONT A font description of the form (FAMILY SIZE FACE), or a FONTDESCRIPTOR data type. This will be the default font for each item
in this group. The default font of the top group is the value of the variable DEFAULTFONT.

COORDINATES One of GROUP or MENU. This property applies only to EXPLICIT formatting. If GROUP, the items in the EXPLICIT group are positioned in coordinates relative to the lower left corner of the group, as determined by the mother group. If MENU, which is the default, the items are positioned relative to the lower left corner of the menu.

LEFT Specifies a left offset for this group, pushing the group to the right.

BOTTOM Specifies a bottom offset for this group, pushing the group up.

ROWSPACE Specifies the number of dots between rows in this group.

COLUMNSPACE Specifies the number of dots between columns in this group.

BOX Specifies the number of dots in the box around this group of items.

BOXSHADE Specifies the shade of the box.

BOXSPACE Specifies the number of bits between the box and the items.

BACKGROUND The background shade of this group. Nested groups inherit this background shade, but items in this group and nested groups do not. This is because, in general, it is difficult to read text on a background, so items appear on a white background by default. This can be overridden by the BACKGROUND Item Property.

Other Group Properties

The following group properties are set up and maintained by Free Menu. The application should probably not change any of these properties.

ITEMS A list of the items in the group.

REGION The region that is the extent of the items in the group.

MOTHER The ID of the group that is the mother of this group.

DAUGHTERS A list of ID of groups which are daughters to this group.

Free Menu Items

Each Free Menu Item is stored as an instance of the data type FREEMENUITEM. Free Menu Items can be thought of as objects, each item having its own particular properties, such as its type, label, and mouse event functions. A number of useful item types, described in Section 28.7.11, Predefined Item Types, are predefined by Free Menu. New types of items can be defined by the application, using
Display items as a base. Each Free Menu Item is created from a Free Menu Item Description when the Free Menu is created.

CAUTION: Edit (and thus Number) Freemenu Items do not perform well when boxed or when there is another item to the right in the same row. The display to the right of the edit item may be corrupted under editing and fm.changelabel operations.

Free Menu Item Descriptions

A Free Menu Item Description is a list in property list format, specifying the properties of the item. For example:

\[(LABEL \text{ Refetch SELECTEDFN MY.REFETCHFN})\]

describes a \textsc{MOMENTARY} item labelled Refetch, with the function \texttt{MY.REFETCHFN} to be called when the item is selected. None of the property values in an item description are evaluated. When constructing Free Menu descriptions that incorporate evaluated expressions (for example labels that are bitmaps) it is helpful to use the backquote facility. For instance, if the value of the variable \texttt{MYBITMAP} is a bitmap, then

\[(\text{FREEMENU '(((LABEL A) (LABEL ,MYBITMAP)))})\]

would create a Free Menu of one row, with two items in that row, the second of which has the value of \texttt{MYBITMAP} as its label.

Free Menu Item Properties

The following Free Menu Item Properties can be set in the Item Description. Any other properties given in an Item Description will be treated as user properties, and will be saved on the \texttt{USERDATA} property of the item.

\begin{itemize}
\item \textbf{TYPE} The type of the item. Choose from one of the Free Menu Item type keywords \textsc{MOMENTARY, TOGGLE, 3STATE, STATE, NWAY, EDITSTART, EDIT, NUMBER, or DISPLAY}. The default is \textsc{MOMENTARY}.
\item \textbf{LABEL} An atom, string, or bitmap. Bitmaps are always copied, so that the original will not be changed. This property must be specified for every item.
\item \textbf{FONT} The font in which the item appears. The default is the font specified for the group containing this item. Can be a font description of the form \texttt{(FAMILY SIZE FACE)}, or a \texttt{FONTDESCRIPTOR} data type.
\item \textbf{ID} May be used to specify a unique identifier for this item, but is not necessary.
\end{itemize}
LEFT and BOTTOM When ROW, COLUMN, or TABLE formatting, these specify offsets, pushing the item right and up, respectively, from where the formatter would have put the item. In EXPLICIT formatting, these are the actual coordinates of the item, in the coordinate system given by the group’s COORDINATES property.

HJUSTIFY Indicates horizontal justification type: LEFT, CENTER, or RIGHT. Specifies that this item is to be horizontally justified within the extent of its group. Note that the main group, as opposed to the smaller row or column group, is used.

VJUSTIFY Specifies that this item is to be vertically justified. Values are TOP, MIDDLE, or BOTTOM.

HIGHLIGHT Specifies the highlighted looks of the item, that is, how the item changes when a mouse event occurs on it. See Section 28.7.12, Free Menu Item Highlighting, for more details on highlighting.

MESSAGE Specifies a string that will be printed in the prompt window after a mouse cursor selects this item for MENUHELDWAIT milliseconds. Or, if an atom, treated as a function to get the message. The function is passed three arguments, ITEM, WINDOW, and BUTTONS, and should return a string. The default is a message appropriate to the type of the item.

INITSTATE Specifies the initial state of the item. This is only appropriate to TOGGLE, 3STATE, and STATE items.

MAXWIDTH Specifies the width allowed for this item. The formatter will leave enough space after the item for the item to grow to this width without collisions.

MAXHEIGHT Similar to MAXWIDTH, but in the vertical dimension.

BOX Specifies the number of bits in the box around this item. Boxes are made around MAXWIDTH and MAXHEIGHT dimensions. If unspecified, no box is drawn.

BOXSHADE Specifies the shade that the box is drawn in. The default is BLACKSHADE.

BOXSPACE Specifies the number of bits between the box and the label. The default is one bit.

BACKGROUND Specifies the background shade on which the item appears. The default is WHITESHADE, regardless of the group’s background.

LINKS Can be used to link this item to other items in the Free Menu.

**Mouse Properties**

The following properties provide a way for application functions to be called under certain mouse events. These functions are called with the ITEM, the WINDOW, and the BUTTONS passed as arguments. These application functions do not interfere with any Free Menu system functions that take care of handling the different item types. In each case, though, the application function is called
after the system function. The default for all of these functions is NIL. The value of each of the following properties can be the name of a function, or a lambda expression.

**SELECTEDFN** Specifies the function to be called when this item is selected. The Edit and EditStart items cannot have a SELECTEDFN. See the Edit Free Menu item description in Section 28.7.11, Predefined Item Types, for more information.

**DOWNFN** Specifies the function to be called when the item is selected with the mouse cursor.

**HELDFN** Specifies the function to be called repeatedly when the item is selected with the mouse cursor.

**MOVEDFN** Specifies the function to be called when the mouse cursor moves off this item (mouse buttons are still depressed).

**System Properties**

The following Free Menu Item properties are set and maintained by Free Menu. The application should probably not change these properties directly.

**GROUPID** Specifies the ID of the smallest group that the item is in. For example, in a row formatted group, the item’s GROUPID will be set to the ID of the row that the item is in, not the ID of the whole group.

**STATE** Specifies the current state of TOGGLE, 3STATE, or STATE items. The state of an NWAY item behaves like that of a toggle item.

**BITMAP** Specifies the bitmap from which the item is displayed.

**REGION** Specifies the region of the item, in window coordinates. This is used for locating the display position, as well as determining the mouse sensitive region of the item.

**MAXREGION** Specifies the maximum region the item may occupy, determined by the MAXWIDTH and MAXHEIGHT properties (see Section 28.7.8, Free Menu item Properties). This is used by the formatter and the display routines.

**SYSDOWNFN**

**SYSMOVEDFN**

**SYSSELECTEDFN** These are the system mouse event functions, set up by Free Menu according to the item type. These functions are called before the mouse event functions, and are used to implement highlighting, state changes, editing, etc.

**USERDATA** Specifies how any other properties are stored on this list in property list format. This list should probably not need to be manipulated directly.

**Predefined Item Types**
MOMENTARY

MOMENTARY items are like command buttons. When the button is selected, its associated function is called.

TOGGLE

Toggle items are simple two-state buttons. When pressed, the button is highlighted; it stays that way until pressed again. The states of a toggle button are T and NIL; the initial state is NIL.

3STATE

3STATE items rotate through NIL, T, and OFF, states each time they are pressed. The default looks of the OFF state are with a diagonal line through the button, while T is highlighted, and NIL is normal. The default initial state is NIL.

The following Item Property applies to 3STATE items:

OFF Specifies the looks of a 3STATE item in its OFF state. Similar to HIGHLIGHT. The default is that the label gets a diagonal slash through it.

NOTE: If you specify special highlighting (a different bitmap of string) for Toggle or 3State items AND use this item in a group formatted as a Column or a Table, the highlight looks of the item may not appear in the correct place.

STATE

STATE items are general multiple state items. The following Item Property determines how the item changes state:

CHANGESTATE This Item Property can be changed at any time to change the effect of the item. If a MENU data type, this menu pops up when the item is selected, and the user can select the new state. Otherwise, if this property is given, it is treated as a function name, which is passed three arguments, ITEM, WINDOW, and BUTTONS. This function can do whatever it wants, and is expected to return the new state (an atom, string, or bitmap), or NIL, indicating the state should not change. The state of the item can automatically be indicated in the Free Menu, by setting up a DISPLAY link to a DISPLAY item in the menu (see Section 28.7.13, Free Menu Item Links). If such a link exists, the label of the DISPLAY item will be changed to the new state. The possible states are not restricted at all, with the exception of selections from a pop-up menu. The state can be changed to any atom, string, or bitmap, manually via FM.CHANGESTATE.

The following Item Properties are relevant to STATE items when building a Free Menu:

MENUITEMS If specified, should be a list of items to go in a pop-up menu for this item. Free Menu will build the menu and save it as the CHANGESTATE property of the item.
WINDOWS AND MENUS

MENUFONT  The font of the items in the pop-up menu.

MENUTITLE  The title of the pop-up menu. The default title is the label of the STATE item.

NWAY  [Free Menu Item]

NWAY items provide a way to collect any number of items together, in any format within the Free Menu. Only one item from each Collection can be selected at a time, and that item is highlighted to indicate this. The following Item Properties are particular to NWAY items:

COLLECTION  An identifier that specifies which NWAY Collection this item belongs to.

NWAYPROPS  A property list of information to be associated with this collection. This property is only noticed in the Free Menu Description on the first item in a COLLECTION. NWAY Collections are formed by creating a number of NWAY items with the same COLLECTION property. Each NWAY item acts individually as a Toggle item, and can have its own mouse event functions. Each NWAY Collection itself has properties, its state for instance. After the Free Menu is created, these Collection properties can be accessed by the macro FM.NWAYPROPS. Note that NWAY Collections are different from Free Menu Groups. There are three NWAY Collection properties that Free Menu looks at:

DESELECT  If given, specifies that the Collection can be deselected, yielding a state in which no item in the Collection is selected. When this property is set, the Collection can be deselected by selecting any item in the Collection and pressing the right mouse button.

STATE  The current state of the Collection, which is the actual item selected.

INITSTATE  Specifies the initial state of the Collection. The value of this property is an Item Link Description

EDIT  [Free Menu Item]

EDIT items are textual items that can be edited. The label for an EDIT item cannot be a bitmap. When the item is selected an edit caret appears at that cursor position within the item, allowing insertion and deletion of characters at that point. If selected with the right mouse button, the item is cleared before editing starts. While editing, the left mouse button moves the caret to a new position within the item. The right mouse button deletes from the caret to the cursor. CONTROL-W deletes the previous word. Editing is stopped when another item is selected, when the user moves the cursor into another TTY window and clicks the cursor, or when the Free Menu function FM.ENDEDIT is called (called when the Free Menu is reset, or the window is closed). The Free Menu editor will time out after about a minute, returning automatically. Because of the many ways in which editing can terminate, EDIT items are not allowed to have a SELECTEDFN, as it is not clear when this function should be called. Each EDIT item should have an ID specified, which is used when getting the state of the Free Menu, since the string being edited is defined as the state of the item, and thus cannot distinguish edit items. The following Item Properties are specific to EDIT items.
MAXWIDTH Specifies the maximum string width of the item, in bits, after which input will be ignored. If MAXWIDTH is not specified, the items becomes infinitely wide and input is never restricted.

INFINITEWIDTH This property is set automatically when MAXWIDTH is not specified. This tells Free Menu that the item has no right end, so that the item becomes mouse sensitive from its left edge to the right edge of the window, within the vertical space of the item.

In Medley, Changestate of an infinite width Edit item to a smaller item clears the old item properly.

LIMITCHARS The input characters allowed can be restricted in two ways: If this item property is a list, it is treated as a list of legal characters; any character not in the list will be ignored. If it is an atom, it is treated as the name of a test predicate, which is passed three arguments, ITEM, WINDOW, and CHARACTER, when each character is typed. This predicate should return T if the character is legal, NIL otherwise. The LIMITCHARS function can also call FM.ENDEDIT to force the editor to terminate, or FM.SKIPNEXT, to cause the editor to jump to the next edit item in the menu.

ECHOCHAR This item property can be set to any character. This character will be echoed in the window, regardless of what character is typed. However the item’s label contains the actual string typed. This is useful for operations like password prompting. If ECHOCHAR is used, the font of the item must be fixed pitch. Unrestricted EDIT items should not have other items to their right in the menu, as they will be replaced. If the item is boxed, input is restricted to what will fit in the box. Typing off the edge of the window will cause the window to scroll appropriately. Control characters can be edited, including the carriage return and line feed, and they are echoed as a black box. While editing, the Skip/Next key ends editing the current item, and starts editing the next EDIT item in the Free Menu.

NUMBER [Free Menu Item]

NUMBER items are EDIT items that are restricted to numerals. The state of the item is coerced to the the number itself, not a string of numerals. There is one NUMBER-specific Item Property:

NUMBERTYPE If FLOATP (or FLOAT), then decimals are accepted. Otherwise only whole numbers can be edited.

EDITSTART [Free Menu Item]

EDITSTART items serve the purpose of starting editing on another item when they are selected. The associated Edit item is linked to the EditStart item by an EDIT link (see Free Menu Item Links below). If the EDITSTART item is selected with the right mouse button, the Edit item is cleared before editing is started. Similar to EDIT items, EDITSTART items cannot have a SELECTEDFN, as it is not clear when the associated editing will terminate.
In Medley, EDITSTART items linked to a Number item properly set number state when editing has completed.

DISPLAY

[Free Menu Item]

DISPLAY items serve two purposes. First, they simply provide a way of putting dummy text in a Free Menu, which does nothing when selected. The item’s label can be changed, though. Secondly, DISPLAY items can be used as the base for new item types. The application can create new item types by specifying \texttt{DOWNFN}, \texttt{HELDFN}, \texttt{MOVEDFN}, and \texttt{SELECTEDFN} for a DISPLAY item, making it behave as desired.

\textbf{Free Menu Item Highlighting}

Each Free Menu Item can specify how it wants to be highlighted. First of all, if the item does not specify a \texttt{HIGHLIGHT} property, there are two default highlights. If the item is not boxed, the label is simply inverted, as in normal menus. If the item is boxed, it is highlighted in the shade of the box. Alternatively, the value of the \texttt{HIGHLIGHT} property can be a SHADE, which will be painted on top of the item when a mouse event occurs on it. Or the \texttt{HIGHLIGHT} property can be an alternate label, which can be an atom, string or bitmap. If the highlight label is a different size than the item label, the formatter will leave enough space for the larger of the two. In all of these cases, the looks of the highlighted item are determined when the Free Menu is built, and a bitmap of the item with these looks is created. This bitmap is stored on the item’s \texttt{HIGHLIGHT} property, and simply displayed when a mouse event occurs. The value of the highlight property in the Item Description is copied to the USERDATA list, in case it is needed later for a label change.

\textbf{Free Menu Item Links}

Links between items are useful for grouping items in abstract ways. In particular, links are used for associating EDITSTART items with their item to edit, and STATE items with their state display. The Free Menu Item property \texttt{LINKS} is a property list, where the value of each Link Name property is a pointer to another item. In the Item Description, the value of the \texttt{LINK} property should be a property list as above. The value of each Link Name property is a Link Description. A Link Description can be one of the following forms:

\begin{itemize}
  \item \texttt{<ID>} An ID of an item in the Free Menu. This is acceptable if items can be distinguished by ID alone.
  \item \texttt{(GROUPID \texttt{<ID>})} A list whose first element is a GROUPID, and whose second element is the ID of an item in that group. This way items with similar purposes, and thus similar ID’s, can be distinguished across groups.
  \item \texttt{(GROUP \texttt{<ID>})} A list whose first element is the keyword GROUP, and whose second element is an item ID. This form describes an item with ID, in the same group that this item is in. This way you do not need to know the GROUPID, just which group it is in.
\end{itemize}
Then after the entire menu is built, the links are set up, turning the Link Descriptions into actual pointers to Free Menu Items. There is no reason why circular Item Links cannot be created, although such a link would probably not be very useful. If circular links are created, the Free Menu will not be garbage collected after it is not longer being used. The application is responsible for breaking any such links that it creates.

### Free Menu Window Properties

**FM.PROMPTWINDOW** Specifies the window that Free Menu should use for displaying the item’s messages. If not specified, PROMPTWINDOW is used.

**FM.BACKGROUND** The background shade of the entire Free Menu. This property can be set automatically by specifying a BACKGROUND argument to the function FREEMENU. The window border must be 4 or greater when a Free Menu background is used, due to the way the Window System handles window borders.

**FM.DONTRESHAPE** Normally, Free Menu will attempt to use empty space in a window by pushing items around to fill the space. When a Free Menu window is reshaped, the items are repositioned in the new shape. This can be disabled by setting the FM.DONTRESHAPE window property.

### Free Menu Interface Functions

**FREEMENU DESCRIPTION TITLE BACKGROUND BORDER**

[Function]

Creates a Free Menu from a Free Menu Description, returning the window. This function will return quickly unless new display fonts have to be created.

### Accessing Functions

**FM.GETITEM ID GROUP WINDOW**

[Function]

Gets item ID in GROUP of the Free Menu in WINDOW. This function will search the Free Menu for an item whose ID property matches, or secondly whose LABEL property matches ID. If GROUP is NIL, then the entire Free Menu is searched. If no matching item is found, NIL is returned.

**FM.GETSTATE WINDOW**

[Function]

Returns in property list format the ID and current STATE of every NWAY Collection and item in the Free Menu. If an item’s or Collection’s state is NIL, then it is not included in the list. This provides an easy way of getting the state of the menu all at once. If the state of only one item or Collection is needed, the application can directly access the STATE property of that object using the Accessing Macros described in Section 28.7.20, Free Menu Macros. This function can be called when editing is in progress, in which case it will provide the label of the item being edited at that point.
Changing Free Menus

Many of the following functions operate on Free Menu Items, and thus take the item as an argument. The *ITEM* argument to these functions can be the Free Menu Item itself, or just a reference to the item. In the second case, *FM.GETITEM* (see Section 28.7.16, Accessing Functions) will be used to find the item in the Free Menu. The reference can be in one of the following forms:

- `<ID>` Specifies the first item in the Free Menu whose ID or LABEL property matches `<ID>`.
- `<GROUPID> <ID>` Specifies the item whose ID or LABEL property matches `<ID>` within the group specified by `<GROUPID>`.

**Function**

- **FM.CHANGELABEL ITEM NEWLABEL WINDOW UPDATEFLG**

  Changes an ITEM's label after the Free Menu has been created. It works for any type of item, and *STATE* items will remain in their current state. If the window is open, the item will be redisplayed with its new appearance. *NEWLABEL* can be an atom, a string, or a bitmap (except for *EDIT* items), and will be restricted in size by the *MAXWIDTH* and *MAXHEIGHT* Item Properties. If these properties are unspecified, the *ITEM* will be able to grow to any size. *UPDATEFLG* specifies whether or not the regions of the groups in the menu are recalculated to take into account the change of size of this item. The application should not change the label of an *EDIT* item while it is being edited. The following Item Property is relevant to changing labels:

  - **CHANGELABELUPDATE** Exactly like *UPDATEFLG* except specified on the item, rather than as a function parameter.

- **FM.CHANGESTATE X NEWSTATE WINDOW**

  Programmatically changes the state of items and *NWAY* Collections. *X* is either an item or a Collection name. For items *NEWSTATE* is a state appropriate to the type of the item. For *NWAY* Collections, *NEWSTATE* should be the desired item in the Collection, or *NIL* to deselect. For *EDIT* and *NUMBER* items, this function just does a label change. If the window is open, the item will be redisplayed.

- **FM.RESETSTATE ITEM WINDOW**

  Sets an *ITEM* back to its initial state.

- **FM.RESETMENU WINDOW**

  Resets every item in the menu back to its initial state.

- **FM.RESETSHAPE WINDOW ALWAYSFLG**

  Reshapes the *WINDOW* to its full extent, leaving the lower-left corner unmoved. Unless *ALWAYSFLG* is *T*, the window will only be increased in size as a result of resetting the shape.

- **FM.RESETGROUPS WINDOW**

  Resets every group in the menu back to its initial state.
Recalculates the extent of each group in the menu, updating group boxes and backgrounds appropriately.

**Function**

(FM.HIGHLIGHTITEM ITEM WINDOW)

Programmatically forces an ITEM to be highlighted. This might be useful for ITEMS which have a direct effect on other ITEMS in the menu. The ITEM will be highlighted according to its HIGHLIGHT property, as described in Section 28.7.12, Free Menu Item Highlighting. This highlight is temporary, and will be lost if the ITEM is redisplayed, by scrolling for example.

**Editor Functions**

(FM.EDITITEM ITEM WINDOW CLEARFLG)

Starts editing an EDIT or NUMBER ITEM at the beginning of the ITEM, as long as the WINDOW is open. This function will most likely be useful for starting editing of an ITEM that is currently the null string. If CLEARFLG is set, the ITEM is cleared first.

(FM.SKIPNEXT WINDOW CLEARFLG)

Causes the editor to jump to the beginning of the next EDIT item in the Free Menu. If CLEARFLG is set, then the next item will be cleared first. If there is not another EDIT item in the menu, this function will simply cause editing to stop. If this function is called when editing is not in progress, editing will begin on the first EDIT item in the menu. This function can be called from any process, and can also be called from inside the editor, in a LIMITCHARS function.

(FMENDEDIT WINDOW WAITFLG)

Stops any editing going on in WINDOW. If WAITFLG is T, then block until the editor has completely finished. This function can be called from another process, or from a LIMITCHARS function.

(FM.EDITP WINDOW)

If an item is in the process of being edited in the Free Menu WINDOW, that item is returned. Otherwise, NIL is returned.

**Miscellaneous Functions**

(FM.REDISPLAYMENU WINDOW)

Redisplays the entire Free Menu in its WINDOW, if the WINDOW is open.

(FM.REDISPLAYITEM ITEM WINDOW)

Redisplays a particular Free Menu ITEM in its WINDOW, if the WINDOW is open.
WINDOWS AND MENUS

(FM.SHADE X SHADE WINDOW) [Function]

X can be an item, or a group ID. SHADE is painted on top of the item or group. Note that this is a temporary operation, and will be undone by redisplaying. For more permanent shading, the application may be able to add a REDDISPLAYFN and SCROLLFN for the window as necessary to update the shading.

(FM.WHICHITEM WINDOW POSorX Y) [Function]

Locates and identifies an item from its known location within the WINDOW. If WINDOW is NIL, (WHICHW) is used, and if POSorX is NIL, the current cursor location is used.

(FM.TOPGROUPID WINDOW) [Function]

Returns the ID of the top group of this Free Menu.

Free Menu Macros

These Accessing Macros are provided to allow the application to get and set information in the Free Menu data structures. They are implemented as macros so that the operation will compile into the actual access form, rather than figuring that out at run time.

(FM.ITEMPROP ITEM PROP {VALUE}) [Macro]

Similar to WINDOWPROP, this macro provides an easy access to the fields of a Free Menu Item. The function FM.GETITEM gets the ITEM, described in Section 28.7.16, Accessing Function. VALUE is optional, and if not given, the current value of the PROP property will be returned. If VALUE is given, it will be used as the new value for that PROP, and the old value will be returned. When a call to FM.ITEMPROP is compiled, if the PROP is known (quoted in the calling form), the macro figures out what field to access, and the appropriate Data Type access form is compiled. However, if the PROP is not known at compile time, the function FM.ITEMPROP, which goes through the necessary property selection at run time, is compiled. The TYPE and USERDATA properties of a Free Menu Item are Read Only, and an error will result from trying to change the value of one of these properties.

(FM.GROUPPROP WINDOW GROUP PROP {VALUE}) [Macro]

Provides access to the Group Properties set up in the PROPS list for each group in the Free Menu Description. GROUP specifies the ID of the desired group, and PROP the name of the desired property. If VALUE is specified, it will become the new value of the property, and the old value will be returned. Otherwise, the current value is returned.

(FM.MENUPROP WINDOW PROP {VALUE}) [Macro]

Provides access to the group properties of the top-most group in the Free Menu, that is to say, the entire menu. This provides an easy way for the application to attach properties to the menu as a whole, as well as access the Group Properties for the entire menu.
(FM.NWAYPROP WINDOW COLLECTION PROP {VALUE}) [Macro]

This macro works just like FM.GROUPPROP, except it provides access to the NWay Collections.

Attached Windows

The attached window facility makes it easy to manipulate a group of window as a unit. Standard window operations like moving, reshaping, opening, and closing can be done so that it appears to the user as if the windows are a single entity. Each collection of attached windows has one main window and any number of other windows that are "attached" to it. Moving or reshaping the main window causes all of the attached windows to be moved or reshaped as well. Moving or reshaping an attached window does not affect the main window.

Attached windows can have other windows attached to them. Thus, it is possible to attach window A to window B when B is already attached to window C. Similarly, if A has other windows attached to it, it can still be attached to B.

(ATTACHWINDOW WINDOWTOATTACH MAINWINDOW EDGE POSITIONONEDGE WINDOWCOMACTION) [Function]

Associates WINDOWTOATTACH with MAINWINDOW so that window operations done to MAINWINDOW are also done to WINDOWTOATTACH (the exact set of window operations passed between main windows and attached windows is described in the Window Operations and Attached Windows section below). ATTACHWINDOW moves WINDOWTOATTACH to the correct position relative to MAINWINDOW.

Note: A window can be attached to only one other window. Attaching a window to a second window will detach it from the first. Attachments can not form loops. That is, a window cannot be attached to itself or to a window that is attached to it. ATTACHWINDOW will generate an error if this is attempted.

EDGE determines which edge of MAINWINDOW the attached window is positioned along; it should be one of TOP, BOTTOM, LEFT, or RIGHT. If EDGE is NIL, it defaults to TOP.

POSITIONONEDGE determines where along EDGE the attached window is positioned. It should be one of the following:

- LEFT: The attached window is placed on the left (of a TOP or BOTTOM edge).
- RIGHT: The attached window is placed on the right (of a TOP or BOTTOM edge).
- BOTTOM: The attached window is placed on the bottom (of a LEFT or RIGHT edge).
- TOP: The attached window is placed on the top (of a LEFT or RIGHT edge).
- CENTER: The attached window is placed in the center of the edge.
The attached window is placed to fill the entire edge. ATTACHWINDOW reshapes the window if necessary.

Note: The width or height used to justify an attached window includes any other windows that have already been attached to MAINWINDOW. Thus (ATTACHWINDOW BBB AAA 'RIGHT 'JUSTIFY) followed by (ATTACHWINDOW CCC AAA 'TOP 'JUSTIFY) will put CCC across the top of both BBB and AAA:

```
  CCC
 /     \
| AAA   |
| BBB   |
```

WINDOWCOMACTION provides a convenient way of specifying how WINDOWTOATTACH responds to right button menu commands. The window property PASSTOMAINCOMS determines which right button menu commands are directly applied to the attached window, and which are passed to the main window (see the Window Operations and Attached Windows section below). Depending on the value of WINDOWCOMACTION, the PASSTOMAINCOMS window property of WINDOWTOATTACH is set as follows:

NIL PASSTOMAINCOMS is set to (CLOSEW MOVEW SHAPEW SHRINKW BURYW), so right button menu commands to close, move, shape, shrink, and bury are passed to the main window, and all others are applied to the attached window.

LOCALCLOSE PASSTOMAINCOMS is set to (MOVEW SHAPEW SHRINKW BURYW), which is the same as when WINDOWCOMACTION is NIL, except that the attached window can be closed independently.

HERE PASSTOMAINCOMS is set to NIL, so all right button menu commands are applied to the attached window.

MAIN PASSTOMAINCOMS is set to T, so all right button menu commands are passed to the main window.

Note: If the user wants to set the PASSTOMAINCOMS window property of an attached window to something else, it must be done after the window is attached, since ATTACHWINDOW modifies this window property.
INTERLISP-D REFERENCE MANUAL

Detaches \texttt{WINDOWTODETACH} from its main window. Returns a dotted pair \((\text{EDGE . POSITIONONEDGE})\) if \texttt{WINDOWTODETACH} was an attached window, \texttt{NIL} otherwise. This does not close \texttt{WINDOWTODETACH}.

\begin{verbatim}
(DETACHALLWINDOWS MAINWINDOW) [Function]

Detaches and closes all windows attached to \texttt{MAINWINDOW}.
\end{verbatim}

\begin{verbatim}
(FREATTACHEDWINDOW WINDOW) [Function]

Detaches the attached window \texttt{WINDOW}. In addition, other attached windows above (in the case of a \texttt{TOP} attached window) or below (in the case of a \texttt{BOTTOM} attached window) are moved closer to the main window to fill the gap.

Note: Attached windows that "reject" the move operation (see \texttt{REJECTMAINCOMS} below) are not moved.

Note: \texttt{FREATTACHEDWINDOW} currently doesn’t handle \texttt{LEFT} or \texttt{RIGHT} attached windows.
\end{verbatim}

\begin{verbatim}
(REMOVEWINDOW WINDOW) [Function]

Closes \texttt{WINDOW}, and calls \texttt{FREATTACHEDWINDOW} to move other attached windows to fill any gaps.
\end{verbatim}

\begin{verbatim}
(REPOSITIONATTACHEDWINDOWS WINDOW) [Function]

Repositions every window attached to \texttt{WINDOW}, in the order that they were attached. This is useful as a \texttt{RESHAPEFN} for main windows with attached window that don’t want to be reshaped, but do want to keep their position relative to the main window when the main window is reshaped.

Note: Attached windows that "reject" the move operation (see \texttt{REJECTMAINCOMS} below) are not moved.
\end{verbatim}

\begin{verbatim}
(MAINWINDOW WINDOW RECURSEFLG) [Function]

If \texttt{WINDOW} is not a window, it generates an error. If \texttt{WINDOW} is closed, it returns \texttt{WINDOW}. If \texttt{WINDOW} is not attached to another window, it returns \texttt{WINDOW} itself. If \texttt{RECURSEFLG} is \texttt{NIL} and \texttt{WINDOW} is attached to a window, it returns that window. If \texttt{RECURSEFLG} is \texttt{T}, it returns the first window up the "main window" chain starting at \texttt{WINDOW} that is not attached to any other window.
\end{verbatim}

\begin{verbatim}
(ATTACHEDWINDOWS WINDOW COM) [Function]

Returns the list of windows attached to \texttt{WINDOW}.

If \texttt{COM} is non-\texttt{NIL}, only those windows attached to \texttt{WINDOW} that do not reject the window operation \texttt{COM} are returned (see \texttt{REJECTMAINCOMS}).
\end{verbatim}

\begin{verbatim}
(ALLATTACHEDWINDOWS WINDOW) [Function]

\end{verbatim}
Returns a list of all of the windows attached to WINDOW or attached to a window attached to it.

(WindowRegion WINDOW COM) [Function]
Returns the screen region occupied by WINDOW and its attached windows, if it has any.
If COM is non-NIL, only those windows attached to WINDOW that do not reject the window operation COM are considered in the calculation (see REJECTMAINCOMS).

(WindowSize WINDOW) [Function]
Returns the size of WINDOW and its attached windows (if any), as a dotted pair (WIDTH . HEIGHT).

(MinAttachedWindowExtent WINDOW) [Function]
Returns the minimum size that WINDOW and its attached windows (if any) will accept, as a dotted pair (WIDTH . HEIGHT).

Attaching Menus To Windows

The following functions are provided to associate menus to windows.

(MenuWindow MENU VERTFLG) [Function]
Returns a closed window that has the menu MENU in it. If MENU is a list, a menu is created with MENU as its ITEMS menu field. Otherwise, MENU should be a menu. The returned window has the appropriate RESHAPEFN, MINSIZE and MAXSIZE window properties to allow its use in a window group.
If both the MENUROWS and MENUCOLUMNS fields of MENU are NIL, VERTFLG is used to set the default menu shape. If VERTFLG is non-NIL, the MENUCOLUMNS field of MENU will be set to 1 (the menu items will be listed vertically); otherwise the MENUROWS field of MENU will be set to 1 (the menu items will be listed horizontally).

(AttachMenu MENU MAINWINDOW EDGE POSITIONONEDGE NOOPENFLG) [Function]
Creates a window that contains the menu MENU (by calling MENUWINDOW) and attaches it to the window MAINWINDOW on edge EDGE at position POSITIONONEDGE. The menu window is opened unless MAINWINDOW is closed, or NOOPENFLG is T.
If EDGE is either LEFT or RIGHT, MENUWINDOW will be called with VERTFLG = T, so the menu items will be listed vertically; otherwise the menu items will be listed horizontally. These defaults can be overridden by specifying the MENUROWS or MENUCOLUMNS fields in MENU.

(CreateMenuedWindow MENU WINDOWTITLE LOCATION WINDOWSPEC) [Function]
Creates a window with an attached menu and returns the main window. \texttt{MENU} is the only required argument, and may be a menu or a list of menu items. \texttt{WINDOWTITLE} is a string specifying the title of the main window. \texttt{LOCATION} specifies the edge on which to place the menu; the default is \texttt{TOP}. \texttt{WINDOWSPEC} is a region specifying a region for the aggregate window; if \texttt{NIL}, the user is prompted for a region.

Examples:

\begin{verbatim}
(SETQ MENUW  
  (MENUNWINDOW  
    (create MENU  
      ITEMS ← '(smaller LARGER)  
      MENUFONT ← '(MODERN 12)  
      TITLE ← "zoom controls"  
      CENTERFLG ← T  
      WHENSELECTEDFN ← (FUNCTION ZOOMMAINWINDOW))))
\end{verbatim}

creates (but does not open) a menu window that contains the two items "smaller" and "LARGER" with the title "zoom controls" and that calls the function \texttt{ZOOMMAINWINDOW} when an item is selected. Note that the menu items will be listed horizontally, because \texttt{MENUNWINDOW} is called with \texttt{VERTFLG = NIL}, and the menu does not specify either a \texttt{MENUROWS} or \texttt{MENUCOLUMNS} field.

\begin{verbatim}
(ATTACHWINDOW MENUW  
  (CREATEW '(50 50 150 50))  
  'TOP  
  'JUSTIFY)
\end{verbatim}

creates a window on the screen and attaches the above created menu window to its top:

\begin{center}
\begin{tabular}{|c|c|}
\hline
\textbf{zoom controls} &  \\
\hline
\textbf{smaller} & \textbf{LARGER} \\
\hline
\end{tabular}
\end{center}

\begin{verbatim}
(CREATEMENUEDWINDOW  
  (create MENU  
    ITEMS ← '(smaller LARGER)  
    MENUFONT ← '(MODERN 12)  
    TITLE ← "zoom controls"  
    CENTERFLG ← T  
    WHENSELECTEDFN ← (FUNCTION ZOOMMAINWINDOW))))
\end{verbatim}

creates the same sort of window in one step, prompting the user for a region.

**Attached Prompt Windows**

Many packages have a need to display status information or prompt for small amounts of user input in a place outside their standard window. A convenient way to do this is to attach a small window to the top of the program’s main window. The following functions do so in a uniform way that can be depended on among diverse applications.
(GETPROMPTWINDOW MAINWINDOW #LINES FONT DONTCREATE)  [Function]

Returns the attached prompt window associated with MAINWINDOW, creating it if necessary. The window is always attached to the top of MAINWINDOW, has DSPSCROLL set to T, and has a PAGEFULLFN of NIL to inhibit page holding. The window is at least #LINES lines high (default 1); if a pre-existing window is shorter than that, it is reshaped to make it large enough. FONT is the font to give the prompt window (defaults to the font of MAINWINDOW), and applies only when the window is first created. If DONTCREATE is true, returns the window if it exists, otherwise NIL without creating any prompt window.

(REMOVEPROMPTWINDOW MAINWINDOW)  [Function]

Detaches the attached prompt window associated with MAINWINDOW (if any), and closes it.

Window Operations And Attached Windows

When a window operation, such as moving or clearing, is performed on a window, there is a question about whether or not that operation should also be performed on the windows attached to it or performed on the window it is attached to. The “right” thing to do depends on the window operation: it makes sense to independently redisplay a single window in a collection of windows, whereas moving a single window usually implies moving the whole group of windows. The interpretation of window operations also depends on the application that the window group is used for. For some applications, it may be desirable to have a window group where individual windows can be moved away from the group, but still be conceptually attached to the group for other operations. The attached window facility is flexible enough to allow all of these possibilities.

The operation of window operations can be specified by each attached window, by setting the following two window properties:

PASSTOMAINCOMS  [Window Property]

Value is a list of window commands (e.g. CLOSEW, MOVEW) which, when selected from the attached window’s right-button menu, are actually applied to the central window in the group, instead of being applied to the attached window itself. The “central window” is the first window up the “main window” chain that is not attached to any other window.

If PASSTOMAINCOMS is NIL, all window operations are directly applied to the attached window. If PASSTOMAINCOMS is T, all window operations are passed to the central window.

Note: ATTACHWINDOW allows this window property to be set to commonly-used values by using its WINDOWCOMACTION argument. ATTACHWINDOW always sets this window property, so users must modify it directly only after attaching the window to another window.

REJECTMAINCOMS  [Window Property]
Value is a list of window commands that the attached window will not allow the main window to apply to it. This is how a window can say "leave me out of this group operation."

If REJECTMAINCOMS is NIL, all window commands may be applied to this attached window. If REJECTMAINCOMS is T, no window commands may be applied to this attached window.

The PASSTOMAINCOMS and REJECTMAINCOMS window properties affect right-button menu operations applied to main windows or attached windows, and the action of programmatic window functions (SHAPEW, MOVEW, etc.) applied to main windows. However, these window properties do not affect the action of window functions applied to attached windows.

The following list describes the behavior of main and attached windows under the window operations, assuming that all attached windows have their REJECTMAINCOMS window property set to NIL and PASSTOMAINCOMS set to (CLOSEW MOVEW SHAPEW SHRINKW BURYW) (the default if ATTACHWINDOW is called with WINDOWCOMACTION = NIL).

The behavior for any particular operation can be changed for particular attached windows by setting the standard window properties (e.g., MOVEFN or CLOSEFN) of the attached window. An exception is the TOTOPFN property of an attached window, that is set to bring the whole window group to the top and should not be set by the user (although users can add functions to the TOTOPFN window property).

**Move**
If the main window moves, all attached windows move with it, and the relative positioning between the main window and the attached windows is maintained. If the region is determined interactively, the prompt region for the move is the union of the extent of the main window and all attached windows (excluding those with MOVEW in their REJECTMAINCOMS window property).

If an attached window is moved by calling the function MOVEW, it is moved without affecting the main window. If the right-button window menu command Move is called on an attached window, it is passed on to the main window, so that all windows in the group move.

**Reshape**
If the main window is reshaped, the minimum size of it and all of its attached windows is used as the minimum of the space for the result. Any space greater than the minimum is distributed among the main window and its attached windows. Attached windows with SHAPEW on their REJECTMAINCOMS window property are ignored when finding the minimum size, creating a "ghost" region, or distributing space after a reshape.

If an attached window is reshaped by calling the function SHAPEW, it is reshaped independently. If the right-button window menu command Shape is called on an attached window, it is passed on to the main window, so the whole group is reshaped.
Note: Reshaping the main window will restore the conditions established by the call to ATTACHWINDOW, whereas moving the main window does not. Thus, if A is attached to the top of B and then moved by the user, its new position relative to B will be maintained if B is moved. If B is reshaped, A will be reshaped to the top of B. Additionally, if, while A is moved away from the top of B, C is attached to the top of B, C will position itself above where A used to be.

Close If the main window is closed, all of the attached windows are closed also and the links from the attached windows to the main window are broken. This is necessary for the windows to be garbage collected.

Open If the main window is opened, it opens all attached windows and reestablishes links from them to the main window.

Attached windows can be opened independently and this does not affect the main window. Note that it is possible to reopen a closed attached window and not have it linked to its main window.

Shrink The collection of windows shrinks as a group. The SHRINKFNs of the attached windows are evaluated but the only icon displayed is the one for the main window.

Redisplay The main or attached windows can be redisplayed independently.

Totop If any main or attached window is brought to the top, all of the other windows are brought to the top also.

Expand Expanding any of the windows expands the whole collection.

Scrolling All of the windows involved in the group scroll independently.

Clear All windows clear independently of each other.

Window Properties Of Attached Windows

Windows that are involved in a collection either as a main window or as an attached window have properties stored on them. The only properties that are intended to be set by the user are the MINSIZE, MAXSIZE, PASSTOMAINCOMS, and REJECTMAINCOMS window properties. The other properties should be considered read only.

MINSIZE [Window Property]
MAXSIZE [Window Property]
Each of these window properties should be a dotted pair (WIDTH . HEIGHT) or a function to apply to the window that returns a dotted pair. The numbers are used when the main window is reshaped. The MINSIZE is used to determine the size of the smallest region acceptable during reshaping. Any amount greater than the collective minimum is spread evenly among the windows until each reaches MAXSIZE. Any excess is given to the main window.

If you give the main window of an attached window group a MINSIZE or MAXSIZE property, its value is moved to the MAINWINDOWMINSIZE or MAINWINDOWMAXSIZE property, so that the main window can be given a size function that computes the minimum or maximum size of the entire group. Thus, if you want to change the main window’s minimum or maximum size after attaching windows to it, you should change the MAINWINDOWMINSIZE or MAINWINDOWMAXSIZE property instead.

This doesn’t address the hard problem of overlapping attached windows side to side, for example if window A was attached as [TOP, LEFT] and B as [TOP, RIGHT]. Currently, the attached window functions do not worry about the overlap.

The default MAXSIZE is NIL, which will let the region grow indefinitely.

**MAINWINDOW**

[Window Property]

Pointer from attached windows to the main window of the group. This link is not available if the main window is closed. The function MAINWINDOW is the preferred way to access this property.

**ATTACHEDWINDOWS**

[Window Property]

Pointer from a window to its attached windows. The function ATTACHEDWINDOWS is the preferred way to access this property.

**WHEREATTACHED**

[Window Property]

For attached windows, a dotted pair (EDGE . POSITIONONEDGE) giving the edge and position on the edge that determine how the attached window is placed relative to its main window.

The TOTOPFN window property on attached windows and the properties TOTOPFN, DOSHAPEFN, MOVEFN, CLOSEFN, OPENFN, SHRINKFN, EXPANDFN and CALCULATEREGIONFN on main windows contain functions that implement the attached window manipulation facilities. Care should be used in modifying or replacing these properties.

Communication of Window Menu Commands between Attached Windows is dependent on the name of function used to implement the window command, e.g., CLOSEW implements CLOSE (refer to PASSTOMAINCOMS documentation under Attached Windows). Consequently, if an application intercepts a window command by changing WHENSELECTEDFN for an item in the WindowMenu (for example, to advise the application that a window is being closed), windows may not behave correctly when attached to other windows.
To get around this problem, the Medley release provides the variable *attached-window-command-synonyms*. This variable is an alist, where each element is of the form (new-command-function-name . old-command-function-name).

For example, if an application redefines the WindowMenu to call my-close-window when CLOSE is selected, that application should:

```
(cl:push '(my-close-window . il:closew) il:*attached-window-command-synonyms*)
```

in order to tell the attached window system that my-close-window is a synonym function for CLOSEW.
28. HARDCOPY FACILITIES

Interlisp-D includes facilities for generating hardcopy in "Interpress" format and "Press" format. Interpress is a file format used for communicating documents to Xerox Network System printers such as the Xerox 8044 and Xerox 5700. Press is a file format used for communicating documents to Xerox laser Xerographic printers known by the names "Dover", "Spruce", "Penguin", and "Raven". There are also library packages available for supporting other types of printer formats (4045, FX-80, C150, etc.). The hardcopy facilities are designed to allow the user to support new types of printers with minimal changes to the user interface.

Files can be in a number of formats, including Interpress files, plain text files, and formatted Tedit files. In order to print a file on a given printer, it is necessary to identify the format of the file, convert the file to a format that the printer can accept, and transmit it. Rather than require that the user explicitly determine file types and do the conversion, the Interlisp-D hardcopy functions generate Interpress or other format output depending on the appropriate choice for the designated printer. The hardcopy functions use the variables PRINTERTYPES and PRINTFILETYPES (described below) to determine the type of a file, how to convert it for a given printer, and how to send it. By changing these variables, the user can define other kinds of printers and print to them using the normal hardcopy functions.

(SEND.FILE.TO.PRINTER FILE HOST PRINTOPTIONS) [Function]

The function SEND.FILE.TO.PRINTER causes the file FILE to be sent to the printer HOST. If HOST is NIL, the first host in the list DEFAULTPRINTINGHOST which can print FILE is used.

PRINTOPTIONS is a property list of the form (PROP1 VALUE1 PROP2 VALUE2 ...

...). The properties accepted depends on the type of printer. For Interpress printers, the following properties are accepted:

DOCUMENT.NAME The document name to appear on the header page (a string). Default is the full name of the file.

DOCUMENT.CREATION.DATE The creation date to appear on the header page (a Lisp integer date, such as returned by IDATE). The default value is the creation date of the file.

SENDER.NAME The name of the sender to appear on the header page (a string). The default value is the name of the user.

RECIPIENT.NAME The name of the recipient to appear on the header page (a string). The default is none.

MESSAGE An additional message to appear on the header page (a string). The default is none.

#COPIES The number of copies to be printed. The default value is 1.
PAGES.TO.PRINT The pages of the document that should be printed, represented as a list (FIRSTPAGE# LASTPAGE#). For example, if this option is (3 5), this specifies that pages 3 through 5, inclusive, should be printed. Note that the page numbering used for this purpose has no connection to any page numbers that may be printed on the document. The default is to print all of the pages in the document.

MEDIUM The medium on which the master is to be printed. If omitted, this defaults to the value of NSPRINT.DEFAULT.MEDIUM, as follows: NIL means to use the printer’s default; T means to use the first medium reported available by the printer; any other value must be a Courier value of type MEDIUM. The format of this type is a list (PAPER (KNOWN.SIZE TYPE)) or (PAPER (OTHER.SIZE (WIDTH LENGTH))). The paper TYPE is one of US.LETTER, US.LEegal, A0 through A10, ISO.B0 through ISO.B10, and JIS.B0 through JIS.B10. For users who use A4 paper exclusively, it should be sufficient to set NSPRINT.DEFAULT.MEDIUM to (PAPER (KNOWN.SIZE "A4")).

When using different paper sizes, it may be necessary to reset the variable DEFAULTPAGEREGION, the region on the page used for printing (measured in micas from the lower-left corner).

STAPLE? True if the document should be stapled.

#SIDES 1 or 2 to indicate that the document should be printed on one or two sides, respectively. The default is the value of EMPRESS#SIDES.

PRIORITY The priority of this print request, one of LOW, NORMAL, or HIGH. The default is the printer’s default.

Note: Press printers only recognize the options #COPIES, #SIDES, DOCUMENT.CREATION.DATE, and DOCUMENT.NAME. For example,

(SEND.FILE.TO.PRINTER 'FOO NIL '('#COPIES 3 #SIDES 2 DOCUMENT.NAME "For John")

SEND.FILE.TO.PRINTER calls PRINTERTYPE and PRINTFILETYPE to determine the printer type of HOST and the file format of FILE. If FILE is a formatted file already in a form that the printer can print, it is transmitted directly. Otherwise, CONVERT.FILE.TO.TYPE.FOR.PRINTER is called to do the conversion. [Note: If the file is converted, PRINTOPTIONS is passed to the formatting function, so it can include properties such as HEADING, REGION, and FONTS.] All of these functions use the lists PRINTERTYPES and PRINTFILETYPES to actually determine how to do the conversion.
LISTFILES (Chapter 17) calls the function LISTFILES1 to send a single file to a hardcopy printing device. Interlisp-D is initialized with LISTFILES1 defined to call SEND.FILE.TO.PRINTER.

(HARDCOPYW WINDOW/BITMAP/REGION FILE HOST SCALEFACTOR ROTATION PRINTERTYPE HARDCOPYTITLE)  [Function]

Creates a hardcopy file from a bitmap and optionally sends it to a printer. Note that some printers may have limitations concerning how big or how "complicated" the bitmap may be printed.

WINDOW/BITMAP/REGION can either be a WINDOW (open or closed), a BITMAP, or a REGION (interpreted as a region of the screen). If WINDOW/BITMAP/REGION is NIL, the user is prompted for a screen region using GETREGION.

If FILE is non-NIL, it is used as the name of the file for output. If HOST = NIL, this file is not printed. If FILE is NIL, a temporary file is created, and sent to HOST.

To save an image on a file without printing it, perform (HARDCOPYW IMAGE FILE).
To print an image to the printer PRINTER without saving the file, perform (HARDCOPYW IMAGE NIL PRINTER).

If both FILE and HOST are NIL, the default action is to print the image, without saving the file. The printer used is determined by the argument PRINTERTYPE and the value of the variable DEFAULTPRINTINGHOST. If PRINTERTYPE is non-NIL, the first host on DEFAULTPRINTINGHOST of the type PRINTERTYPE is used. If PRINTERTYPE is NIL, the first printer on DEFAULTPRINTINGHOST that implements the BITMAPSCALE (as determined by PRINTERTYPES) operation is used, if any. Otherwise, the first printer on DEFAULTPRINTINGHOST is used.

The type of hardcopy file produced is determined by HOST if non-NIL, else by PRINTERTYPE if non-NIL, else by the value of DEFAULTPRINTINGHOST, as described above.

SCALEFACTOR is a reduction factor. If not given, it is computed automatically based on the size of the bitmap and the capabilities of the printer type. This may not be supported for some printers.

ROTATION specifies how the bitmap image should be rotated on the printed page. Most printers (including Interpress printers) only support a ROTATION of multiples of 90.

PRINTERTYPE specifies what type of printer to use when HOST is NIL. HARDCOPYW uses this information to select which printer to use or what print file format to convert the output into, as described above.

The background menu contains a "Hardcopy" command (Chapter 28) that prompts the user for a region on the screen, and sends the image to the default printer.

Hardcopy output may also be obtained by writing a file on the printer device LPT, e.g. (COPYFILE 'FOO '{LPT}). When a file on this device is closed, it is converted to Interpress or some other format (if necessary) and sent to the default printer (the first host
INTERLISP-D REFERENCE MANUAL

on DEFAULTPRINTINGHOST). One can include the printer name directly in the file
name, e.g. (COPYFILE 'FOO {LPT}TREMOR:) will send the file to the printer
TREMOR:.

HARDCOPYTITLE is a string specifying a title to print on the page containing the screen
image. If NIL, the string "Window Image" is used. To omit a title, specify the null string.

(PRINTERSTATUS PRINTER) [Function]

Returns a list describing the current status of the printer named PRINTER. The exact form
of the value returned depends on the type of printer. For InterPress printers, the status
describes whether the printer is available or busy or needs attention, and what type of
paper is loaded in the printer.

Returns NIL if the printer does not respond in a reasonable time, which can occur if the
printer is very busy, or does not implement the printer status service.

DEFAULTPRINTINGHOST [Variable]

The variable DEFAULTPRINTINGHOST is used to designate the default printer to be
used as the output of printing operations. It should be a list of the known printer host
names, for example, (QUAKE LISPPRINT:). If an element of
DEFAULTPRINTINGHOST is a list, is interpreted as (PRINTERTYPE HOST),
specifying both the host type and the host name. The type of the printer, which
determines the protocol used to send to it and the file format it requires, is determined by
the function PRINTERTYPE.

If DEFAULTPRINTINGHOST is a single printer name, it is treated as if it were a list of
one element.

(PRINTFILETYPE FILE —) [Function]

Returns the format of the file FILE. Possible values include INTERPRESS, TEDIT, etc.
If it cannot determine the file type, it returns NIL. Uses the global variable
PRINTFILETYPES.

(PRINTERTYPE HOST) [Function]

Returns the type of the printer HOST. Currently uses the following heuristic:

1. If HOST is a list, the CAR is assumed to be the printer type and CADR
   the name of the printer
2. If HOST is a litatom with a non-NIL PRINTERTYPE property, the
   property value is returned as the printer type
3. If HOST contains a colon (e.g., PRINTER:PARC:XEROX) it is
   assumed to be an INTERPRESS printer
4. If HOST is the CADR of a list on DEFAULTPRINTINGHOST, the CAR is returned as the printer type.

5. Otherwise, the value of DEFAULTPRINTERTYPE is returned as the printer type.

Low-level Hardcopy Variables

The following variables are used to define how Interlisp should generate hardcopy of different types. The user should only need to change these variables when it is necessary to access a new type of printer, or define a new hardcopy document type (not often).

PRINTERTYPES

The characteristics of a given printer are determined by the value of the list PRINTERTYPES. Each element is a list of the form

\[(\text{TYPES} \ (\text{PROPERTY}_1 \ \text{VALUE}_1) \ (\text{PROPERTY}_2 \ \text{VALUE}_2) \ . \ . \ .)\]

TYP\(ES\) is a list of the printer types that this entry addresses. The \((\text{PROPERTY}_n \ \text{VALUE}_n)\) pairs define properties associated with each printer type.

The printer properties include the following:

- CANPRINT Value is a list of the file types that the printer can print directly.
- STATUS Value is a function that knows how to find out the status of the printer, used by PRINTERSTATUS.
- PROPERTIES Value is a function which returns a list of known printer properties.
- SEND Value is a function which invokes the appropriate protocol to send a file to the printer.
- BITMAPSCALE Value is a function of arguments WIDTH and HEIGHT in bits which returns a scale factor for scaling a bitmap.
- BITMAPFILE Value is a form which, when evaluated, converts a bitmap to a file format that the printer will accept.

Note: The name 8044 is defined on PRINTERTYPES as a synonym for the INTERPRESS printer type. The names SPRUCE, PENGUIN, and DOVER are defined on PRINTERTYPES as synonyms for the PRESS printer type. The printer types FULLPRESS and RAVEN are also defined the same as PRESS, except that these printer types indicate that the printer is a "Full Press" printer that is able to scale bitmap images, in addition to the normal Press printer facilities.
PRINTFILETYPES

The variable PRINTFILETYPES contains information about various file formats, such as Tedit files and Interpress files. The format is similar to PRINTERTYPES. The properties that can be specified include:

TEST  Value is a function which tests a file if it is of the given type. Note that this function is passed an open stream.

CONVERSION  Value is a property list of other file types and functions that convert from the specified type to the file format.

EXTENSION  Value is a list of possible file extensions for files of this type.
29. TERMINAL INPUT/OUTPUT

Most input/output operations in Interlisp can be simply modeled as reading or writing on a linear stream of bytes. However, the situation is much more complex when it comes to controlling the user’s "terminal," which includes the keyboard, the mouse, and the display screen. For example, Interlisp coordinates the operation of these separate I/O devices so that the cursor on the screen moves as the mouse moves, and any characters typed by the user appear in the window currently containing a flashing cursor. Most of the time, this system works correctly without need for user modification.

The purpose of this chapter is to describe how to access the low-level controls for the terminal I/O devices. It documents the use of interrupt characters, the keyboard characters that generate interrupts. Then, it describes terminal tables, used to determine the meaning of the different editing characters (character delete, line delete, etc.). Then, the "dribble file" facility that allows terminal I/O to be saved onto a file is presented (see the Dribble Files section below). Finally, the low-level functions that control the mouse and cursor, the keyboard, and the screen are documented.

Interrupt Characters

Errors and breaks can be caused by errors within functions, or by explicitly breaking a function. The user can also indicate his desire to go into a break while a program is running by typing certain control characters known as "interrupt characters". The following interrupt characters are currently enabled in Interlisp-D:

Control-B Causes a break within the mouse process (if busy) or the TTY process. Use Control-G to break a particular process.

Control-D Aborts the mouse process (if busy) or the TTY process, and unwinds its stack to the top level. Calls \texttt{RESET} (see Chapter 14).

Control-E Aborts the mouse process (if busy) or the TTY process, and unwinds its stack to the last \texttt{ERRORSET}. Calls \texttt{ERROR!} (see Chapter 14).

Control-G Pops up a menu listing all of the currently-running processes. Selecting one of the processes will cause a break to take place in that process.

Control-P This interrupt is no longer supported in Medley.

Note: In Interlisp-D with multiple processes, it is not sufficient to say that "the computation" is broken, aborted, etc; it is necessary to specify which process is being acted upon. Usually, the user wants interrupts to occur in the TTY process, which is the one currently receiving keyboard input. However, sometimes the user wants to interrupt the mouse process, if it is currently busy executing a menu command or waiting for the user to specify a region on the screen. Most of the interrupt characters below take place in the mouse process if it is busy, otherwise the TTY process. Control-G can be used to break arbitrary processes. For more information, see Chapter 23.
**Control-T** Flashes the TTY process' window and prints status information for the TTY process. First it prints "**IO wait,"** "**Waiting,"** or "**Running,"** depending on whether the TTY process is currently in waiting for characters to be typed, waiting for some other reason, or running. Next, it prints the names of the top three frames on the stack, to show what is running. Then, it prints a line describing the percentage of time (since the last control-T) that has been spent running a program, swapping, garbage collecting, doing local disk I/O, etc. For example:

**Running in TTWAITFORINPUT in TTBIN in TTYIN1**

95% Util, 0% Swap, 4% GC

**DELETE** Clears typeahead in all processes.

The user can disable and/or redefine Interlisp interrupt characters, as well as define new interrupt characters. Interlisp-D is initialized with the following interrupt channels: RESET (**Control-D**), ERROR (**Control-E**), BREAK (**Control-B**), HELP (**Control-G**), PRINTLEVEL (**Control-P**), RUBOUT (**DELETE**), and RAID. Each of these channels independently can be disabled, or have a new interrupt character assigned to it via the function `INTERRUPTCHAR` described below. In addition, the user can enable new interrupt channels, and associate with each channel an interrupt character and an expression to be evaluated when that character is typed.

**(INTERRUPTCHAR CHAR TYP/FORM HARDFLG —)** [Function]

Defines CHAR as an interrupt character. If CHAR was previously defined as an interrupt character, that interpretation is disabled.

CHAR is either a character or a character code (see Chapter 2). Note that full sixteen-bit NS characters can be specified as interrupt characters (see Chapter 2). CHAR can also be a value returned from INTERRUPTCHAR, as described below.

If **TYP/FORM** = NIL, CHAR is disabled.

If **TYP/FORM** = T, the current state of CHAR is returned without changing or disabling it.

If **TYP/FORM** is one of the literal atoms RESET, ERROR, BREAK, HELP, PRINTLEVEL, RUBOUT, or RAID, then INTERRUPTCHAR assigns CHAR to the indicated Interlisp interrupt channel, (reenabling the channel if previously disabled).

If the argument **TYP/FORM** is a symbol designating a predefined system interrupt (RESET, ERROR, BREAK, etc), and HARDFLG is omitted or NIL, then the hardness defaults to the standard hardness of the system interrupt (e.g., MOUSE for the ERROR interrupt).

If **TYP/FORM** is any other literal atom, CHAR is enabled as an interrupt character that when typed causes the atom **TYP/FORM** to be immediately set to T.
If TYP/FORM is a list, CHAR is enabled as a user interrupt character, and TYP/FORM is the form that is evaluated when CHAR is typed. The interrupt will be hard if HARDFLG = T, otherwise soft.

(INTERRUPTCHAR T) restores all Interlisp channels to their original state, and disables all user interrupts.

HARDFLG determines what process the interrupt should run in. If HARDFLG is NIL, the interrupt will run in the TTY process, which is the process currently receiving keyboard input. If HARDFLG is T, the interrupt will occur in whichever process happens to be running. If HARDFLG is MOUSE, the interrupt will happen in the mouse process, if the mouse is busy, otherwise in the TTY process.

INTERRUPTCHAR returns a value which, when given as the CHAR argument to INTERRUPTCHAR, will restore things as they were before the call to INTERRUPTCHAR. Therefore, INTERRUPTCHAR can be used in conjunction with RESETFORM or RESETLST (see Chapter 14).

INTERRUPTCHAR is undoable.

(RESET.INTERRUPTS PERMITTEDINTERRUPTS SAVECURRENT?) [Function]

PERMITTEDINTERRUPTS is a list of interrupt character settings to be performed, each of the form (CHAR TYP/FORM HARDFLG). The effect of RESET.INTERRUPTS is as if (INTERRUPTCHAR CHAR TYP/FORM HARDFLG) were performed for each item on PERMITTEDINTERRUPTS, and (INTERRUPTCHAR OTHERCHAR NIL) were performed on every other existing interrupt character.

If SAVECURRENT? is non-NIL, then RESET.INTERRUPTS returns the current state of the interrupts in a form that could be passed to RESET.INTERRUPTS, otherwise it returns NIL. This can be used with a RESET.INTERRUPTS that appears in a RESETFORM, so that the list is built at "entry", but not upon "exit".

(LISPINTERRUPTS) [Function]

Returns the initial default interrupt character settings for Interlisp-D, as a list that RESET.INTERRUPTS would accept.

(INTERRUPTABLE FLAG) [Function]

if FLAG = NIL, turns interrupts off. If FLAG = T, turns interrupts on. Value is previous setting. INTERRUPTABLE compiles open.

Any interrupt character typed while interrupts are off is treated the same as any other character, i.e., placed in the input buffer, and will not cause an interrupt when interrupts are turned back on.
Terminal Tables

A read table (see Chapter 25) contains input/output information that is media-independent. For example, the action of parentheses is the same regardless of the device from which the input is being performed. A terminal table is an object that contains information that pertains to terminal input/output operations only, such as the character to type to delete the last character or to delete the last line. In addition, terminal tables contain such information as how line-buffering is to be performed, how control characters are to be echoed/printed, whether lowercase input is to be converted to upper case, etc.

Using the functions below, the user may change, reset, or copy terminal tables, or create a new terminal table and install it as the primary terminal table via SETTERMTABLE. However, unlike read tables, terminal tables cannot be passed as arguments to input/output functions.

(GETTERMTABLE TTBL)

If TTBL = NIL, returns the primary (i.e., current) terminal table. If TTBL is a terminal table, return TTBL. Otherwise, generates an ILLEGAL TERMINAL TABLE error.

COPYTERMTABLE TTBL

Returns a copy of TTBL. TTBL can be a real terminal table, NIL (copies the primary terminal table), or ORIG (returns a copy of the original system terminal table). Note that COPYTERMTABLE is the only function that creates a terminal table.

(SETTINGMTABLE TTBL)

Sets the primary terminal table to be TTBL. Returns the previous primary terminal table. Generates an ILLEGAL TERMINAL TABLE error if TTBL is not a real terminal table.

(RESETTINGMTABLE TTBL FROM)

Copies (smashes) FROM into TTBL. FROM and TTBL can be NIL or a real terminal table. In addition, FROM can be ORIG, meaning to use the system’s original terminal table.

TERMTABLEP TTBL

Returns TTBL, if TTBL is a real terminal table, NIL otherwise.

Terminal Syntax Classes

A terminal table associates with each character a single "terminal syntax class", one of CHARDELETE, LINEDELETE, WORDDELETE, RETYPE, CTRLV, EOL, and NONE. Unlike read table classes, only one character in a particular terminal table can belong to each of the classes (except for the default class NONE). When a new character is assigned one of these syntax classes by SETSYNTAX (see Chapter 25), the previous character is disabled (i.e., reassigned the syntax class NONE), and the value of SETSYNTAX is the code for the previous character of that class, if any, otherwise NIL.
The terminal syntax classes are interpreted as follows:

**CHARDELETE** (Initially BackSpace and Control-A in Interlisp-D) Typing this character deletes the previous character typed. Repeated use of this character deletes successive characters back to the beginning of the line.

**LINEDELETE** (Initially Control-Q in Interlisp-D) Typing this character deletes the whole line; it cannot be used repeatedly.

**WORDDELETE** (Initially Control-W in Interlisp-D) Typing this character deletes the previous "word", i.e., sequence of non-separator characters.

**RETYPE** (Initially Control-R) Causes the line to be retyped as Interlisp sees it (useful when repeated deletions make it difficult to see what remains).

**CTRLV**

**CNTRLV** (Initially Control-V) When followed by A, B, ... Z, inputs the corresponding control character control-A, control-B, ... control-Z. This allows interrupt characters to be input without causing an interrupt.

**EOL** On input from a terminal, the EOL character signals to the line buffering routine to pass the input back to the calling function. It also is used to terminate inputs to READLINE (see Chapter 13). In general, whenever the phrase carriage-return linefeed is used, what is meant is the character with terminal syntax class EOL.

**NONE** The terminal syntax class of all other characters.

GETSYNTAX, SETSYNTAX, and SYNTAXP all work on terminal tables as well as read tables (see page X.XX). As with read tables, full sixteen-bit NS characters can be specified in terminal tables (see Chapter 2). When given NIL as a TABLE argument, GETSYNTAX and SYNTAXP use the primary read table or primary terminal table depending on which table contains the indicated CLASS argument. For example, (SETSYNTAX CH 'BREAK) refers to the primary read table, and (SETSYNTAX CH 'CHARDELETE) refers to the primary terminal table. In the absence of such information, all three functions default to the primary read table; e.g., (SETSYNTAX '{ '%'[]) refers to the primary read table. If given incompatible CLASS and table arguments, all three functions generate errors. For example, (SETSYNTAX CH 'BREAK TTBL), where TTBL is a terminal table, generates an ILLEGAL READTABLE error, and (GETSYNTAX 'CHARDELETE RDTBL) generates an **ILLEGAL TERMINAL TABLE** error.

**Terminal Control Functions**

(ECHOCHAR CHARCODE MODE TTBL)
ECHOCHAR sets the "echo mode" of the character CHARCODE to MODE in the terminal table TTBL. The "echo mode" determines how the character is to be echoed or printed. Note that although the name of this function suggests echoing only, it affects all output of the character, both echoing of input and printing of output.

CHARCODE should be a character code. CHARCODE can also be a list of characters, in which case ECHOCHAR is applied to each of them with arguments MODE and TTBL. Note that echo modes can be specified for full sixteen-bit NS characters (see Chapter 2).

MODE should be one of the litatoms IGNORE, REAL, SIMULATE, or INDICATE which specify how the character should be echoed or printed:

- IGNORE  CHARCODE is never printed.
- REAL  CHARCODE itself is printed. Some terminals may respond to certain control and meta characters in interesting ways.
- SIMULATE  Output of CHARCODE is simulated. For example, control-I (tab) may be simulated by printing spaces. The simulation is machine-specific and beyond the control of the user.
- INDICATE  For control or meta characters, CHARCODE is printed as # and/or ↑ followed by the corresponding alphabetic character. For example, Control-A would echo as ↑A, and meta-Control-W would echo as #↑W.

The value of ECHOCHAR is the previous echo mode for CHARCODE. If MODE = NIL, ECHOCHAR returns the current echo mode without changing it.

Warning: In some fonts, control and meta characters may be used for printable characters. If the echomode is set to INDICATE for these characters, they will not print out correctly.

(ECHOCONTROL CHAR MODE TTBL)

ECHOCONTROL is an old, limited version of ECHOCHAR, that can only specify the echo mode of control characters. CHAR is a character or character code. If CHAR is an alphabetic character (or code), it refers to the corresponding control character, e.g., (ECHOCONTROL 'Z 'INDICATE) if equivalent to (ECHOCHAR (CHARCODE ↑) 'INDICATE).

(ECHOMODE FLG TTBL)

If FLG = T, turns echoing for terminal table TTBL on. If FLG = NIL, turns echoing off. Returns the previous setting.

Note: Unlike ECHOCHAR, this only affects echoing of typed-in characters, not printing of characters.

(GETECHOMODE TTBL)

Returns the current echo mode for TTBL.
The following functions manipulate the "raise mode," which determines whether lower case characters are converted to upper case when input from the terminal. There is no "raise mode" for input from files.

(\texttt{RAISE FLG TTBL}) \hspace{1cm} \textbf{[Function]}

Sets the RAISE mode for terminal table TTBL. If \texttt{FLG = NIL}, all characters are passed as typed. If \texttt{FLG = T}, input is echoed as typed, but lowercase letters are converted to upper case. If \texttt{FLG = 0}, input is converted to uppercase before it is echoed. Returns the previous setting.

(\texttt{GETRAISE TTBL}) \hspace{1cm} \textbf{[Function]}

Returns the current RAISE mode for TTBL.

(\texttt{DELETECONTROL TYPE MESSAGE TTBL}) \hspace{1cm} \textbf{[Function]}

Specifies the output protocol when a CHARDELETE or LINEDELETE is typed, by specifying character strings to print when characters are deleted.

Interlisp-10 (designed for use on hardcopy terminals) echos the characters being deleted, preceding the first by a \texttt{\textbackslash} and following the last by a \texttt{\textbackslash}, so that it is easy to see exactly what was deleted. Interlisp-D is initially set up to physically erase the deleted characters from the display, so the DELETECONTROL strings are initialized to the null string.

The various values of \texttt{TYPE} specify different phases of the deletion, as follows:

- \texttt{1STCHDEL} \hspace{1cm} MESSAGE is the message printed the first time CHARDELETE is typed. Initially "\textbackslash" in Interlisp-10.
- \texttt{NTHCHDEL} \hspace{1cm} MESSAGE is the message printed when the second and subsequent CHARDELETE characters are typed (without intervening characters). Initially "" in Interlisp-10.
- \texttt{POSTCHDEL} \hspace{1cm} MESSAGE is the message printed when input is resumed following a sequence of one or more CHARDELETE characters. Initially "\textbackslash" in Interlisp-10.
- \texttt{EMPTYCHDEL} \hspace{1cm} MESSAGE is the message printed when a CHARDELETE is typed and there are no characters in the buffer. Initially "## cr" in Interlisp-10.
- \texttt{ECHO} \hspace{1cm} If \texttt{TYPE = ECHO}, the characters deleted by CHARDELETE are echoed. \texttt{MESSAGE} is ignored.
- \texttt{NOECHO} \hspace{1cm} If \texttt{TYPE = NOECHO}, the characters deleted by CHARDELETE are not echoed. \texttt{MESSAGE} is ignored.
- \texttt{LINEDELETE} \hspace{1cm} MESSAGE is the message printed when the LINEDELETE character is typed. Initially "## cr".
Note: In Interlisp-10, the LINEDELETE, 1STCHDEL, NTHCHDEL, POSTCHDEL, and EMPTYCHDEL messages must be 4 characters or fewer in length.

DELETECONTROL returns the previous message as a string. If MESSAGE = NIL, the value returned is the previous message without changing it. For TYPE = ECHO and NOECHO, the value of DELETECONTROL is the previous echo mode, i.e., ECHO or NOECHO.

(GETDELETECONTROL TYPE TTBL) [Function]

Returns the current DELETECONTROL mode for TYPE in TTBL.

**Line-Buffering**

Characters typed at the terminal are stored in two buffers before they are passed to an input function. All characters typed in are put into the low-level "system buffer", which allows type-ahead. When an input function is entered, characters are transferred to the "line buffer" until a character with terminal syntax class EOL appears (or, for calls from READ, when the count of unbalanced open parentheses reaches 0). Note that PEEKC is an exception; it returns the character immediately when its second argument is NIL. Until this time, the user can delete characters one at a time from the line buffer by typing the current CHARDELETE character, or delete the entire line buffer back to the last carriage-return by typing the current LINEDELETE.

This line editing is not performed by READ or RATOM, but by Interlisp, i.e., it does not matter (nor is it necessarily known) which function will ultimately process the characters, only that they are still in the Interlisp line buffer. However, the function that is requesting input at the time the buffering starts does determine whether parentheses counting is observed. For example, if a program performs (PROGN (RATOM) (READ)) and the user types in "A (B C D)", the user must type in the carriage-return following the right parenthesis before any action is taken, because the line buffering is happening under RATOM. If the program had performed (PROGN (READ) (READ)), the line-buffering would be under READ, so that the right parenthesis would terminate line buffering, and no terminating carriage-return would be required.

Once a carriage-return has been typed, the entire line is "available" even if not all of it is processed by the function initiating the request for input. If any characters are "left over", they are returned immediately on the next request for input. For example, (LIST (RATOM) (READC) (RATOM)) when the input is "A Bcr" returns the three-element list (A % B) and leaves the carriage-return in the buffer.

If a carriage-return is typed when the input under READ is not "complete" (the parentheses are not balanced or a string is in progress), line buffering continues, but the lines completed so far are not available for editing with CHARDELETE or LINEDELETE.

The function CONTROL is available to defeat line-buffering:

(CONTROL MODE TTBL) [Function]
If \( \text{MODE} = T \), eliminates Interlisp's normal line-buffering for the terminal table \( \text{TTBL} \). If \( \text{MODE} = \text{NIL} \), restores line-buffering (normal). When operating with a terminal table in which \((\text{CONTROL}\ T)\) has been performed, characters are returned to the calling function without line-buffering as described below.

\( \text{CONTROL} \) returns its previous setting.

\[
\text{(GETCONTROL TTBL)}
\]

Returns the current control mode for \( \text{TTBL} \).

The function that initiates the request for input determines how the line is treated when \((\text{CONTROL} \ T)\) is in effect:

**READ** If the expression being typed is a list, the effect is the same as though done with \((\text{CONTROL} \ \text{NIL})\), i.e., line-buffering continues until a carriage-return or matching parentheses. If the expression being typed is not a list, it is returned as soon as a break or separator character is encountered, e.g., \((\text{READ})\) when the input is "ABC<space>" immediately returns ABC. \( \text{CHARDELETE} \) and \( \text{LINEDELETE} \) are available on those characters still in the buffer. Thus, if a program is performing several reads under \((\text{CONTROL} \ T)\), and the user types "NOW IS THE TIME" followed by Control-Q, only TIME is deleted, since the rest of the line has already been transmitted to \( \text{READ} \) and processed.

An exception to the above occurs when the break or separator character is an opening parenthesis, bracket or double-quote, since returning at this point would leave the line buffer in a "funny" state. Thus if the input to \( \text{READ} \) is "ABC(", the ABC is not read until a carriage-return or matching parentheses is encountered. In this case the user could \( \text{LINEDELETE} \) the entire line, since all of the characters are still in the buffer.

**RATOM** Characters are returned as soon as a break or separator character is encountered. Until then, \( \text{LINEDELETE} \) and \( \text{CHARDELETE} \) may be used as with \( \text{READ} \). For example, \((\text{RATOM})\) followed by "ABC<control-A><space>" returns AB. \((\text{RATOM})\) followed by "<control-A>" returns ( and types ## indicating that control-A was attempted with nothing in the buffer, since the ( is a break character and would therefore already have been read.

**READC**

**PEEKC** The character is returned immediately; no line editing is possible. In particular, \((\text{READC})\) is perfectly happy to return
The system buffer and line buffer can be directly manipulated using the following functions.

\textbf{(CLEARBUF FILE FLG)} \hfill [Function]

Clears the input buffer for \textit{FILE}. If \textit{FILE} is \text{T} and \textit{FLG} is \text{T}, the contents of Interlisp’s system buffer and line buffer are saved (and can be obtained via \textit{SYSBUF} and \textit{LINBUF} described below).

When you type Control-D or Control-E, or any of the interrupt characters that require terminal interaction (Control-G, or Control-P), Interlisp automatically performs \textbf{(CLEARBUF T T)}. For Control-P and, when the break is exited normally, control-H, Interlisp restores the buffer after the interaction.

The action of \textbf{(CLEARBUF T)}, i.e., clearing of typeahead, is also available as the \textit{RUBOUT} interrupt character, initially assigned to the delete key in Interlisp-D. Note that this interrupt clears both buffers at the time it is typed, whereas the action of the \textit{CHARDELETE} and \textit{LINEDELETE} character occur at the time they are read.

\textbf{(SYSBUF FLG)} \hfill [Function]

If \textit{FLG} = \text{T}, returns the contents of the system buffer (as a string) that was saved at the last \textbf{(CLEARBUF T T)}. If \textit{FLG} = \text{NIL}, clears this internal buffer.

\textbf{(LINBUF FLG)} \hfill [Function]

Same as \textit{SYSBUF} for the line buffer.

If both the system buffer and Interlisp’s line buffer are empty, the internal buffers associated with \textit{LINBUF} and \textit{SYSBUF} are not changed by a \textbf{(CLEARBUF T T)}.

\textbf{(BKSYSBUF X FLG RDTBL)} \hfill [Function]

\textit{BKSYSBUF} appends the \textit{PRIN1}-name of \textit{X} to the system buffer. The effect is the same as though the user typed \textit{X}. Some implementations have a limit on the length of \textit{X}, in which case characters in \textit{X} beyond the limit are ignored. Returns \textit{X}.

If \textit{FLG} is \text{T}, then the \textit{PRIN2}-name of \textit{X} is used, computed with respect to the readtable \textit{RDTBL}. If \textit{RDTBL} is \text{NIL} or omitted, the current readable of the \textit{TTY} process (which is to receive the characters) is used. Use this for copy selection functions that want their output to be a readable expression in an Exec.

Note that if you are typing at the same time as the \textit{BKSYSBUF} is being performed, the relative order of the typein and the characters of \textit{X} is unpredictable.

\textbf{(BKLINBUF STR)} \hfill [Function]
**TERMINAL INPUT/OUTPUT**

`STR` is a string. `BKLINBUF` sets Interlisp’s line buffer to `STR`. Some implementations have a limit on the length of `STR`, in which case characters in `STR` beyond the limit are ignored. Returns `STR`.

`BKSYSCHARCODE CODE` [Function]

This function appends the character code `CODE` to the system input buffer. The function `BKSYSBUF` is implemented by repeated calls to `BKSYSCHARCODE`.

`BKLINBUF`, `BKSYSBUF`, `LINBUF`, and `SYSBUF` provide a way of "undoing" a `CLEARBUF`. Thus to "peek" at various characters in the buffer, one could perform `(CLEARBUF T T)`, examine the buffers via `LINBUF` and `SYSBUF`, and then put them back.

The more common use of these functions is in saving and restoring typeahead when a program requires some unanticipated (from the user's standpoint) input. The function `RESETBUFS` provides a convenient way of simply clearing the input buffer, performing an interaction with the user, and then restoring the input buffer.

`RESETBUFS FORM1, FORM2,... FORMN` [NLambda NoSpread Function]

Clears any typeahead (ringing the terminal's bell if there was, indeed, typeahead), evaluates `FORM1, FORM2,... FORMN`, then restores the typeahead. Returns the value of `FORMN`. Compiles open.

**Dribble Files**

A dribble file is a "transcript" of all of the input and output on a terminal. In Interlisp-D, `DRIBBLE` opens a dribble file for the current process, recording the terminal input and output for that process. Multiple processes can have separate dribble files open at the same time.

`DRIBBLE FILE APPENDFLG THAWEDFLG` [Function]

Opens `FILE` and begins recording the typescript. Returns the old dribble file if any, otherwise `NIL`. If `APPENDFLG = T`, the typescript will be appended to the end of `FILE`. If `THAWEDFLG = T`, the file will be opened in "thawed" mode, for those implementations that support it. `(DRIBBLE)` closes the dribble file for the current process. Only one dribble file can be active for each process at any one time, so `(DRIBBLE FILE1)` followed by `(DRIBBLE FILE2)` will cause `FILE1` to be closed.

`DRIBBLEFILE` [Function]

Returns the name of the current dribble file for the current process, if any, otherwise `NIL`.  

29 - 11
Terminal input is echoed to the dribble file a line buffer at a time. Thus, the typescript produced is somewhat neater than that appearing on the user’s terminal, because it does not show characters that were erased via Control-A or Control-Q. Note that the typescript file is not included in the list of files returned by (OPENP), nor will it be closed by a call to CLOSEALL or CLOSEF. Only (DRIBBLE) closes the typescript file.

Cursor and Mouse

A mouse is a small box connected to the computer keyboard by a long wire. On the top of the mouse are two or three buttons. On the bottom is a rolling ball or a set of photoreceptors, to detect when the mouse is moved. As the mouse is moved on a surface, a small image on the screen, called the cursor, moves to follow the movement of the mouse. By moving the mouse, the user can cause the cursor to point to any part of the display screen.

The mouse and cursor are an important part of the Interlisp-D user interface. The Interlisp-D window system allows the user to create, move, and reshape windows, and to select items from displayed menus, all by moving the mouse and clicking the mouse buttons. This section describes the low-level functions used to control the mouse and cursor.

Changing the Cursor Image

Interlisp-D maintains the image of the cursor on the screen, moving it as the mouse is moved. The bitmap that becomes visible as the cursor can be accessed by the following function:

\[
\text{(CURSORBITMAP)} \quad \text{[Function]}
\]

Returns the cursor bitmap.

\[
\text{CURSORWIDTH} \quad \text{[Variable]}
\]

\[
\text{CURSORHEIGHT} \quad \text{[Variable]}
\]

Value is the width and height of the cursor bitmap, respectively.

The cursor bitmap can be changed like any other bitmap by BITBLTing into it or pointing a display stream at it and printing or drawing curves. The CURSOR datatype has the following field names CUBITSPERPIXEL CUIMAGE, CUMASK, CUHOTSPOTX, CUHOTSPOTY, CUDATA.

CURSOR objects can be saved on a file using the file package command CURSORS, or the UGLYVARS file package command.

\[
\text{(CURSORCREATE BITMAP X Y)} \quad \text{[Function]}
\]

Returns a cursor object which has BITMAP as its image and the location \((X, Y)\) as the hot spot. If \(X\) is a POSITION, it is used as the hot spot. If BITMAP has dimensions different from CURSORWIDTH by CURSORHEIGHT, the lesser of the widths and the lesser of the
heights are used to determine the bits that actually get copied into the lower left corner of
the cursor. If \( X \) is NIL, 0 is used. If \( Y \) is NIL, CURSORHEIGHT-1 is used. The default
cursor is an uparrow with its tip in the upper left corner and its hot spot at
\((0, \text{CURSORHEIGHT}-1)\).

\[
\text{CURSOR NEWCURSOR} \quad \text{[Function]}
\]

Returns a CURSOR record instance that contains (a copy of) the current cursor
specification. If NEWCURSOR is a CURSOR record instance, the cursor will be set to the
values in NEWCURSOR. If NEWCURSOR is T, the cursor will be set to the default cursor
DEFAULTCURSOR, an upward left pointing arrow.

\[
\text{SETCURSOR NEWCURSOR} \quad \text{[Function]}
\]

If NEWCURSOR is a CURSOR record instance, the cursor will be set to the values in
NEWCURSOR. This does not return the old cursor, and therefore, provides a way of
changing the cursor without using storage.

\[
\text{FLIPCURSOR} \quad \text{[Function]}
\]

Inverts the cursor.

The following list describes the cursors used by the Interlisp-D system. Most of them are
stored as the values of various variables.

- In variable DEFAULTCURSOR. This is the default cursor.
- In variable WAITINGCURSOR. Represents an hourglass. Used during long computations.
- In variable MOUSECONFIRMCURSOR. Indicates that the system is
  waiting for the user to confirm an action by pressing the left mouse
  button, or aborting the action by pressing any other button. Used by
  the function MOUSECONFIRM (see Chapter 28).
- In variable SYSOUTCURSOR. Indicates that the system is saving
  the virtual memory in a sysout file. See SYSOUT, Chapter 12.
- In variable SAVINGCURSOR. Indicates that SAVEVM has been called
  automatically to save the virtual memory state after the system is idle
  for long enough. See SAVEVMWAIT, Chapter 12.
- In variable CROSSHAIRS. Used by GETPOSITION (see Chapter 28)
to indicate a position.
In variable BOXCURSOR.  Used by GETBOXPOSITION (see Chapter 28) to indicate where to place the corner of a box.

In variable FORCEPS.  Used by GETREGION (see Chapter 28) when the user switches corners.

In variable EXPANDINGBOX.  Used by GETREGION (see Chapter 28) when a box is first displayed.

In variable UpperRightCursor.

In variable LowerRightCursor.

In variable UpperLeftCursor.

In variable LowerLeftCursor.

The previous four cursors are used by GETREGION (see Chapter 28) to indicate the four corners of a region.

In variable VertThumbCursor.  Used during scrolling to indicate thumbing in a vertical scroll bar.

In variable VertScrollCursor.

In variable ScrollUpCursor.

In variable ScrollDownCursor.

The previous four cursors are used by SCROLL.HANDLER (see Chapter 28) during vertical scrolling.

In variable HorizThumbCursor.  Used during scrolling to indicate thumbing in a horizontal scroll bar.

In variable HorizScrollCursor.

In variable ScrollLeftCursor.

In variable ScrollRightCursor.

The previous four cursors are used by SCROLL.HANDLER (see Chapter 28) during horizontal scrolling.
These cursors are used by the Teleraid low-level debugger. These cursors are not accessible as standard Interlisp-D cursors.

**Flashing Bars on the Cursor**

The low-level Interlisp-D system uses the cursor to display certain system status information, such as garbage collection or swapping. This is done because changing the cursor image is very quick, and does not require interacting with the window system. Interlisp inverts horizontal bars on the cursor when the system is swapping pages, or doing certain stack operations. Normally, these bars are only inverted for a very short time, so they look like they are flashing. These cursor changes are interpreted as follows:

- **Inverted cursor:** Whatever image is being displayed as the cursor, whenever Interlisp does a garbage collection, the whole cursor is inverted.

- **Top bar:** Swap read. On when Interlisp is swapping in a page from the virtual memory file into the real memory. It is also on when Interlisp allocates a new virtual memory page, even though that doesn’t involve a disk read. If this is flashing a lot, the system is doing a lot of swapping. This is an indication that the virtual memory working set is fragmented (see Chapter 22). Performance may be improved by reloading a clean Interlisp system.

- **Upper middle bar:** Stack operations. If this is flashing a lot, it suggests that some process is neglecting to release stack pointers in a timely fashion (see Chapter 11).

- **Lower middle bar:** Stack operations. On when Interlisp is moving frames on the stack. If the system is slow, and this is flashing a lot, Hardseset (see Chapter 23) sometimes helps.

- **Bottom bar:** Swap write. On when Interlisp writes a dirty virtual memory page from the real memory back into the virtual memory file.

**Cursor Position**

The position at which the cursor bitmap is being displayed can be read or set using the following functions:

\[
\text{(CURSORPOSITION NEWPOSITION DISPLAYSTREAM OLDPOSITION)}
\]  

[Function]

Returns the location of the cursor in the coordinate system of DISPLAYSTREAM (or the current display stream, if DISPLAYSTREAM is NIL). If NEWPOSITION is non-NIL, it
should be a position and the cursor will be positioned at \textit{NEWPOSITION}. If \textit{NEWPOSITION} is \textit{NIL}, the current position is simply returned.

The current position of the cursor is the position of the "hot spot" of the cursor, not the position of the cursor bitmap.

If \textit{OLDPOSITION} is a \texttt{POSITION} object, this object will be changed to point to the location of the cursor and returned, rather than allocating a new \texttt{POSITION}. This can improve performance if \texttt{CURSORPOSITION} is called repeatedly to track the cursor.

To get the location of the cursor in absolute screen coordinates, use the variables \texttt{LASTMOUSEX} and \texttt{LASTMOUSEY}.

\begin{verbatim}
(adjjustcursorposition deltax deltax)  [Function]
\end{verbatim}

Moves the cursor \texttt{DELTAX} points in the \textit{X} direction and \texttt{DELTAY} points in the \textit{Y} direction. \texttt{DELTAX} and \texttt{DELTAY} default to 0.

**Mouse Button Testing**

There are two or three keys on the mouse. These keys (also called buttons) are referred to by their location: LEFT, MIDDLE, or RIGHT. The following macros are provided to test the state of the mouse buttons:

\begin{verbatim}
(mousestate buttonform)  [Macro]
\end{verbatim}

Reads the state of the mouse buttons, and returns \texttt{T} if that state is described by \texttt{BUTTONFORM}. \texttt{BUTTONFORM} can be one of the key indicators \texttt{LEFT}, \texttt{MIDDLE}, or \texttt{RIGHT}; the atom \texttt{UP} (indicating all keys are up); the form \texttt{(ONLY KEY)}; or a form of \texttt{AND}, \texttt{OR}, or \texttt{NOT} applied to any valid button form.

For example: \texttt{(MOUSESTATE LEFT)} will be true if the left mouse button is down. \texttt{(MOUSESTATE (ONLY LEFT))} will be true if the left mouse button is the only one down. \texttt{(MOUSESTATE (OR (NOT LEFT) MIDDLE))} will be true if either the left mouse button is up or the middle mouse button is down.

\begin{verbatim}
(lastmousestate buttonform)  [Macro]
\end{verbatim}

Similar to \texttt{MOUSESTATE}, but tests the value of \texttt{LASTMOUSEBUTTONS} (below) rather than getting the current state. This is useful for determining which keys caused \texttt{MOUSESTATE} to be true.

\begin{verbatim}
(untilmousestate buttonform interval)  [Macro]
\end{verbatim}

\texttt{BUTTONFORM} is as described in \texttt{MOUSESTATE}. Waits until \texttt{BUTTONFORM} is true or until \texttt{INTERVAL} milliseconds have elapsed. The value of \texttt{UNTILMOUSESTATE} is \texttt{T} if \texttt{BUTTONFORM} was satisfied before it timed out, otherwise \texttt{NIL}. If \texttt{INTERVAL} is \texttt{NIL}, it waits indefinitely. This compiles into an open loop that calls the TTY wait background
function. This form should not be used inside the TTY wait background function. UNTILMOUSESTATE does not use any storage during its wait loop.

**Low Level Mouse Functions**

This section describes the functions and variables that provide low level access to the mouse and cursor.

((LASTMOUSEX DISPLAYSTREAM) [Function]

Returns the value of the cursor’s X position in the coordinates of DISPLAYSTREAM (as of the last call to GETMOUSESTATE, below).

((LASTMOUSEY DISPLAYSTREAM) [Function]

Returns the value of the cursor’s Y position in the coordinates of DISPLAYSTREAM (as of the last call to GETMOUSESTATE, below).

LASTMOUSEX [Variable]

Value is the X position of the cursor in absolute screen coordinates (as of the last call to GETMOUSESTATE, below).

LASTMOUSEY [Variable]

Value is the Y position of the cursor in absolute screen coordinates (as of the last call to GETMOUSESTATE, below).

LASTMOUSEBUTTONS [Variable]

Value is an integer that has bits on corresponding to the mouse buttons that are down (as of the last call to GETMOUSESTATE, below). Bit 4Q is the left mouse button, 2Q is the right button, 1Q is the middle button.

LASTKEYBOARD [Variable]

Value is an integer encoding the state of certain keys on the keyboard (as of the last call to GETMOUSESTATE, below). Bit 200Q = lock, 100Q = left shift, 40Q = ctrl, 10Q = right shift, 4Q = blank Bottom, 2Q = blank Middle, 1Q = blank Top. If the key is down, the corresponding bit is on.

(GETMOUSESTATE) [Function]

Reads the current state of the mouse and sets the variables LASTMOUSEX, LASTMOUSEY, and LASTMOUSEBUTTONS. In polling mode, the program must remember the previous state and look for changes, such as a key going up or down, or the cursor moving outside a region of interest.

((DECODEBUTTONS BUTTONSTATE) [Function]
Returns a list of the mouse buttons that are down in the state `BUTTONSTATE`. If `BUTTONSTATE` is not a small integer, the value of `LASTMOUSEBUTTONS` (above) is used. The button names that can be returned are: `LEFT`, `MIDDLE`, `RIGHT` (the three mouse keys).

**Keyboard Interpretation**

For each key on the keyboard and mouse there is a corresponding bit in memory that the hardware turns on and off as the key moves up and down. System-level routines decode the meaning of key transitions according to a table of "key actions", which may be to put particular character codes in the sysbuffer, cause interrupts, change the internal shift/control status, or create events to be placed in the mouse buffer.

\[(KEYDOWNP KEYNAME)\] [Function]

Used to read the instantaneous state of any key, independent of any buffering or pre-assigned key action. Returns `T` if the key named `KEYNAME` is down at the moment the function is executed.

Most keys are named by the characters on the key-top. Therefore, `(KEYDOWNP 'a)` or `(KEYDOWNP 'A)` returns `T` if the "A" key is down.

There are a number of keys that do not have standard names printed on them. These can be accessed by special names as follows:

- Space `SPACE`
- Carriage return `CR`
- Line-feed `LF`
- Backspace `BS`
- Tab `TAB`

Blank keys on 1132

The 1132 keyboard has three unmarked keys on the right of the normal keyboard. These can be accessed by `BLANK-BOTTOM`, `BLANK-MIDDLE`, and `BLANK-TOP`.

- Escape `ESCAPE`
- Shift keys `LSHIFT` for the left shift key, `RSHIFT` for the right shift key.
- Shift lock key `LOCK`
- Control key `CTRL`

Mouse buttons

The state of the mouse buttons can be accessed using `LEFT`, `MIDDLE`, and `RIGHT`. 
If KEYNAME is a small integer, it is taken to be the internal key number. Otherwise, it is taken to be the name of the key. This means, for example, that the name of the "6" key is not the number 6. Instead, spelled-out names for all the digit keys have been assigned. The "6" key is named SIX. It happens that the key number of the "6" key is 2. Therefore, the following two forms are equivalent:

(KEYDOWNP 'SIX)
(KEYDOWNP 2)

(SHIFTDOWNP SHIFT)  [Function]
Returns T if the internal "shift" flag specified by SHIFT is on; NIL otherwise.
If SHIFT = 1SHIFT, 2SHIFT, LOCK, META, or CTRL, SHIFTDOWNP returns the state of the left shift, right shift, shift lock, control, and meta flags, respectively.
If SHIFT = SHIFT, SHIFTDOWNP returns T if either the left or right shift flag is on.
If SHIFT = USERMODE1, USERMODE2, or USERMODE3, SHIFTDOWNP returns the state of one of three user-settable flags that have no other effect on key interpretation. These flags can be set or cleared on character transitions by using KEYACTION (below).

(KEYACTION KEYNAME ACTIONS -)  [Function]
Changes the internal tables that define the action to be taken when a key transition is detected by the system keyboard handler. KEYNAME is specified as for KEYDOWNP. ACTIONS is a dotted pair of the form (DOWN-ACTION . UP-ACTION), where the acceptable transition actions and their interpretations are:

NIL

IGNORE Take no action on this transition (the default for up-transitions on all ordinary characters).

(CHAR SHIFTEDCHAR LOCKFLAG)
If a transition action is a three-element list, CHAR and SHIFTEDCHAR are either character codes or (non-numeric) single-character litatoms standing for their character codes. Note that CHAR and SHIFTEDCHAR can be full sixteen-bit NS characters (see page X.XX). When the transition occurs, CHAR or SHIFTEDCHAR is transmitted to the system buffer, depending on whether either of the two shift keys are down.

LOCKFLAG is optional, and may be LOCKSHIFT or NOLOCKSHIFT. If LOCKFLAG is LOCKSHIFT, then SHIFTEDCHAR will also be transmitted when the LOCK shift is down (the alphabetic keys initially specify LOCKSHIFT, but the digit keys specify NOLOCKSHIFT). For
example, (a A LOCKSHIFT) and (61Q ! NOLOCKSHIFT) are the initial settings for the down transitions of the "a" and "1" keys respectively.

1SHIFTUP, 1SHIFTDOWN
2SHIFTUP, 2SHIFTDOWN
CTRLUP, CTRLDOWN
METAUP, METADOWN

Change the status of the internal "shift" flags for the left shift, right shift, control, and meta keys, respectively. These shifts affect the interpretation of ordinary key actions. If either of the shifts is down, then SHIFTEDCHARs are transmitted. If the control flag is on, then the seventh bit of the character code is cleared as characters are transmitted. If the meta flag is on, the eighth bit of the character code is set (normally cleared) as characters are transmitted. For example, the initial keyactions for the left shift key is (1SHIFTDOWN 1SHIFTUP).

LOCKUP, LOCKDOWN, LOCKTOGGLE

Change the status of the internal "shift" flags for the shift lock key. If the lock flag is down, then SHIFTEDCHARs are transmitted if the key action specified LOCKSHIFT. LOCKUP and LOCKDOWN clear and set the shift lock flag, respectively. LOCKTOGGLE complements the flag (turning it off if the flag is on; on if the flag is off).

USERMODE1UP, USERMODE1DOWN, USERMODE1TOGGLE
USERMODE2UP, USERMODE2DOWN, USERMODE2TOGGLE
USERMODE3UP, USERMODE3DOWN, USERMODE3TOGGLE

Change the status of the three user flags USERMODE1, USERMODE2, and USERMODE3, whose status can be determined by calling SHIFTDOWNP (above). These flags have no other effect on key interpretation.

EVENT
An encoding of the current state of the mouse and selected keys is placed in the mouse-event buffer when this transition is detected.

KEYACTION returns the previous setting for KEYNAME. If ACTIONS is NIL, returns the previous setting without changing the tables.

(MODIFY.KEYACTIONS KEYACTIONS SAVECURRENT?) [Function]

KEYACTIONS is a list of key actions to be set, each of the form (KEYNAME ACTIONS). The effect of MODIFY.KEYACTIONS is as if (KEYACTION KEYNAME ACTIONS) were performed for each item on KEYACTIONS.
If `SAVECURRENT?` is non-NIL, then `MODIFY.KEYACTIONS` returns a list of all the results from `KEYACTION`, otherwise it returns NIL. This can be used with a `MODIFY.KEYACTIONS` that appears in a `RESETFORM`, so that the list is built at “entry”, but not upon “exit”.

`(METASHIFT FLG)`

[NoSpread Function]

If `FLG` is T, changes the keyboard handler (via `KEYACTION`) so as to interpret the “stop” key on the 1108 as a metashift: if a key is struck while the meta is down, it is read with the 200Q bit set. For CHAT users this is a way of getting an "Edit" key on your simulated Datamedia.

If `FLG` is other than NIL or T, it is passed as the `ACTIONS` argument to `KEYACTION`. The reason for this is that if someone has set the “STOP” key to some random behavior, then `(RESETFORM (METASHIFT T) --)` will correctly restore that random behavior.

**Display Screen**

Medley supports a high-resolution bitmap display screen. All printing and drawing operations to the screen are actually performed on a bitmap in memory, which is read by the computer hardware to become visible as the screen. This section describes the functions used to control the appearance of the display screen.

`(SCREENBITMAP)`

[Function]

Returns the screen bitmap.

`SCREENWIDTH`

`SCREENHEIGHT`

[Variable]

[Variable]

Value is the width and height of the screen bitmap, respectively.

`WHOLEDISPLAY`

[Variable]

Value is a region that is the size of the screen bitmap.

The background shade of the display window can be changed using the following function:

`(CHANGEBACKGROUND SHADE --)`

[Function]

Changes the background shade of the window system. `SHADE` determines the pattern of the background. If `SHADE` is a texture, then the background is simply painted with it. If `SHADE` is a `BITMAP`, the background is tesselated (tiled) with it to cover the screen. If `SHADE` is T, it changes to the original shade, the value of `WINDOWBACKGROUND SHADE`. It returns the previous value of the background.

`WINDOWBACKGROUND SHADE`

[Variable]
Value is the default background shade for the display.

**Value**

Sets the interpretation of the bits in the screen bitmap. If \texttt{BLACKFLG} is \texttt{NIL}, a 0 bit will be displayed as white, otherwise a 0 bit will be displayed as black. \texttt{VIDEOCOLOR} returns the previous setting. If \texttt{BLACKFLG} is not given, \texttt{VIDEOCOLOR} will return the current setting without changing anything.

Note: This function only works on the Xerox 1100 and Xerox 1108.

**Value**

Sets the rate at which the screen is refreshed. \texttt{TYPE} is one of \texttt{NORMAL} or \texttt{TAPE}. If \texttt{TYPE} is \texttt{TAPE}, the screen will be refreshed at the same rate as TV (60 cycles per second). This makes the picture look better when video taping the screen. Note: Changing the rate may change the dimensions of the display on the picture tube.

Maintaining the video image on the screen uses cpu cycles, so turning off the display can improve the speed of compute-bound tasks. When the display is off, the screen will be white but any printing or displaying that the program does will be visible when the display is turned back on.

Note: Breaks and \texttt{PAGEFULLFN} waiting (see Chapter 28) turn the display on, but users should be aware that it is possible to have the system waiting for a response to a question printed or a menu displayed on a non-visible part of the screen. The functions below are provided to turn the display off.

Note: These functions have no effect on the Xerox 1108 display.

**Value**

Sets the display to only show the top \texttt{NSCANLINES} of the screen. If \texttt{NSCANLINES} is \texttt{T}, resets the display to show the full screen. Returns the previous setting.

**Value**

Evaluates \texttt{FORM} (with the display set to only show the top \texttt{NSCANLINES} of the screen), and returns the value of \texttt{FORM}. It restores the screen to its previous setting. If \texttt{NSCANLINES} is not given, it defaults to 0.

**Value**

Flashes (reverse-videos) the screen \texttt{N} times (default 1). On the Xerox 1108, this also beeps through the keyboard speaker.

**Value**

**Miscellaneous Terminal I/O**
On the Xerox 1108, PLAYTUNE plays a sequence of notes through the keyboard speaker. Frequency/Duration pairlist should be a list of dotted pairs (FREQUENCY . DURATION). PLAYTUNE maps down its argument, beeping the 1108 keyboard buzzer at each frequency for the specified amount of time. Specifying NIL for a frequency means to turn the beeper off the specified amount of time. The units of time are TICKS (Chapter 12), which last about 28.78 microseconds on the Xerox 1108. PLAYTUNE makes no sound on a Xerox 1132. The default "simulate" entry for Control-G (ASCII BEL) on the 1108 uses PLAYTUNE to make a short beep.

PLAYTUNE is implemented using BEEPON and BEEPOFF:

(BEEPON FREQ) [Function]
On the Xerox 1108, turns on the keyboard speaker playing a note with frequency FREQ, measured in Hertz (see Chapter 12). The speaker will continue to play the note until BEEPOFF is called.

(BEEPOFF) [Function]
Turns off the keyboard speaker on the Xerox 1108.

(SETMAINTPANEL N) [Function]
On the Xerox 1108, this sets the four-digit "maintanance panel" display on the front of the computer to display the number N.
Inspecting and Repairing Notefiles

Xerox Corporation

Randy Trigg

[First written: 8/9/85 Randy Trigg]
[Last updated: 8/26/85 Randy Trigg]

This document describes the Notefile inspector facility available via the Inspect&Repair option on the Notefile Ops menu in NoteCards Release1.2i.

The old Repair Notefile facility rebuilt the links in a Notefile from the contents of card substances. This was used whenever a notefile was thought to have inconsistent links. The problem was that notefiles with inconsistent links often had other problems that caused Repair to break. Thus the motivation for developing the notefile inspector documented here was to verify a notefile’s readability before invoking the link rebuilder. As it turns out, this inspector is useful generally for checking the health of a notefile, deleting cards and backing up other cards (or more precisely, card parts) to previous versions. Thus, you may want to use the inspector even if your notefile is healthy and doesn’t need its links rebuilt.

The notefile inspector has three separate phases: reading the notefile’s data area searching for healthy card parts, allowing the user to make modifications, and rebuilding the links. The process can be aborted after phase 1 or 2 if desired. This document begins with a brief discussion of the organization of a notefile. Then follows sections describing each of the three phases. Finally, I outline some tips, strategies and pitfalls to watch for.

1. What you need to know about a notefile’s innards.

1.1 Notefile structure.

A notefile consists of two parts, the index and the data area. Each card in the notefile has an entry in the index. An index entry has 5 parts, a status field and 4 pointers. The status field specifies whether the index entry is free or occupied by an active or deleted card. There is one pointer in the index entry to each of the 4 parts of a card: substance, title, links and property list. These point into the data area. Whenever you change, say, the title of a card, the new title is written to the end of the data area and the index entry title pointer for that card is updated to point to the new location in the data area. Thus, in general, a notefile’s data area grows every time any part of any card is changed. To throw away the old versions of card parts, it is necessary to compact the notefile.

1.2 Card IDs.

Every card in the notefile has a unique ID, e.g. NC00023. The top level fileboxes; Contents, Orphans, and To Be Filed have IDs NC00001, NC00002, and NC00003, respectively. Note that these boxes cannot be deleted. The IDs from NC00004 through NC00020 are unused. Currently, an old ID is never reused, even if its card is deleted and the notefile is compacted. Thus, if the inspector shows no entry in the card inspector menu for some ID, it is because that card has been deleted. If you’ve asked to show deleted cards and it still doesn’t appear, it’s because the notefile has been compacted since that card was deleted.

1.3 Card parts.
Of the four parts of a card, the title and property list are simplest. The title is simply a string while the property list is a list of attribute value pairs. If you have not been attaching properties to your cards, then the inspector will only show those properties that the system maintains. Currently the only such property is "Updates" with value equal to a list of dates on which the card was updated going chronologically backwards from the front of the list to the back.

The substance of the card is simply its contents. Thus a text card’s substance is a text stream, a browser card’s is its graph, etc. These are stored on the file in a manner appropriate to the substance type. Thus a text substance on the notefile looks like the way TEdit writes out text streams (text followed by "looks" information).

1.4 Links on the notefile.

The links of a card are divided into three groups: to links, from links, and global links, where the global links form a subset of the to links. The to links of a card are those links pointing from this card to some other card. The from links are those links pointing from another card to this one. Finally, the global links are those to links that are global, that is, they point from this card as a whole to another card. (Global links are the ones that aren’t anchored in the source card’s substance. Source links are an example.)

The confusing thing about links out on the notefile is that they are stored in several places. All links are stored as to links with their source card and as from links with their destination card. Furthermore, links that are not global are also stored within the substance of their source card inside of a link icon. Links that are global are also stored on the global links list of their source card. Thus, all links are stored in three places: as a to link on the source card, as a from link on the destination card and either in the substance of the source card or on its global links list. If these three records of a link don’t agree for some reason, then we say that the notefile is inconsistent and needs its links rebuilt.

1.5 The links rebuilder.

The third phase of the inspector rebuilds the links of a notefile as follows: First it removes all the to and from links for every card. Then it reads the substances for each card and recreates to links and from links by looking at the links found inside the link icons in the substance.

The link rebuilder is also able to rebuild bad filebox substances. It does this by looking for all cards in the notefile with from links from the bad box and creating a new substance for the box containing only links to those cards. This process loses any text that the box might have contained as well as scrapping the original ordering of links. Nonetheless, in some cases this may be preferred to backing up the substance to a previous version or to deleting the box altogether.

The links rebuilder can rebuild the notefile’s list of link types in a similar manner. That is, it records the set of link types seen on valid links and replaces the old links types with the new set. Note that this throws away any link types for which there are no links in the notefile.

Finally, the links rebuilder can rebuild bad global links for a card. It does this by looking for any cards with from links from the bad card that are global. This assumes that the card at the destination end has good links. Thus, if the cards at both ends of a global link have unreadable links, then there is no way to recover that link.
The inspector provides the option of having the links rebuilder phase rebuild bad filebox substances, bad link types, and bad global links. See Section ?? below.

2. Running the Notefile inspector: Phase 1: Scouring the data area

To start the inspector, first be sure that there is no open notefile. Then select the item Inspect&Repair from the NoteFile Ops menu. There is one option available at this level by "pulling to the side" called ReadSubstances. This ensures that substances of all cards pronounced valid by the inspector are readable. If this option is not invoked, then a check is still run on the length of the substance, but not on its contents. Unfortunately, the ReadSubstances option requires MUCH more work by phase 1. I recommend that you only use this option if Phase 3 (link rebuilding) breaks with some error like "Bad Piece Tbl" from TEdit. In that case, up-arrow out of the break and start the Inspect&Repair process over again, this time using the slower but more comprehensive ReadSubstances option.

Selecting Inspect&Repair will invoke phase 1 of the inspector, wherein the data area of the notefile is scoured for valid card parts. A record of all such parts is kept and statistics printed out at the end. You'll be asked to position the window in which those statistics as well as later inspector communications will be printed. You can monitor the progress of phase 1 by watching the prompt window. It will be printing messages like "Processing byte xxxxx of yyyyy."

When phase 1 has completed and you've positioned the interaction window, statistics on your notefile will be provided. You'll be told the total number of card IDs used and the number of those that are currently associated with active and deleted cards. (The rest are free and will never be reused. See Section 1.2 above.) If all seems well with the world, the next line will read "All active cards look okay." If not, there will be various messages outlining the problems. (See Figure 1.)

```
Inspect&Repair Interaction Window

Fileboxes (NC00002 NC00003 NC00033 NC00154) have bad substance(s).
If you don't delete them or back up to a previous version, then phase 3 of Inspect&Repair will rebuild their contents.
Out of 240 card IDs:
    there are 176 active cards and 11 deleted cards.
    Of the active ones,
        1 have improper prop list data.
        3 have improper links data.
        4 have improper substance data.
```

Figure 1: Snapshot of a sample interaction window

Note that several fileboxes have bad substances and that a special message is printed on their behalf. This indicates that if you don’t wish to delete or back these up to a previous version, then phase 3 will rebuild them. (See Section 1.5 above.)
If there are cards having user-defined types whose type definition code has not been loaded, then you'll get a message to that effect, something like "<n> cards have unknown card types (FOO BAR)." At this point you should load the lisp files containing the definitions of the unknown card types. If not, then these cards will show up with bad substance in phase 2. If you have a card for which no substance versions could be read, then you’ll also get unknown card type messages for it (reading something like "<n> cards have unknown card types (NIL)"). This is because the inspector couldn’t find a card type on the notefile for that card.

A menu of options appears attached to the upper right corner of the interaction window. The particular options you get in that menu depend on the state of your notefile and are described below. The first two options appear in all cases. The other two may or may not be present in the menu you get. In any case, you should select one of the options before attempting any other NoteCards-related work.

ABORT: Choosing this option aborts the Inspect&Repair process entirely, throwing away any changes you might have made (such as card deletions or back ups.)

INSPECT CARDS: This brings up a menu of active card IDs with which you can inspect, delete, or back up particular cards. There is a "pull-across" menu item called INCLUDE DELETED CARDS, which if selected will include card IDs for deleted cards as well as active ones. Using this option, one can undelete deleted cards and restore some previous version.

END INSPECT&REPAIR: This option is only available if it seems that you don’t need to continue to the link rebuilding phase. You will not get this option if you’ve deleted any cards, or generally if there are problems with the notefile. Choosing this option causes the Inspect&Repair process to end gracefully (via a normal checkpoint and close notefile), thus skipping phase 3, rebuilding links.

CONTINUE INSPECT&REPAIR: This option is only available if the notefile is in fairly good health (i.e. okay except for fileboxes to rebuild or global links to rebuild - see Section 1.5 above). Selecting it causes Inspect&Repair to move to phase 3 and rebuild your notefile’s links.

3. Running the Notefile inspector: Phase 2: Your chance to tinker

After selecting INSPECT CARDS in the interaction window’s attached menu, a menu containing Notecards IDs will pop up and be attached to the interaction window’s lower left corner. It will contain IDs for all active cards and possibly deleted cards as well if you selected the submenu item INCLUDE DELETED CARDS described above. The menu can hold some 200 card IDs. If your notefile has more than that, then the menu will be composed of several pages each containing around 200 IDs. Rapid switching between pages is possible.

Attached to the upper right corner of the cards inspector menu is a menu containing at least the two options: ABORT and DONE. If the menu has multiple pages (there are more than 200 active cards in the notefile), then the attached menu will also include the items NEXT PAGE, PREVIOUS PAGE, and FIRST PAGE. Selecting these causes the current menu to be swapped with either the next menu, previous menu, or first menu, respectively.

Clicking ABORT causes the entire Inspect&Repair process to quit, throwing away any changes you’ve made. (This is equivalent to choosing ABORT from the inspector window as described in Section 2.)

Choosing DONE from this attached menu indicates that you’re done tinkering with card parts and wish to return to the main interaction window. Normally, this causes the card inspector
menu to close and the phase 1 process outlined in Section 2 to be performed again. Thus the
data area will be rescoured and new statistics on the health of your notefile will be printed. This
cycle of scour data area (phase 1) followed by inspect (phase 2) can be repeated as often as
desired. Eventually, you must either abort, end the Inspect&Repair process gracefully, or
continue to phase 3. Because phase 1 can be quite slow for large uncompacted notefiles, there is
one optimization: if you’ve made no changes in phase 2, then the data area scouring is not
repeated in phase 1. Rather, the old information from the last scouring is recovered and used
instead.

If you’ve clicked DONE, but there are still cards with bad prop lists, titles, or links (because you
haven’t either deleted them or backed up their card parts to previous versions), you will be asked
up to three questions. The list of card IDs of cards with bad prop lists is printed out and you’re
asked whether it’s okay to set the prop lists of those cards to NIL. Then, the list of card IDs of
cards with bad titles is printed out and you’re asked whether it’s okay to set the titles of those
cards to "Untitled." Finally, card IDs for cards with bad links are printed out and you’re asked
whether it’s okay to set the global links to nil. (Global links will be rebuilt as much as possible
in phase 3. See Sections 1.5 and 4.) If you want phase 3 to be able to run, it is necessary to
either answer yes to these questions or fix each of the bad card parts by hand in phase 2.

3.1 The card inspector menu

In the card inspector menu, those IDs corresponding to deleted cards have a line drawn through
them. Those having some sort of problem appear shaded. In addition, an upper-case letter suffix
is attached to such IDs indicating the problem. For example, a shaded menu item NC00023SL
indicates that ID NC00023 has bad substance and bad links. The letter codes are S, L, P, and T
indicating bad substance, links, property list, and title, respectively. If such a letter code appears
in lower case, then the indication is that the current version of that card part is beyond the last
checkpoint pointer. For example, NC00023t indicates that NC00023’s current title was changed
since the last checkpoint. (There may have been a crash, for example, thus preventing the
notefile from closing normally.)

In addition to menu entries for each card ID, there is also one entry labeled LNTYPES allowing
you to inspect (and possibly back up to a previous version) the Link Types for this notefile.

If you button an ID in the card inspector menu, then a popup menu allows up to two choices
Inspect and/or Delete. If the card is currently deleted (has a line drawn through it), then the
Delete option is replaced by Undelete. Certain card IDs cannot be deleted and thus their popup
menus only contain the Inspect option. These are the top level file boxes NC00001, NC00002,
NC00003. The link types menu entry LNTYPES also does not allow deletion.

Choosing Delete or Undelete from this popup menu causes the card to be deleted or undeleted,
respectively and the line through the menu item either drawn or undrawn. Note, however, that
this action (and all others) can be undone by choosing ABORT from either the card inspector
menu or the interaction window menu.

Choosing Inspect from the popup menu for a card ID entry brings up a card parts inspector for
that card.

3.2 The card parts inspector

Figure 2 below shows an example of a card parts inspector. It is composed of four attached
menus arranged vertically and one attached operations menu atop the stack.
Figure 2: A card parts inspector

The four menus contain entries for every valid version of card parts for the card with ID NC00027. The top menu is for version of titles and below that are menus for versions of the card’s substance, links, and prop list. For example, the Substance submenu contains entries for three versions of the substance of this card. The current version of each card part is shaded. Each menu entry gives the date that that version was written if available or the string "NO DATE AVAILABLE" if there is no date on the notefile. (The latter is the case for old notefiles prior to the time we began recording card parts write dates.)

If the current version of the card part is bad, then the menu entry will be a string so indicating, for example, "BADSUBSTANCE."

The title of the top menu includes the card’s type and ID. In addition, each menu item contains a bit of information, in square brackets, before the date. In the title versions menu, this information is the first few characters of the title. In the substance versions menu, it is the number of bytes in the substance. In the links versions menu, it is a triple of numbers giving the number of to links, from links, and global links for this card. Finally, the proplist versions menu includes the number of entries on the property list for this card (i.e. twice the number of attribute-value pairs).

Atop the stack of menus is an attached menu of operations, described below.

ABORT: This aborts this card parts inspector, throwing away any changes made.

UPDATE: This closes the card parts inspector, effecting any changes (backing up to previous versions of card parts) you might have done.

DELETE: This option closes the card parts inspector and deletes the card. (Again, this can be undone by choosing ABORT from the card inspector menu.)

UNDELETE: For cards that have been deleted, this option appears instead of DELETE. Choosing it causes the card to be undeleted.
RESET: This causes the selections in the submenus to be restored to the values they had when the card parts inspector was first brought up. (Equivalent to doing ABORT and then inspecting this ID again from the card inspector menu.)

Note that cards that can’t be deleted don’t have the DELETE option on their card parts inspector.

Buttoning an entry in a submenu of a card parts inspector pops up a short menu unless the entry is for a bad version (e.g. "BADSUBSTANCE"). This menu contains at least the entry Inspect and possibly Change Selection, if the selected entry is not the same as the current one (i.e. not shaded).

Choosing Inspect allows further inspection of the details of the selected card part version. For example, inspecting a title version brings up the Interlisp inspector on a record containing the title, date and card ID. Similarly, inspecting a links or prop list version brings up the Interlisp inspector on a record containing the lists of links (for to links, from links and global links) or the prop list. Note that if you wish to continue inspecting a links version down to the single link level, choose to inspect the link as a NOTECARDLINK. This is somewhat more communicative about record field names. Note also that changing values out in the Interlisp inspectors has no affect on the notefile and is ignored.

All substance versions for cards having substance types TEXT, SKETCH and GRAPH can currently be inspected. (This includes all cards except those having user-defined substance types, like the NCFile card.) Inspecting a card’s substance version will bring up a window showing a copy of the substance. (Note that changes to this copy have no affect on the notefile.) Any links in the substance of the card will show up as bracketed strings describing the link.

Choosing Change Selection from the card part version popup menu causes the current selection to be changed, thus backing up the card to the selected version. (This change can be undone by resetting or aborting the card parts inspector as well as by later aborting the card inspector or interaction window.)

4. Running the Notefile inspector: Phase 3: Rebuilding your links

To complete the Inspect&Repair process, select the Continue Inspect&Repair option from the interaction window menu. This invokes phase 3, the links rebuilder. Normally, this simply rebuilds links from card substances (see Section 1.5). In certain circumstances, it may do extra work as well. If your link types list is bad, and you didn’t back it up to a previous version, then phase 3 will rebuild it. If there are fileboxes with bad substances that you haven’t either deleted or backed up to previous versions, then phase 3 will rebuild them. Finally, if there are cards with bad links that you haven’t backed up or deleted, then phase 3 will rebuild those links as well. (It rebuilds ALL to links and from links anyway. For those cards, it will rebuild global links as well.) Again, for details, see Section 1.5.

5. Tips and hints for using Inspect&Repair

This section contains a list of strategies and tips for using Inspect&Repair. For the most part, they are ordered from the useful and obvious to the esoteric. Several of these are implicit in the first four sections of the document, but are repeated here for emphasis and completeness.

When in doubt, abort! All your changes will be lost, but then if you’re uncertain about what’s happened this is the safe course. Often, in fact, you may simply want to check the health of your notefile and abort without tinkering.
Fixing versus tinkering. There are two main ways to use the inspector, either for fixing a broken notefile, or tinkering with a healthy one. The latter case occurs when you wish to recover some card that you inadvertently deleted. Or back up a card that you inadvertently changed to a previous version.

Compacting. Old versions of card parts have always been stored in notefiles, but up till now have been inaccessible. Thus, there was little reason not to compact your notefile often. Now there is a tradeoff between the need to save space by compacting versus the need to be able to back up using Inspect&Repair. Probably the safest course is to keep a backed up copy of the pre-compact ed notefile around until you have confidence that the compacted one is healthy and that you have no need for previous versions of any of its cards.

Inspect&Repair can’t run when notefile is open. This means that if you are working in your notefile and notice a card you’d like to inspect a previous version of, you must record the card’s ID and close the notefile. Then, run Inspect&Repair, find the card ID in the inspector menu and tinker with it as desired.

Fixing enough problems to allow phase 3 to run. You can’t run phase 3 unless Inspect&Repair thinks your notefile is above a certain threshold of health. There are certain problems it can handle (e.g. bad filebox substances, see Sections 1.5 and 4), and others that it can’t (e.g. bad title). You have to decide either to fix these sorts of problems yourself in phase 2, let phase 3 attempt to rebuild them, or just abort the whole thing (always an option).

Sometimes these decisions can be tricky. For example, suppose a filebox’s substance is bad. Call it BadBox. Should you (a) delete BadBox altogether, (b) back its substance up to a previous version, or (c) allow phase 3 to rebuild it by looking for from links in other cards from BadBox? Option (c) may not be advisable if there was important text in BadBox or if the order of cards in BadBox was important. On the other hand, option (b) may be of little use if the last good version is too out of date (or if there is no good version at all).
Introduction

This document describes a facility whereby users with some programming know-how can obtain a lisp interface to NoteCards. In this way, they can create and modify Notefiles, cards and links under program control.

The functions described below are divided into 7 groups:

1. NoteFile Creation and Access
2. Creating and Accessing NoteCard Types
3. Creating NoteCards and FileBoxes
4. Accessing NoteCards and FileBoxes
5. Creating and Accessing Links
6. Creating and Accessing Link Labels
7. Handy Miscellaneous Functions

1. NoteFile Creation and Access

For each of the following functions (except NCP.CloseNoteFile), the argument is a filename. The suffix ".NoteFile" is added if not already present. In any case, the filename used by NoteCards always has this suffix.
(NCP.CreateNoteFile <filename>)

If <filename> is not already a notefile, then create a notefile <filename>.NoteFile, and return this filename which can later be passed to NCP.OpenNoteFile.

(NCP.OpenNoteFile <filename> <don’tCreateFlg> <convertw/oConfirmFlg>)

If there is no currently open notefile, then open <filename> and make it the currently active NoteFile. Returns resultant stream if successful, else nil. If <don’tCreateFlg> is non-nil, then a new file will not be created if the given one doesn’t exist. If <convertw/oConfirmFlg> is non-nil, then if needed, the file will be converted to release 1.1 format without user confirmation.

(NCP.CloseNoteFile [<stream>])

Closes <stream> if it is corresponds to a currently open Notefile. Returns its filename if successful. If <stream> is nil, then closes current open notefile.

(NCP.CheckpointSession)

Checkpoint the current Notecards session, first writing out any dirty cards. In case of a system crash or abort, the notefile can be recovered to the last checkpoint. Note that closing a notefile does a checkpoint.

(NCP.AbortSession)

Abort the current Notecards session, losing all work since last checkpoint or successful close.

(NCP.RepairNoteFile <filename>)

Rebuilds the link structure of <filename>. It must *not* be currently open.

(NCP.CompactNoteFile <filename>)

Copies <filename> to a later version, recovering space. Must not be open.

(NCP.CompactNoteFileInPlace <filename>)

Compacts <filename> in place, replacing the old version. Must not be open.

(NCP.DeleteNoteFile <filename>)

Removes the <filename> notefile. Must not be open.

(NCP.CurrentNoteFileStream)
Returns the currently open notefile stream if there is one, else nil.

(NCP.CurrentNoteFile)

Returns the full name of the currently active notefile if there is one, else nil.

(NCP.CheckOutNoteFile <fromFilename> <toFilename>)

Copies <fromFilename> to <toFilename> unless <fromFilename> is locked. If successful, creates a lock file in <fromFilename>’s directory. The name of the lock file is formed by concatenating the atom LOCKFILE onto <fromFilename>.

(NCP.CheckInNoteFile <fromFilename> <toFilename>)

Check lock file for <toFilename>. If none, then just copy <fromFilename> to <toFilename>. If there is one and it’s owned by us, then do the copy and remove the lock file. If there is a lock file owned by someone else or if date of <toFilename> is more recent than date of lock file, then print a message and do nothing.

2. Creating and Accessing NoteCard Types

These functions give the user access to the NoteCard user-defined types facility. For an explanation of this facility, see the NoteCards Types Mechanism documentation.

(NCP.CardTypes)

(NCP.SubstanceTypes)

Returns lists of all currently defined NoteCard types and substances, respectively.

(NCP.CreateCardType <TypeName> <SuperType> <SubstanceType> <FnsAssocList> <VarsAssocList>)

Makes a new NoteCard type with name <TypeName>, super type <SuperType>, substance <SubstanceType>. Any functions not appearing in <FnsAssocList> will be inherited from <SuperType>. The CardWidth and CardHeight vars fields will be inherited if not specified in <VarsAssocList>. Other vars fields default to nil. Note that, for now, specializing the FileBox card type is not allowed.
(NCP.CreateSubstanceType <SubstanceName> <FnsAssocList> <VarsAssocList>)

Makes a new substance type with name <SubstanceName> and the given functions and vars fields. None of the function fields should be nil (but might conceivably be the function NILL).

(NCP.CardTypeSuper <type>)

Returns the super type of <type>.

(NCP.CardTypeSubstance <type>)

Returns <type>’s substance type.

(NCP.CardTypeLinkDisplayMode <type>)

Returns the link display mode of <type>.

(NCP.CardTypeFn <type> <fn>) (NCP.CardTypeVar <type> <var>)

Returns the <fn> (<var>) field for <type>.

(NCP.CardTypeInheritedField <type> <field>)

Returns the value of the card type function or variable <field> for <type>. This is possibly different from the value returned by NCP.CardTypeFn or NCP.CardTypeVar in that if the defined value for <field> of <type> is nil, then the super is checked for a non-nil value. This checking continues until either a non-nil <field> is found or we reach the top of the super hierarchy. In that case, the value of <type>’s substance’s <field> is used. Note that among the variable fields, only CardDefaultWidth and CardDefaultHeight inherit, so for the other Var fields, the result of NCP.CardTypeVar is valid (even if it’s nil).

(NCP.SubstanceTypeFn <substance> <fn>) (NCP.SubstanceTypeVar <substance> <var>)

Returns the <fn> (<var>) field for the substance <substance>.

(NCP.ValidCardType <type>)

Returns non-nil if <type> is an existing NoteCard type.

(NCP.ValidSubstanceType <substance>)
Returns non-nil if <type> is an existing NoteCard substance type.

(NCP.ValidCardTypeFn <fn>)
(NCP.ValidCardTypeVar <var>)

  Returns non-nil if <fn> (<var>) is a valid function (variable) field for NoteCard types, for example, the litatom MakeCardFn (CardDefaultWidth). In other words, <fn> (<var>) can serve as the <fn> (<var>) arg to NCP.CardTypeFn (NCP.CardTypeVar).

(NCP.ValidSubstanceTypeFn <fn>)
(NCP.ValidSubstanceTypeVar <var>)

  These return non-nil if <fn> (<var>) is a valid function (variable) field for substance types. In other words, <fn> (<var>) can serve as the <fn> (<var>) arg to NCP.SubstanceTypeFn (NCP.SubstanceTypeVar).

(NCP.CardTypeFns)
(NCP.CardTypeVars)
(NCP.SubstanceTypeFns)
(NCP.SubstanceTypeVars)

  These return lists of all valid Fn (Var) fields for NoteCard types and substances respectively.

3. Creating NoteCards and FileBoxes

The following functions create various sorts of cards and boxes within the currently open note file.

(NCP.CreateTextCard <title> <nodisplayflg> <props> <parentfileboxes>)

  Creates and returns a new notecard having type Text. If <title> is non-nil, it is installed as the Notecard’s title, otherwise the title is "Untitled." <props>, if non-nil, should be a prop-list of properties and values to be placed on the user property list of the Notecard. If <parentfileboxes> is non-nil, then it should be a list of FileBoxes in which to initially file this card.
(NCP.CreateFileBox <title> <nodisplayflg> <props> <childcardsboxes> <parentfileboxes>)

Creates and returns a new Filebox with title <title> (or a gensym’ed name if <title> is nil). It will initially contain child cards and boxes from the list <childcardsboxes> (if that arg is non-nil). If <parentfileboxes> is nil, then the new filebox will be filed in the value of (NCP.GetToBeFiledFileBox). The <props> arg is handled as it was for NCP.CreateNoteCard.

(NCP.CreateBrowserCard <title> <paramList> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns a new browser card with given title, props and parents. <paramList> should be a prop list of browser parameters. The properties currently recognized are:

**ROOTCARDS:** A list of Notecards to serve as roots of the forest or lattice generated by the browser. If omitted or NIL then user is asked to choose root cards.

**LINKTYPES:** A list of link types to follow when creating the browser. Any label present in the list having the backarrow prefix ("_") represents that link type but in the reverse direction. This list can also contain the atoms ALL or _ALL in which case browsing will be done on all links in either the forward or reverse direction. If both ALL and _ALL are specified, then links in both directions will be used (generally making a mess).

**DEPTH:** The depth at which to cut off the browser. This should be a non-negative integer. If NIL or omitted, then will assume no limit. (Currently integers greater than 9 are assumed equivalent to infinity.)

**FORMAT:** This should be a list of one, two or three elements. The first should be an atom indicating grapher format. The choices are FAST (laid out as a forest, sacrificing screen space for speed), COMPACT (laid out as a forest, using minimal screen space), LATTICE (laid out as a directed acyclic graph, the default), *GRAPH* (laid out as a graph, i.e. virtual nodes are eliminated). The second element of the FORMAT list, if present, should be either HORIZONTAL (the default) or VERTICAL specifying whether the graph is laid on its side or up and down. The third element, if present, should be the atom REVERSE. This indicates that horizontal graphs should be laid out from right to left instead of left to right and that vertical graphs should be laid out from bottom to top rather than vice versa.

(NCP.CreateSketchCard <title> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns an initially empty sketch/map card having given title, props, and parents.

(NCP.CreateGraphCard <title> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns an initially empty graph card having given title, props, and parents.
(NCP.CreateCard <type> <title> <nodisplayflg> <props> <parentfileboxes> <otherargs>)

Creates and returns a card of the given (possibly user-defined) type, with given title, props, and parents. <otherargs> is a possibly nil list of args that will be passed to the MakeCardFn of <type>. Card is initially displayed or not according to value of <nodisplayflg>.

(NCP.MakeDocument <rootcard> <parametersProplist> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns a Document card starting from <rootcard>. The default set of parameters for making documents can be accessed via NCP.DocumentParameters, but some of these can be given new values just for the duration of this MakeDocument by specifying a non-nil <parametersProplist>. For example, a value of '(TitlesFromNoteCards Bold ExpandEmbeddedLinks ALL) for <parametersProplist> would cause temporary changes to the values of the parameters TitlesFromNoteCards and ExpandEmbeddedLinks. As usual, the resulting card will have the given props and parents.

(NCP.MakeLinkIndex <linktypes> <backpointersP> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns a LinkIndex text card consisting of a sorted record of all instances of links in the current notefile having one of the given link types. <linktypes> can contain the litatoms ALL and/or _ALL as well as any particular backwards links. (See the above description of NCP.MakeDocument.) Backpointer links are inserted in the text if <backpointersP> is non-nil. Resulting card will have given props and parents.

4. Accessing NoteCards and FileBoxes

The following functions provide access to the cards and boxes present in the current notefile. Note that whether a card’s window has been brought up on the screen has little or no effect on the following functions. If the user changes some field of a card while that card is visible on the screen, then the field will update itself automatically. Thus, users can switch between program-driven and screen-interface-driven modes at will.

Cards can be active or inactive. An active card has its information cached (on its property list) thus saving time at the expense of memory. All cards visible on the screen are active. Most of the following functions leave the card in the same state as it was when they started (except NCP.BringUpCard, which makes it active). Thus, users needing to do several consecutive operations to the same card should consider temporarily caching the card’s information via NCP.ActivateCards (and then uncache with NCP.DeactivateCards).
Most of the following functions take as first argument a card or filebox. If this does not in fact correspond to an existing card or box, then an error message is printed and nil is returned.

(NCP.BringUpCard <card> <region/position>)

Brings up on the screen the given card in the given region or at the given position. If <region/position> is nil, then user is asked to specify position with mouse.

(NCP.ActiveCardP <card>)

Returns non-nil if given card or box is currently active (i.e. information is currently cached in memory).

(NCP.ActivateCards <cardList>)

For each card or box in <cardList> (or just the one, if the argument is atomic), make it active (i.e. cache its information in memory).

(NCP.DeactivateCards <cardList>)

For each card or box in <cardList> (or just the one, if the argument is atomic), make it inactive (i.e. uncache its information back into the file). If any cards in <cardList> were on the screen then this will close their windows.

(NCP.CardType <card>)

Returns the type of <card> or NIL if the card does not exist.

(NCP.ValidCard <card>)

Returns non-nil if <card> exists (hasn’t been deleted). (This is currently a synonym for NCP.CardType.)

(NCP.CardTitle <card> [<newtitle>])

Returns old title of <card>. If <newtitle> is present, then set <card>’s title to <newtitle>. <newtitle> can be an atom or string. Note, however, that all titles are converted internally to strings by NoteCards.

(NCP.FileCards <cards> <fileboxes>)

Every card or box in <cards> is filed in every box in <fileboxes>. Either arg may be an atom or a list.
(NCP.UnfileCards <cards> <fileboxes>)

Every card or box in <cards> is unfiled from every box in <fileboxes>. Furthermore if <cards> is
the litatom ALL, then the boxes in <fileboxes> will be cleared of all children. Similarly, if
<fileboxes> is the litatom ALL, then the cards and boxes in <cards> will be unfiled from all their
parent boxes. Either arg may be an atom or a list.

(NCP.CardParents <card>)

Returns list of fileboxes in which <card> has been filed.

(NCP.FileBoxChildren <filebox>)

Returns list of children of <filebox> in the order in which they appear in the box’s textstream.

(NCP.GetLinks <cards> <destinationCards> <labels>)

Returns list of all links from any of <cards> to any of <destinationCards> having any label in
<labels>. Any of these arguments can be nil. For example, if <destinationCards> is nil, then all
links pointing from <cards> to anywhere with a label in <labels> are returned. If both <cards>
and <destinationCards> are nil, then this returns all links having a label in <labels>. If all three
args are nil, then this is a slow synonym for NCP.AllLinks.

(NCP.CardPropList <card>)

Returns the prop list of the given card.

(NCP.CardProp <card> <propname> [<newvalue>])

Returns old value of property <propname> on <card>’s prop list. If <newvalue> is present, then
set <card>’s <propname> property to <newvalue>. (Semantics are analogous to the Interlisp
function WINDOWPROP.)

(NCP.CardAddProp <card> <propname> <newitem>)

Adds <newitem> to the list present on the <propname> property of <card>. Returns old value of
property. (Semantics are analogous to WINDOWADDPROP.)

(NCP.CardDelProp <card> <propname> <itemToDelete>)

Deletes <itemToDelete> from the <propname> property of <card> if it is there, returning the
previous value of that property. If not there, return nil. (Semantics are analogous to
WINDOWDELPROP.)

(NCP.CardSubstance <card>)
Returns the substance of <card>. This is a textstream in the case that the type of <card> has TEXT substance. Otherwise, it is the appropriate underlying structure if <card> has GRAPH or SKETCH substance.

(NCP.CardRegion <card>)

Returns the region of <card>. This works even if <card> is not currently up on the screen, since the region information is stored on the notefile.

(NCP.CardAddText <card> <textstr> <loc>)

Adds the text within the string <textstr> to the text card <card>. If <loc> is the litatom START or END, then the text will be placed at the start or end of the card respectively. If <loc> is a number, then it is assumed to be a character count within the card at which to place the new text. If <loc> is NIL, then the text is placed at the current cursor location.

(NCP.ChangeLoc <card> <loc>)

Changes the cursor’s location in <card>’s textstream to <loc>. Possible values for <loc> are as described for NCP.CardAddText.

(NCP.DeleteCards <cards>)

Deletes the given cards and fileboxes from the current notefile, or deletes just the one if <cards> is atomic.

(NCP.FileBoxP <card>)

Returns non-nil if <card> is a filebox.

(NCP.AllCards)

Returns a list of all extant cards for the current notefile.

(NCP.AllBoxes)

Returns a list of all fileboxes in the current notefile.

(NCP.MapCards <fn>)

Maps down the set of all cards in the current notefile, applying <fn> to each.

(NCP.MapBoxes <fn>)

Maps down the set of all fileboxes in the current notefile, applying <fn> to each.
These functions retrieve the three predefined FileBoxes for the currently open NoteFile. These boxes can be modified (but not deleted) by the user in the same way as any other filebox.

5. Creating and Accessing Links

Links can be connected to points within a card or to the card as a whole, thus the following four link creation functions are provided. Those that connect to points within a card specify at least one of <fromloc> or <toloc>. If nil, then the link icon is placed at the current cursor location in the card. If the arg is the litatom START or END, then it is placed at the front or end of the text respectively. If the loc arg is a number, then it is assumed to be a character count at which to place the link icon.

(NCP.GlobalGlobalLink <label> <sourceCard> <destinationCard>)

Creates and returns a new link with label <label>, connecting <sourceCard> to <destinationCard>.

(NCP.LocalGlobalLink <label> <sourceCard> <destinationCard> <fromloc> <displaymode>)

Creates and returns a new link with label <label>, connecting from <fromloc> of <sourceCard> card to <destinationCard>. If <displaymode> is non-nil, then the new link is displayed in the given mode. Otherwise the default displaymode for the source card’s type is used.

(NCP.GlobalLocalLink <label> <sourceCard> <destinationCard> <toloc>)

Not implemented at this time.

(NCP.LocalLocalLink <label> <sourceCard> <destinationCard> <fromloc> <toloc>)

Not implemented at this time.

(NCP.LinkDesc <link>)
Returns list of three items (\texttt{<label>} \texttt{<sourceDesc>} \texttt{<destinationDesc>}) where \texttt{<label>} is the link type and \texttt{<sourceDesc>} and \texttt{<destinationDesc>} have the form (\texttt{<anchor mode>} \texttt{<card>} \texttt{<loc>}). \texttt{<anchor mode>} is either \texttt{LOCAL} or \texttt{GLOBAL}, \texttt{<card>} is the card at this end of the link, and \texttt{<loc>} gives a position in the text of \texttt{<card>} if \texttt{<anchor type>} is \texttt{LOCAL} and \texttt{<card>}'s substance's type is \texttt{TEXT}.

\texttt{(NCP.LinkDisplayMode \texttt{<link>} \texttt{[<newdisplaymode>])}}

Returns old display mode of \texttt{<link>}. If \texttt{<newdisplaymode>} is present, then set \texttt{<link>}'s displaymode accordingly. If non-nil, it can be one of the litatoms \texttt{Icon}, \texttt{Title}, \texttt{Label}, or \texttt{Both}. Or it can be an instance of the \texttt{LINKDISPLAYMODE} record. This has the 3 fields \texttt{SHOWTITLEFLG}, \texttt{SHOWLINKTYPEFLG}, and \texttt{ATTACHBITMAPFLG}. Each field can have one of the three values \texttt{T}, \texttt{NIL}, or \texttt{FLOAT}. If a field, say \texttt{SHOWTITLEFLG}, has value \texttt{FLOAT} then the corresponding global parameter (\texttt{DefaultLinkIconShowTitle}, in this case) will be consulted to decide whether or not to display the destination card’s title in this icon. (See Section 7 for a description of the global parameters.)

\texttt{(NCP.LinkLabel \texttt{<link>} \texttt{[<newlabel>])}}

Returns old label of \texttt{<link>}. If \texttt{<newlabel>} is present, set \texttt{<link>}'s label to \texttt{<newlabel>}.

\texttt{(NCP.GetLinkSource \texttt{<link>})}

Returns the card at the source end of \texttt{<link>}.

\texttt{(NCP.GetLinkDestination \texttt{<link>})}

Returns the card at the destination end of \texttt{<link>}.

\texttt{(NCP.DeleteLinks \texttt{<links>})}

Removes all links in \texttt{<links>} (or the single one if \texttt{<links>} is atomic).

\texttt{(NCP.ValidLink \texttt{<link>})}

Returns non-nil if \texttt{<link>} is a link in the current notefile.

\texttt{(NCP.AllLinks)}

Returns a list of all existing links in the current notefile. (This is equivalent to but faster than \texttt{(NCP.GetLinks NIL NIL NIL)}.)

\texttt{(NCP.MapLinks \texttt{<fn>})}

Maps down the set of all links in the current notefile, applying \texttt{<fn>} to each one.
6. Creating and Accessing Link Labels

The following functions allow the user to manipulate link labels.

(NCP.CreateLinkLabel <label>)

Creates a new link label with name <label> for current notefile unless there is already one defined by that name.

(NCP.DeleteLinkLabel <label>)

Deletes the link label <label> from the current notefile. The label must exist and must not be the label of any existing link, and it must not be a system-defined link label (e.g. SubBox or FiledCard).

(NCP.RenameLinkLabel <label> <newlabel>)

Changes any links having label <label> to have label <newlabel>. <label> must exist and neither <label> nor <newlabel> should be a system-defined label.

(NCP.GetLinkLabels)

Returns a list of all existing link labels including system-defined ones.

(NCP.GetReverseLinkLabels)

Returns a list of the reverse labels for every existing link label. Thus, whereas SubBox would appear in the list returned by NCP.GetLinkLabels, _SubBox would appear in the list returned by NCP.GetReverseLinkLabels.

(NCP.GetUserLinkLabels)

Returns a list of all existing user-defined link labels.

(NCP.ValidLinkLabel <label>)

Returns non-nil if <label> is a defined link label for current notefile.

7. Handy Miscellaneous Functions
(NCP.TitleSearch <key> <key> ... )

Returns a list of all cards having all of the <key>s (can be atoms, numbers or strings) within their titles.

(NCP.PropSearch <propOrPair> <propOrPair> ...)

Returns a list of all cards such that for every <propOrPair> arg, if it is atomic, then the card must contain that property. If it is a list of two elements, then the card must have a property EQ to the first element with value EQ to the second element.

(NCP.WhichCard <x> <y>)

Returns the card currently displayed on the screen whose window contains the position in screen coordinates of <x> if <x> is a POSITION, the position (<x>,<y>) if <x> and <y> are numbers, or the position of the cursor if <x> is NIL. Returns NIL if the coordinates are not in the window of any card. If they are in the window of more than one card, then returns the uppermost. If <x> is a window, then NCP.WhichCard will return the card associated with that window.

(NCP.CardFromWindow <window>)

Returns the card associated with <window>, or NIL if not a notecards window.

(NCP.CardWindow <card>)

Returns <card>’s window if <card> is currently displayed somewhere on the screen.

(NCP.SelectCards)

Returns a list of those cards selected from the screen. A menu appears near the top of the screen with buttons for "DONE" and "CANCEL". Selections are made by left buttoning in the title bars of the desired cards.

(NCP.DocumentParameters <parametersProplist>)

Returns the old value of the document parameters in the form of a proplist. If <parametersProplist> is non-nil then it should be a proplist whose properties are (some of the) valid document parameter names and whose values are permissible values for those parameters. The valid parameters and possible values are as follows:

HeadingsFromFileboxes: NumberedBold, UnnumberedBold, NONE.

TitlesFromNoteCards: Bold, NotBold, NONE.
**BuildBackpointers**: ToCardsBoxes, ToCards, ToBoxes, NONE.

**CopyEmbeddedLinks**: ALL, NONE, <listOfLinkLabels>.

**ExpandEmbeddedLinks**: ALL, NONE, <listOfLinkLabels>.

[See the Notecards user's manual for an explanation of these parameters and how their values affect the document created.]

**NCP.NoteCardsParameters <parametersProplist>**

Returns the old value of the global Notecards parameters in the form of a proplist. If <parametersProplist> is non-nil then it should be a proplist whose properties are (some of the) valid document parameter names and whose values are permissible values for those parameters. The valid parameters and possible values are as follows:

- **DefaultCardType**: <legalCardType>
- **FixedTopLevelMenu**: T or NIL
- **ShortWindowMenus**: T or NIL
- **ForceSources**: T or NIL
- **ForceFiling**: T or NIL
- **ForceTitles**: T or NIL
- **CloseCardsOffScreen**: T or NIL
- **MarkersInFileBoxes**: T or NIL
- **AlphabetizedFileBoxChildren**: T or NIL
- **DefaultLinkIconAttachBitmap**: T or NIL
- **DefaultLinkIconShowTitle**: T or NIL
- **DefaultLinkIconShowLinkType**: T or NIL
- **LinkDashingInBrowsers**: T or NIL
- **ArrowHeadsInBrowsers**: one of the litatoms {AtEndpoint, AtMidpoint, None}
- **SpecialBrowserSpecs**: T or NIL
- **AnnoAccessible**: T or NIL
EnableBravoToTEditConversion: T or NIL

DefaultFont: a font

LinkIconFont: a font

Here, <legalCardType> should be an existing Notecard type, i.e. one that appears in the list returned by NCP.CardTypes.

(NCP.PrintMsg <window> <clearFirstFlg> <arg1> <arg2> ...)

Prints a message in the prompt window of <window>. If <window> is NIL, then prints message in the Lisp prompt window. If <clearFirstFlg> is non-nil, then clears the prompt window first. The args are PRIN1'ed one at a time.

(NCP.ClearMsg <window> <closePromptWinFlg>)

Clears the prompt window associated with <window> (or with the main Lisp prompt window if <window> is NIL) and closes it if <closePromptWinFlg> is non-nil.

(NCP.AskUser <Msg> <prompt> <FirstTry> <ClearFirstFlg> <MainWindow> <DontCloseAtEndFlg> <DontClearAtEndFlg> <PROMPTFORWORDFlg>)

This function can be used to ask questions of the user in a window's prompt window. The <Msg> and <prompt> are printed along with <FirstTry> (if non-nil). The value returned is whatever the user types. If <ClearFirstFlg> is non-nil, then the prompt window is cleared first. If <MainWindow> is nil, then the top level prompt window is used. If <DontCloseAtEndFlg> is non-nil, then the prompt window won't be closed after the question is answered and if <DontClearAtEndFlg> is non-nil, then the prompt window won't be cleared at the end. If <PROMPTFORWORDFlg> is non-nil, then the PROMPTFORWORD typein protocol will be used rather than TTYIN. The former doesn't allow mouse editing of the string typed in. On the other hand, typing automatically overwrites the prompt when PROMPTFORWORD is used.

(NCP.AddTitleBarMenuItems <Win> <NewMenuItems>)

Adds the given menu items to the left button title bar menu of <Win>. <Win> should be the window of a visible notecard.

(NCP.GetDates <Card>)

Returns a NOTECARDDATES record structure containing the dates of last modification of each of the four card parts of <Card>. The fields of the record are SUBSTANCEDATE, TITLEDATE, LINKSDATE and PROPLISTDATE.
Notice of release of Notecards 1.2i

The 1.2i Intermezzo release of Notecards is hereby officially released.

To run NoteCards, load onto an Intermezzo sysout the file
{qv}<notecards>release1.2i>notecards.dcom. As usual, send bug reports by choosing
"NoteCards Report" from the Lafite middle button send mail menu. Mail of more general
interest to the NoteCards community should be sent to NoteCards^pa.

Even if you have been using 1.2i for some time and feel comfortable with Notecards, please take
a look at the release notes in {qv}<notecards>release1.2i>doc>ReleaseNotes.ted.

The release notes describe in detail the changes since 1.1. These include incorporation of the
latest version of sketch, new functionality in the browser, a new notefile inspect and repair
facility, several new library packages, and many other feature additions and bug fixes.

Also on {qv}<notecards>release1.2i>doc> you can find updated documentation on the
programmer’s interface, ProgIntFace.ted, and a new document describing the inspect and repair
facility, NoteFileInspector.ted.

The library packages and accompanying documentation can be found in
{qv}<notecards>release1.2i>library>.

Enjoy!

- Randy
NoteCards Release1.2i Announcement

Xerox Corporation

Randy Trigg
Frank Halasz

This document updates the NoteCards Release1.1 User’s Manual, describing changes and new features for Release1.2i. As usual, send bug reports to NoteCardsSupport.pa (or use the Lafite SendMail middle button menu) and matters of more global interest to Notecards^pa.

You must be in Intermezzo to run NoteCards Release1.2i. From now on, you can depend on the letter suffix following the release number to indicate the appropriate version of Interlisp.

Changes from 1.1 are mostly in the following areas: the NoteCards browser, notefiles interface, link icon display and user interface. In addition, there are various miscellaneous changes, a couple of new card types, and fixes of several outstanding 1.1 bugs.

1. Operating on a Notefile.

Checkpointing and aborting a session:

A fundamental change was made to the way Notecards updates its working notefile that allows 1.2i users to checkpoint their work, abort a session (losing work since the last checkpoint), and recover more gracefully from crashes. First, a word about the way Notecards notefiles are structured.

A notefile consists of two parts, an index area and a data area. The index includes for each notecard, several pointers into the data area. There are separate pointers for the notecard’s substance, title, prop list, and links. When, say, a notecard’s title is changed, the new title is written at the end of the data area (in fact the end of the file) and the index pointer is changed. In Release1.1 (and earlier), the index modifications happened out on the file as they occurred. Now, in Release1.2i they happen in an in-core array and are not written to the file till checkpoint (or close) time. In addition, there is a checkpoint pointer that points to the end of file at the time of the last checkpoint or close. New data (such as a new title) is still written to the file, but always at the end of the file. Thus if a crash occurs and later the notefile is reopened, Notecards can notice the extra data beyond the checkpoint pointer and truncate the file at that point (if you confirm).

More concretely, there are now two new NoteFile Ops menu entries: "Checkpoint Session" and "Abort Session." Checkpointing causes any active cards to have their contents saved to the notefile (but not closed), the index array to be written back out to the file, and the checkpoint pointer to be reset to the end of the file. (Note that closing a notefile automatically does a CheckpointSession.) Aborting a session causes Notecards to close down, discarding all work since the last checkpoint or close.

When a notefile is opened, the checkpoint pointer is compared with the end of file pointer. If they don’t agree, then you’re asked whether the file should be truncated. You’re also given the
option of saving the extra work since the last checkpoint to a file. If valuable cards were created (or modifications made) since the last checkpoint, then you should answer yes and provide the name of a file in which to store the truncated information.

Next, you should open the truncated notefile and bring up a separate TEdit window on the file containing the truncated information. Though TEdit formatting information is lost, you can recover a card’s text by browsing this file. (Note that scrolling from back to front will retrieve the most recent version of each card.)

[Note that closing (or saving without closing) a card writes it out to the file, but does not force the index to be updated. Thus, if crashes are anticipated, do CheckpointSession often.]

Compacting a Notefile:

Because Notecards never actually overwrites any information in the data area of a notefile, it is necessary to periodically compact the notefile. This facility has been improved in Release1.2i in two ways. It is now possible to specify a target file name for the compaction (rather than always going to the same name), and it is now possible to compact a notefile in place. These two choices form a submenu of the CompactNotefile entry in the Notefile Ops menu.

Copying, restoring, and backing up notefiles:

The menu entries for RestoreFromFloppy and BackupToFloppy have been removed from the NotefileOps menu. In their place is a general CopyNotefile option. It prompts you for source and target file names for the copy.

There is a new facility for checking in and out notefiles using locks for multiple users sharing a notefile. Still in the experimental stages, it must be called via the programmer’s interface. See the programmer’s interface documentation.

Inspecting and healing broken notefiles:

The old Repair option on the Notefile Ops menu is now called Inspect&Repair and has been improved considerably. Before rebuilding the links of your notefile, it reads the entire data area looking for good card parts (including outdated and deleted versions). It then allows you to delete and/or back up card parts to previous versions. All this is done interactively through a menu driven interface. Only when the notefile is deemed healthy are you allowed to perform the link rebuilding. For details on the operation of Inspect&Repair, see the document titled NotefileInspector.ted.

2. Changes to the Notecards user interface.

Stylesheets:

Several places in Notecards now use Tayloe Stansbury’s stylesheet package for user interaction, in particular, changing a link’s display mode, a browser’s specs, or the default text and link icon fonts from the global parameters menu. Stylesheets allow packaging of several menus together with "buttons" governing individual menus and the stylesheet as a whole. Menus within a stylesheet can optionally allow multiple selections. All stylesheets have three global buttons "Done," "Reset," and "Abort." "Done" causes the new values to be accepted. "Reset" causes the original values (when the stylesheet was entered) to be recovered. "Abort" causes the stylesheet to be exited without changing any values. Menus allowing multiple selections also have the
buttons "All" and "Clear" attached. "All" causes all values in the menu to be selected while "Clear" unselects the entire menu. Toggling of menu entries is accomplished by left clicking the entry.

New global parameters:

The top level global parameters menu has several new additions. These (as well as some old 1.1 ones) are described below. To change the value of a global parameter, click on the variable name. The value will toggle between "Yes" and "No" if binary, and allow selection from an appropriate menu otherwise.

ForceSources, ForceFiling, ForceTitles: These dictate whether to bother you at card closing time about incomplete information for the card. If ForceFiling is set, for example, then you are asked to designate parent fileboxes of the card before closing. Similarly, for sources and titles. If ForceFiling is off (value is "No"), then cards without parents will be filed automatically in the ToBeFiled filebox at closing time. If ForceTitles is off, then an untitled card will be left with the title "Untitled." ForceTitles and ForceFiling default to "Yes," while ForceSources defaults to "No."

CloseCardsOffScreen: If "Yes," then when a card is closed, it is first dragged off screen so that the close happens invisibly.

MarkersInFileBoxes: If "Yes," then new fileboxes will contain the markers "FILE BOXES" and "NOTE CARDS." New child boxes are inserted under the FILE BOXES marker and new child cards under the NOTE CARDS marker. If "No," then new fileboxes come up without markers and new children are inserted at the current cursor position. Note that regardless of the MarkersInFileBoxes setting, if a filebox has no markers (because you’ve deleted them) then new children are inserted at the cursor position.

AlphabetizedFileBoxChildren: If "Yes," then new fileboxes will have the property OrderingFn set to NC.IDAlphOrder. This will cause any new cards put into such a filebox to be inserted in alphabetical order. For further details on OrderingFn’s for fileboxes see Section 4.

DefaultLinkIconAttachBitmap, DefaultLinkIconShowTitle, DefaultLinkIconShowLinkType: These dictate the manner in which link icons are displayed if not currently specified in the icon. There are three fields of a link’s display mode that can be set, unset, or floated independently. If a field is floated, then the global parameter for that field is consulted. For example, if a link icon’s display mode has value FLOAT for the ShowTitle field, then whether the title gets shown inside the link icon depends on the value of DefaultLinkIconShowTitle. See below for a further description of a link’s display mode.

LinkDashingInBrowsers: If "Yes," then browser links are drawn with dashed lines with the dashing style corresponding to the link’s type. See Section 3 for further details on browser changes. Defaults to "No."

ArrowHeadsInBrowsers: This dictates whether arrow heads are drawn on browser links. The variable can be set to either "AtMidpoint," "AtEndpoint," or "None." See Section 3 for details. Defaults to "None."

EnableBravoToTEditConversion: If "Yes" then TEdit checks when getting a file whether that file is in Bravo format and if so, converts. This defaults to "No" for efficiency.

DefaultFont: This dictates the font that new text cards default to.
LinkIconFont: This dictates the font for text appearing in link icons.

Link icon display mode:

The display mode of a link icon can be changed by middle buttoning in the icon and selecting from the three menus in the resulting stylesheet. These are: AttachBitmap, ShowTitle, and ShowLinkType. AttachBitmap, if "Yes," causes link icons to be shown with a bitmap representing the type of the destination card attached at the left. ShowTitle and ShowLinkType, if "Yes," cause the link icon to contain the title of the destination card and/or the link type. Any of the three fields can have the value FLOAT, in which case the appropriate global parameter will be consulted. (See description of global parameters above.) If all fields are set to "No" (or the floating ones inherit No from the global parameters), then a small, uninformative icon is used to display the link.

"Pushing" and "Pulling" link icons:

There are now two ways to move or copy a link icon between cards or within a card. "Pulling" works like TEdit shift-select. That is, to move an icon, put the cursor where you want to move to and hold down the shift key (or shift and ctrl keys) while left clicking in the left or right quarter of the icon. The new style is called "pushing" and is done by holding down the shift key while left clicking in the middle part of the icon. Then move the cross-hairs cursor to the icon’s new home and left-click. To abort a "push," just left click in the background. Note that "pushing" currently only works for copying, not moving.

Specifying notefile names and card titles:

A different editor has been incorporated into Notecards for obtaining card titles, file names, etc. This editor is the same one used in the top level lisp exec window (TTYIN). Thus you can change the title (or file name) given as prompt via mouse edits.

3. Changes to the Notecards browser.

Multiple roots:

Browsers can now contain multiple roots, in which case the graph will be laid out as a forest.

Dashed links:

Dashed browser links was a rarely used option in Release 1.1, largely because of speed considerations. The speed of drawing dashed links has improved in Release 1.2i by taking advantage of improvements in Grapher. There are currently nine different dashing styles possible. If a browser contains instances of more than nine different link types, then the last dashing style will be used repeatedly for each link type beyond the ninth. As before, link dashing is a user-settable option in the GlobalParameters menu (see Section 2).

Arrowheads:

Arrowheads can now be drawn on browser links. These show the direction of the notecards link being represented in the browser. This is a user-settable parameter in the GlobalParameters menu with possible values AtMidpoint, AtEndpoint, or None. If AtMidpoint or AtEndpoint is specified, then arrowheads will be drawn at link midpoints or endpoints, respectively. However,
in either case, if two browser nodes are connected by more than one link, then any arrowheads for those links will appear at the midpoints (so as not to overlap).

**Browser specs:**

Whereas in Release1.1 only the link types to traverse could be specified, in Release1.2i, link types is one of a number of browser specs. Also included are browser depth, format, and orientation. These are accessible through a BrowserSpecs stylesheet, a collection of 5 menus. For general details on the stylesheet interface see Section 2. In this case, the forward and backward link types menus are multi-selectable, that is, more than one entry can be chosen. The other three menus are used to make single selections.

Forward and backward link types function as in Release1.1. That is, the browser will contain only nodes for cards reachable from the root cards by following forward links in "line of direction" or backward links in "reverse line of direction."

Browser depth is chosen from a menu containing entries for the integers 0 through 9 and INF (or infinite depth). The default is INF, meaning that the browser will not be cut off until there are no more links to follow from leaf nodes. Choosing depth 0 means that only the root nodes will appear (and no links).

Browser format is one of *GRAPH*, LATTICE, COMPACT, or FAST. The latter three are provided by the grapher package and correspond to lattice, compact forest and fast forest, respectively. COMPACT and FAST generate virtual nodes (in double boxes) whenever two or more links would be drawn to the same node. LATTICE only generates virtual nodes when a cycle exists in the graph. *GRAPH* is a new format that never generates virtual nodes. The drawback to using *GRAPH* is that a cycle can cause lines to be drawn that cross boxes or overlap other lines. Thus you may have to move nodes around for legibility after computing the browser. The default is LATTICE.

Browser orientation is one of Horizontal, Vertical, Reverse/Horizontal, or Reverse/Vertical. These specify whether the graph is layed out left-to-right, top-to-bottom, right-to-left, or bottom-to-top, respectively. The default is Horizontal.

**New middle button title bar menu options:**

Several new entries have been added to the middle button menu invoked from a browser's title bar. The options are now RecomputeBrowser, RelayoutGraph, ReconnectNodes, UnconnectNodes, ExpandBrowserNode, GraphEditMenu, and ChangeBrowserSpecs.

**RecomputeBrowser** causes the current contents of the browser to be thrown away and recomputed as in Release1.1. However, in Release1.2i, you can optionally specify a new set of root nodes.

**RelayoutGraph** does not rebuild the graph, but rather causes the nodes and links of the graph to be repositioned on the screen (using Grapher's LAYOUTGRAPH). This will destroy any work you have done moving nodes within the graph.

**ReconnectNodes** first causes any link edges in the graph to be erased. (Note, however, that non-link edges, those created by "AddEdge", as described below, are ignored.) Then, each node in the graph is connected to every other node in the graph for which there is a link between them having one of the currently selected link types. This can be useful for several reasons:
1. when the linking structure between cards has changed, but the current browser layout needs to be preserved.

2. when some browser nodes need to be moved, but dragging the connected links is too slow. In this case, do UnconnectNodes followed by ReconnectNodes (after you’ve moved the nodes around).

3. when special browser layouts are desired. For example, suppose you like the layout that Grapher gives you when certain links are left out or when you limit the depth. Then calling ReconnectNodes will fill in the missing links without affecting the graph’s layout.

**UnconnectNodes** simply erases all edges in the browser. This is useful for positioning a browser’s nodes before invoking ReconnectNodes.

**ExpandBrowserNode** allows you to enlarge the graph under a given node. After selecting a node, you’re asked for a depth (defaults to 1). The graph is then expanded under the selected node to the given depth, following any currently selected links. Note that ExpandBrowserNode calls LAYOUTGRAPH so any existing special node arrangements will be lost.

**GraphEditMenu** brings up the graph editing menu. See the description below.

**ChangeBrowserSpecs** brings up the BrowserSpecs stylesheet to allow you to change any of the browser specs. These changes will be noticed at the next RecomputeBrowser, ExpandBrowserNode, etc.

*Editing the browser manually and "structure editing":*

The browser can be edited through the use of the GraphEditMenu. This menu can be obtained either by right-buttoning in the browser window or by choosing GraphEditMenu from the title bar middle button menu. The GraphEditMenu includes options for "structure editing"; that is, changing underlying NoteCards structure by editing the browser. The old options for editing without changing structure are also present. Given below are the menu items in GraphEditMenu and the actions they engender.

**CreateCard&Node** causes a new card to be created in the current Notefile and a corresponding node for it to be included in the browser. You’re asked for the type of the new card, its title, and where to position the node representing it.

**CreateLink&Edge** causes a new link to be created between two existing cards and a corresponding edge to be drawn in the browser. (We call such an edge representing a Notecards link, a "link edge." See AddEdge below for creating non-link edges.) You’re asked for the "From" and "To" nodes in the browser corresponding to the cards to be linked as well as a link type. The link icon for the new link is positioned at the cursor point in the From card if the card has text substance and an open window. Text cards with closed windows have links inserted at the start of the text stream. Otherwise, the new link is a global link. You can have multiple link edges between pairs of cards. In this case the edges are displayed in a spline or "flower" arrangement.

**DeleteCard&Node** causes a card to be deleted and its corresponding node in the browser to be removed. You are asked first to choose the node representing the card to be deleted and then to confirm the removal of the node (type "y" to confirm) and the deletion of the card. If the
selected node is one of a set of virtual nodes (double boxed), then all nodes in the set (i.e. representing the given card) are removed.

**DeleteLink&Edge** causes a link in the Notefile to be deleted and the corresponding edge in the browser to be removed. You first pick the "From" and "To" nodes corresponding to the source and destination ends of the link respectively. Then, if there is only one link between those two cards, the link is deleted after user confirms. If there are multiple links between the two cards, then the user chooses from a menu of link types.

**AddLabel** puts a "label node" into the browser that does not represent a Notecard. You are prompted for a string forming the node’s label and then must position the label node. This node is not boxed. (But note that "virtual" label nodes can be boxed and thus can be confused with non-virtual regular nodes.)

**AddNode** adds a node into the browser corresponding to some existing card. You are asked to point to a card (title bar or link icon) on the screen that this node is to represent and then to position the node.

**AddEdge** draws a line between two nodes in the browser. This edge does not correspond to a real link in the Notefile. To avoid confusion, it is best to have the arrowheads option on (see Section ??) in this case, since edges formed by AddEdge do not have arrowheads (or dashing). Only one such edge is allowed between any two nodes and none if there are already link edges between the nodes. Thus doing CreateLink&Edge will remove any existing non-link edge.

**RemoveNode** removes a node from the browser. It does not delete the card (if any) that the node represents. Edges into and out of the node are also removed. If the selected node is one of a set of virtual nodes representing the same card, then you will be told how many nodes will be removed with this one and will be asked to confirm. The only way to remove only one node of a set of virtual nodes, is to first manually remove edges into and out of it using RemoveEdge. Then RemoveNode can be used to remove only the one virtual node.

**RemoveEdge** removes an edge from the browser. It does not delete the link (if any) that the edge represents. The user is asked to select the "From" and "To" nodes of the edge.

**MoveNode** allows you to change the position of any node, rubber banding any edges pointing to it. You’re asked to point to the node by left-buttoning, and holding down the left button, drag the node to its new position.

**LabelSmaller** is used to decrease the font size of label nodes. Note that it does not work for regular non-label nodes.

**LabelLarger** is used to increase the font size of label nodes.

**<>Shade** toggles the shade of a node between black-on-white and white-on-black. This can only be performed on label nodes (not on nodes representing Notecards).

**FIX MENU** causes the GraphEditMenu to be affixed to the lower right edge of the browser window. Note that this does not prevent you from obtaining the menu via right button inside the window.

[Note that the above editing commands do not work on old 1.1 browsers. Such browsers should either be recomputed (via RecomputeBrowser) or unconnected and reconnected.]
4. Miscellaneous changes.

Links ordering within text cards:

The internal list of outgoing links in a text card is now kept in the same order that the links appear in the card’s text. This means, for example, that the daughters of a browser node for a filebox will appear in the correct order.

Link insertion:

The title bar menu entry for "InsertLinks" now has an attached submenu containing entries for adding single links, multiple links, and global links. When inserting multiple links (or adding multiple global links) you’re only asked for one link type which is used to label all the new links and all are inserted at the same place in the text.

Show links:

This is now a normal entry in the left button title bar menu of a card (rather than a subentry under Edit Properties). The format of the ShowLinks display has been changed slightly. The prefix is now either TO, FROM, or Global TO. The link type is shown in the icon. Also, for text cards, the TO links should appear in the correct order.

Sketch changes and fixes:

Notecards now uses the latest version of sketch. See the sketch documentation for details on changes. Several long-standing bugs having to do with link icons in sketch cards have been fixed.

Sketches and graphs in text cards:

It is possible to shift-copy the contents of sketch and graph/browser cards into text cards. In addition, the Document card is now able to include the contents of sketch and graph cards if encountering them during card gathering. (It is still not possible for Document to include the contents of cards having user-defined substance types such as NCFile cards.)

Data saved at card closing:

When a card is closed, only those parts that are dirty are written out to the notefile. A message indicating which parts are being saved is now printed to the card’s prompt window during closing. Furthermore, certain card types (in particular, browsers) were saving their substance even if no changes were made. This source of space inefficiency has been fixed in Release1.2i.

Ordering cards in a filebox:

It is now possible to dictate the relative placement of new cards in a filebox. If the OrderingFn property of a card has a value, it should be a lisp function that takes two card ID arguments and returns T if the first should appear before the second and NIL otherwise. You can make such a function appear automatically on new boxes for the case of alphabetizing by using the global parameter AlphabetizeFileBoxChildren. See section 2.

Programmer’s interface:
The Programmer’s interface has been updated. Thus users with existing programmer’s interface code should read the revised PI documentation. The changes are not all forward compatible.

**Notecards system date:**

You can find the date of your Notecards system in the variable NC.SystemDate. The ’NewestFile property on the NC.SystemDate atom contains the name of the last modified Notecards file.

**The Notecards library packages:**

The old Release1.1 library packages have been converted to 1.2i and documented and several new ones have been added. These can be found on {qv}<notecards>release1.2>library> and include NCScreen, NCCluster, NCChain, NCF ileCard, NCKeys, NCHacks, and ARIDemo. Documentation can be found in <filename>.ted.

NCScreen defines several handy functions for arranging cards on the screen callable from the programmer’s interface. NCCluster defines several new card types, most notably CaseCluster, a cluster of cards for use in the sample domain of legal case analysis. NCChain defines the Chain card type, useful for breaking up a large text card into a linked chain of cards. NCF ileCard defines the File card type and FILE substance allowing a notefile to link to external files via standard Notecards links. NCKeys provides a shorthand language for invoking various handy programmer’s interface functions. NCHacks contains several handy functions written using the programmer’s interface. Two of these allow global text searches and replaces throughout a notefile. In addition there is a function that searches by last card modification date and one that links cards to form chains. Finally, ARIDemo is an example of how the programmer’s interface can be used to construct notefiles that demo themselves.

**Loading NoteCards from different directories:**

NoteCards now uses the values of four directories variables to decide from whence to load the code. These are NOTECARDSDIRECTORIES, NOTECARDSMAPDIRECTORIES, QUADTREEDIRECTORY, and MAPFILEDIRECTORY. They default to {QV}<NOTECARDS>RELEASE1.2I>, {QV}<NOTECARDS>MAPS>NEW>, {QV}<NOTECARDS>MAPS>, and {QV}<NOTECARDS>MAPS> respectively.

**5. Known bugs and plans for future improvements:**

- The compactor should check first for available space.

- There are major speed problems in redrawing large browsers. Changing link display mode could also use some streamlining.

- Integrate the document compiler and the types mechanism so that instances of new card types can be sucked into TEdit documents.

- Make links into full-fledged objects having properties and type hierarchies.
The NoteCards Types Mechanism

Release 1.2

Frank G. Halasz
Xerox PARC

First Written:  22-Mar-85
Modified:  26-Mar-85 by Frank G. Halasz
Modified:  1-Aug-85 by Lissa Monty

1. Introduction

The NoteCards types mechanism allows a user with some knowledge of Interlisp to add new types of note cards to the system. The types mechanism is built around an inheritance hierarchy of note card types. If the user needs to create a new card type that is a small change from an already existing card type, he or she need only define the few functions or parameters that account for the differences between the new card and the existing card. However, if the user wishes to create a totally new type of card, then he or she must define the 20-odd functions and parameters that make up a note card type.

Every note card has a substance. A substance is essentially a data structure that contains the information in the note card. Different types of note cards have different types of substances. Associated with every substance type is an editor that can be used to create and/or modify the data structure of that substance type. For example, the substance of a Text card is a TEXTSTREAM that can be edited using TEdit. Similarly, the substance of a Browser card is a GRAPH record that can be edited using GRAPHER. Defining a new note card type involves specifying the functions necessary to handle the card’s substance and its editor.

1.1 The Inheritance Hierarchy

The inheritance hierarchy in NoteCards has two parts: a tree of NoteCardTypes and a list of SubstanceTypes. Every NoteCardType has a super-type and a substance type. The super-type is an already existing NoteCardType from which the NoteCardType will inherit fields. Thus, the set of NotecardTypes forms a tree structure based on the super-type field. The substance type of a NoteCardType is an already existing SubstanceType.

The inheritance process for a given field of a NoteCardType works as follows: if the field has a non-NIL value in the NoteCardType then this value is used, otherwise the field value is inherited from its super-type. If there are no non-NIL values anywhere in the inheritance path for the NoteCardType, then the field value is taken from the corresponding field in the substance type for the NoteCardType. Substance types are guaranteed to have values in all of their fields.
Example: ProtectedText is a card with super-type Text. Text in turn has super-type NoteCard (the null root of the NoteCardType tree). In addition, Text has substance type TEXT. If an EditCardFn is not defined in ProtectedText, then it will be inherited from Text. If Text doesn’t have an EditCardFn then the EditSubstanceFn from the TEXT SubstanceType will be used (since NoteCard by definition does not have an EditCardFn).

Functions are inherited all or none. Often, however, a new NoteCardType will require only a minor addition to the corresponding function of its super-type. In this case, the new card type should define a new function, but this function can call the corresponding function of its super-type to do the bulk of the work. The following construction will accomplish this goal:

\[
\text{(APPLY* (NCP.CardTypeInheritedField (NCP.CardTypeSuper <type>) <fn> <arg1> <arg2> ...))}
\]

where <type> is the TypeName of the card type in question, <fn> is the name of the function in question, and <arg1> <arg2> ... are the arguments to that function. For example the following might be the definition of the EditCardFn for the passworded Text card called ProtectedText:

\[
\text{(DEFINEQ (NC.EditProtectedTextCard (LAMBDA (ID Substance Region/Position)
               (* * Edit a Protected Text card, asking for the password first.)
               (PROG (Password Result)
                 (* * Get this card’s password from the prop list)
                 (SETQ Password (NCP.CardProp ID (QUOTE Password)))
                 (COND
                  ((EQUAL Password (NC.GetPassword ID))
                   (* Password is okay.
                    Call the EditCardFn of my super-type)
                   (SETQ Result (APPLY*
                        (NCP.CardTypeInheritedField
                         (NCP.CardTypeSuper (QUOTE ProtectedText))
                         (QUOTE EditCardFn)))
                    ID Substance Region/Position)))
                  (T (* Password is bad. Express condolences)
                   (NCP.PrintMsg Window T "Sorry." (CHARACTER 13)
                    "You do not know the password!!"
                    (CHARACTER 13)
                    "Bye."
                    (CHARACTER 13))
                   (DISMISS 2000)))
               (RETURN Result))))}
\]

### 1.2 Links and Link Icons

An integral part of NoteCards is the ability to create a link between two note cards. Presently, there are two kinds of links: GlobalToGlobal links and LocalToGlobal links. GlobalToGlobal links connect one entire card with another entire card and are stored separately from either card’s substance.
GlobalToGlobal links are maintained (almost) entirely by the NoteCards system code and therefore do not vary across note card types.

LocalToGlobal links connect a particular position within the substance of one card (the source card) to the entirety of the other card (the destination card). Within the source card, the link is represented by an image object called a link icon that must be contained by the card’s substance. Since substances vary across note card types, the handling of link icons varies across note card types. The destination (or Global) end of a LocalToGlobal links is maintained by the NoteCards system code.

Not all note cards can be the source of LocalToGlobal links. Card types that support LocalToGlobalLinks must have their LinkAnchorModesSupported parameter set to T. If this parameter has any other value, then cards of this type can be the source of only GlobalToGlobal links. These Global-links-only card types need to provide only one piece of functionality in support of the linking mechanism. In particular, they must provide user access to the function `NCP.GlobalGlobalLink` from the editor that runs when the card is being displayed. For example, the editor’s command menu might include an "Insert Global Link" command. All other link maintenance is carried out by the NoteCards system.

If a card type supports LocalToGlobal links, then it must contain the necessary mechanisms for supporting link icons in its substance. Link icons are instances of standard Interlisp-D image objects (See documentation of Image Objects in Interlisp-D). The mechanisms supporting link icons include functions for inserting, deleting, updating, and collecting the link icons contained in a card’s substance. These functions are described in detail below. In addition to these functions, a note card type supporting LocalToGlobal links must provide user access to the function `NCP.LocalGlobalLink` from the editor that runs when the card is being displayed. In addition the editor must provide user access to the function `NCP.GlobalGlobalLink`.

Inside the link icon image object is a link record containing all of the information about the link. These link records can be manipulated using the link manipulation functions provided by NoteCards’ programmer’s interface (e.g., `NCP.GetLinkDestination` returns the destination field of a link record). The functions required to define a note card or substance type deal in both link records and link icons. You can translate between these two representations using the functions `NC.MakeLinkIcon` and `NC.FetchLinkFromLinkIcon`. `NC.MakeLinkIcon` will create a link icon image object from a link record, while `NC.FetchLinkFromLinkIcon` will return the link record contained in a link icon.

### 1.3 Using the Types Mechanism

Most uses of the types mechanism involve defining new NoteCardTypes. Usually, these new NoteCardTypes involve specifying a TypeName, a SuperType, a SubstanceType, and one or two functions that differ from the SuperType. The most commonly defined functions are the MakeCardFn, the EditCardFn and the QuitCardFn.

Definition of new substance types occurs only when a new kind of substance (e.g., a spreadsheet) and its corresponding editor are to be added to the system. When defining a substance, all of its fields must be fully defined since there is no inheritance among SubstanceTypes.
2. The NoteCardType

Each note card type in the system is defined by a record structure (i.e., a NoteCardType) containing about 20 names, functions and parameters. The functions implement behaviors that are required by the NoteCards system but vary across the different card types. For example, one function is responsible for writing the card's substance to the NoteFile. The parameters represent specifications that inform NoteCards about the specific properties of each card type, e.g., whether it handles local links or not.

The NoteCardTypes are organized into an inheritance hierarchy. Each NoteCardType has a super-type. If any of the functions or parameters is not specified for a given NoteCardType, that function or parameter is inherited from its super-type (or its super-type's super-type, if the function or parameter is not specified for the super-type either). Each NoteCardType also has a SubstanceType. If any of the functions or parameters cannot be found along the super-type chain of the NoteCardType, then the card type inherits the function or parameter from its SubstanceType.

Overall, a card type is a data structure with the following 21 fields:

Inheritance Hierarchy Specifications
1) TypeName
2) SuperType
3) SubstanceType

Functions
4) MakeCardFn
5) EditCardFn
6) QuitCardFn
7) GetCardFn
8) PutCardFn
9) CopyCardFn
10) MarkCardDirtyFn
11) CardDirtyPFN
12) CollectLinksInCardFn
13) DeleteLinksInCardFn
14) UpdateLinkIconsInCardFn
15) InsertLinkInCardFn
16) TranslateWindowPositionToCardPositionFn

Parameters
17) LinkDisplayMode
18) CardDefaultWidth
19) CardDefaultHeight
20) CardLinkAnchorModesSupported
21) CardDisplayedInMenuFlg
These fields are defined as follows:

1. **TypeName**: The atom that is the name of this card type. TypeNames must be unique among the NoteCardTypes tree, though they may overlap with SubstanceNames. The convention is that NoteCardType TypeNames have only the first letter capitalized. This is to set them apart from SubstanceNames which are by convention all caps.

2. **SuperType**: The TypeName of the NoteCardType that is the super-type for this NoteCardType. When a new NoteCardType is created, its SuperType must be an existing NoteCardType.

3. **SubstanceType**: The SubstanceName for the substance of this card type. When a new card is created, its SubstanceType must be the name of an existing SubstanceType (see Section 3.0 below). The basic NoteCards system includes the following substance types: TEXT, SKETCH, GRAPH which represent the substances handled by the TEdit, Sketch, and Grapher packages respectively.

4. **MakeCardFn**: The name of a function to be applied to an ID, a Title, and a NoDisplayFlg. The function should create a new card of this type. The ID is the note card ID that will be assigned to the newly created card. It should be used to set the various properties of the new card. The title is a string specifying the title of the new card. It can be used in messages to the user or to set the title of any windows created. NoDisplayFlg determines whether the new card is to be displayed on the screen or not. If NoDisplayFlg is non-NIL, then the card is to be displayed in a window on the screen. If NoDisplayFlg is NIL, then the card is to be created but not displayed on the screen.

The MakeCardFn should return the window of the new card if NoDisplayFlg is non-NIL and the ID if NoDisplayFlg is NIL.

Before returning, every MakeCardFn is required to set the substance property of ID by calling (NC.SetSubstance ID Substance) where Substance is whatever is considered a substance for this card type. For example, a TextStream for Text cards, a Graph record for Graph cards, or a Sketch record for Sketch cards.

By convention, every MakeCardFn sets the SHRINKFN of any window it creates to the function NC.ShrinkFn using WINDOWPROP.

5. **EditCardFn**: The name of a function to be applied to ID, Substance, and Region/Position. The function should start an editor for the given card. ID is the note card ID of the card. Substance is the substance of the card; it will be a thing of whatever type is considered a substance for this card type, e.g., a TextStream or Sketch record. Region/Position is a Region or a Position on the screen that specifies where the card is to be placed.

(NC.DetermineDisplayRegion ID Region/Position) is a function that will determine the exact region for the card’s window given the ID and the Region/Position.
The EditCardFn should return the editor window.

The EditCardFn is responsible for checking to make there is not already an editor for card ID already on the screen. If there is, the EditCardFn should just flash the previous editor window.

By convention an EditCardFn sets the SHRINKFN of any window it creates to the function **NC.ShrinkFn** using WINDOWPROP. Also by convention, an EditCardFn should set the title of the editor window to be the value of (**NCP.CardTitle** ID).

6. **QuitCardFn**: The name of a function to be applied to **WindowOrSubstanceOrlID** which is either the editor window for a card or the substance of a card or a note card ID. QuitCardFn should quit out of the editor currently operative on the specified card and close the window containing the card.

The value returned by QuitCardFn is unspecified.

Before returning the QuitCardFn should apply the function **NC.DeactivateCard** to the ID of the card. Note that the ID may have to be computed from the Window or Substance passed to the QuitCardFn. The function **NC.CoerceToID** will do this computation.

The QuitCardFn should also insure that all processes related to this card are completed (or guaranteed to eventually complete) before returning.

7. **GetCardFn**: The name of a function to be applied to the DatabaseStream, a card ID, and a screen Region. The GetCardFn should read the substance of the note card specified by ID from the DatabaseStream. The format of the data to be read is determined by the PutCardFn (see below). When the GetCardFn is called, the file pointer for DatabaseStream is positioned on the first byte of the data to be read.

The GetCardFn should return a pointer to the substance read from the DatabaseStream.

GetCardFn need produce no side-effects. The ID and the Region are for reference purposes only.

Note that the GetCardFn need only read the substance of the card, i.e., that information about the card which is specific to its card type. General information about a card such as its title, its property list, its list of links, etc. is read from the DatabaseStream by the system.

8. **PutCardFn**: The name of a function to be applied to a note card ID and the DatabaseStream. The PutCardFn should write the substance of the note card specified by ID to the DatabaseStream. When the PutCardFn is called, the file pointer for DatabaseStream is positioned at the first byte assigned to the card. When the PutCardFn returns, the file pointer should be positioned immediately after the last byte written.
The format for writing the card's substance is fairly unrestricted. The data written on the DatabaseStream can take up any number of bytes, but the bytes must be contiguous. It must be written so that it can be recovered by reading from the DatabaseStream using the GetCardFn. The only other restriction is that the first 6 bytes of the substance must contain the file position of the start and end of the substance: 3 bytes for the start file pointer and 3 bytes for the end file pointer. These pointers are for use by the CopyCardFn.

The value returned by the PutCardFn is unspecified.

Note that the PutCardFn need only write out the substance of the card, i.e., that information about the card which is specific to its card type. General information about a card such as its title, its property list, its list of links, etc. is written to the DatabaseStream by the system.

9. CopyCardFn: The name of a function to be applied to a note card ID, a "from" DatabaseStream, and a "to" DatabaseStream. The CopyCardFn should copy the substance for the note card specified by ID from the "from" DatabaseStream to the "to" DatabaseStream. When the CopyCardFn is called the file pointer for the "from" DatabaseStream is positioned on the first byte of the data to be copied. The file pointer for the "to" DatabaseStream is positioned at the first byte of the space assigned to the card on the "to" DatabaseStream.

The format for writing the substance on the "to" DatabaseStream has the same restrictions as for the PutCardFn.

Most often the the CopyCardFn is a simple COPYBYTES that uses the start and end pointers written by PutCardFn in the first 6 bytes of the substance. Note, however, that all file absolute pointers (including the start and end pointers) must be updated; the file location on the "to" DatabaseStream is almost never the same as the original file location on the "from" DatabaseStream.

The value returned by the CopyCardFn is unspecified.

The CopyCardFn is used primarily by the compactor that eliminates "dead" space in the database. Thus, it is important that the CopyCardFn be as time efficient as possible.

10. MarkCardDirtyFn: The name of a function to be applied to a note card ID and a ResetFlg. If the ResetFlg is non-NIL, the function should mark the card specified by ID as being dirty (i.e., changed since it was last written to the DatabaseStream). If the ResetFlg is NIL, the function should reset the "dirtiness" of the card.

The MarkCardDirtyFn is called by NoteCards system functions that change the card. It is not necessarily called by user operations inside the editor on the card. Therefore, it is best if the mechanism used by the MarkCardDirtyFn is somehow coordinated with the corresponding mechanism used by the editor on the card. (See the CardDirtyPFn below.)

The value returned by the MarkCardDirtyFn is unspecified.
The card specified by ID is guaranteed to be active.

11. *CardDirtyPFn*: The name of a function to be applied to a note card ID. The function should return a non-NIL value if the card specified by ID is dirty, i.e., if it was changed since it was last written to the DatabaseStream. NIL should be returned otherwise.

Note that a "dirty" card is one that has been changed in any way. Only NoteCards specific changes to a card will result in a call to the card’s MarkCardDirtyFn. Changes made through the editor on the card will use the editors "mark dirty" mechanism and will not call the MarkCardDirtyFn. Therefore, the CardDirtyPFn should check all dirty flags, i.e., the dirty flag set by the MarkCardDirtyFn as well as any set by the card’s editor.

The card specified by ID is guaranteed to be active.

12. *CollectLinksInCardFn*: The name of a function to be applied to a note card ID, a CheckAndDeleteFlg, a DatabaseStream, a ReturnLinkIconsFlg, and a ReturnLocationsFlg. The function should examine the substance of the card specified by ID and produce a list of the links (or link icons) contained by the substance. The ReturnLinkIconsFlg and the ReturnLocationsFlg determine the contents of the list to be returned as follows:

- ReturnLinkIconsFlg and ReturnLocationsFlg both NIL: the list to be returned should be a list of link records.
- ReturnLinkIconsFlg is non-NIL, ReturnLocationsFlg is NIL: the list to be returned should be a list of link icons.
- ReturnLinkIconsFlg is NIL, ReturnLocationsFlg is non-NIL: the list to be returned should be a list of pairs where the first memeber of the pair is a link record and the second member of the pair is the "location" of the link icon for that link inside the substance.
- ReturnLinkIconsFlg and ReturnLocationsFlg both non-NIL: the list to be returned should be a list of pairs where the first memeber of the pair is a link icon and the second member of the pair is the "location" of that link icon.

If CheckAndDeleteFlg is non-NIL, then the list produced by CollectLinksInCardFn should contain valid links only. Any links found to be invalid should be deleted. To check the validity of a link, the function *NC.ValidLinkP* should be applied to the link record and the DatabaseStream. To delete a link, apply the function *NC.MakeInvalidLink* to the link icon.

The CollectLinksInCardFn should return the list produced CONSed to a dirty flag. The dirty flag should be non-NIL if any links were deleted, NIL otherwise.

The card specified by ID is guaranteed to be active.

13. *DeleteLinksInCardFn*: The name of a function to be applied to a "source" note card ID and a link record or "destination" note card ID. If the second argument is a link, the function should
remove from the substance of the card specified by "source" ID the link icon corresponding to link. If the second argument is a "destination" note card ID, the function should remove from the substance of the card specified by "source" ID all link icons corresponding to links pointing to the card specified by "destination" ID.

To "remove" a link icon, the link icon should be replaced in the substance by the image object that is the value of \texttt{NC.DeletedLinkImageObject}. Note that before deleting the link icon, it is best to replace the \texttt{IMAGEOBJFNS} of the link icon with the value of \texttt{NC.NoDeleteImageFns}. This will prevent the link icon's \texttt{WHENDELETEDFN} from being activated when the deletion takes place.

The value returned by the \texttt{DeleteLinksInCardFn} is unspecified.

The card specified by "source" ID is guaranteed to be active.

14. \texttt{UpdateLinkIconsInCardFn}: The name of a function to be applied to a "source" note card ID or window and a "destination" note card ID. The function should update (i.e., force a redisplay of) all link icons in the "source" card that represent links pointing to the "destination" card. This function is called when some property of the link is changed by the NoteCards code. It is also called when certain properties of the destination card (e.g., its title) are changed.

The value returned by the \texttt{UpdateLinkIconsInCardFn} is unspecified.

The "source" card is guaranteed to be active.

15. \texttt{InsertLinkInCardFn}: The name of a function to be applied to a window, a link, and a position. The function should insert a link icon containing the link into the card being edited in the window at the position specified. The position is whatever object is returned by the \texttt{TranslateWindowPositionToCardPositionFn}.

The value returned by the \texttt{InsertLinkInCardFn} is unspecified.

The ID of the card being edited by the window is guaranteed to be the \texttt{SOURCEID} of the link.

16. \texttt{TranslateWindowPositionToCardPositionFn}: The name of a function to be applied to a window, an X-coordinate in that window, and a Y-coordinate in that window. The window is an editor window on the substance of some card. The function should return a position object that describes the position in the card substance that is currently located at the given X-Y position in the window. The format of the position object is undefined. It will be passed to the \texttt{InsertLinkInCardFn} and used as the position at which to insert a links in the card being edited in the window.

17. \texttt{LinkDisplayMode}: determines the default display mode for link icons inserted into cards of this type. It must be a record of type \texttt{LINKDISPLAYMODE}. \texttt{LINKDISPLAYMODE} describes what information will be displayed in a link icon. It consists of three flags: \texttt{SHOWTITLEFLG}, \texttt{SHOWLINKTYPEFLG}, and \texttt{ATTACHBITMAPFLG}. If \texttt{SHOWTITLEFLG} is non-NIL, the link icon will display the destination card's title. If \texttt{SHOWLINKTYPEFLG} is non-NIL, the link icon will
display the type of the link. If ATTACHBITMAPFLG is non-NIL, a bit map describing the type of the destination card will be attached to the right of the link icon.

Note: This property in NOT inherited.

18. CardDefaultWidth: The default width for editor windows on cards of this type.

19. CardDefaultHeight: The default height for editor windows on cards of this type.

20. CardLinkAnchorModesSupported: an atom that determines the kind of links this card type will support (i.e., the kind of links for which cards of this type can be a source). If NIL, then this card type does not support links of any type. If Global, this card supports only Global links. If Local, this card supports only local links. If T, this card supports both Global and Local links.

Note: This property in NOT inherited.

21. CardDisplayedInMenuFlg: if non-NIL then this card type will appear in the choice of card types in the menu used during card creation using the "Create" entry in the main NoteCards menu. If NIL, then this card type will not appear in this menu.

3. The SubstanceType

The SubstanceType is a record structure whose fields are virtually identical to those of the NoteCardType record. In particular, the SubstanceType has the following 17 fields:

1) SubstanceName
2) CreateSubstanceFn
3) EditSubstanceFn
4) QuitSubstanceFn
5) GetSubstanceFn
6) PutSubstanceFn
7) CopySubstanceFn
8) MarkSubstanceDirtyFn
9) SubstanceDirtyPFn
10) CollectLinksInSubstanceFn
11) DeleteLinksInSubstanceFn
12) UpdateLinkIconsInSubstanceFn
13) InsertLinkInSubstanceFn
14) TranslateWindowPositionToSubstancePositionFn
15) SubstanceDefaultWidth
16) SubstanceDefaultHeight
17) SubstanceLinkAnchorModesSupported

These fields are defined as follows:

1. **SubstanceName**: The atom that is the name of this substance type. SubstanceNames must be unique among the substance types, though they may overlap with card TypeNames. The convention is that SubstanceNames are all in caps. This is to set them apart from card TypeNames which by convention have only their first letter capitalized.

2 Thru 14. **Functions**: All of the functions are identical to the corresponding functions in the NoteCardType record structure. Note the (arbitrary) use of "create" instead of "make" in the name of the CreateSubstanceFn.

15 Thru 17. **Parameters**: The parameters are identical to the corresponding parameters in the NoteCardType data structure. There are no parameters for the LinkDisplayMode and the DisplayInMenuFlg because these two parameters are not inherited. They must be specified separately for each card type.

4. **Adding a New NoteCardType or SubstanceType to the System**

The functions **NCP.CreateCardType** and **NCP.CreateSubstanceType** can be used to add new Types to the system.

**NCP.CreateCardType** takes 5 arguments: the TypeName, its SuperType, its SubstanceType, a functions list, and a parameters list. The functions list is an ASSOC list where the CAR of each sub-list is one of the function field names given above (e.g., EditCardFn, MakeCardFn, etc.). The CDR of the sublist should contain the name of the required function. Any function field name for which there is no entry will be set to NIL and will thus be inherited. The parameters list is analogous to the functions list, except that it applies to the parameter field names (i.e., LinkDisplayMode, CardDefaultWidth, CardDefaultHeight, and CardLinkAnchorModesSupported).

**NC.CreateSubstanceType** takes 3 arguments: the SubstanceName, a functions list, and a parameters list. The functions and parameters list are analogous to those for **NCP.CreateCardType** except that all of the function and parameter fields specified above MUST have an entry in the ASSOC lists.

Both **NCP.CreateCardType** and **NC.CreateSubstanceType** will overwrite existing types (NoteCard and Substance, respectively) of the same name.
5. Example: Defining the ProtectedText NoteCardType

The following is an example of defining a new card type called the ProtectedText card. The card type is created by specifying new MakeCardFn and EditCardFn functions. All other functions are inherited from the super-type, i.e., the Text card. All of the parameters are specified directly for this card.

· The function that creates the new ProtectedText card type:

\[
\text{(NC.AddProtectedTextCardType} \\
\text{(LAMBDA NIL} \\
\text{(* fgh: "26-Mar-85 15:48")} \\
\text{(* * Create the ProtectedText card type)} \\
\text{(NCP.CreateCardType (QUOTE ProtectedText)} \\
\text{(QUOTE Text)} \\
\text{(QUOTE TEXT)} \\
\text{(QUOTE ((MakeCardFn NC.MakeProtectedTextCard)} \\
\text{(EditCardFn NC.EditProtectedTextCard)))}} \\
\text{(QUOTE ((LinkDisplayMode (T NIL NIL))} \\
\text{(CardDefaultHeight 300)} \\
\text{(CardDefaultWidth 400)} \\
\text{(CardLinkAnchorModesSupported T)} \\
\text{(CardDisplayInMenuFlg T))})\\n\]

· The MakeCardFn for the ProtectedText card type:

\[
\text{(NC.Make ProtectedTextCard} \\
\text{(LAMBDA (ID Title NoDisplayFlg)} \\
\text{(* fgh: "26-Mar-85 15:23")} \\
\text{(* * Make a protected Text card} \\
\text{by calling the make card fn for a Text card} \\
\text{and then attaching a password to the card)} \\
\text{(PROG (Window WindowOrID)} \\
\text{(* * Create the Text card)} \\
\text{(SETQ WindowOrID (APPLY*} \\
\text{(NCP.CardTypeFn (NCP.CardTypeSuper} \\
\text{(QUOTE ProtectedText)} \\
\text{(QUOTE MakeCardFn))} \\
\text{ID Title NoDisplayFlg))}} \\
\text{(* * Get the window for the card, if there is one)} \\
\text{(SETQ Window (WINDOWP WindowOrID))} \\
\text{(* * Get the password from the user} \\
\text{and add it to the cards prop list)} \\
\text{(NCP.CardProp ID (QUOTE Password)} \\
\text{(NC.GetPassword Window))} \\
\text{(* * Return whatever the super-type’s MakeCardFn returned)} \\
\text{(RETURN WindowOrID))})\\n\]

· The EditCardFn for the ProtectedText card type:
(NC.EditProtectedTextCard
   (LAMBDA (ID Substance Region/Position)
   (* fgh: "26-Mar-85 17:21")
   (* * Edit a Protected Text card, asking for the password first.)
   (PROG (ExactRegion Window Password Result)
   (* * Open a window for this card)
   (SETQ ExactRegion (NC.DetermineDisplayRegion ID
    Region/Position))
   (* * Get this card’s password from the prop list)
   (SETQ Password (NCP.CardProp ID (QUOTE Password)))
   (COND
    ((EQUAL Password (NC.GetPassword Window))
     (* Password is okay.
      Call the EditCardFn of my super-type)
     (SETQ Result (APPLY*
      (NCP.CardTypeInheritedField
       (NCP.CardTypeSuper (QUOTE ProtectedText))
       (QUOTE EditCardFn))

Medley for the Novice
# 1. BRIEF GLOSSARY

The following definitions will acquaint you with general terms used throughout this primer. You will probably want to read through them now, and use this chapter as a reference while you read through the rest of the primer.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>advising</td>
<td>A Medley facility for specifying function modifications without necessarily knowing how a particular function works or even what it does. Even system functions can be changed with advising.</td>
</tr>
<tr>
<td>argument</td>
<td>A piece of information given to a Lisp function so that it can execute successfully. When a function is explained in the primer, the arguments that it requires will also be given. Arguments are also called Parameters.</td>
</tr>
<tr>
<td>atom</td>
<td>The smallest structure in Lisp; like a variable in other programming languages, but can also have a property list and a function definition.</td>
</tr>
<tr>
<td>Background Menu</td>
<td>The menu that appears when the mouse is not in any window and the right mouse button is pressed.</td>
</tr>
<tr>
<td>binding</td>
<td>The value of a variable. It could be either a local or a global variable. See unbound.</td>
</tr>
<tr>
<td>bitmap</td>
<td>A rectangular array of &quot;pixels,&quot; each of which is on or off representing one point in the bitmap image.</td>
</tr>
<tr>
<td>BREAK</td>
<td>An Lisp function that causes a function to stop executing, open a Break window, and allows you to find out what is happening while the function is halted.</td>
</tr>
<tr>
<td>Break Window</td>
<td>A window that opens when an error is encountered while running your program (i.e., when your program has broken). There are tools to help you debug your program from this window. This is explained further in Chapter 14.</td>
</tr>
<tr>
<td>browse</td>
<td>To examine a data structure by use of a display that allows you to &quot;move&quot; around within the data structure.</td>
</tr>
<tr>
<td>button</td>
<td>(1) (n.) A key on a mouse.</td>
</tr>
<tr>
<td></td>
<td>(2) (v.t.) To press one of the mouse keys when making a selection.</td>
</tr>
<tr>
<td>CAR</td>
<td>A function that returns the head or first element of a list. See CDR.</td>
</tr>
<tr>
<td>caret</td>
<td>The small blinking arrowhead that marks where text will appear when it is typed in from the keyboard.</td>
</tr>
<tr>
<td>CDR</td>
<td>A function that returns the tail (that is, everything but the first element) of a list. See CAR.</td>
</tr>
</tbody>
</table>
1. BRIEF GLOSSARY

**CLISP**
A mechanism for augmenting the standard Lisp syntax. One such augmentation included in Interlisp is the iterative statement. See Chapter 9.

**cr**
Press your Return key.

**datatype**
(1) The kind of a datum. In Interlisp, there are many system-defined datatypes, e.g., Floating-Point, Integer, Atom, etc.

(2) A datatype can also be user-defined. In this case, it is like a record made up from system types and other user-defined datatypes.

**DWIM**
"Do-what-I-mean." Many errors made by Medley users could be corrected without any information about the purpose of the program or expression in question (e.g., misspellings, certain kinds of parenthesis errors). The DWIM facility is called automatically whenever an error occurs in the evaluation of an Interlisp expression. If DWIM is able to make a correction, the computation continues as though no error had occurred; otherwise, the standard error mechanism is invoked.

**error**
Occasionally, while a program is running, an error may occur which will stop the computation. Interlisp provides extensive facilities for detecting and handling error conditions, to enable the testing, debugging, and revising of imperfect programs.

**evaluate or EVAL**
To find the value of a form. For example, if the variable \( x \) is bound to 5, we get 5 by evaluating \( x \). Evaluation of a Lisp function involves evaluating the arguments and then applying the function.

**Executive Window**
This is your main window, where you will run functions and develop your programs. This is the window that the caret is in when you turn on your machine and load Medley.

**file package**
A set of functions and conventions that facilitate the bookkeeping involved with working in a large system consisting of many source code files and their compiled counterparts. Essentially, the file package keeps track of where things are and what things have changed. It also keeps track of which files have been modified and need to be updated and recompiled.

**form**
Another way of saying s-expression. A Lisp expression that can be evaluated.

**function**
A piece of Lisp code that executes and returns a value.

**history**
The programmer's assistant is built around a memory structure called the history list. The history functions (e.g. **FIX**, **UNDO**, **REDO**) are part of this assistant. These operations allow you to conveniently rework previously specified operations.

**History List**
As you type on the screen, you will notice a number followed by a slash, followed by another number. The first number is the exec number, the second is the event number. Each number, and the information on that line, is stored sequentially as the History List. Using the History List, you
can easily reexecute lines typed earlier in a work session. See Chapter 2.

**icon** A pictorial representation, usually of a shrunken window.

**inspector** An interactive display program for examining and changing the parts of a data structure. Medley has inspectors for lists and other data types.

**iterative statement** (also called i.s.) A statement in Interlisp that repetitively executes a body of code. For example, \( (\text{for } x \text{ from 1 to 5 do (PRINT x)}) \) is an i.s.

**iterative variable** (also called i.v.) Usually, an iterative statement is controlled by the value that the i.v. takes on. In the iterative statement example above, \( x \) is the iterative variable because its value is being changed by each cycle through the loop. All iterative variables are local to the iterative statement where they are defined.

**Lisp** Family of languages invented for "list processing." These languages have in common a set of basic primitives for creating and manipulating symbol structures. Interlisp-D is an implementation of the Lisp language together with an environment (set of tools) for programming, and a set of packages that extend the functionality of the system.

**list** A collection of atoms and lists; a list is denoted by surrounding its contents with a pair of parentheses.

**Masterscope** A program analysis tool. When told to analyze a program, Masterscope creates a database of information about the program. In particular, Masterscope knows which functions call other functions and which functions use which variables. Masterscope can then answer questions about the program and display the information with a browser.

**menu** A way of graphically presenting you with a set of options. There are two kinds of menus: pop-up menus are created when needed and disappear after an item has been selected; permanent menus remain on the screen after use until deliberately closed.

**mouse** The mouse is the box attached to your keyboard. It controls the movement of the cursor on your screen. As you become familiar with the mouse, you will find it much quicker to use the mouse than the keyboard.

**Mouse Cursor** The small arrow on the screen that points to the northwest.

**Mouse Cursor Icons** Four types of mouse cursor icons are shown below.

- ![Wait icon](image)
  - Wait. The processor is busy.

- ![Mouse Confirm Cursor](image)
  - The Mouse Confirm Cursor. It appears when you have to confirm that the choice you just made was correct. If it was, press the left button. If the choice was not correct, press the right button to abort.
This means "sweep out" the shape of the window. To do this, move the mouse to a position where you want a corner. Press the left mouse button, and hold it down. Move the mouse diagonally to sketch a rectangle. When the rectangle is the desired size and shape, release the left button.

This is the "move window" prompt. Move the mouse so that the large "ghost" rectangle is in the position where you want the window. When you click the left mouse button, the window will appear at this new location.

NIL

NIL is the Lisp symbol for the empty list. It can also be represented by a left parenthesis followed by a right parenthesis ( ). It is the only expression in Lisp that is both an atom and a list.

pixel

Pixel stands for "picture element." The computer monitor screen is made up of a rectangular array of pixels. Each pixel corresponds to one bit. When a bit is turned on (i.e., set to 1), the pixel on the screen represented by this bit is black.

pretty printing

Pretty printing refers to the way Lisp functions are printed with special indentation, to make them easier to read. Functions are pretty printed in the structure editor, SEdit (see Chapter 7). You can pretty print uncompiled functions by calling the function PP with the function you would like to see as an argument, i.e. (PP function-name). For an example of this, see Figure 1.5.

```
Exec (INTERLISP)
PP PP
PP definition for PP:
(DECLARE (LOCALVARS T))
(PRINT (ALIAS DMASK))
(FUNCTION PP)
  (PP DMASK)
  (LAMBDA X (* --) )
  (DECLARE (LOCALVARS T))
  (PRINTF (ALIAS DMASK X))
  (FUNCTION (LAMBDA NAME))
  
  (RETURN TYPE IN (TYPESOF NAME NIL ' (FIELD))
  
  "CURRENT"
  do (NIL :FORMAT "TERMINAL-ID = A definition for"
  "0.00" TYPE NAME)
  
  (SHOWSAVE NAME TYPE))
```

Figure 1.5. Example of Pretty Printing Function PP

Programmer’s Assistant

The programmer’s assistant accesses the History List to allow you to FIX, UNDO, and/or REDO your previous expressions typed to the executive window (see Chapter 2).

Prompt Window

The narrow black window at the top of the screen. It displays system prompts, or prompts you have developed (see Figure 1.6).
1. BRIEF GLOSSARY

**property list**
A list of the form ( <property-name1> <property-value1> <property-name2> <property-value2> ....) associated with an atom. It accessed by the functions `GETPROP` and `PUTPROP`.

**record**
A record is a data structure that consists of named "fields". Accessing elements of a record can be separated from the details of how the data structure is actually stored. This eliminates many programming details. A record definition establishes a record template, describing the form of a record. A record instance is an actual record storing data according to a particular record template. (See datatype, second definition.)

**Right Button Default Window Menu**
This is the menu that appears when the mouse is in a window, and the right mouse button is pressed. It looks like the menu in Figure 1.7. If this menu does not appear when you press the right button of the mouse and the mouse is in the window, move the mouse so that it is pointing to the title bar of the window, and press the right button.

**s-expression**
Short for "symbolic expression". In Lisp, this refers to any well-formed collection of left parentheses, atoms, and right parentheses.

**stack**
A pushdown list. Whenever a function is entered, information about that specific function call is pushed onto (i.e., added to the front of) the stack. This information includes the variable names and their values associated with the function call. When the function is exited, that data is popped off the stack.

**sysout**
A file containing a whole Lisp environment: namely, everything you defined or loaded into the environment, the windows that appeared on the screen, the amount of memory used, and so on. Everything is stored in the sysout file exactly as it was when the function `SYSOUT` was called.
<table>
<thead>
<tr>
<th><strong>TRACE</strong></th>
<th>A function that creates a trace of the execution of another function. Each time the traced function is called, it prints out the values of the arguments it was called with, and prints out the value it returns upon completion.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>unbound</strong></td>
<td>Without value; an atom is unbound if a value has never been assigned to it.</td>
</tr>
<tr>
<td><strong>window</strong></td>
<td>A rectangular area of the screen that acts as the main display area for some Lisp process,</td>
</tr>
</tbody>
</table>
PREFACE

It was dawn and the local told him it was down the road a piece, left at the first fishing bridge in the country, right at the appletree stump, and onto the dirt road just before the hill. At midnight he knew he was lost.  

Anonymous

Welcome to the Medley Lisp Development Environment, a collection of powerful tools for assisting you in programming in Lisp, developing sophisticated user interfaces, and creating prototypes of your ideas in a quick and easy manner. Unfortunately, along with the power comes mind-numbing complexity. The Medley documentation set describes all the tools in detail, but it would be unreasonable for us to expect a new user to wade through all of it, so this primer is intended as an introduction, to give you a taste of some of the features.

We developed this primer to provide a starting point for new Medley users, to enhance your excitement and challenge you with the potential before you. We're going to make some assumptions about you. For starters, we're going to assume that you're sitting at a workstation that can run Medley. All of the examples in the book figure that you're going to want to try things out. We're also going to assume that you've had some exposure to Lisp, hopefully Common Lisp.

Medley actually consists of two complete Lisp implementations, Common Lisp and InterLisp. All the screen I/O and some of the system functions are in InterLisp. However, thanks to the package system, you can call back and forth between the two languages by simply including a package delimiter in front of a symbol name. This sounds complicated, but it will become clearer once we do some examples.

Throughout we make reference to the Interlisp-D Reference Manual by section and page number. The material in the primer is just an introduction. When you need more depth, use the detailed treatment provided in the manual.

While only you can plot your ultimate destination, you will find this primer indispensable for clearly defining and guiding you to the first landmarks on your way.

Acknowledgements

The early inspiration and model for this primer came from the Intelligent Tutoring Systems group and the Learning Research and Development Center at the University of Pittsburgh. We gratefully acknowledge their pioneering contribution to more effective artificial intelligence.

This primer was originally developed by Computer Possibilities, a company committed to making AI technology available. Primary development and writing was done by Cynthia Cosic, with technical writing support provided by Sam Zordich. It has been re-done by Venue staff to reflect changes in the environment since the original publication.

At Xerox Artificial Intelligence Systems, John Vittal managed and directed the project. Substantial assistance was provided by many members of the AIS staff who provided both editorial and systems support.
2. TYPING SHORTCUTS

Once you have logged in to Medley, you are in Lisp. The functions you type into the Executive Window will now execute, that is, perform the designated task. Lisp is case-sensitive; it often matters whether text is typed in upper- or lowercase letters. Use the Shift-Lock key on your keyboard to ensure that everything typed is in capital letters.

You must type all Lisp functions in parentheses. The Lisp interpreter will read from the left parenthesis to the closing right parenthesis to determine both the function you want to execute and the arguments to that function. Executing this function is called “evaluation.” When the function is evaluated, it returns a value, which is then printed in the Executive Window. This entire process is called the read-eval-print loop, and is how most Lisp interpreters, including the one for Lisp, run.

The prompt in is a number followed by a left-pointing arrow (see Figure 2.3). This number is the function’s position on the History List—a list that stores your interactions with the Lisp interpreter. Type the function (PLUS 3 4), and notice the History List assigns to the function (the number immediately to the left of the arrow). Lisp reads in the function and its arguments, evaluates the function, and then prints the number 7.

Programmer’s Assistant

In addition to this read-eval-print loop, there is also a “programmer’s assistant.” It is the programmer’s assistant that prints the number as part of the prompt in the executive window, and uses these numbers to reference the function calls typed after them.

When you issue commands to the programmer’s assistant, you will not use parentheses as you do with ordinary function calls. You simply type the command, and some specification that indicates which item on the history list the command refers to. Some programmer’s assistant commands are FIX, REDO, and UNDO. They are explained in detail below.

Programmer’s assistant commands are useful only at the Lisp top level, that is, when you are typing into the Executive Window. They do not work in user-defined functions.

As an example use of the programmer’s assistant, use REDO to redo your function call (PLUS 3 4). Type REDO at the prompt (programmer’s assistant commands can be typed in either upper- or lowercase), then specify the previous expression in one of the following ways:

- When you originally typed in the function you now want to refer to, there was a History List number to the left of the arrow in the prompt. Type this number after the programmer’s assistant command. This is the method illustrated in Figure 2-1.

![Figure 2-1. Using a Programmer’s Assistant Command to REDO a Function](image-url)
A negative number will specify the function call typed in that number of prompts ago. In this example, you would type in -1, the position immediately before the current position. This is shown in Figure 2-2.

Figure 2-2. Using a Negative Number after the Programmer's Assistant Command

- You can also specify the function for the programmer's assistant with one of the items that was in that function call. The programmer's assistant will search backwards in the History List, and use the first function it finds that includes that item. For example, type REDO PLUS to have the function (PLUS 3 4) reevaluated.

- If you type a programmer's assistant command without specifying a function (i.e., simply typing the command, following by a Return), the programmer's assistant executes the command using the function entered at the previous prompt.

Figure 2-3 shows a few more examples of how to use the programmer's assistant.

Figure 2-3. Some Applications of the Programmer's Assistant

**If You Make a Mistake**

Editing in the Executive Window is explained in detail in Chapter 7. In the following section, only a few of the most useful commands are repeated.

To move the caret to a new place in the command being typed, point the mouse cursor at the appropriate position. Then press the left mouse button.
To move the caret back to the end of the command being typed, press Control-X (hold the Control key down, and type X).
2. TYPING SHORTCUTS

To delete:

Character behind the caret  Press the Backspace key

Word behind the caret  Press Control-W (hold the Control key down and type W)

Any part of the command  Move the caret to the appropriate place in the command. Hold the right mouse button down and move the mouse cursor over the text. All of the blackened text between the caret and mouse cursor is deleted when you release the right mouse button.

Entire command  Press Control-U (hold the Control key down and type U)

Deletions can be undone. Just press the UNDO key.

To add more text to the line, move the caret to the appropriate position and start to type. Whatever you type will appear at the caret.

3. USING MENUS

The purpose of this chapter is to show you how to use menus. Many things can be done more easily using menus, and there are many different menus provided in the Medley environment. Some are "pop-up" menus that are only available until a selection is made, then disappear until they are needed again. An example of one of these is the Background Menu that appears when the mouse is not in any window and the right mouse button is pressed. A background menu is shown in Figure 3-1. Your background menu may have different items on it.

```
Idle
SaveVM
Snap
Hardcopy
EXEC
PSW
```

Figure 3-1. Background Menu

Another common pop-up menu is the right button default window menu. This menu is explained more in Chapter 6.

Other menus are more permanent, such as the menu that is always available for use with the Filebrowser. This menu is shown in Figure 3-2., and the specifics of its use with the filebrowser are explained in Chapter 5.

```
FB Commands
Delete
Undelete
Copy
Rename
Hardcopy
See
Exit
Load
Compile
Expunge
Recompute
Sort
```

Figure 3-2. Filebrowser Menu

**Making a Selection from a Menu**

To make a selection from a menu, point with the mouse to the item you would like to select. If one of the mouse buttons is already pressed, the menu item should be highlighted in reverse video. If it is a permanent menu, you must press the left mouse button to highlight the item. When you release the button, the item will be selected. Figure 3-3 shows a menu with the item "Undo" chosen.
Explanation of Menu Items

Many menu items have explanations associated with them. If you are not sure what the consequences of choosing a particular menu item will be, highlight the menu item but do not release the left mouse button. If the menu item has an explanation associated with it, the explanation will be printed in the prompt window. Figure 3-4 shows the explanation associated with the item “Snap” from the background menu.

Submenus

Some menu items have submenus associated with them. This means that, for these items, you can make even more precise choices if you would like to.

A submenu can also be found as described below.

As shown in Figure 3-5, a submenu can be indicated by a gray arrow to the right of the menu item. To see the submenu, highlight the menu item and move the mouse to the right to follow the arrow. Choosing an item from a submenu is done the same way you make a choice from the menu. Any submenus that might be associated with the items in the submenu are indicated in the same way as the submenus associated with the items in the menu.
Summary

In summary, here are a few rules of thumb to remember about the interactions of the mouse and system menus:

- Press the left mouse button to select a menu item
- Press the middle mouse button to get more options on a submenu
- Press the right mouse button to see the default right button window menu, and the background menu
4. HOW TO USE FILES

Types of Files

A program file, or Lisp file, contains a series of expressions that can be read and evaluated by the Lisp interpreter. These expressions can include function or macro definitions, variables and their values, properties of variables, and so on. How to save Interlisp-D expressions on these files is explained in Chapter 7. Loading a file is explained in the Simple Commands for Manipulating Files section below.

Not all files, however, have Lisp expressions stored on them. For example, TEdit files store text; sketches are stored on files made with the package Sketch, or can be incorporated into TEdit files. These files are not loaded directly into the environment, but are accessed with the package used to create them, such as TEdit or Sketch.

When you name a file, there are conventions that you should follow. These conventions allow you to tell the type of file by the extension to its name.

If a file contains: Then:

Lisp expressions It should not have an extension or have the extension LISP. For example, a file called MYCODE should contain Lisp expressions.

Compiled Code It should have the extension .LCOM or .DFASL. For example, a file called MYCODE.DFASL should contain compiled code.

A Sketch Its extension should be .SKETCH. For example, a file called MOUNTAINS.SKETCH should contain a Sketch.

Text It should have the extension .TEDIT. For example, a file called REPORT.TEDIT should contain text that can be edited with the editor TEDIT.

Directories

This section focuses on how you can find files, and how you can easily manipulate files. To see all the files listed on a device, use the function DIR. For example, to see what files are stored in your current directory, type:

(DIR *.* )

Partial directory listings can be gotten by specifying a file name, rather than just a device name. The wildcard character * can be used to match any number of unknown characters. For example, the command (DIR T*) will list the names of all files that begin with the letter T. An example using the wildcard is shown in Figure 4-1.
Directory Options

Various words can appear as extra arguments to the `DIR` command. These words give you extra information about the files.

`SIZE` displays the size of each file in the directory. For example, type:

```
(DIR {DSK} SIZE)
```

`DATE` displays the creation date of each file in the directory. An example of this is shown in Figure 4-2.

```
(exec INTERLISP)
126+ (DIR {DSK}/USERS/PORTER/TMP/* DATE)

127+  {DSK}<users>porter>tmp>
DRAFT.TEDIT;1 26-Jan-92 11:26:21
DRAFT2.TEDIT;1 26-Jan-92 11:26:22
128+
```

Figure 4-2. Example Using `DATE`

`DEL` deletes all the files found by the directory command.

Subdirectories

Subdirectories are very helpful for organizing files. A set of files that have a single purpose (for example, all the external documentation files for a system) can be grouped together into a subdirectory.

To associate a subdirectory with a filename, simply include the desired subdirectory as part of the name of the file. Subdirectories are specified after the device name and before the simple filename. The first subdirectory should be between less-than and greater-than signs (angle brackets) `< >`, with nested subdirectory names only followed by a greater than sign `>`. For example:

```
{DSK}<Directory>SubDirectory>SubSubDirectory>...>filename
```

or use the UNIX convention:

```
{DSK}/Directory/Subdirectory/Subsubdirectory/filename
```
To See What Files Are Loaded

If you type FILELST<CR>, the names of all the files you loaded will be displayed.

Type SYSFILES<CR> to see what files are loaded to create the sysout.

Simple Commands for Manipulating Files

When using these functions, always be sure to specify the full filename, including subfile directories if appropriate.

To have the contents of a file displayed in a window:

(SEE ‘filename)

To copy a file (see Figure 4-3):

(COPYFILE ‘oldfilename newfilename)

Figure 4-3. Example Use of COPYFILE

To delete a file (see Figure 4-4):

(DELFILE ‘filename)

Figure 4-4. Example Use of DELFILE

To rename a file:

(RENAMEFILE ‘oldfilename newfilename)

Files that contain Lisp expressions can be loaded into the environment. That means that the information on them is read, evaluated, and incorporated into the Medley environment. To load a file, type:

(LOAD ‘filename)

Connecting to a Directory

Often, each person or project has a subdirectory where files are stored. If this is your situation, you will want any files you create to be put into this directory automatically. This means you should "connect" to the directory.
CONN is the Medley command that connects you to a directory. For example, CONN in Figure 4-5 connects you to the subsubdirectory IM, in the subdirectory PRIMER, the directory LISPFILES, on the device DSK. This information—the device and the directory names down to the subdirectory to which you want to be connected—is called the “path” to that subdirectory. CONN expects the path to a directory as an argument.

```
139+ CONN {dsk}/users/porter/
{DSK}<users>porter>
140+
```

Figure 4-5. CONNECTING TO SUBDIRECTORY PRIMER SUBSUBDIRECTORY IM

Once you are connected to a directory, the command DIR will assume you want to see the files in that directory, or any of its subdirectories.

Other commands that require a filename as an argument (e.g., SEE, above) will assume that the file is in the connected directory if there is no path specified with the filename. This will often save you typing.

File Version Numbers

When stored, each filename is followed by a semicolon and a number, as shown in this example:

```
MYFILE.TEDIT;1
```

The number is the version number of the file. This is the system’s way of protecting your files from being overwritten. Each time the file is written, a new file is created with a version number one greater than the last. This new file will have everything from your previous file, plus all of your changes.

In most cases, you can exclude the version number when referencing the file. When the version is not specified, and there is more than one version of the file on that particular directory, the system generally uses your most recent version. An exception is the function DELFILE, which deletes the oldest version (the one with the lowest version number) if none is specified.
The FileBrowser is a Lisp Library Package that works with files stored on disk and floppy devices, and can be used as a file directory editor. If it is not loaded into your sysout, you need to load it first by typing:

\[
\text{(LOAD 'FILEBROWSER.LCOM)}
\]

### Calling the FileBrowser

Calling the FileBrowser with the directory calls up the files stored in that directory:

\[
\text{(FB '<usr>local>lde>)}
\]

Another way to call a FileBrowser is to choose "FileBrowser" from the background menu. You will be prompted for a description of the files to be included (see Figure 5-1). Type an asterisk (*), then press Return to see all the files in the connected directory.

![Figure 5-1. Prompt for Files to Include in FileBrowser](image)

These show a directory of the device in a window you can leave on the screen at all times. The parts of the FileBrowser window are shown below.
Now you do not need to continually type the directory command.

To use the FileBrowser, choose a file by pointing to the file with the mouse and pressing the left or middle mouse button. A small dark arrow appears to the left of the file name. Choose a command from the menu at the right. In Figure 5-3, the files OCH1.TEDIT;1, OCH10.TEDIT;1, and OCH11.TEDIT;1 have been selected.

The left mouse button only allows you to choose one file at a time. Even if you choose other files, only the last file you selected with the left mouse button will remain marked as chosen. When you use the middle mouse button to select a file, the file is added to those already chosen.

To unpick an already chosen file, hold the Control key down while pressing the middle mouse button.
The next section contains a summary of the FileBrowser commands.

**FileBrowser Commands**

**Delete**
In the FileBrowser, this command marks a file, or files, for deletion (see Figure 5-4). These files are marked by a black line crossing through them. You may select and mark any number of files for deletion. **Delete** does not actually remove these files from the device. The **Expunge** command actually wipes out the files previously marked for deletion.

![Figure 5-4. Files Marked for Deletion](image)

**Undelete**
Undoes the delete command for one or more files. **Undelete** erases the black line through a file marked for deletion.

**Copy**
This command copies the chosen file. The destination filename should be typed at a prompt that appears in the window above the FileBrowser. Wildcards do not work for this prompt. You must type the whole unquoted filename. If more than one file is chosen to be copied, you will be prompted for a directory name. The files will be copied into the directory you give, but with the same filenames as the ones they have in their original location.

**Rename**
This command works much like the **Copy** command, but does not leave the original file. The chosen file will be renamed to the destination filename. You will be prompted, in the prompt window, for the destination filename. Give the complete unquoted filename. If more than one file is chose to be renamed, you will be prompted for a directory name. The files will be moved into the directory you give.

**Hardcopy**
If you do not have a hardcopy device, using this command causes an error. Otherwise, it gives a hardcopy of the file.

**See**
Shows you a file in a window. To use this command, choose a single filename, then the **See** command. You are prompted for a window. Each time the **See** command is chosen, a new window is opened to display the file.

**Edit**
Calls the editor with the file as input. If the file is an executable one (i.e., Lisp code as opposed to a documentation file), only the **FILECOMS** list is edited. The **FILECOMS** list is the list of variables, lists, and
functions that are contained on that file. FileBrowser loads it and then allows you to edit the FILECOMS.

**Load**  Choose a file with the left mouse button, or a group of files with the middle mouse button. Once the filenames have been blackened, choose the Load command to load them all into Medley.

**Compile**  This command calls the file compiler with the chosen filename(s) as arguments. The compiler compiles a file found on a storage device (\texttt{DSK}), not the functions defined in the Medley image. If any functions on a loaded file have been changed, run the function (MAKEFILE 'filename) to write the current version before compiling it. Files do not have to be loaded to use the Compile command.

**Expunge**  This command completely deletes all the marked files from the directory. This allows you to remove unwanted files from your storage device.

**Recompute**  Choose this command when you know that the directory has been changed and should be reread (e.g., after creating new versions of a file).
6. THOSE WONDERFUL WINDOWS!

A window is a designated area on the screen. Every rectangular box on the screen is a window. While Medley supplies many of the windows (such as the Executive Window), you may also create your own. Among other things, you will type, draw pictures, and save portions of your screen with windows.

Windows Provided by Medley

Two important windows are available as soon as you enter the Medley environment. One is the Executive Window, the main window where you will run your functions. It is the window that the caret is in when you turn on your machine, and load Medley. It is shown in Figure 6-1.

![Figure 6-1. Medley Executive Window](image)

The other window that is open when you enter Medley is the "Prompt Window". It is the long thin black window at the top of the screen. It displays system prompts, or prompts you have associated with your programs. (See Figure 6-2.)

![Figure 6-2. Prompt Window](image)

Other programs, such as the editors, also use windows. These windows appear when the program starts to run, and close (no longer appear on the screen) when the program is done running.
Creating a Window

To create a new window, type: \texttt{(CREATEW)}. The mouse cursor will change, and have a small square attached to it. (See Figure 6-3.)

![Figure 6-3. Mouse Cursor Asking You to Sweep Out Window](image)

There may be a prompt in the prompt window to create a window. Press and hold the left mouse button. Move the mouse around, and notice that it sweeps out a rectangle. When the rectangle is the size that you'd like your window to be, release the left mouse button. More specific information about the creation of windows, such as giving them titles and specifying their size and position on the screen when they are created, is given in the \texttt{WINDOWPROP} section of Chapter 12.

Right Button Default Window Menu

Position the cursor inside the window you just created, and press and hold the right mouse button. A menu of commands should appear (do not release the right button!), like the one in Figure 6-4. To execute one of the commands on this menu, choose the item. Making a choice from a menu is explained in Chapter 3.

![Figure 6-4 Right Button Default Window Menu](image)

As an example, select "Move" from this menu. The mouse cursor will become a ghost window (just an outline of a window, the same size as the one you are moving), with a square attached to one corner, like the one shown in Figure 6-5.
THOSE WONDERFUL WINDOWS!

Figure 6-5 Mouse Cursor for Moving a Window

Move the mouse around. The ghost window will follow. Click the left mouse button to place the window in a new location.

Choose “Shape”, and notice that you are prompted to sweep out another window. Your original window will have the shape of the window you sketch out.

Explanation of Each Menu Item

The meaning of each right button default window menu item is explained below:

- **Close**: Removes the window from the screen
- **Snap**: Copies a portion of the screen into a new window
- **Paint**: Allows drawing in a window
- **Clear**: Clears the window by erasing everything within the window boundaries
- **Bury**: Puts the window beneath all other windows that overlap it
- **Redisplay**: Redisplays the window contents
- **Hardcopy**: Sends the contents of the window to a printer or to a file
- **Move**: Allows the window to be moved to a new spot on the screen
- **Shape**: Repositions and/or reshapes the window
- **Shrink**: Reduces the window to a small black rectangle called an icon, or, if appropriate, to the shape for that window type (see Figure 6-6).

![Figure 6-6 Example Icon](image)

Expand: Changes an icon back to its original window. Position the mouse cursor on the icon, depress the right button, and select Expand. Or, just button the icon with the middle mouse button.

These right-button default window menu selections are available in most windows, including the Executive Window. When the right button has other functions in a window (as in an editor window), the right button default window menu should be accessible by pressing the Right button in the black border at the top of the window.
Scrollable Windows

Some windows in Medley are "scrollable". This means that you can move the contents of the window up and down, or side to side, to see anything that doesn't fit in the window.

Point the mouse cursor to the left or bottom border of a window. If the window is scrollable, a "scroll bar" will appear. The mouse cursor will change to a double headed arrow. (See Figure 6-7.)

![Figure 6-7. Scroll Bar of Scrollable Window](image)

The scroll bar represents the full contents of the window. The example scroll bar is completely white because the window has nothing in it. When a part of the scroll bar is shaded, the amount shaded represents the amount of the window's contents currently shown. If everything is showing, the scroll bar will be fully shaded. (See Figure 6-8.) The position of the shading is also important. It represents the relationship of the section currently displayed to the full contents of the window. For example, if the shaded section is at the bottom of the scroll bar, you are looking at the end of the file.

![Figure 6-8 Top of File When Shading at Top of Scroll Bar](image)

When the scroll bar is visible, you can control the section of the window's contents displayed:

- To move the contents higher in the window (scroll the contents up in the window), press the left button of the mouse, the mouse cursor changes to look like this:

![Figure 6-9. Upward Scrolling Cursor](image)
The contents of the window will scroll up, making the line that the cursor is beside the topmost line in the window.

- To move the contents lower in the window (scroll the contents "down" in the window), press the right button of the mouse, and the mouse cursor changes to look like this:

  ![Downward Scrolling Cursor](image)

  **Figure 6-10. Downward Scrolling Cursor**

- To show a specific section of the window's contents, remember that the scroll bar represents the full contents of the window. Move the mouse cursor to the relative position of the section you want to see (e.g., to the top of the scroll bar if you want to see the top of the window's contents). Press the middle button of the mouse. The mouse cursor will look like this:

  ![Proportional Scrolling Cursor](image)

  **Figure 6-11 Proportional Scrolling Cursor**

  When you release the middle mouse button, the window's contents at that relative position will be displayed.

  The position of the mouse in the scroll bar defines how much of the window will be scrolled. If it is near the top, then only a little will be scrolled. If it is near the bottom, most of the window will be scrolled.

### Other Window Functions

**PROMPTPRINT**

Prints an expression to the black prompt window.

For example, type

(PROMPTPRINT "THIS WILL BE PRINTED IN THE PROMPT WINDOW")

The message will appear in the prompt window. (See Figure 6-12.)
6. THOSE WONDERFUL WINDOWS!

**WHICHW**

Returns as a value the name of the window that the mouse cursor IS in.

`(WHICHW)` can be used as an argument to any function expecting a window, or to reclaim a window that has no name (that is not attached to some particular part of the program.).
7. EDITING AND SAVING

This chapter explains how to define functions, how to edit them, and how to save your work.

Defining Functions

DEFUN can be used to define new functions. The syntax for it is:

```
(DEFUN (<functionname> (<parameter-list><body-of-function>))
```

New functions can be created with DEFUN by typing directly into the Executive Window. Once defined, a function is a part of the Medley environment. For example, the function EXAMPLE-ADDER is defined in Figure 7-1.

![Figure 7-1. Defining the Function EXAMPLE-ADDER](image)

Now that the function is defined, it can be called from the Executive Window:

![Figure 7-2. After EXAMPLE-ADDER is defined, it can be executed](image)

The function returns 6, after printing out the message.

Functions can also be defined using the editor DEdit described above. To do this, simply type

```
(ED function-name 'FUNCTIONS)
```

You will be told that no definition exists for the function, and a menu will pop up asking you what type of function you would like to create:
**7. EDITING AND SAVING**

**Exec 3 (XCL)**

NIL
3/39 (ed 'foo 'functions)
FOO has no FUNCTIONS definition.
Select a definer to use for a dummy definition.

<table>
<thead>
<tr>
<th>Select a definer for a dummy defn:</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINE-MODIFY-MACRO</td>
</tr>
<tr>
<td>DEFINE-MACRO</td>
</tr>
<tr>
<td>DEFINE-LINE</td>
</tr>
<tr>
<td>DEFUN</td>
</tr>
<tr>
<td>DEFDEFINER</td>
</tr>
<tr>
<td>Don’t make a dummy defn</td>
</tr>
</tbody>
</table>

---

**Figure 7-3 Selecting a Function Template**

Selecting the appropriate type will pop up an editor window with a function template. The use of the editor is explained in the Using the List Structure Editor section below.

---

**Simple Editing in the Executive Window**

First, type in an example function to edit:

```lisp
3/41> (defun your-first-function (a b)
  (if (> a b)
    '(the first is greater)
    '(the second is greater))
```

To run the function, type:

```lisp
3/42> (YOUR-FIRST-FUNCTION 3 5)
(THREE IS GREATER)
```

Now, let's alter this. Type:

```lisp
3/43> FIX 41
```

Note that your original function is redisplayed, and ready to edit. (See Figure 7-4.)

---

**Exec 3 (XCL)**

YOUR-FIRST-FUNCTION
3/47> fix 41
3/47> (defun your-first-function (a b)
  (if (> a b)
    '(THE FIRST IS GREATER)
    '(THE SECOND IS GREATER)))

---

**Figure 7-4. Using FIX to Edit a Function**

**Move** the text cursor to the appropriate place in the function by positioning the mouse cursor and pressing the left mouse button.

**Delete** text by moving the caret to the beginning of the section to be deleted. Hold the right mouse button down and move the mouse cursor over the text. All of the highlighted text between the caret and mouse cursor is deleted when you release the right mouse button.

**If you make a mistake**, deletions can be undone. Press the UNDO key on the keypad to the left of the keyboard.

**Now change** GREATER to BIGGER:
1. Position the mouse cursor on the G of GREATER, and click the left mouse button. The text cursor is now where the mouse cursor is.

2. Next, press the right mouse button and hold it down. Notice that if you move the mouse cursor around, it will blacken the characters from the text cursor to the mouse cursor. Move the mouse so that the word "GREATER" is highlighted.

3. Release the right mouse button and GREATER is deleted.

4. Without moving the cursor, type in BIGGER.

5. There are two ways to end the editing session and run the function. One is to type Control-X. (Hold the Control key down, and type X.) Another is to move the text cursor to the end of the line and crø In both cases, the function has been edited!

Try the new version of the function by typing:

\[
3/48\text{-}48 (\text{YOUR-FIRST-FUNCTION 8 9)}
\]

(The SECOND IS BIGGER)

and get the new result, or you can type:

\[
3/49\text{-}49 \text{ RE}DO 42
\]

(The SECOND IS BIGGER)

**Using the List Structure Editor**

If the function you want to edit is not readily available (i.e. the function is not in the Executive Window, and you can't remember the history list number, or you simply have a lot of editing), use the List Structure Editor, often called SEdit. This editor is evoked with a call to ED:

\[
81\text{-}81 (\text{ED 'YOUR-FIRST-FUNCTION 'FUNCTIONS})
\]

Your function will be displayed in an edit window, as in Figure 7-5.

If there is no edit window on the screen, you will be prompted to create a window. As before, hold the left mouse button down, move the mouse until it forms a rectangle of an acceptable size and shape, then release the button. Your function definition will automatically appear in this edit window.

```
SEdit:YOUR-FIRST-FUNCTION Package: XCL-USER
\[\text{DEFUN YOUR-FIRST-FUNCTION (A B)}
\]
\[
\text{(IF (> A B)}
\]
\[
\text{(THE FIRST IS GREATER)}
\]
\[
\text{'(THE SECOND IS GREATER)'))
\]
```

Figure 7-5. An Edit Window

Many changes are easily done with the structure editor. Notice that by pressing the left mouse button you can place the caret in position, and by pressing the middle mouse button you can select atoms or s-expressions. Repeated pressing of the middle button selects bigger pieces of text.
To add an expression that does not appear in the edit window (i.e., it cannot simply be underlined), place the caret at the insertion point and type it in. For example, to replace the first \texttt{GREATER} with \texttt{LARGER}, place the caret to the left of \texttt{GREATER}, as shown in Figure 7-6.

\begin{verbatim}
  (DEFUN YOUR-FIRST-FUNCTION (A B)
    (IF (> A B)
        '(THE FIRST IS GREATER)
        '(THE SECOND IS GREATER)))
\end{verbatim}

\textbf{Figure 7-6. Caret Placement Prior to Changing GREATER with LARGER}

Now press the DELETE key seven times, and type in \texttt{LARGER}. The window now looks like this:

\begin{verbatim}
  (DEFUN YOUR-FIRST-FUNCTION (A B)
    (IF (> A B)
        '(THE FIRST IS LARGER)
        '(THE SECOND IS GREATER)))
\end{verbatim}

\textbf{Figure 7-7. GREATER Changed to LARGER}

Notice the asterisk in the left edge of the title bar of the window. This designates that the function has been changed. Now exit the edit session by typing Control-X, and the function will be redefined.

\section*{Commenting Functions}

Text can be marked as a comment by typing a semi-colon before the text of the comment.

\begin{verbatim}
  ; This is the form of a comment
\end{verbatim}

Inside an editor window, the comment will be printed in a different font and may be moved to the far right of the code. SE\textit{dit} is familiar with the Common Lisp convention of single comments being on the far right, double comments being justified with the function level, and triple comments being on the far left, as is shown in Figure 7-8.

\begin{verbatim}
  ; ; ; print out the appropriate text
  ; ; ; check for a > b
  ; (THE FIRST IS LARGER)
  ; (THE SECOND IS GREATER))
  ; ; ; Now we're done
\end{verbatim}
7. EDITING AND SAVING

There are other editor commands which can be very useful. To learn about them, read Appendix B of the Release Notes.

File Functions and Variables: How to See and Save Them

With Medley, all work is done inside the Lisp environment. There is no operating system or command level other than the Executive Window. All functions and data structures are defined and edited using normal Lisp commands. This section describes tools in the Medley environment that will keep track of any changes that you make in the environment that you have not yet saved on files, such as defining new functions, changing the values of variables, or adding new variables. And it then has you save the changes in a file you specify. All of these functions are in the INTERLISP (IL:) package.

File Variables

Certain system-defined global variables are used by the file package to keep track of the environment as it stands. You can get system information by checking the values of these variables. Two important variables follow.

- **FILELST** evaluates to a list, all files that you have loaded into the Medley environment.

- **filenameCOMS** (Each file loaded into the Lisp environment has associated with it a global variable, whose name is formed by appending COMS to the end of the filename.) This variable evaluates to a list of all the functions, variables, bitmaps, windows, and soon, that are stored on that particular file.

For example, if you type:

```lisp
MYFILECOMS
```

the system will respond with something like:

```lisp
((FNS YOUR-FIRST-FUNCTION )
 VARS))
```

Saving Interlisp-D on Files

The functions `(FILES?)` and `(MAKEFILE 'filename)` are useful when it is time to save function, variables, windows, bitmaps, records and whatever else to files.

`(FILES?)` displays a list of variables that have values and are not already a part of any file, and then the functions that are not already part of any file.

Type:

```lisp
.FILES?
```

the system will respond with something like:

```
the variables: MY.VARIABLE CURRENT.TURTLE...to be dumped
```
the functions: RIGHT LEFT FORWARD BACKWARD CLEAR-SCREEN...to be dumped

want to say where the above go?

If you type Y, the system will prompt with each item. There are three options:

1. To save the item, type the filename (unquoted) of the file where the item should be placed. (This can be a brand new file or an existing file.)

2. To skip the item, without removing it from consideration the next time (FILES?) is called, type crø This will allow you to postpone the decision about where to save the item.

3. If the item should not be saved at all, type }. Nowhere will appear after the item.

Part of an example interaction is shown in the following figure:

```
Exec (INTERLISP)
> (FILES?)
To be dumped:
NEWFILE ...changes to VARS: NEWFILECOMS
   FNS: TEST
   plus the Common Lisp structures: MyStruct
   plus the functions: Function
want to say where the above go? yes
(Common Lisp structures)
MyStruct Nowhere
(functions)
Function File name: NFILE
create new file NFILE? yes
To be compiled: FOREIGN-FUNCTIONS, FOO
To be listed: PAINT, FOREIGN-FUNCTIONS, FOO, COURIERSERVER
```

Figure 7-9. Part of an interaction using the function FILES?

(FILES?) assembles the items by adding them to the appropriate file’s COMS variable (see the File Variables section above). (FILES?) does NOT write the file to secondary storage (disks or floppies). It only updates the global variables discussed in the File Variables section above.

(MAKEFILE ‘filename)

actually writes the file to secondary storage.

Type:

(MAKEFILE ‘MY.FILE.NAME)

and the system will create the file. The function returns the full name of the file created. (i.e. {DSK}MY.FILE.NAME.; 1).
Files written to (DSK) are permanent files. They can be removed only by the user deleting them or by reformatting the disk.

Other file manipulation functions can be found in Chapter 4.
8. YOUR INIT FILE

Lisp has a number of global variables that control the environment. Global variables make it easy to customize the environment to fit your needs. One way to do this is to develop an INIT file. This is a file that is loaded when you start an image. You can use it to set variables, load files, define functions, and any other things that you want to do to make the Medley environment suit you.

Using the USERGREETFILES Variable

As described in File Variables section of Chapter 11, each program file has a global variable associated with it, whose name is formed by appending COMS to the end of the root filename. For any of the standard INIT file names, the variable INITCOMS is used.

To set up an init file, begin by editing this variable. Type:

```
(DV INITCOMS)
```

Making an Init File

As described in File Variables section of Chapter 11, each program file has a global variable associated with it, whose name is formed by appending COMS to the end of the root filename. For any of the standard INIT file names, the variable INITCOMS is used. To set up an init file, begin by editing this variable. Type:

```
(DV INITCOMS)
```
An SEdit window will appear. This window is the same as the one called with the function DF, and described in the Using the List Structure Editor section in Chapter 7. This chapter assumes that you know how to use the SEdit structure editor.

The COMS variable is a list of lists. The first atom in each internal list specifies for the file package what types of items are in the list, and what it is to do with them. This section will deal with three types of lists: VARS, FILES, and P. Please read about others in Chapter 17 of the IRM.

Notice that inside the vars list, there is yet another list. The first item in the list is the name of the variable. It is bound to the value of the second item. There are many other variables that you can set by adding them to the VARS list. Some of these variables are described in Chapter 24, and many others can be found in the IRM.

If you want to automatically load files, that can be done in your init file also. For example, if you always want to load the library file SPY.LCOM, you can load it by editing the INITCOMS variable to list the appropriate file in the list starting with FILES:

```
  .
  .
  (FILES SPY)
  .
  .
```

Figure 8-2. INITCOMS Changed to Load SPY.LCOM File

Other files can also be added by simply adding their names to this FILES list.

Another list that can appear in a COMS list begins with P. This list contains Lisp expressions that are evaluated when the file is loaded. Do not put DEFINEQ expressions in this list. Define the function in the environment, and then save it on the file in the usual way (see Chapter 7).

One type of expression you might want to see here, however, is a FONTCREATE function (see Chapter 16). For example, if you want to use a Helvetica 12 BOLD font, and there is not a fontdescriptor for it normally in your environment, the appropriate call to FONTCREATE should be in the "P" list. The INITCOMS would look like this:

```
  .
  .
  (FILES SPY)
  (P (FONTCREATE 'HELVETICA 12 'BOLD))
  .
  .
```

Figure 8-3. INITCOMS Edited to Include a call to FONTCREATE

To quit, exit from SEdit in the usual way. When you run the function MAKEFILES (see Chapter 7), be sure that you are connected to the directory (see Chapter 4) where the INIT file should appear. Now when GREET is run, your Init file will be loaded.
9. MEDLEY FORGIVENESS: DWIM

**DWIM** (Do What I Mean) is an Interlisp utility that makes life easier.

**DWIM** tries to match unrecognized variable and function names to known ones. This allows Lisp to interpret minor typing errors or misspellings in a function, without causing a break. Line 152 of Figure 9-1 illustrates how the misspelled **BANNANNA** was replaced by **BANANA** before the expression was evaluated.

```
<table>
<thead>
<tr>
<th>Exec (INTERLISP)</th>
</tr>
</thead>
<tbody>
<tr>
<td>151+ (DEFINEQ (PEEL (BANANA) (CDR BANANANNA)))</td>
</tr>
<tr>
<td>152+ (PEEL '(A B D))</td>
</tr>
<tr>
<td>BANANANNA {in PEEL} → BANANA ? Yes</td>
</tr>
<tr>
<td>(B D)</td>
</tr>
<tr>
<td>153+</td>
</tr>
</tbody>
</table>
```

Figure 9-1. Examples of **DWIM** Features

Sometimes **DWIM** may alter an expression you didn't want it to. This may occur if, for example, a hyphenated function name (e.g., **(MY-FUNCTION)**) is misused. If the system does not recognize the function name, it may think you are trying to subtract "FUNCTION" from "MY". **DWIM** also takes the liberty of updating the function, so it will have to be fixed. However, this is as much a blessing as a curse, since it points out the misused expression!
10. BREAKPACKAGE

The Break Package is a part of Interlisp that makes debugging your programs much easier.

Break Windows

A break is a function either called by the programmer or by the system when an error has occurred. A separate window opens for each break. This window works much like the Executive Window, except for extra menus unique to a break window. Inside a break window, you can examine variables, look at the call stack at the time of the break, or call the editor. Each successive break opens a new window, where you can execute functions without disturbing the original system stack. These windows disappear when you resolve the break and return to a higher level.

Break Package Example

This example illustrates the basic break package functions. A more complete explanation of the breaking functions, and the break package will follow.

The correct definition of FACTORIAL is:

```
(defun factorial (x)
  (if (zerop x)
      1
      (* x (factorial (1 - x)))))
```

To demonstrate the break package, we have edited in an error: DUMMY in the IF statement is an unbound atom, it lacks a value.

```
(defun factorial (x)
  (if (zerop x)
      dummy
      (* x (factorial (1 - x)))))
```

The evaluated function

```
(factorial 4)
```

should return 24, but the above function has an error. DUMMY is an unbound atom, an atom without an assigned value, so Lisp will "break". A break window appears (Figure 10-1), that has all the functionality of the typing lisp expressions into the Executive Window (The top level), in addition to the break menu functions. Each consecutive break will move to another level "down".
Move the mouse cursor into the break window and hold down the middle mouse button. The Break Menu will appear. Choose BT. Another menu, called the stack menu, will appear beside the break window. Choosing stack items from this menu will display another window. This window displays the function’s local variable bindings, or values (see Figure 10-2). This new window, titled FACTORIAL Frame, is an inspector window (see inspector Chapter 17).

From the break window, you can call the editor for the function FACTORIAL by middle-buttonning on the word FACTORIAL and selecting DisplayEdit from the menu that pops up.

Replace the unbound atom DUMMY with 1. Exit the editor.

The function is fixed, and you can restart it from the last call on the stack. (It does not have to be started again from the Top Level.) To begin again from the last call on the stack, choose the last (top) FACTORIAL call in the BT menu. Select REVERT from the middle button break window, or type it into the window. The break window will close, and a new one will appear with the message: Breakpoint at FACTORIAL

To start execution with this last call to FACTORIAL, choose OK from the middle button break menu. The break window will disappear, and the correct answer, 24, will be returned to the top level.
Ways to Stop Execution from the Keyboard (Breaking Lisp)

There are ways you can stop execution from the keyboard. They differ in terms of how much of the current operating state is saved:

Control-G Provides you with a menu of processes to interrupt. Your process will usually be "EXEC". Choose it to break your process. A break window will then appear.

Control-B Causes your function to break, saves the stack, then displays a break window with all the usual break functions. For information on other interrupt characters, see Chapter 30 in the IRM.

Break Menu

Move the mouse cursor into the break window. Hold the middle button down, and a new menu will pop up, like the one in Figure 10-3.

![Middle Button Menu in Break window](image)

Five of the selections are particularly important when just starting to use Medley:

**BT** Back Trace displays the stack in a menu beside the break window. Back Trace is a very powerful debugging tool. Each function call is placed on the stack and removed when the execution of that function is complete. Choosing an item on the stack will open another window displaying that item's local variables and their bindings. This is an inspector window that offers all the power of the inspector. (For details, see the section on the Inspector, Chapter 17.)

? = Before you use this menu option, display the stack by choosing BT from this menu, and choose a function from it. Now, choose ?. It will display the current values of the arguments to the function that has been chosen from the stack.

↑ Move back to the previous break window, or if there is no other break window, back to the top level, the Executive Window.

**REVERT** Move the point of execution back to a specified function call before the error. The function to revert back to is, by default, the last function call before the break. If, however, a different function call is chosen on the BT menu, revert will go back to the start of this function and open a new break window. The items on the stack above the new starting place will no longer exist. This is used in the tutorial example (see the Break Package Example section above).
OK  Continue execution from the point of the break. This is useful if you have a simple error, i.e., an unbound variable or a nonnumeric argument to an arithmetic function. Reset the variable in the break window, then select OK. (see the Break Package Example section above).

In addition to being available on the middle button menu of the break window, all of these functions can be typed directly into the window. Only BT behaves differently when typed. It types the stack into the trace window instead of opening a new window.)

Returning to Top Level

Typing Control-D will immediately take you to the top level from any break window. The functions called before the break will stop, but any side effects of the function that occurred before the break remain. For example, if a function set a global variable before it broke, the variable will still be set after typing Control-D.
11. WHAT TO DO IF ...

The purpose of this chapter is to explain what to do in some of the problems commonly experienced by Medley users.

**Executive Window turns black**

An example is shown in Figure 11-1.

Press any key to unfreeze the window and continue. This pause happens when the command you just typed causes enough information to be printed to fill the window. It gives you a chance to read that one window of text before moving on.

![Figure 11-1. Blackened Executive Window](image)

**You closed the Executive Window**

Open another from the Background Menu.

**Mouse disappears**

Type \texttt{(CURSOR T)} in the Executive Window. The cursor will reappear.

**Second window appears**

This probably happens because you made a typing mistake, as in Figure 11-2.

![Figure 11-2. Second Window Appears (Break Window) after Typing Error Made](image)

Type a Control-D by simultaneously pressing the Control key and the "D". This aborts the error condition, returning control to the Executive Window.

**You keep getting beeped at**

Usually the beeping means that Medley want input from you. Look for the flashing caret. It will usually be preceded by some kind of prompt, indicating what you should type.
11. WHAT TO DO IF...

You cannot delete the first letter

of the filename you are typing to (FILES?). Type Control-E (error) You will get a
linefeed and ←←← printed to the window. Now type the correct filename.

Your function is just sitting there

It is not returning a value, and you think that your program may be in an infinite loop
or is having some other major problem. You can see what process is currently running
by typing Control-T, or you could interrupt the process by typing Control-E.

A Break Window appears

If the Break Window look something like that shown in Figure 11-3, you are trying to
save a file, but there is not enough space on the hard disk.

![Figure 11-3. Break Window Caused by Insufficient Space in Save File](image)

Exit from the Break Window by typing an up arrow ↑ followed by a Return. Delete old
versions of files, and any other files you do not need. Then try again to save the file.

You have run out of space

Generally, a Break Window has appeared. The GAINSPACE function allows you to
delete non-essential data structures. To use it, type:

```
(GAINSPACE)
```

into the Executive Window. Answer N to all questions except the following:

- Delete edit history
- Delete history list
- Delete values of old variables
- Delete your MASTERSCOPE database
- Delete information for undoing your greeting.

Save your work and reload Lisp as soon as possible.

A redefined message appears

The message (Some.Crucial.Function.Or.Variable redefined) appears in the
Executive Window (see Figure 11-4). The function, variable, or other property has been
"smashed" (i.e., its original definition has been changed). If this is not what you
wanted, type UNDO immediately!
UNBOUND ATOM

If this occurs, you probably just typed something wrong, or you passed an argument that should have been quoted to a function.

UNDEFINED CAR OF FORM

First, look at what caused the error. If the CAR of the form is a list, then you typed something wrong. If it is an atom, then perhaps that atom does not have a function associated with it. If it is a CLISP word like if or for, then DWIM may have been turned off (see Chapter 9). Type (DWIM ‘c) to reenable DWIM.

You have traced APPLY

and your screen is spewing out information about everything going on in the environment. Type Control E, and type (UNBREAK ‘APPLY) before rereturning to the Executive.
12.  WINDOWS AND REGIONS

Windows

Windows have two basic parts: an area on the screen containing a collection of pixels, and a property list. The window properties determine how the window looks, the menus that can be accessed from it, what should happen when the mouse is inside the window and a mouse button is pressed, and soon.

CREATEW

Some of the window's properties can be specified when a window is created with the function CREATEW. In particular, it is easy to specify the size and position of the window; its title; and the width of its borders.

\[(\text{CREATEW region title borderwidth})\]

Region is a record (named REGION, with the fields left, bottom, width, and height) or a list. A region describes a rectangular area on the screen, the window's dimensions and position. The fields left and bottom refer to the position of the bottom left corner of the region on the screen. Width and height refer to the width and height of the region. The usable space inside the window will be smaller than the width and height, because some of the window's region is consumed by the title bar, and some is taken by the borders.

Title is a string that will be placed in the title bar of the window.

Borderwidth is the width of the border around the exterior of the window, in number of pixels.

For example, typing:

\[(\text{SETQ MY.WINDOW (CREATEW (CREATEREGION 100 150 300 200) "THIS IS MY OWN WINDOW")})\]

or

\[(\text{SETQ MY.WINDOW (CREATEW (CREATEW '(100 150 300 200) "THIS IS MY OWN WINDOW")})}\]

produces a window with a default borderwidth. Note that you did not need to specify all the window's properties (see Figure 12-1).
In fact, if `(CREATEW)` is called without specifying a region, you will be prompted to sweep out a region for the window (see Chapter 10)

**WINDOWPROP**

The function to access or add to any property of a window’s property list is `WINDOWPROP`.

```
(WINDOWPROP window property <value>)
```

When you use `WINDOWPROP` with only two arguments—window and property—it returns the value of the window’s property. When you use `WINDOWPROP` with all three arguments—window, property and value—it sets the value the window’s property to the value you inserted for the third argument.

For example, consider the window, MY WINDOW, created using `(CREATEW)`. TITLE and REGION are both properties. Type

```
(WINDOWPROP MY.WINDOW 'TITLE)
```

and the value of MY.WINDOW’s TITLE property is returned, "THIS IS MY OWN WINDOW". To change the title, use the `WINDOWPROP` function, and give it the window, the property title, and the new title of the window.

```
(WINDOWPROP MY.WINDOW 'TITLE "MY FIRST WINDOW")
```

automatically changes the title and automatically updates the window. Now the window looks like Figure 12-2.
Figure 12-2. TITLE is a Window Property

Altering the region of the window, MY.WINDOW, is also be done with WINDOWPROP, in the same way you changed the title. (Changing either of the first two numbers of a region changes the position of the window on the screen. Changing either of the last two numbers changes the dimensions of the window itself.)

Getting Windows to Do Things

Four basic window properties will be discussed here: CURSORINFN, CURSOROUTFN, CURSORMOVEDFN, and BUTTONEVENTFN.

A function can be stored as the value of the CURSORINFN property of a window. It is called when the mouse cursor is moved into that window.

Look at the following example:

1. First, create a window called MY.WINDOW. Type:

   (SETQ MY.WINDOW
       (CREATEW
            (CREATEREGION 200 200 200 200)
            "THIS WINDOW WILL SCREAM!"))

   This creates a window.

2. Now define the function SCREAMER. It will be stored on the property CURSORINFN. (Notice that this function has one argument, WINDDOWNAME. All functions called from the property CURSORINFN are passed the window it was called from. So the value of MY.WINDOW is bound to WINDDOWNAME. When it is called, SCREAMER simply rings bells.)
(DEFINEQ (SCREAMER (WINDOWNAME)
   (RINGBELLS)
   (PROMPTPRINT "YAY - IT WORKS!")
   (RINGBELLS)))

3. Now, alter that window's CURSORINFN property, so that the system calls the function SCREAMER at the appropriate time. Type:

   (WINDOWPROP MY.WINDOW 'CURSORINFN
   (FUNCTION SCREAMER))

4. After this, when you move the mouse cursor into MY.WINDOW, the CURSORINFN property's function is called, and it rings bells twice.

CURSORINFN is one of the many window properties that come with each window - just as REGION and TITLE did. Other properties include:

CURSOROUTFN The function that is the value of this property is executed when the cursor is moved out of a window.

CURSORMOVEDFN The function that is the value of this property is executed when the cursor is moved while it is inside the window.

BUTTONEVENTFN The function that is the value of this property is executed when either the left or middle mouse buttons are pressed (or released).

Figure 12-3 shows MY.WINDOW's properties. Notice that the CURSORINFN has the function SCREAMER stored in it. The properties were shown in this window using the function INSPECT. INSPECT is covered in Chapter 17.

Figure 12-3. Inspecting MY.WINDOW for Mouse-Related Window Properties
You can define functions for the values of the properties CURSOROUTFN and CURSORMOVEDFN in much the same way as you did for CURSORINFN. The function that is the value of the property BUTTONEVENTFN, however, can be specialized to respond in different ways, depending on which mouse button is pressed. This is explained in the next section.

**BUTTONEVENTFN**

BUTTONEVENTFN is another property of a window. The function that is stored as the value of this property is called when the mouse is inside the window, and a mouse button is pressed. As an example of how to use it, type:

```
(WINDOWPROP MY.WINDOW 'BUTTONEVENTFN
 (FUNCTION SCREAMER))
```

When the mouse cursor is moved into the window, bells will ring because of the CURSORINFN, but it will also ring bells when either the left or middle mouse button is pressed. Notice that the right mouse button functions as it usually does, with the window manipulation menu. If only the left button should evoke the function SCREAMER, then the function can be written to do just this, using the function MOUSESTATE, and a form that only MOUSESTATE understands, ONLY. For example:

```
(DEFINEQ
 (SCREAMER2 (WINDOWNAME)
 (if (MOUSESTATE (ONLY LEFT))
 then (RINGBELLS)))
```

In addition to (ONLY LEFT), MOUSESTATE can also be passed (ONLY MIDDLE), (ONLY RIGHT) or combinations of these (e.g. (OR (ONLY LEFT) (ONLY MIDDLE))). You do not need to use ONLY with MOUSESTATE for every application. ONLY means that that button is pressed and no other.

If you do write a function using (ONLY RIGHT), be sure that your function also checks position of the mouse cursor. Even if you want your function to be executed when the mouse cursor is inside the window and the right button is pressed, there is a convention that the function DOWINDOWCOM should be executed when the mouse cursor is in the title bar or the border of the window and the right mouse button is pressed. Please program your windows using this tradition! For more information, please see Chapter 28 in the IRM.

**Looking at a Window’s Properties**

INSPECT is a function that displays a list of the properties of a window, and their values. Figure 12.3 shows the INSPECT function run with MY.WINDOW. Note the properties introduced in CREATEW: WBORDER is the window's border, REG is the region, and WTITLE is the window's title.

**Regions**

A region is a record, with the fields LEFT, BOTTOM, WIDTH, and HEIGHT. LEFT and BOTTOM refer to where the bottom left hand corner of the region is positioned on the screen. WIDTH and HEIGHT refer to the width and height of the region.
CREATEREGION creates an instance of a record of type REGION. Type:

```
(SETQ MY.REGION (CREATEREGION 15 100 200 450))
```

To create a record of type REGION that denotes a rectangle 200 pixels high, and 450 pixels wide, whose bottom left corner is at position (15, 100). This record instance can be passed to any function that requires a region as an argument, such as CREATEW, above.
13. WHAT ARE MENUS?

While Medley provides a number of menus of its own (see Chapter 3), this section addresses the menus you wish to create. You will learn how to create a menu, display a menu, and define functions that make your menu useful. Menus are instances of records (see Chapter 24). There are 27 fields that determine the composition of every menu. Because Medley provides default values for most of these descriptive fields, you need to familiarize yourself with only a few that we describe in this section.

Two of these fields, the TITLE of your menu, and the ITEMS you wish it to contain, can be typed into the executive window as shown below:

```
Exec 2 (INTERLISP)
2/154+ (SETQ MY.MENU (CREATE MENU
  TITLE + "PLEASE CHOOSE ONE OF THE
  ITEMS"
  ITEMS + '(QUIT NEXT-QUESTION
            NEXT-TOPIE SEE-TOPIE)))
{MENU}#371,223164
2/155+  
```

Figure 13-1. Creating a menu

Note that creating a menu does not display it. MY . MENU is set to an instance of a menu record that specifies how the menu will look, but the menu is not displayed.

Displaying Menus

Typing either the MENU or ADDMENU functions will display your menu on the screen. MENU implements pop-up menus, like the Background Menu or the Window Menu. ADDMENU puts menus into a semi-permanent window on the screen, and lets you select items from it.

(MENU MENU POSITION) pops up a menu at a particular position on the screen.

Type:

```
(MENU MY.MENU NIL)
```

to position the menu at the end of the mouse cursor. Note that the POSITION argument is NIL. In order to go on, you must either choose an item, or move outside the menu window and press a mouse button. When you do either, the menu will disappear. If you choose an item, then want to choose another, the menu must be redisplayed.

(ADDMENU menu window position) positions a permanent menu on the screen, or in an existing window.

Type:

```
(ADDMENU MY.MENU)
```

to display the menu as shown in Figure 13-2. This menu will remain active, (will stay on the screen) without stopping all the other processes. Because ADDMENU can display a menu without stopping all other processes, it is very popular in users programs.
13. WHAT ARE MENUS?

If window is specified, the menu is displayed in that window. If window is not specified, a window the correct size for the menu is created, and the menu is displayed in that window.

If position is not specified, the menu appears at the current position of the mouse cursor.

Getting Menus to Do Stuff

One way to make a menu do things is to specify more about the menu items. Instead of items simply being the strings or atoms that will appear in the menu, items can be lists, each list with three elements (see Figure 13-3). The first element of each list is what will appear in the menu; the second expression is what is evaluated, and the results of the evaluation returned, when the item is selected; and the third expression is the expression that should be printed in the Prompt window when a mouse button is held down while the mouse is pointing to that menu item. This third item should be thought of as help text for the user. If the third element of the list is NIL, the system responds with Will select this item when you release the button.

Example:

```
100+ (setq MY-MENU2 (create menu
   title "PLEASE CHOOSE ONE OF THE ITEMS"
   items '((quit (print "STOPPED") "CHOOSE THIS TO STOP")
            (next-question
              (print "HERE IS THE NEXT QUESTION...")
              "CHOOSE THIS TO BE ASKED THE NEXT QUESTION")
            (next-topic
              (print "HERE IS THE NEXT TOPIC...")
              "CHOOSE THIS TO MOVE ON TO THE NEXT TOPIC")
            (see-topics
              (print "THE FOLLOWING HAVE NOT BEEN COVERED")
              "CHOOSE THIS TO SEE TOPICS NOT YET LEARNED")
            (stop)))))
```

```
100* (admenu my-menu2)
101* (window) #343,132150
110* (princ)
```

Figure 13-3. Creating a Menu to do Things, then displaying it with the function ADMMENU
Now when an item is selected from MY.MENU2, something will happen. When a mouse button is held down, the expression typed as the third element in the item’s specification will be printed in the Prompt window. (See Figure 13-4.)

<table>
<thead>
<tr>
<th>PLEASE CHOOSE ONE OF THE ITEMS</th>
<th>Prompt Window</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUIT</td>
<td></td>
</tr>
<tr>
<td>NEXT-QUESTION</td>
<td></td>
</tr>
<tr>
<td>NEXT-TOPIC</td>
<td></td>
</tr>
<tr>
<td>SEE-TOPICS</td>
<td></td>
</tr>
</tbody>
</table>

Figure 13-4. Mouse Button Held Down While Mouse Cursor Selects NEXT-QUESTION

When the mouse button is released (i.e., the item is selected) the expression that was typed as the second element of the item’s specification will be run. (See Figure 13-5.)

<table>
<thead>
<tr>
<th>PLEASE CHOOSE ONE OF THE ITEMS</th>
<th>TTY window for PRINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUIT</td>
<td>&quot;HERE IS THE NEXT QUESTION...&quot;</td>
</tr>
<tr>
<td>NEXT-QUESTION</td>
<td></td>
</tr>
<tr>
<td>NEXT-TOPIC</td>
<td></td>
</tr>
<tr>
<td>SEE-TOPICS</td>
<td></td>
</tr>
</tbody>
</table>

Figure 13-5. NEXT-QUESTION Selected

**WHENHELD FN and WHENSELECTED FN Fields of a Menu**

Another way to get a menu to do things is to define functions, and make them the values of the menu’s WHENHELD FN and WHENSELECTED FN fields. As the value of the WHENHELD FN field of a menu, the function you defined will be executed when you press and hold a mouse button inside the menu. As the value of the WHENSELECTED FN field of a menu, the function you defined will be executed when you choose a menu item. This example has the same functionality as the previous example, where each menu item was entered as a list of three items.

As an example, type in these two functions so that they can be executed when the menu is created and displayed:
13. WHAT ARE MENUS?

Now, to create the menu, type:

```
(SETQ MY.MENU3 (CREATE MENU
    TITLE ← "PLEASE CHOOSE ONE OF THE ITEMS"
    ITEMS ← '(QUIT NEXT-QUESTION NEXT-TOPIC SEE-TOPICS)
    WHENHELDFN ← (FUNCTION MY.MENU3.WHENHELD)
    WHENSELECTEDFN ← (FUNCTION MY.MENU3.WHENSELECTED)))
```

To see your menu work, type

```
(ADDMENU MY.MENU3)
```

Now, due to executing the WHENHELDFN function, holding down any mouse button while pointing to a menu item will display an explanation of the item in the prompt window. The screen will once again look like Figure 13-4 when the mouse button is held when the mouse cursor is pointing to the item NEXT-TOPIC.

Now due to executing the WHENSELECTEDFN function, releasing the mouse button to select an item will cause the proper actions for that item to be taken. The screen will once again look like Figure 13-5 when the item NEXT-TOPIC is selected. The crucial thing to note is that the functions you defined for WHENHELDFN and WHENSELECTEDFN are automatically given the following arguments:

1. The item that was selected, ITEM.SELECTED
2. The menu it was selected from, MENU.FROM
3. The mouse button that was pressed BUTTON.PRESSED

These functions, MY.MENU3.WHENHELD and MY.MENU3.WHENSELECTED, were quoted using FUNCTION instead of QUOTE both for program readability and so that the compiler can produce faster code when the program is compiled. It is good style to quote functions in Lisp by using the function FUNCTION instead of QUOTE.
Looking at a Menu’s Fields

The function `INSPECT` is a function that displays a list of the fields of a menu, and their values. Figure 13-6 shows the various fields of `MY.MENU3` when the function `(INSPECT MY.MENU3)` was called. Notice the values that were assigned by the examples, and all the defaults.

```
(INSPECT MY.MENU3)
{WINDOW}#357,73064

{MENU}#338,174484 Inspector

ITEMWIDTH  236
ITEMHEIGHT  12
IMAGEWIDTH  236
IMAGEHEIGHT 62
MENUREGIONLEFT  -1
MENUREGIONBOTTOM  -1
IMAGE  {WINDOW}#376,26000
SAVEIMAGE  NIL

```

Figure 13-6. `MY.MENU3` Fields
A bitmap is a rectangular array of dots. The dots are called "pixels" (for picture elements). Each dot, or pixel, is represented by a single bit. When a pixel or bit is turned on (i.e. that bit set to 1), a black dot is inserted into a bitmap. If you have a bitmap of a floppy on your screen (Figure 14-1), then all of the bits in the area that make up the floppy are turned on, and the surrounding bits are turned off.

![Figure 14-1. Bitmap of a Floppy](image)

**BITMAPCREATE** creates a bitmap, even though it can't be seen.

```
(BITMAPCREATE width height)
```

If the width and height are not supplied, the system will prompt you for them.

**EDITBM** edits the bitmap. The syntax of the function is:

```
(EDITBM bitmapname)
```

Try the following to produce the results in Figure 14-4:

```
(setq my.bitmap (bitmapcreate 60 40))
(EDITBM MY.BITMAP)
```

**To draw** In the bitmap, move the mouse into the gridded section of the bitmap editor, and press and hold the left mouse button. Move the mouse around to turn on the bits represented by the spaces in the grid. Notice that each space in the grid represents one pixel on the bitmap.

**To erase** Move the mouse into the gridded section of the bitmap editor, and press and hold the center mouse button. Move the mouse around to turn off the bits represented by the spaces in the gridded section of the bitmap editor.
To work on a different section Point with the mouse cursor to the picture of the actual bitmap (the upper left corner of the bitmap editor). Press and hold the left mouse button. A menu with the single item, Move will appear. (See Figure 14-2.) Choose this item.

You will be asked to position a ghost window over the bitmap. This ghost window represents the portion of the bitmap that you are currently editing. Place it over the section of the bitmap that you wish to edit and click the left mouse button (see Figure 14-3).
To end the session, bring the mouse cursor into the upper-right portion of the window (the grey area) and press the center button. Select OK from the menu to save your artwork.

**Figure 14-4. Editing a Bitmap**

**BITBLT** is the primitive function for moving bits (or pixels) from one bitmap to another. It extracts bits from the source bitmap, and combines them in appropriate ways with those of the destination bitmap. The syntax of the function is:

```
(BITBLT sourcebitmap sourceleft sourcetop bottom destinationbitmap
destinationleft destinationbottom width height sourcetype
operation texture clippIngregion)
```

Here's how it's done —using **MY.BITMAP** as the sourcebitmap and **MY.WINDOW** as the destinationbitmap.

```
(BITBLT MY.BITMAP NIL NIL
       MY.WINDOW NIL NIL NIL NIL 'INPUT 'REPLACE)
```

Note that the destination bitmap can be, and usually is, a window. Actually, it is the bitmap of a window, but the system handles that detail for you. Because of the NILs (meaning "use the default"), **MY.BITMAP** will be **BITBLT**'d into the lower right corner of **MY.WINDOW** (see Figure 14-5).
14. BITMAPS

Figure 14-5. BITBLTing a Bitmap onto a Window

Here is what each of the BITBLT arguments to the function mean:

- **sourcebitmap**: The bitmap to be moved into the destinationbitmap.
- **sourceleft**: A number, starting at 0 for the left edge of the sourcebitmap, that tells BITBLT where to start moving pixels from the sourcebitmap. For example, if the leftmost 10 pixels of sourcebitmap were not to be moved, sourceleft should be 10. The default value is 0.
- **sourcebottom**: A number, starting at 0 for the bottom edge of the sourcebitmap, that tells BITBLT where to start moving pixels from the sourcebitmap. For example, if the bottom 10 rows of pixels of sourcebitmap were not to be moved, sourcebottom should be 10. The default value is 0.
- **destinationbitmap**: The bitmap that will receive the sourcebitmap. This is often a window (actually the bitmap of a window, but Interlisp-D takes care of that for you).
- **destinationleft**: A number, starting at 0 for the left edge of the destinationbitmap, that tells BITBLT where to start placing pixels from the sourcebitmap. For example, to place the sourcebitmap 10 pixels in from the left, destinationleft should be 10. The default value is 0.
destinationbottom  A number, starting at 0 for the bottom edge of the destinationbitmap, that tells BITBLT where to start placing pixels from the sourcebitmap. For example, to place the sourcebitmap 10 pixels up from the bottom, destinationbottom should be 10. The default value is 0.

width  How many pixels in each row of sourcebitmap should be moved. The same amount of space is used in destinationbitmap to receive the sourcebitmap. If this argument is NIL, it defaults to the number of pixels from sourceleft to the end of the row of sourcebitmap.

height  How many rows of pixels of sourcebitmap should be moved. The same amount of space is used in destinationbitmap to receive the sourcebitmap. If this argument is NIL, it defaults to the number of rows from sourcebottom to the top of the sourcebitmap.

sourcetype  Refers to one of three ways to convert the sourcebitmap for writing. For now, just use 'INPUT.

operation  Refers to how the sourcebitmap gets BITBLT'd on to the destinationbitmap. 'REPLACE will BLT the exact sourcebitmap. Other operations allow you to AND, OR or XOR the bits from the sourcebitmap onto the bits on the destinationbitmap.

texture  Just use NIL for now.

clippingregion  Just use NIL for now.

For more information on these operations, see Chapter 27 in the IRM.
15. DISPLAYSTREAMS

A displaystream is a generalized “place to display”. They determine exactly what is displayed where. One example of a displaystream is a window. Windows are the only displaystreams that will be used in this chapter. If you want to draw on a bitmap that is not a window, other than with BITBLT, or want to use other types of displaystreams, please refer to Chapter 27 in the IRM.

This chapter explains functions for drawing on displaystreams: DRAWLINE, DRAWTO, DRAWCIRCLE, and FILLCIRCLE. In addition, functions for locating and changing your current position in the displaystream are covered: DSPXPOSITION, DSPYPOSITION, and MOVETO.

Drawing on a Displaystream

The examples below show you how the functions for drawing on a display stream work. First, create a window. Windows are displaystreams, and the one you create are used for the examples in this chapter. Type:

```
(SETQ EXAMPLE.WINDOW (CREATEW))
```

DRAWLINE

DRAWLINE draws a line in a displaystream. For example, type:

```
(DRAWLINE 10 15 100 150 5 'INVERT EXAMPLE.WINDOW)
```

The results should look like Figure 15-1:

![Figure 15-1. Line Drawn onto the EXAMPLE.WINDOW Displaystream](image)

The syntax of DRAWLINE is

```
(DRAWLINE x1 y1 x2 y2 width operation stream color dashing)
```

The coordinates of the left bottom corner of the displaystream are 0 0.
15. DISPLAYSTREAMS

- \(x_1\) and \(y_1\) are the \(x\) and \(y\) coordinates of the beginning of the line.
- \(x_2\) and \(y_2\) are the ending coordinates of the line.
- Width is the width of the line, in pixels.
- Operation is the way the line is to be drawn. \texttt{INVERT} causes the line to invert the bits that are already in the displaystream. Drawing a line the second time using \texttt{INVERT} erases the line. For other operations, see Chapter 27 in the IRM.
- Stream is the displaystream. In this case, you used a window.

**DRAWTO**

\texttt{DRAWTO} draws a line that begins at your current position in the displaystream. For example, type:

\begin{verbatim}
(DRAWTO 120 135 5 'INVERT EXAMPLE.WINDOW)
\end{verbatim}

The results should look like Figure 15-2:

\begin{center}
\includegraphics[width=0.5\textwidth]{figure15-2.png}
\end{center}

Figure 15-2. Another Line drawn onto the \texttt{EXAMPLE.WINDOW} Displaystream

The syntax of \texttt{DRAWTO} is

\begin{verbatim}
(DRAWTO x y width operation stream color dashing)
\end{verbatim}

The line begins at the current position in the displaystream.

- \(x\) is the \(x\) coordinate of the end of the line.
- \(y\) is the \(y\) coordinate of the end of the line.
- Width is the width of the line.
- Operation is the way the line is to be drawn. \texttt{INVERT} causes the line to invert the bits that are already in the displaystream. Drawing a line the second time using \texttt{INVERT} erases the line. For other operations, see Chapter 27 in the IRM.
- Stream is the displaystream. In this case, you used a window.
**DRAWCIRCLE**

**DRAWCIRCLE** draws a circle on a displaystream. To use it, type:

```
(DRAWCIRCLE 150 100 30 '(VERTICAL 5) NIL EXAMPLE.WINDOW)
```

Now your window, EXAMPLE.WINDOW, should look like Figure 15-3:

![Circle Drawn onto the EXAMPLE.WINDOW Displaystream](image)

**Figure 15-3. Circle Drawn onto the EXAMPLE.WINDOW Displaystream**

The syntax of **DRAWCIRCLE** is

```
(DRAWCIRCLE centerx centery radius brush dashing stream)
```

- **centerx** x coordinate of the center of the circle
- **centery** coordinate of the center of the circle
- **radius** radius of the circle in pixels
- **brush** list.- The first item of the list is the shape of the brush. Some of your options include **ROUND**, **SQUARE**, and **VERTICAL**. The second item of that list is the width of the brush in pixels.
- **dashing** list of positive integers. The brush is "on" for the number of units indicated by the first element of the list, "off" for the number of units indicated by the second element of the list. The third element specifies how long it will be on again, and so forth. The sequence is repeated until the circle has been drawn.
- **stream** displaystream. In this case, you used a window.

**FILLCIRCLE**

**FILLCIRCLE** draws a filled circle on a displaystream. To use it, type:

```
(FILLCIRCLE 200 150 10 GRAYSHADE EXAMPLE.WINDOW)
```

EXAMPLE.WINDOW now looks like Figure 15-4:
The syntax of `FILLCIRCLE` is:

```
(FILLCIRCLE centerx centery radius texture stream)
```

centerx  x coordinate of the center of the circle

centery  y coordinate of the center of the circle

radius   radius of the circle in pixels

texture  shade that will be used to fill in the circle. Interlisp-D provides you with three shades: `WHITESHADE`, `BLACKSHADE`, and `GRAYSHADE`. You can also create your own shades. For more information on how to do this, see Chapter 27 in the IRM.

stream   displaystream. In this case, you used a window

There are many other functions for drawing on a displaystream. Please refer to Chapter 27 in the IRM.

Text can also be placed into displaystreams. To do this, use printing functions such as `PRIN1` and `PRIN2`, but supply the name of the displaystream as the "file" to print to. To place the text in the proper position in the displaystream, see the section below.

### Locating and Changing Your Position in a Displaystream

There are functions provided to locate, and to change your current position in a displaystream. This can help you place text, and other images where you want them in a displaystream. This primer will only discuss three of these. There are others, and they can be found in the Chapter 27 of the IRM.

**DSPXPOSITION**

`DSPXPOSITION` is a function that will either change the current x position in a displaystream, or simply report it. To have the function report the current x position in `EXAMPLE.WINDOW`, type:

```
(DSPXPOSITION NIL EXAMPLE.WINDOW)
```
DSPXPOSITION expects two arguments. The first is the new x position. If this argument is NIL, the current position is not changed, merely reported. The second argument is the displaystream.

**DSPYPOSITION**

DSPYPOSITION is an analogous function, but it changes or reports the current y position in a displaystream. As with DSPXPOSITION, if the first argument is a number, the current y position will be changed to that position. If it is NIL, the current position is simply reported. To have the function report the current y position in EXAMPLE.WINDOW, type:

```
(DSPYPOSITION NIL EXAMPLE.WINDOW)
```

**MOVETO**

The function MOVETO always changes your position in the displaystream. It expects three arguments:

```
(MOVETO x y stream)
```

- **x** new x position in the display stream
- **y** new y position in the display stream
- **stream** display stream. The examples so far have used a window
16. FONTS

This chapter explains fonts and fontdescriptors, what they are and how to use them, so that you can use functions requiring fontdescriptors.

You have already been exposed to many fonts in Medley. For example, when you use the structure editor, DEdit (see the Using the List Structure Editor section of Chapter 7), you noticed that the comments were printed in a smaller font than the code, and that CLISP words (see the CLISP section of Chapter 9) were printed in a darker font than the other words in the function. These are only some of the fonts that are available in Medley.

In addition to the fonts that appear on your screen, Medley uses fonts for printers that are different than the ones used for the screen. The fonts used to print to the screen are called DISPLAYFONTS. The fonts used for printing are called INTERPRESSFONTS, or PRESSFONTS, depending on the type of printer.

What Makes Up a Font

Fonts are described by family, weight, slope, width, and size. This section discusses each of these, and describes how they affect the font you see on the screen.

Family is one way that fonts can differ. Here are some examples of how "family" affects the look of a font:

- **CLASSIC**: This family makes the word "Able" look like this: Able
- **MODERN**: This family makes the word "Able" look like this: Able
- **TITAN**: This family makes the word "Able" look like this: Able

Weight also determines the look of a font. Once again, "Able" will be used as an example, this time only with the Classic family. A font's weight can be:

- **BOLD**: And look like this: Able
- **MEDIUM** or **REGULAR**: And look like this: Able

The slope of a font is italic or regular. Using the Classic family font again, in a regular weight, the slope affects the font like this:

- **ITALIC**: Looks like this: Able
- **REGULAR**: Looks like this: Able

The width of a font is called its "expansion". It can be COMPRESSED, REGULAR, or EXPANDED.

Together, the weight, slope, and expansion of a font specifies the font's "face". Specifically, the face of a font is a three element list:

(weight slope expansion)

To make it easier to type, when a function requires a font face as an argument, it can be abbreviated with a three-character atom. The first specifies the weight, the second the
slope, and the third character the expansion. For example, some common font faces are abbreviated:

MRR       This is the usual face, MEDIUM, REGULAR, REGULAR
MIR       Makes an italic font. It stands for: MEDIUM, ITALIC, REGULAR
BRR       Makes a bold font. The abbreviation means: BOLD, REGULAR, REGULAR
BIR       Means that the font should be both bold and italic. BIR stands for BOLD, ITALIC, REGULAR

The above examples are used so often, that there are also more mnemonic abbreviations for them. They can also be used to specify a font face for a function that requires a face as an argument. They are:

STANDARD  This is the usual face: MEDIUM, REGULAR, REGULAR; it was abbreviated above, MRR
ITALIC     This was abbreviated above as MIR, and specifies an italic font
BOLD      Makes a bold font; it was abbreviated above, BRR
BOLDITALIC Makes a font both bold and italic: BOLD, ITALIC, REGULAR; it was abbreviated above, BIR

A font also has a size. It is a positive integer that specifies the height of the font in printers points. A point is, on an 1108 screen, about 1/72 of an inch. On the screen of an 1186, a point is 1/80 of an inch. The size of the font used in this chapter is 10. For comparison, here is an example of a TITAN, MRR, size 12 font: Able.

Fontdescriptors and FONTCREATE

For Medley to use a font, it must have a fontdescriptor. A fontdescriptor is a data type in Interlisp-D that that holds all the information needed in order to use a particular font. When you print out a fontdescriptor, it looks like this:

   {FONTPROJECTOR}#74,45540

Fontdescriptors are created by the function FONTCREATE. For example,

   (FONTPROJECTOR 'HELVETICA 12 'BOLD)

creates a fontdescriptor that, when used by other functions, prints in HELVETICA BOLD size 12. Interlisp-D functions that work with fonts expect a fontdescriptor produced with the FONTCREATE function.

The syntax of FONTCREATE is:

   (FONTPROJECTOR family size face)

Remember from the previous section, face is either a three element list (weight slope expansion), a three character atom abbreviation, e.g. MRR, or one of the mnemonic abbreviations, e.g. STANDARD.

If FONTCREATE is asked to create a fontdescriptor that already exists, the existing fontdescriptor is simply returned.
Display Fonts

Display fonts require files that contain the bitmaps used to print each character on the screen. All of these files have the extension .DISPLAYFONT. The file name itself describes the font style and size that uses its bitmaps. For example:

MODERN12.DISPLAYFONT

contains bitmaps for the font family MODERN in size 12 points. Wherever you put your .DISPLAYFONT files, you should make this one of the values of the variable DISPLAYFONTDIRECTORIES. Its value is a list of directories to search for the bitmap files for display fonts. Usually, it contains the "FONT" directory where you copied the bitmap files, and the current connected directory. The current connected directory is specified by the atom NIL. When looking for a .DISPLAYFONT file, the system checks the FONT directory on the hard disk, then the current connected directory.

Figure 16-1 shows an example value of DISPLAYFONTDIRECTORIES:

```
Exec (INTERLISP)

183> DISPLAYFONTDIRECTORIES
("{dsk}/users/sybalsky/sd/" "{dsk}/usr/local/1de/Lispcore>XeroxPrivate>Fonts>"
   "{Pallas:mv:envos}<Fonts>display>presentation>"
   "{Pallas:mv:envos}<Fonts>display>publishing>"
   "{Pallas:mv:envos}<Fonts>display>printwheel>"
   "{Pallas:mv:envos}<Fonts>display>miscellaneous>"
   "{Pallas:mv:envos}<Fonts>display>JIS1>"
   "{Pallas:mv:envos}<Fonts>display>JIS2>"
   "{Pallas:mv:envos}<Fonts>display>CHINESE>")

184>
```

Figure 16-1. Value for the Atom DISPLAYFONTDIRECTORIES

InterPress Fonts

InterPress is the format that is used by Xerox laser printers. These printers normally have a resolution that is much higher than that of the screen: 300 points per inch.

To format files appropriately for output on such a printer, Interlisp must know the actual size for each character that is to be printed. This is done through the use of width files that contain font width information for fonts in InterPress format. For InterPress fonts, you should make the location of these files one of the values of the variable INTERPRESSFONTDIRECTORIES. Its value is a list of directories to search for the font widths files for InterPress fonts. Figure 16-2 is an example value of INTERPRESSFONTDIRECTORIES:
Functions for Using Fonts

**FONTPROP** Looking at Font Properties

It is possible to see the properties of a font descriptor. This is done with the function `FONTPROP`. For the following examples, the font descriptor used will be the one returned by the function `(DEFAULTFONT 'DISPLAY)`. In other words, the font descriptor examined will be the default display font for the system.

There are many properties of a font that might be useful for you. Some of these are:

- **FAMILY**
  To see the family of a font descriptor, type:
  
  ```lisp
  (FONTPROP (DEFAULTFONT 'DISPLAY) 'FAMILY)
  ```

- **SIZE**
  As above, this is a positive integer that determines the height of the font in printer’s points. As an example, the `SIZE` of the current default font is:
  
  ```lisp
  (FONTPROP (DEFAULTFONT 'DISPLAY) 'SIZE)
  10
  ```

- **ASCENT**
  The value of this property is a positive integer, the maximum height of any character in the specified font from the baseline (bottom). The top of
the tallest character in the font, then, will be at \((\text{BASELINE} + \text{ASCENT} - 1)\). For example, the \text{ASCENT} of the default font is:

\[
\text{ASCENT} = 9
\]

**Figure 16-4. Value Font Property \text{ASCENT} of Default Font**

**DESCENT**

The DESCENT is an integer that specifies the maximum number of points that a character in the font descends below the baseline (e.g., letters such as "p" and "g" have tails that descend below the baseline.). The bottom of the lowest character in the font will be at \((\text{BASELINE} - \text{DESCENT})\). To see the DESCENT of the default font, type:

\[
(\text{FONTPROP} \ (\text{DEFAULTFONT} \ '\text{DISPLAY}) \ '\text{DESCENT})
\]

**HEIGHT**

HEIGHT is equal to \((\text{DESCENT} - \text{ASCENT})\).

**FACE**

The value of this property is a list of the form (weight slope expansion). These are the weight, slope, and expansion described above. You can see each one separately, also. Use the property that you are interested in, \text{WEIGHT}, \text{SLOPE}, or \text{EXPANSION}, instead of \text{FACE} as the second argument to \text{FONTPROP}

For other font properties, see Chapter 27 of the IRM.

**STRINGWIDTH**

It is often useful to see how much space is required to print an expression in a particular font. The function \text{STRINGWIDTH} does this. For example, type:

\[
(\text{STRINGWIDTH} \ "\text{Hi there!}" \ (\text{FONTCREATE} \ \text{GACHA} \ 10 \ '\text{STANDARD}))
\]

The number returned is how many left to right pixels would be needed if the string were printed in this font. (Note that this doesn't just work for pixels on the screen, but for all kinds of streams. For more information about streams, see Chapter 15.) Compare the number returned from the example call with the number returned when you change \text{GACHA} to \text{TIMESROMAN}.

**DSPFONT - Changing the Font in One Window**

The function \text{DSPFONT} changes the font in a single window. As an example of its use, first create a window to write in. Type:

\[
(\text{SETQ} \ \text{MY.FONT.WINDOW} \ (\text{CREATEW}))
\]

in the Executive Window. Sweep out the window. To print something in the default font, type:

\[
(\text{PRINT} \ '\text{HELLO} \ \text{MY.FONT.WINDOW})
\]

in the Executive Window. Your window, \text{MY.FONT.WINDOW}, will look something like Figure 16-5:
Now change the font in the window. Type:

```lisp
(DSPFONT (FONTCREATE 'HELVETICA 12 'BOLD) MY.FONT.WINDOW)
```

in the Executive Window. The arguments to `FONTCREATE` can be changed to create any desired font. Now retype the `PRINT` statement, and your window will look something like Figure 16-6:

![Figure 16-6. Font in MY.FONT.WINDOW Changed](image)

Notice the font has been changed.

### Personalizing Your Font Profile

Medley keeps a list of default font specifications. This list is used to set the font in all windows where the font is not specifically set by the user (see the `DSPFONT` section above). The value of the atom `FONTPROFILE` is this list (see Figure 16-7).

A `FONTPROFILE` is a list of font descriptions that certain system functions access when printing output. It contains specifications for big fonts (used when pretty printing a function to type the function name), small fonts (used for printing comments in the editor), and various other fonts.
The list is in the form of an association list. The font class names (e.g., DEFAULTFONT, or BOLDFONT) are the keywords of the association list. When a number follows the keyword, it is the font number for that font class.

The lists following the font class name or number are the font specifications, in a form that the function FONTCREATE can use. The first font specification list after a keyword is the specification for printing to windows. The list (GACHA 10) in the figure above is an example of the default specification for the printing to windows. The last two font specification lists are for Press and InterPress file printing, respectively. For more information, see Chapter 27 in the IRM.

Now, to change your default font settings, change the value of the variable FONTPROFILE. Medley has a list of profiles stored as the value of the atom FONTDEFS. Choose the profile to use, then install it as the default FONTPROFILE.

Evaluate the atom FONTDEFS and notice that each profile list begins with a keyword (see Figure 16-8). This keyword corresponds to the size of the fonts included. BIG, SMALL, and STANDARD are some of the keywords for profiles on this list—SMALL and STANDARD appear in Figure 16-8.
To install a new profile from this list, follow the following example, but insert any keyword for BIG.

To use the profile with the keyword BIG instead of the standard one, evaluate the following expression:

```
(FONTSET 'BIG))
```

Now the fonts are permanently replaced. (That is, until another profile is installed.)
17. THE INSPECTOR

The Inspector is a window-oriented tool designed to examine data structures. Because Medley is such a powerful programming environment, many types of data structures would be difficult to see in any other way.

Calling the Inspector

Take as an example an object defined through a sequence of pointers (i.e., a bitmap on the property list of a window on the property list of an atom in a program.)

To inspect an object named $\text{NAME}$, type:

\[ \text{(INSPECT 'NAME)} \]

If $\text{NAME}$ has many possible interpretations, an option menu will appear. For example, in Interlisp-D, a litatom can refer to both an atom and a function. For example, if $\text{NAME}$ was a record, had a function definition, and had properties on its property list, then the menu would appear as in Figure 17-1.

![Figure 17-1. Option Window for Inspection of NAME](image)

If $\text{NAME}$ were a list, then the option menu shown in Figure 17.2 would appear. The options include:

- Calling the display editor on the list
- Calling the TTY editor (see Chapter 6)
- Seeing the list’s elements in a display window. If you choose this option, each element in the list will appear in the right column of the Inspector window. The left column of the Inspector window will be made up of numbers (see Figure 17-3).
- Inspecting the list as a record type (this last option would produce a menu of known record types). If you choose a record type, the items in the list will appear in the right column of the Inspector window. The left column of the Inspector window will be made up of the field names of the record.

![Figure 17-2. Option Window for Inspection of List](image)
Using the Inspector

If you choose to display your data structure in an edit window, simply edit the structure and exit in the normal manner when done. If you choose to display the data structure in an inspect window, then follow these instructions:

- To select an item, point the mouse cursor at it and press the left mouse button.
- Items in the right column of an Inspector window can themselves be inspected. To do this, choose the item, and press the center mouse button.
- Items in the right column of an Inspector window can be changed. To do this, choose the corresponding item in the left column, and press the center mouse button. You will be prompted for the new value, and the item will be changed. The sequence of steps is shown in Figure 17-3.

The item in the left column is selected, and the middle mouse button pressed. Select the SET option from the menu that pops up.

You will then be prompted for the new value. Type it in.

The item in the right column is updated to the value of what you typed in.

```plaintext
(INPECT-ME-TOO1 INPECT:
  1  INSPECT-ME-TOO1
  2  INSPECT-ME-TOO2
  3  INSPECT-ME-TOO3
)
```

![Figure 17-3. Steps Involved in Changing Value in Right Column of Inspector Window](image)

Inspector Example

This example will use ideas discussed in Chapter 21. An example, ANIMALGRAPH, is created in that section. You do not need to know the details of how it was created, but the structure is examined in this chapter.

If you type

```plaintext
(INPECT ANIMAL.GRAPH)
```

and then choose the Inspect option from the menu, a display appears as shown in Figure 17-4. ANIMAL.GRAPH is being inspected as a list. Note the numbers in the left column of the inspector window.
17. THE INSPECTOR

If you choose the "As A Record" option, and choose "GRAPH" from the menu that appears, the inspector window looks like Figure 17-5. Note the fieldnames in the left column of the inspector window.

```
(((FISH & --) (BIRD & --) (CAT & --)) T NIL NIL --)
1  (((FISH & NIL NIL --) (BIRD & NIL NIL

11  NIL
12  NIL
```

Figure 17-4. Inspector Window For ANIMAL.GRAPH, Inspected as List

Figure 17-5. Inspector Window for ANIMAL.GRAPH, Inspected as Instance of GRAPH Record

The remaining examples will use ANIMAL.GRAPH inspected as a list. When the first item in the Inspector window is chosen with the left mouse button, the Inspector window looks like Figure 17-6.

```
(((FISH & --) (BIRD & --) (CAT & --)) T NIL NIL --)
1  (((FISH & NIL NIL --) (BIRD & NIL NIL
2   T
3   NIL
4   NIL
5   NIL
6   NIL
7   NIL
8   NIL
9   NIL
10  NIL
11  NIL
12  NIL
```

Figure 17-6. Inspector Window for ANIMAL.GRAPH With First Element Selected

When you use the middle mouse button to inspect the selected list element, the display looks like Figure 17-7.
17. THE INSPECTOR

How you can see that six items make up the list, and you can further choose to inspect one of these items. Notice that this is also inspected as a list. As usual, it could also have been inspected as a record.

Select item 5 - MAMMAL DOG CAT - with the left mouse button. Press the middle mouse button. Choose "Inspect" to inspect your choice as a list. The Inspector now displays the values of the structure that makes up MAMMAL DOG CAT. (See Figure 17-8.)

Figure 17-8. Inspector Window for Element 5 From Figure 17.7 That Begins ((MAMMAL DOG CAT).
Masterscope is a tool that allows you to quickly examine the structure of complex programs. As your programs enlarge, you may forget what variables are global, what functions call other functions, and so forth. Masterscope keeps track of this for you.

To use Masterscope, first load `MASTERSCOPE.DFASL` and `EXPORTS.ALL`.

Suppose that `JVTO` is the name of a file that contains many of the functions involved in a complex system and that `LINTRANS` is the file containing the remaining functions. The first step is to ask Masterscope to analyze these files. These files must be loaded. All Masterscope queries and commands begin with a period followed by a space, as in

```
.MASTERSCOPE
```

The `ANALYZE` process takes a while, so the system prints a period on the screen for each function it has analyzed. (See Figure 18-1)

```
Exec 2 (INTERLISP)
2/106> . ANALYZE FNS ON MSCOPEDEMO
...........
2/107>
```

Figure 18-1. Executive Window After Analyzing Files

If you are not quite sure what functions were just analyzed, type the file's `COMS` variable (see the File Variables section in Chapter 7) into the Executive Window. The names of the functions stored on the file will be a part of the value of this variable.

A variety of commands are now possible, all referring to individual functions within the analyzed files. Substantial variation in exact wording is permitted. Some commands are:

```
.SHOW PATHS FROM ANY TO ANY
.EDIT WHERE ANY CALLS functionname
.EDIT WHERE ANY USES variablename
.WHO CALLS WHOM
.WHO CALLS functionname
.BY WHOM IS functionname CALLED
.WHO USES variablename AS FIELD
```

Note that the function is being called to invoke each command. Refer to the IRM for commands not listed here.

Figure 18-2 shows the Executive Window after the commands `.WHO CALLS GobbleDump` and `.WHO DOES JVL inScan CALL`.

```
Exec 2 (INTERLISP)
...........
2/107> . WHO CALLS GetCType (ReadBeginEnd ParseList)
2/108> . WHO DOES ReadBeginEnd CALL (ConcatList ParseList GetCType PrintError apply)
2/109>
```

Figure 18-2. Sample Masterscope Output
SHOW DATA Command and GRAPHER

When the library package GRAPHER is loaded (to load this package, type `(FILESLOAD GRAPHER)`), Masterscope’s SHOWPATHS command is modified. The command will be changed to generate a tree structure showing how the program’s functions interact instead of a tabular printout into the Executive window. For example, typing:

```
.SHOW PATHS FROM ProcessEND
```

produced the display shown in Figure 18-3.

![Diagram of SHOW PATHS Display Example](image.png)

Figure 18-3. SHOW PATHS Display Example

All the functions in the display are part of this analyzed file or a previously analyzed file. Boxed functions indicate that the function name has been duplicated in another place on the display.

Selecting any function name on the display will pretty print the function in a window (see Figure 18-4).

![Diagram of PATHS FROM ProcessEND](image.png)

Figure 18-4. Browser Printout Example

Selecting it again with the left mouse button will produce a description of the function’s role in the overall system (see Figure 18-5).
Figure 18-5. Browser Description Example
SPY is an Lisp library package that shows you where you spend your time when you run your system. It is easy to learn, and very useful when trying to make programs run faster.

How to Use Spy with the SPY Window

The function SPY.BUTTON brings up a small window which you will be prompted to position. Using the mouse buttons in this window controls the action of the SPY program. When you are not using SPY, the window appears as in Figure 19.1.

![Figure 19.1. SPY Window When SPY is Not Being Used](image1)

To use SPY, click either the left or middle mouse button with the mouse cursor in the SPY window. The window will appear as in Figure 19.2, and means that SPY is accumulating data about your program.

![Figure 19.2. SPY Window When SPY is Being Used](image2)

To turn off SPY after the program has run, again click a mouse button in the SPY window. The eye closes, and you are asked to position another window. This window contains SPY's results. An example of the resulting window is shown in Figure 19.3.
WHERE DOES ALL THE TIME GO? SPY

This window is scrollable horizontally and vertically. This is useful, since the whole tree does not fit in the window. If a part that you want to see is not shown, you can scroll the window to show the part you want to see.

How to Use SPY from the Lisp Top Level

SPY can also be run while a specific function or system is being used. To do this, type the function WITH.SPY:

```
(WITH.SPY form)
```

The expression used for form should be the call to begin running the function or system that SPY is to watch. If you watch the SPY window, the eye will blink! To see your results, run the function SPY.TREE. To do this, type:

```
(SPY.TREE)
```

The results of the last running of SPY will be displayed. If you do this, and SPY.TREE returns (no SPY samples have been gathered), your function ran too fast for SPY to follow.

Interpreting SPY's Results

Each node in the tree is a box that contains, first, the percentage of time spent running that particular function, and second, the function name. There are two modes that can be used to display this tree.

The default mode is cumulative. In this mode, each percentage is the amount of time that function spent on top of the stack, plus the amount of time spent by the functions it calls. The second mode is individual. To change the mode to individual, point to the title bar of the window, and press the middle mouse button. Choose Individual from the menu that appears. In this mode, the percentage shown is the amount of time the function spent on the top of the stack.

To look at a single branch of the tree, point with the mouse cursor at one of the nodes of the tree, and press the right mouse button. From the menu that appears, choose the
option SubTree. Another SPY window will appear, with just this branch of the tree in it.

Another way to focus within the tree is to remove branches from the tree. To do this, point to the node at the top of the branch you would like to delete. Press the middle mouse button, and choose Delete from the menu that appears.

There are also different amounts of “merging” of functions that can be done in the window. A function can be called by another function more than once. The amount of merging determines where the subfunction, and the functions that it calls, appear in the tree, and how often. (For a detailed explanation of merging, see the Lisp Library Packages Manual.)
20. FREE MENUS

Free Menu is a library package that is even more flexible than the regular menu package. It allows you to create menus with different types of items in them, and formats them as you require. Free menus are particularly useful when you want a “fill in the form” type interaction with the user.

Each menu item is described with a list of properties and values. The following example will give you an idea of the structure of the description list, and some of your options. The most commonly used properties, and each type of menu item will be described in the Parts of a Free Menu Item and Types of Free Menu Items section below.

Free Menu Example

Free menus can be created and formatted automatically! It is done with the function FM.FORMATMENU. This function takes one argument, a description of the menu. The description is a list of lists; each internal list describes one row of the free menu. A free menu row can have more than one item in it, so there are really lists of lists of lists! It really isn't hard, though, as you can see from the following example:

```lisp
(SETQ ExampleMenu
  (FM.FORMATMENU
   '(((TYPE TITLE LABEL TitlesDoNothing)
      TYPE 3STATE LABEL Example3State))
   ((TYPE EDITSTART LABEL PressToStartEditing
      ITEMS (EDITEM))
    (TYPE EDIT ID EDITEM LABEL "")
    (WINDOWPROPS TITLE "Example Does Nothing"))))
```

The first row has two items in it: one is a TITLE, and the second is a 3STATE item. The second row also has two items. The second, the EDIT item, is invisible, because its label is an empty string. The caret will appear for editing, however, if the EDITSTART item is chosen. Windowprops can appear as part of the description of the menu, because a menu is, after all, just a special window. You can specify not only the title with WINDOWPROPS, but also the position of the free menu, using the "left" and "bottom" properties, and the width of the border in pixels, with the "border" property. Evaluating this expression will return a window. You can see the menu by using the function OPENW. The following example illustrates this:

```
Figure 20.1. Example Free Menu
```

The next example shows you what the menu looks like after the EDITSTART item, PressToStartEditing, has been chosen.

```
Figure 20.2. Free menu after EDITSTART Item Chosen
```

The following example shows the menu with the 3STATE item in its T state, with the item highlighted. (In the previous bitmaps, it was in its neutral state.)

```
Figure 20.3. Free menu with 3STATE Item in its T State
```
Finally, Figure 20.4 shows the 3STATE item in its NIL state, with a diagonal line through the item.

Figure 20.4 Free menu with the 3STATE item in its NIL State

If you would like to specify the layout yourself, you can do that too. See the Lisp Library Packages Manual for more information.

Parts of a Free Menu Item

There are eight different types of items that you can use in a free menu. No matter what type, the menu item is easily described by a list of properties, and values. Some of the properties you will use most often are listed below:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LABEL</td>
<td>Required for every type of menu item. It is the atom, string, or bitmap that appears as a menu selection.</td>
</tr>
<tr>
<td>TYPE</td>
<td>One of eight types of menu items. Each of these are described in the section below.</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>The message that appears in the prompt window if a mouse button is held down over the item.</td>
</tr>
<tr>
<td>ID</td>
<td>An item's unique identifier. An ID is needed for certain types of menu items.</td>
</tr>
<tr>
<td>ITEMS</td>
<td>Used to list a series of choices for an NCHOOSE item, and to list the ID's of the editable items for an EDITSTART item.</td>
</tr>
<tr>
<td>SELECTEDFN</td>
<td>The name of the function to be called if the item is chosen.</td>
</tr>
</tbody>
</table>

Types of Free Menu Items

Each type of menu item is described in the following list, including an example description list for each one.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOMENTARY</td>
<td>This is the familiar sort of menu item. When it is selected, the function stored with it is called. A description for the function that creates and formats the menu looks like this:</td>
</tr>
<tr>
<td></td>
<td>(TYPE MOMENTARY</td>
</tr>
<tr>
<td></td>
<td>LABEL Blink-N-Ring</td>
</tr>
<tr>
<td></td>
<td>MESSAGE &quot;Blinks the screen and rings bells&quot;</td>
</tr>
<tr>
<td></td>
<td>SELECTEDFN RINGBELLS)</td>
</tr>
<tr>
<td>TOGGLE</td>
<td>This menu item has two states, T and NIL. The default state is NIL, but choosing the item toggles its state. The following is an example description list, without code for the SELECTEDFN function, for this type of item:</td>
</tr>
<tr>
<td></td>
<td>(TYPE TOGGLE</td>
</tr>
<tr>
<td></td>
<td>LABEL DwimDisable</td>
</tr>
<tr>
<td></td>
<td>SELECTEDFN ChangeDwimState)</td>
</tr>
</tbody>
</table>
3STATE  This type of menu item has three states, NEUTRAL, T, and NIL. NEUTRAL is the default state. T is shown by highlighting the item, and NIL is shown with diagonal lines. The following is an example description list, without code for the SELECTEDFN function, for this type of item:

```
(TYPE 3STATE
   LABEL CorrectProgramAllOrNoSpelling
   SELECTEDFN ToggleSpellingCorrection)
```

TITLE  This menu item appears on the menu as dummy text. It does nothing when chosen. An example of its description:

```
(TYPE TITLE LABEL "Choices:")
```

NWAY  A group of items, only one of which can be chosen at a time. The items in the NWAY group should all have an ID field, and the ID’s should be the same. For example, to set up a menu that would allow the user to choose between Helvetica, Gacha, Modern, and Classic fonts, the descriptions might look like this (once again, without the code for the SELECTEDFN):

```
(TYPE NWAY ID FONTCHOICE
   LABEL Helvetica
   SELECTEDFN ChangeFont)
(TYPE NWAY ID FONTCHOICE
   LABEL Gacha
   SELECTEDFN ChangeFont)
(TYPE NWAY ID FONTCHOICE
   LABEL Modern
   SELECTEDFN ChangeFont)
(TYPE NWAY ID FONTCHOICE
   LABEL Classic
   SELECTEDFN ChangeFont)
```

NCHOOSE  This type of menu item is like NWAY except that the choices are given to the user in a submenu. The list to specify an NCHOOSE menu item that is analogous to the NWAY item above might look like this:

```
(TYPE NCHOOSE
   LABEL FontChoices
   ITEMS Helvetica Gacha Modern Classic)
   SELECTEDFN ChangeFont)
```

EDITSTART  When this type of menu item is chosen, it activates another type of item, an EDIT item. The EDIT item or items associated with an EDITSTART item have their ID’s listed on the EDITSTART’s ITEMS property. An example description list is:

```
(TYPE EDITSTART LABEL "Function to add?" ITEMS (Fn))
```

EDIT  This type of menu item can actually be edited by you. It is often associated with an EDITSTART item (see above), but the caret that prompts for input will also appear if the item itself is chosen. An EDIT item follows the same editing conventions as editing in Executive Window:

- **Add characters** by typing them at the caret.
- **Move the caret** by pointing the mouse at the new position, and clicking the left button.
Delete characters from the caret to the mouse by pressing the right button of the mouse. Delete a character behind the caret by pressing the backspace key.

Stop editing by typing a carriage return, a Control-X, or by choosing another item from the menu.

An example description list for this type of item is:

(TYPE EDIT ID Fn LABEL **)
21. THE GRAPHER

Say it with Graphs

Grapher is a collection of functions for creating and displaying graphs, networks of nodes and links. Grapher also allows you to associate program behavior with mouse selection of graph nodes. To load this package, type

(FILELOAD GRAPHER)

Figure 21-1 shows a simple graph.

In Figure 21-1 there are six nodes (ANIMAL, MAMMAL, DOG, CAT, FISH, and BIRD) connected by five links. A GRAPH is a record containing several fields. Perhaps the most important field is GRAPHNODES—which is itself a list of GRAPHNODE records. Figure 21-2 illustrates these data structures. The window on top contains the fields from the simple graph. The window on the bottoms an inspection of the node, DOG.
21. THE GRAPHER

The GRAPHNODE data structure is described by its text (NODEID), what goes into it (FROMNODES), what leaves it (TONODES), and other fields that specify its looks. The basic model of graph building is to create a bunch of nodes, then layout the nodes into a graph, and finally display the resultant graph. This can be done in a number of ways. One is to use the function NODECREATE to create the nodes, LAYOUTGRAPH to lay out the nodes, and SHOWGRAPH to display the graph. The primer shows you two simpler ways, but please see the Library Packages Manual for more information about these other functions. The primer's first method is to use SHOWGRAPH to display a graph with no nodes or links, then interactively add them. The second is to use the function LAYOUTSEXPR, which does the appropriate NODECREATES and a LAYOUTGRAPH, with a list.

The function SHOWGRAPH displays graphs and allows you to edit them. The syntax of SHOWGRAPH is

```
(SHOWGRAPH graph window lefbuttonfn middlebuttonfn
topjustifyflg alloweditflg copybuttoneventfn)
```

Obviously the graph structure is very complex. Here's the easiest way to create a graph.

```
(SETQ MY.GRAPH NIL)
(SHOWGRAPH MY.GRAPH "My Graph" NIL NIL NIL T)
```
21. THE GRAPHER

Figure 21-3. My Graph

You will be prompted to create a small window as in Figure 21-3. This graph has the title My Graph. Hold down the right mouse button in the window. A menu of graph editing operations will appear as in Figure 21-4.

Here’s how to use this menu. The commands in this menu are easy to learn. Experiment with them!

Add a Node

Start by selecting Add Node. Grapher will prompt you for the name of the node (see Figure 21-5.) and then its position.

Position the node by moving the mouse cursor to the desired location and clicking a mouse button. Figure 21-6 shows the graph with two nodes added using this menu.
21. THE GRAPHER

**Add a Link**

Select Add Link from the graph editing menu. The Prompt window will prompt you to select the two nodes to be linked. (See Figure 21-7.) Do this, and the link will be added.

**Delete a Link**

Select Delete Link from the graph editing menu. The Prompt window will prompt you to select the two nodes that should no longer be linked. (See Figure 21-8.) Do this, and the link will be deleted.

**Delete a Node**

Select Delete Node from the graph editing menu. The Prompt window will prompt you to select the node to be deleted. (See Figure 21-9.) Do this, and the node will be deleted.
Move a Node

Select Delete Node from the graph editing menu. Choose a node pointing to the it with the mouse cursor, and pressing and holding the left mouse button. When you move the mouse cursor, the node will be dragged along. When the node is at the new position, release the mouse button to deposit the node.

Making a Graph from a List

Typically, a graph is used to display one of your program's data structures. Here is how that is done.

LAYOUTSEXPR takes a list and returns a GRAPH record. The syntax of the function is

(LAYOUTSEXPR sexpr format boxing font motherd personald famlyd)

For example:

(SETQ ANIMAL.TREE '(ANIMAL (MAMMAL DOG CAT) BIRD FISH))
(SETQ ANIMAL.GRAPH
    (LAYOUTSEXPR ANIMAL.TREE 'HORIZONTAL))
(SHOWGRAPH ANIMAL.GRAPH "My Graph" NIL NIL NIL T)

This is how Figure 21.1 was produced.

Incorporating Grapher into Your Program

The Grapher is designed to be built into other programs. It can call functions when, for example, a mouse button is clicked on a node. The function SHOWGRAPH does this:

(SHOWGRAPH graph window leftbuttonfn midlebuttonfn
topjustifyflg alloweditflg copybuttoneventfn)

For example, the third argument to SHOWGRAPH, leftbuttonfn, is a function that is called when the left mouse button is pressed in the graph window. Try this:

(DEFINEQ (MY.LEFT.BUTT0N.FUNCTION
    (THE.GRAPHNODE THE.GRAPH.WINDOW)
    (INSPECT THE.GRAPHNODE)))

(SHOWGRAPH FAMILY.GRAPH "Inspectable family"
    (FUNCTION MY.LEFT.BUTTON.FUNCTION)
    NIL NIL NIL T)

In the example above, MY.LEFT.BUTTON.FUNCTION simply calls the inspector. The function should be written assuming it will be passed a graphnode and the window that holds the graph. Try adding a function of your own.

More of Grapher

Some other Library packages make use of the Grapher. (Grapher needs to be loaded with the packages to use these functions.)
• **MASTERSCOPE**: The Browser package modifies the Masterscope command, `. SHOW PATHS`, so that its output is displayed as a graph (using Grapher) instead of simply printed.

• **GRAPHZOOM**: allows a graph to be redisplayed larger or smaller automatically.
22. RESOURCE MANAGEMENT

Naming Variables and Records

You will find times when one environment simultaneously hosts a number of different programs. Running a demo of several programs, or reloading the entire Medley environment from floppies when it contains several different programs, are two examples that could, if you aren’t careful, provide a few problems. Here are a few tips on how to prevent problems:

- If you change the value of a system variable, `MENUHELDWAIT` for example, or connect to a directory other than `{DSK}<LISPFILES>`, write a function to reset the variable or directory to its original value. Run this function when you are finished working. This is especially important if you change any of the system menus.

- Do not redefine Medley functions or CLISP words. Remember, if you reset an atom’s value or function definition at the top level (in the Executive Window), the message `(Some.Crucial.Function.Or.Variable redefined)`, appears. If this is not what you wanted, type `UNDO` immediately!

If, however, you reset the value or function definition of an atom inside your program, a warning message will not be printed.

- Make the atom names in your programs as unique as possible. To do this without filling your program with unreadable names that no one, including you, can remember, prefix your variable names with the initials of your program. Even then, check to see that they are not already being used with the function `BOUNDP`. For example, type:

  ```lisp
  (BOUNDP 'BackgroundMenu)
  ```

  This atom is bound to the menu that appears when you press the left mouse button when the mouse cursor is not in any window. `BOUNDP` returns `T`. `BOUNDP` returns `NIL` if its argument does not currently have a value.

- Make your function names as unique as possible. Once again, prefixing function names with the initials of your program can be helpful in making them unique, but even so, check to see that they are not already being used. `GETD` is the Interlisp-D function that returns the function definition of an atom, if it has one. If an atom has no function definition, `GETD` returns `NIL`. For example, type:

  ```lisp
  (GETD 'CAR)
  ```

  A non-`NIL` value is returned. The atom `CAR` already has a function definition.

- Use complete record field names in record FETCHES and REPLACES when your code is not compiled. A complete record field name is a list consisting of the record declaration name and the field name. Consider the following example:

  ```lisp
  (RECORD NAME (FIRST LAST))
  (SETQ MyName (create Name FIRST ←‘John LAST ←‘Smith))
  (FETCH (NAME FIRST) OF MyName)
  ```

- Avoid reusing names that are field names of Lisp system records. A few examples of system records follow. Do not reuse these names.

  ```lisp
  (RECORD REGION (LEFT BOTTOM WIDTH HEIGHT))
  (RECORD POSITION (XCOORD YCOORD))
  ```
When you select a record name and field names for a new record, check to see whether those names have already been used.

Call the function **RECLOCK**, with your record name as an argument, in the Executive Window (see Figure 22-1). If your record name is already a record, the record definition will be returned; otherwise the function will return **NIL**.

![Exec 2 (INTERLISP)](image)

```lisp
NIL
2/170> (RECLOCK 'POSITION)
(RECORD POSITION (XCOORD . YCOORD)
  [TYPE? (AND (LISP-DATUM)
              (NUMBERP (CAR DATUM)))
  (NUMBERP (CDR DATUM))
  (SYSTEM)))
2/171> (RECLOCK 'NewPos)
NIL
2/172>
```

Figure 22-1. Response to **RECLOCK**

Call the function **FIELDLOOK** with your new field name in the Executive Window (see Figure 22-2). If your field name is already a field name in another record, the record definition will be returned; otherwise the function will return **NIL**.

![Exec 2 (INTERLISP)](image)

```lisp
NIL
2/170> (FIELDLOOK 'XCOORD)
((RECORD POSITION (XCOORD . YCOORD)
  [TYPE? (AND (LISP-DATUM)
              (NUMBERP (CAR DATUM)))
  (NUMBERP (CDR DATUM))
  (SYSTEM)))
2/173> (FIELDLOOK 'XPos)
NIL
2/174>
```

Figure 22-2. Response to **FIELDLOOK**

### Some Space and Time Considerations

In order for your program to run at maximum speed, you must efficiently use the space available on the system. The following section points out areas that you may not know are wasting valuable space, and tips on how to prevent this waste.

Often programs are written so that new data structures are created each time the program is run. This is wasteful. Write your programs so that they only create new variables and other data structures conditionally. If a structure has already been created, use it instead of creating a new one.

Some time and space can be saved by changing your **RECORD** and **TYPERECORD** declarations to **DATATYPE**. **DATATYPE** is used the same way as the functions **RECORD** and **TYPERECORD**. In addition, the same **FETCH** and **REPLACE** commands can be used with the data structure **DATATYPE** creates. The difference is that the data structure **DATATYPE** creates cannot be treated as a list the way **RECORDS** and **TYPERECORDS** can.
Global Variables

Once defined, global variables remain until Lisp is reloaded. Avoid using global variables if at all possible! One specific problem arises when programs use the function \texttt{GENSYM}. In program development, many atoms are created that may no longer be useful. Hints:

- Use
  \[
  \text{(DELDEF atomname \texttt{\textsc{\`prop}})}
  \]
  to delete property lists, and
  \[
  \text{(DELDEF atomname \texttt{\textsc{\`vars}})}
  \]
  to have the atom act like it is not defined.

These not only remove the definition from memory, but also change the appropriate file\texttt{COMS} that the deleted object was associated with so that the file package will not attempt to save the object (function, variable, record definition, and so forth) the next time the file is made. Just doing something like

\[
\text{(SETQ (arg atomname) \texttt{\textsc{\`nobind}})}
\]

looks like it will have the same effect as the second \texttt{DELDEF} above, but the \texttt{SETQ} does not update the file package.

- If you are generating atom names with \texttt{GENSYM}, try to keep a list of the atom names that are no longer needed. Reuse these atom names, before generating new ones. There is a (fairly large) maximum to the number of atoms you can have, but things slow down considerably when you create lots of atoms.

- When possible, use a data structure such as a list or an array, instead of many individual atoms. Such a structure has only one pointer to it. Once this pointer is removed, the whole structure will be garbage-collected and space will be reclaimed.

Circular Lists

If your program is creating circular lists, a lot of space may be wasted. (Many crosslinked data structures end up having circularities.) Hints when using circular lists:

- Write a function to remove pointers that make lists circular when you are through with the circular list.

- If you are working with circular lists of windows, bind your main window to a unique global variable. Write window creation conditionally so that if the binding of that variable is already a window, use it, and only create a new window if that variable is unbound or \texttt{NIL}.

Here is an example that illustrates the problem. When several auxiliary windows are built, pointers to these windows are usually kept on the main window's property list. Each auxiliary window also typically keeps a pointer to the main window on its property list. If the top level function creates windows rather than reusing existing ones, there will be many lists of useless windows cluttering the work space. Or, if such a main window is closed and will not be used again, you will have to break the links by deleting the relevant properties from both the main window and all of the auxiliary windows first. This is usually done by putting a special \texttt{CLOSEFN} on the main window and all of its auxiliary windows.
When You Run Out of Space

Typically, if you generate a lot of structure that won't get garbage collected, you will eventually run out of space. The important part is being able to track down those structures and the code that generates them to become more space efficient.

Use the Lisp Library Package `GCHAX.DCOM` to track down pointers to data structures. The basic idea is that `GCHAX` will return the number of references to a particular data structure.

A special function exists that allows you to get a little extra space so that you can try to save your work when you get toward the edge (usually noted by a message indicating that you should save your work and load a new Medley environment). The `GAINSPACE` function allows you to delete non-essential data structures. To use it, type:

```
(GAINSPACE)
```

into the Executive Window. Answer `N` to all questions except the following:

- Delete edit history
- Delete history list.
- Delete values of old variables.
- Delete your `MASTERSCOPE` database
- Delete information for undoing your greeting.

Save your work and reload Lisp as soon as possible.
The purpose of this chapter is to show you how to build a moderately tricky interactive interface with the various Medley display facilities. In particular how to move a large bitmap (larger than 16 x 16 pixels) around inside a window. To do this, you will change the CURSORINFN and CURSOROUTFN properties of the window. If you would also like to then set the bitmap in place in the window, you must reset the BUTTONEVENTFN. This chapter explains how to create the mobile bitmap.

**GETMOUSESTATE Example Function**

One function that you will use to “trace the cursor” (have a bitmap follow the cursor around in a window) is GETMOUSESTATE. This function finds the current state of the mouse, and resets global system variables, such as LASTMOUSEX and LASTMOUSEY.

As an example of how this function works, create a window by typing

```
(setq example.window (createw))
```

into the Executive Window, and sweeping out a window. Now, type in the function

```
(defineq (printcoords (w)
  (promptprint "(" lastmousex ", " lastmousey ")")
  (block)
  (getmousestate)))
```

This function calls GETMOUSESTATE and then prints the new values of LASTMOUSEX and LASTMOUSEY in the prompt window. To use it, type

```
(windowprop example.window 'cursmovedfn 'printcoords)
```

The window property CURSORMOVEDFN, used in this example, will evaluate the function PRINTCOORDS each time the cursor is moved when it is inside the window. The position coordinates of the mouse cursor will appear in the prompt window. (See Figure 23.1.)

Figure 23.1. Current Position Coordinates of Mouse Cursor in Prompt Window

**Advising GETMOUSESTATE**

For the bitmap to follow the moving mouse cursor, the function GETMOUSESTATE is advised. When you advise a function, you can add new commands to the function without knowing how it is actually implemented. The syntax for advise is

```
(advise fn when where what)
```

fn is the name of the function to be augmented. when and where are optional arguments. when specifies whether the change should be made before, after, or around the body of the function. The values expected are BEFORE, AFTER, or AROUND.

what specifies the additional code.
In the example, the additional code, what, moves the bitmap to the position of the mouse cursor. The function GETNOUSESTATE will be ADVISED when the mouse moves into the window. This will cause the bitmap to follow the mouse cursor. ADVISE will be undone when the mouse leaves the window or when a mouse button is pushed. The ADVISEing will be done and undone by changing the CURSORINFN, CURSOROUTFN, and BUTTONEVENTFN for the window.

**Changing the Cursor**

One last part of the example, to give the impression that a bitmap is dragged around a window, the original cursor should disappear. Try typing:

```
(CURSOR (CURSORCREATE (BITMAPCREATE 1 l) 1 1]
```

into the Executive Window. This causes the original cursor to disappear. It reappears when you type

```
(CURSOR T)
```

When the cursor is invisible, and the bitmap moves as the cursor moves, the illusion is given that the bitmap is dragged around the window.

**Functions for Tracing the Cursor**

To actually have a bitmap trace (follow) the cursor, the environment must be set up so that when the cursor enters the tracing region the trace is turned on, and when the cursor leaves the tracing region the trace is turned off. The function Establish/Trace/Data will do this. Type it in as it appears (include comments that will help you remember what the function does).

```
(DEFINEQ (Establish/Trace/Data
 [LAMBDA (wnd tracebitmap cursor/rightoffset cursor/heightoffset
 GCGAGP)

 (* * This function is called to establish the data to trace
 the desired bitmap. "wnd" is the window in which the tracing
 is to take place, "tracebitmap" is the tracing bitmap,
 "cursor/rightoffset" and "cursor/heightoffset" are integers
 which determine the hotspot of the tracing bitmap.
 As "cursor/heightoffset" and "cursor/rightoffset" increase
 the cursor hotspot moves up and to the right.
 If GCGAGP is non-NIL, GCGAG will be disabled.)

 (PROG NIL

 (if (OR (NULL wnd)
 (NULL tracebitmap))
 then (PLAYTUNE (LIST (CONS 1000 4000)))
 (RETURN))
 (if GCGAGP
 then (GCGAG))

 (* * Create a blank cursor.)

 (SETQ *BLANKCURSOR* (BITMAPCREATE 16 16))
 (SETQ *BLANKTRACECURSOR* (CURSORCREATE *BLANKCURSOR*))
```
23. SIMPLE INTERACTIONS WITH CURSOR, BITMAP, AND WINDOW

(* * Set the CURSOR IN and OUT FNS for wnd to the following:*)

(WINPROP wnd (QUOTE CURSORINFN)
 (FUNCTION SETUP/TRACE))
(WINPROP wnd (QUOTE CURSOROUTFN)
 (FUNCTION UNTRACE/CURSOR))

(* * To allow the bitmap to be set down in the window by pressing a mouse button, include this line. Otherwise, it is not needed)

(WINPROP wnd (QUOTE BUTTONEVENTFN)
 (FUNCTION PLACE/BITMAP/IN/WINDOW))
(WINPROP wnd (QUOTE CURSOROUTFN)

(* * Set up Global Variables for the tracing operation)

(SETQ *TRACEBITMAP* tracebitmap
(SETQ *RIGHT_TRACE/OFFSET* (OR cursor/rightoffset 0))
(SETQ *HEIGHT_TRACE/OFFSET* (OR cursor/heightoffset 0))
(SETQ *OLDBITMAPPOSITION* (BITMAPCREATE (BITMAPWIDTH
tracebitmap)
BITMAPHEIGHT
tracebitmap)))
(SETQ *TRACEWINDOW* wnd)))

When the function Establish/Trace/Data is called, the functions SETUP/TRACE and UNTRACE/CURSOR will be installed as the values of the window's WINDOWPROPS, and will be used to turn the trace on and off. Those functions should be typed in, then:

.DEFINEQ (SETUP/TRACE
 [LAMBDA (wnd)

 (* * This function is wnd's CURSORINFN. It simply resets the last trace position and the current tracing region. It also readvises GETMOUSESTATE to perform the trace function after each call.)

 (if *TRACEBITMAP*
 then (SETQ *LAST_TRACE-XPOS* -2000)
 (SETQ *LAST_TRACE-YPOS* -2000)
 (SETQ *WNDREGION* (WINDOWPROP wnd (QUOTE REGION)))
 (WINDOWPROP wnd (QUOTE TRACING)
 T)

 (* * make the cursor disappear)

 (CURSOR *BLANKTRACECURSOR*)
 (ADVISE (QUOTE GETMOUSESTATE)
 (QUOTE AFTER)
 NIL
 (QUOTE (TRACE/CURSOR)))

 DEFINEQ (UNTRACE/CURSOR
 [LAMBDA (wnd)

 (* * This function is wnd's CURSOROUTFN. The function first checks if the cursor is currently being traced; if so, it replaces the tracing bitmap with what is under it and then turns tracing off by unadvising GETMOUSESTATE and setting the TRACING window property of *TRACEWINDOW* to NIL.)

 (if (WINDOWPROP *TRACEWINDOW* (QUOTE TRACING))
23. SIMPLE INTERACTIONS WITH CURSOR, BITMAP, AND WINDOW

then (BITBLT *OLDBITMAPPOSITION* 0 0 (SCREENBITMAP)
   (IPLUS (CAR *WNDREGION*) *LAST-TRACE-XPOS*)
   (IPLUS (CADR *WNDREGION*) *LAST-TRACE-YPOS*)
   (WINDOWPROP *TRACEWINDOW* (QUOTE TRACING) NIL))

(* * replace the original cursor shape)

(CURSOR T)

(* * unadvise GETMOUSESTATE)

(UNADVISE (QUOTE GETMOUSESTATE)))

The function SETUP/TRACE has a helper function that you must also type in. It is TRACE/CURSOR:

(DEFINED (TRACE/CURSOR
   (LAMBDA NIL
      (* * This function does the actual BITBLTing of the tracing bitmap. This function is called after a GETMOUSESTATE, while tracing.)
      (PROG ((xpos (IDDIFFERENCE (LASTMOUSEX *TRACEWINDOW*) *RIGHTTRACE/OFFSET*))
         (ypos (IDDIFFERENCE (LASTMOUSEY *TRACEWINDOW*) *HEIGHTTRACE/OFFSET*))
         (* * If there is an error in the function, press the right button to unadvise the function. This will keep the machine from locking up.)
         (if (LASTMOUSESTATE RIGHT) then (UNADVISE (QUOTE GETMOUSESTATE)))
         (if (AND (NEQ xpos *LAST-TRACE-XPOS*)
              (NEQ ypos *LAST-TRACE-YPOS*))
            then
            (* * Restore what was under the old position of the trace bitmap)
            (BITBLT *OLDBITMAPPOSITION* 0 0 (SCREENBITMAP)
              (IPLUS (CAR *WNDREGION*) *LAST-TRACE-XPOS*)
              (IPLUS (CADR *WNDREGION*) *LAST-TRACE-YPOS*))
            (* * Save what will be under the position of the new trace bitmap)
            (BITBLT (SCREENBITMAP)
              (IPLUS (CAR *WNDREGION*) xpos)
              (IPLUS (CADR *WNDREGION*) ypos) *OLDBITMAPPOSITION* 0 0)
            (* * BITBLT the trace bitmap onto the new position of the mouse)
            (BITBLT *TRACEBITMAP* 0 0 (SCREENBITMAP)
              (IPLUS (CAR *WNDREGION*) xpos)
              (IPLUS (CADR *WNDREGION*) ypos)
              NIL NIL (QUOTE INPUT) (QUOTE PAINT))
            (* * Save the current position as the last trace position.)
            (SETQ *LAST-TRACE-XPOS* xpos)
The helper function for UNTRACE/CURSOR, called UNDO/TRACE/DATA, must also be added to the environment:

```
(DEFINEQ (UNDO/TRACE/DATA
       (LAMBDA NIL
          
            (* * The purpose of this function is to turn tracing off
               and to free up the global variables used to trace the
               bitmap so that they can be garbage collected.)

            (* * Check if the cursor is currently being traced.
               It so, turn it off.)

            (UNTRACE/CURSOR)
            (WINDOWPROP *TRACEWINDOW* (QUOTE CURSORINFN) NIL)
            (WINDOWPROP *TRACEWINDOW* (QUOTE CURSOROUTFN) NIL)
            (SETQ *TRACEBITMAP* NIL)
            (SETQ *RIGHTTRACE/OFFSET* NIL)
            (SETQ *HEIGHTTRACE/OFFSET* NIL)
            (SETQ *OLDBITMAPPOSITION* NIL)
            (SETQ *TRACEWINDOW* NIL)
            
            (* * Turn GCGAG on)

            (GCGAG T))
```

Finally, if you included the WINDOWPROP to allow the user to place the bitmap in the window by pressing a mouse button, you must also type this function:

```
(DEFINEQ (PLACE/BITMAP/IN/WINDOW
       (LAMBDA (wnd)
          
            (UNADVISE (GETMOUSESTATE))
            (BITBLT *TRACEBITMAP* 0 0 (SCREENBITMAP)
                   (IPLUS (CAR *WNDREGION*) xpos)
                   (IPLUS (CADR *WNDREGION*) ypos)
                   NIL NIL (QUOTE INPUT)
                   (QUOTE PAINT)

            That's all the functions!
```

Running the Functions

To run the functions you just typed in, first set a variable to a window by typing something like

```
(SETQ EXAMPLE.WINDOW (CREATEW))
```

into the Executive Window, and sweeping out a new window. Now, set a variable to a bitmap, by typing, perhaps,

```
(SETQ EXAMPLE.BTM (EDITBM))
```
Type

(Establish/Trace/Data EXAMPLE.WINDOW EXAMPLE.BTM)

When you move the cursor into the window, the cursor will drag the bitmap.

(If you want to be able to make menu selections while tracing the cursor, make sure that the hotspot of the cursor is set to the extreme right of the bitmap. Otherwise, the menu will be destroyed by the BITBLTs of the trace functions.)

To stop tracing, do one of the following:
- Move the mouse cursor out of the window
- Press the right mouse button
- Call the function UNTRACE/CURSOR
24. GLOSSARY OF GLOBAL SYSTEM VARIABLES

As you can tell by now, there are many system variables in Medley that are useful to know. The following sections gather many of the important variables together into groups relating to directory searching, system flags, history lists, system menus, windows, and, of course, the catchall miscellaneous category.

Directories

DISPLAYFONTDIRECTORIES

Its value is a list of directories to search for the bitmap files for display fonts. Usually, it contains the FONT directory where you copies the bitmap files (see Chapter 16), and the current connected directory. The current connected directory is specified by the atom NIL. Here is an example value of DISPLAYFONTDIRECTORIES.

<table>
<thead>
<tr>
<th>DISPLAYFONTDIRECTORIES Package: INTERLISP</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;{DSK}&lt;usr&lt;local&lt;ide&lt;Fonts&gt;display&gt;presentation}&quot;</td>
</tr>
<tr>
<td>&quot;{DSK}&lt;usr&lt;local&lt;ide&lt;Fonts&gt;display&gt;publishing}&quot;</td>
</tr>
<tr>
<td>&quot;{DSK}&lt;usr&lt;local&lt;ide&lt;Fonts&gt;display&gt;printwheel}&quot;</td>
</tr>
</tbody>
</table>

Figure 24.1. Value for the Atom DISPLAYFONTDIRECTORIES

INTERPRESSFONTDIRECTORIES

Is set to a list of directories to search for the font width files for InterPress fonts.

DIRECTORIES

This variable is bound to a list of the directories you will be using (see Figure 24-2). The system uses this variable when it is trying to find a file to load. It checks each directory in the list, until the file is found. NIL in list means to check the current connected directory.

LISPUSERSDIRECTORIES

Its value is a list of directories to search for library package files.
24. GLOSSARY OF GLOBAL SYSTEM VARIABLES

Flags

**DWIMIFYCOMPPFLG**

This flag, if set to T, will cause all expressions to be completely dwimified before the expression is compiled (see Chapter 9). In this state, when the system does not recognize a function of keyword, it will compare the word to a system maintained list to determine whether the word is a macro, CLISP word, or misspelled user-defined variable.

An example of dwimifying before compilation is to convert an IF call to a COND. before they are compiled. Undwimified expressions can cause inaccurate compilation. This flag is set by the system to NIL. Normally, you want this set to T. For more information on DWIM, refer to the IRM.

**SYSPRETTYFLAG**

When set to T, all lists returned to the executive window are pretty printed. This flag is originally set by the system to NIL.

**CLISPIFTRANFLG**

When set to T, keeps the IF expression, rather than the COND translation in your code.

**PRETTYTABFLG**

When set to T, the pretty printer puts out a tab character rather than several spaces to try to make code align. If NIL, it uses space characters instead.

**FONTCHANGEFLG**

If NIL, then when pretty printing no font changes will happen (e.g., a smaller font for comments, bold for clip words, and so forth). The default is the atom ALL, so different fonts are used where appropriate.

**AUTOBACKTRACEFLG**

There are many possible values for this variable. They affect when the back trace window appears with the break window, and how much detail is included in it. The values of this variable include:

- NIL, its initial value. The back trace window is not brought up when an error is generated, until you open it yourself.
- T, which means that the back trace BT window is opened for error breaks
- BT! brings up a back trace window with more detail, BT!, window for error breaks
- ALWAYS brings up a backtrace BT window for both error breaks, and breaks caused by calling the function BREAK
- ALWAYS! brings up a backtrace window with more detail, BT!, for both error breaks and breaks caused by calling the function
NOSPELLFLG

Is initially bound to \texttt{NIL}, so that \texttt{DWIM} tries to correct all spelling errors, whether they are in a form you just typed in or within a function being run. If the variable is \texttt{T}, then no spelling correction is performed. This variable is automatically reset to \texttt{T} when you are compiling a file. If it has some other non-\texttt{NIL} value, then spelling correction is only performed on type-in.

\section*{History Lists}

\subsection*{LISPXHISTORY}

Originally set to the list \texttt{(NIL 0 30 100)}, with the following argument interpretation. The \texttt{NIL} is the list (implemented as a circular queue) to which the top level commands append. 0 is the current prompt number. 30 is the maximum length of the history list. 100 is the highest number used as a prompt. This is a system maintained list used by the programmers assistant commands \texttt{REDO}, \texttt{UNDO}, \texttt{FIX}, and \texttt{??} use to retrieve past function calls.

To delete the history list, reset the variable \texttt{LISPXHISTORY} to its original value of \texttt{(NIL 0 30 100)}.

Setting this variable to \texttt{NIL} disables all the programmers assistant features.

\subsection*{EDITHISTORY}

This is also set to \texttt{(NIL 0 30 100)}, and has the same description as \texttt{LISPXHISTORY}. This list allows you to \texttt{UNDO} edits. You reset this the same way as \texttt{LISPXHISTORY}.

\section*{System Menus}

System menus are all bound to global variables and are easy to modify. If the menu name is set to the \texttt{NIL} value, the menu will be recreated using an items list bound to a global variable.

To change a system menu, edit the items list bound to the appropriate global variable (system menus use this items list with the default \texttt{WHENSELECTEDFN}), then set the value of the name to \texttt{NIL}. The next time you need the menu, it will be created from the items list you just edited. The names of system menus and the items lists follow.

\subsection*{BackgroundMenu}

This is the variable bound to the menu this displays when you press the right button in the grey background area of the screen.

\subsection*{BackgroundMenuCommands}

This list is used for the list of \texttt{ITEMS} for the background menu when it is created.

\subsection*{WindowMenu}

This is the variable bound to the default window menu displayed when the right mouse button is pressed inside of a window.
WindowMenuCommands

This is the list of ITEMS for the WindowMenu.

BreakMenu

The menu displayed when the middle mouse button is pressed in a break window.

BreakMenuCommands

The list of ITEM for the BreakMenu.

Windows

PROMPTWINDOW

Global name of the prompt window.

T

Although the value T has several meanings (such as universal TRUE), it also stands for the standard output stream. As this is usually the executive window, it may be used as the name for the TTY Window at the top level. Mouse processes have their own TTY Windows. A reference to the window T in a mouse driven function (e.g., a WHENSELECTEFN, Chapter 12) will open a TTY Window for Mouse.

Miscellaneous

CLEANUPOPTION

This is a list of options that you set to automate clean-up after a work session. Example options are listing files, or recompilation. You will want to keep this set to NIL until you become comfortable with the machine.

FILELST

The list of all the files you loaded.

SYSFILES

The list of all the files you loaded for the SYSOUT file.

INITIALS

An atom you can bind to your name. If bound, the editor will add your name, in addition to the date, in the editor comment at the beginning of each function.

FIRSTNAME

If this variable is set, the system will use it to greet you personally when you log on to your machine.
INITIALSLST

A list of elements of the form (USERNAME . INITIALS) or (USERNAME FIRSTNAME INITIALS). This list is used by the function GREET to set your INITIALS, and your FIRSTNAME when you log in.

#CAREFULCOLUMNS

An integer. PRETTYPRINT estimates the number of characters in an atom, instead of computing it, for efficiency. Unfortunately, for very long atom names, errors can occur. #CAREFULCOLUMNS is the number of columns from the right within which PRETTYPRINT should compute the number of characters in each atom, to prevent these errors. Initially this is set to zero. PRETTYPRINT never computes the number of characters in an atom. If you set it to 20 or 30, when PRETTYPRINT comes within 20 or 30 columns of the right of the window, it will begin computing exactly how many characters are in each atom. This will prevent errors.

DWIMWAIT

Bound to the number of seconds DWIM should wait before it uses the default response, FIXSPELLDEFAULT, to answer its question.

FIXSPELLDEFAULT

Bound to either Y or N. Its value is used as the default answer to questions asked by DWIM that you don’t answer in DWIMWAIT seconds. It is initially bound to Y, but is rebound to N when DWIMIFYing.

\TimeZoneComp

This is the global variable set to the absolute value of the time offset from Greenwich. For EST, \TimeZoneComp should be set to 5.
25. OTHER USEFUL REFERENCES

Here are some references to works that will be useful to you in addition to this primer. Some of these you have already been referred to, such as:

- The Interlisp-D Reference Manual (IRM)
- The Library Packages Manual
- The User’s Guide to SKETCH

In addition, you can learn more about Lisp with the books:

- **Interlisp-D: The language and its usage** by Steven H. Kaisler. This book was published in 1986 by John Wiley and Sons, NY.
- **Essential LISP** by John Anderson, Albert Corbett, and Brian Reiser. This book was published in 1986 by Addison Wesley Publishing Company, Reading, MA. It was informed by research on how beginners learn LISP.
- **The Little Lisper** by Daniel P. Friedman and Matthias Felleisen. The second edition of this book was published in 1986 by SRA Associates, Chicago. This book is a deceptively simple introduction to recursive programming and the flexible data structures provided by LISP.
- **LISP** by Patrick Winston and Berthold Horn. The second edition of this book was published in 1985 by the Addison Wesley Publishing Company, Reading, MA.

Finally, there are three articles about the Interlisp Programming environment:

- **Power Tools For Programmers** by Beau Sheil. It appeared in Datamation in February, 1983, Pages 131 - 144.

Each of these articles was reprinted in the book **Interactive Programming Environments** by David R. Barstow, Howard E. Shrobe, and Erik Sandewall. This book was published in 1984 by McGraw Hill, NY. The first article can be found on pages 19 - 30, the second on pages 83 - 96, and the third on pages 31 - 80.

PREFACE

it was dawn and the locd told him it was down the road a piece, left & the hst fishing bridge in the counvy right at the apple tree stump, and onto the dirt road just before the hill. At midnight he knew he was lost.
-Anonymous

Welcome to the Interlisp-D programming environment! The Interlisp-D environment truly must be one of the most sophisticated and powerful tools in use by human beings. Overall, it is flexible, well thought out, and full of pleasant surprises: "Wow, here are exactly the set of functions I thought I’d need to write." Unfortunately, along with the power comes mind-numbing complexity. The Interlisp Reference Manual describes the functions and some of the tools available in the Interlisp-D environment. To do this takes three large volumes. Other volumes are needed to document the library packages and other newly written tools. Needless to say, it is very difficult to learn such a huge amount of material when there is no way to determine where to start!

We developed this primer to provide a starting point for new Interlisp-D users, to enhance your excitement and challenge you with the potential before you. We assume you know a little about LISP, most likely received from taking a survey course in Artificial Intelligence (AI), and have seen a demonstration of how Interlisp-D runs on your 1186 or 1108. We further assume that your machine is not on a network system with a file server - though this is addressed, and that you will be working from floppy disks and the hard disk that is part of the machine. If this describes your situation, you are ready to sit down in front of your machine and follow the step-by-step examples provided in this primer.

The primer is broken into many small chapters, and these chapters are organized into five parts. You may want to read
Parts 1 through 3 straight through, since they describe the basics of using the machine. Each chapter in Sections 4 and 5, however, can be used to learn a specific skill whenever you are ready to for it.

Part one, "Introduction", includes Chapters 1 and 2. Part two, "Getting Into/Out of Interlisp", includes Chapters 3 through 5. Part three, "The Interlisp-D language and Programming Environment", includes Chapters 6 through 15. These chapters discuss primary elements in Interlisp-D, and orient you in relation to those elements. Part four, "Important Other Things to Know to Work Successfully", includes Chapters 16 through 31. Part five, "More Language and Environment and Packages", includes Chapters 32 through 44.

PREFACE

Through out we make reference to the Interlisp-D Reference Manual by section and page number. The material in the primer is just an introduction. When you need more depth use the detailed treatment provided in the manual.

While only you can plot your ultimate destination, you will find this primer indispensable for clearly defining and guiding you to the first landmarks on your way.

Acknowledgements The early inspiration and model for this primer came from the Intelligent Tutoring Systems group and the Learning Research and Development Center at the University of Pittsburgh. We gratefully acknowledge their pioneering contribution to more effective artificial intelligence.

This primer was developed by Computer Possibilities, a company committed to making AI technology available. Primary development and writing was done by Cynthia Cosic, with technical writing support provided by Sam Zordich.

At Xerox Artificial Intelligence Systems, John Vittal managed and directed the project. Substantial assistance was provided by many members of the AIS staff who provided both editorial and systems support.

PREFACE ø1
1. ABRIEFGLOSSARY

The following definitions will acquaint you with general terms
used throughout this primer. You will probably want to read
through them now, and use this chapter as a reference while you
read through the rest of the primer.

advising An Interlis-D facility for specifying function modifications
without necessarily knowing how a particular function works or
even what it does. Even system functions can be changed with
advising.

argument An argument is a piece of information given to an Interlis-D
function so that it can execute successfully. When a function is
explained in the primer, the arguments that it requires will also
be given. Arguments are also called Parameters.

atom The smallest structure in Lisp; like a variable in other
programming languages, but can also have a property list and a
function definition.

Background Menu The menu that appears when the mouse is not in any window
and the right mouse button is pressed. A typical background
menu is shown in Figure I.I.

Loops Icon
FileBrowser

Figure 1.1. The Menu that appears when the mouse is not in any window,
and the right mouse button is pressed. Your background menu may have some
different items in it

binding The value of a variable. It could be either a local or a global
variable. See unbound.

bitmap A rectangular array of ‘0’ pixels, ‘0’ each of which is on or off
representing one point in the bitmap image.

BREAK An Interlisp function that causes a function to stop executing,
open a Break window, and allow the user to find out what is
happening while the function is halted.

Break Window A window that opens when an error is encountered while
running your program (i.e., when your program has broken).
There are tools to help you debug your program from this
window. This is explained further in Chapter 14, Page 14.1.

browse To examine a data structure by use of a display that allows the
user to "move" around within the data structure.

button
A BRIEF GLOSSARY 1.1

1

A BRIEF GLOSSARY

(1) (n.) A key on a mouse.

(2) (v.t.) To depress one of the mouse keys when making a selection.

EAR A function that returns the head or first element of a list. See CDR.

caret The small blinking arrowhead that marks where text will appear when it is typed in from the keyboard. An example of the caret in the Interlisp-D Executive Window is shown in Figure 1.2.

NIL

B6+(PLUS 3A

Figure 1.1. The caret is to the right of the number 3. When a character is typed at the keyboard, it will appear at the caret.

CDR A function that returns the tail (that is, everything but the first element) of a list. See EAR.

CLISP A mechanism for augmenting the standard Lisp syntax. One such augmentation included in Interlisp is the iterative statement. See Section 13.1.

cr Please press your carriage return key.

datatype

(1) The kind of a datum. In Interlisp, there are many System-define datatypes e.g. Floating Point, Integer, Atom, etc.

(2) A datatype can also be user-defined. In this case it is like a record made up from system types and other user-defined datatypes.

DWIM D-what-it-mean. Many errors made by Interlisp users could be corrected without any information about the purpose of the program or expression in question (e.g. misspellings, certain kinds of parenthesis error). The DWIM facility is called automatically whenever an error occurs in the evaluation of an Interlisp expression. If DWIM is able to make a correction, the computation continues as though no error had occurred; otherwise, the standard error mechanism is invoked.

error Occasionally, while a program is running, an error may occur which will stop the computation. Interlisp provides extensive facilities for detecting and handling error conditions, to enable the testing, debugging, and revising of imperfect programs.

evaluate or EVAL Means to find the value of a form. For example, if the variable X is bound to 5, we get 5 by evaluating X. Evaluation of an Interlisp function involves evaluating the arguments and then applying the function.

file package A set of functions and conventions that facilitate the bookkeeping involved with working in a large system consisting of many source code files and their compiled counterparts.

Essentially, the file package k:ps track of who did what and when.

1, A BRIEF GLOSSARY 1.1

1
A BRIEF GLOSSARY

whet things have changed. N 4150 kapps track of which files have been modified and need to be updated and recompiled.

form Another way of saying expression. An Interlisp-D expression between be evaluated.

function A Lisp function is a piece of code that executes and returns a value.

history The programmer's assistant is built around a memory structure called the history list. The history functions (e.g. FIX, UNDO, REDO) are part of this assistant. These operations allow you to conveniently rework previously specified operations.

History List As you type on the screen, you will notice a number followed by a prompt after. Each number, and the information on that line, is sequentially stored as the History List. Using the History List, you can easily reexecute lines typed earlier in a work session. See Chapter 6.

icon A pictorial representation, usually of a shrunken window.

Interlisp-D Executive Window This is your main window, where you will run functions and develop your programs. See Figure 1.3. This is the window that the caret is in when you turn on your machine and load Interlisp-D.

NIL

8-PRO*PRINT "HELLO" A

FQR J. m window

inspector An interactive display program for examining and changing the parts of a data structure. Interlisp-D has inspectors for lists and other data types.

iterative statement (also called i.s.) A statement in Interlisp that repetitively executes a body of code. (E.g. (FORX FROM 1 TO 5 DO (PRINT X)) is an i.s.)

iterative variable (also called i.v.) Usually, an iterative statement is controlled by the value that the i.v. takes on. In the iterative statement example above,

x

is the iterative variable because its value is being changed by each cycle through the loop. All iterative variables are local to the iterative statement where they are defined.

LISP Family of languages invented for "list processing." These languages have in common a set of basic primitives for creating and manipulating symbol structures. Interlisp-D is an implementation of the LISP language together with an environment (set of tools) for programming, and a set of packages that extend the functionality of the system.

list A collection of atoms and lists; a list is denoted by surrounding its contents with a pair of parentheses.

A BRIEF GLOSSARY II

1
Loading LJSP This is the process of bringing Interlis-D from floppy disks, hard disks, or some other secondary storage into your main, or working, memory. You will need to load (i.e., install, and boot) Interlis-D if you have not logged off the machine at the end of a session. The process of loading Interlis-D is explained in Chapter 3.

Maintenance Panel Codes Should you have a problem with your equipment, these codes will indicate the status of your processor. On the 1108, these are the red LED numbers under the floppy drive door. There is a cover over these numbers. Pull down the cover located immediately under the floppy door button. The code numbers are defined for the 1108 in the 1108 User Guide, in the MP Codes chapter.

If there is a problem with the 1186, the mouse cursor will change from its normal arrow to the code number that describes the problem. The code numbers are defined for the 1186 in the 1186 User’s Guide in the Cursor Codes subsection of the Diagnostics Chapter.

Masterscope A program analysis tool. When told to analyze a program, Masterscope creates a data base of information about the program. In particular, Masterscope knows which functions call other functions and which functions use which variables. Masterscope can then answer questions about the program and display the information with a browser.

Menu A way of graphically presenting the user with a set of options. There are two kinds of menus: popup menus are created when needed and disappear after an item has been selected; permanent menus remain on the screen after use.

Mouse The Mouse is the box to the right of your keyboard. It controls the movement of the cursor on your screen. As you become familiar with the mouse, you will find it much quicker to use the mouse than the keyboard. See Figure 1.4. (Note: Some mice have three buttons; the button in the center is known as the middle mouse button. If your mouse has only two buttons, you can simulate a middle button by pressing the left and right buttons simultaneously.).

Mouse Cursor The small arrow on the screen that points to the northwest. See Figure 1.5.

A IRIEF GLOSSARY

I Wait The processor is busy.

The processor is saving a snapshot or your current system session. This is usually done when the processor has been idle for a while.

The "Mouse Confirm Cursor". It appears when you have to confirm that the choice you just made was correct. If it was, press the left button. If the choice was not right, press the right button to abort.
F=’*x This means "sweep out" the shape of the window. To do this, move the mouse to a position where you want a corner. Press the left mouse button, and hold it down. Move the mouse diagonally to sketch a rectangle. When the rectangle is the desired size and shape, release the left button.

NIL NIL is the Interlis-D symbol for the empty list it can also be represented by a left paren followed by a right paren: (). It is the only expression in Interlis-D that is both an atom and a list pixel Pixel stands for Picture Element. The screen of your Lisp Machine is made up of a rectangular array of pixels. Each pixel corresponds to one bit When a bit is turned on, i.e. set to 1, the pixel on the screen represented by this bit is black.

pretty printing Pretty printing refers to the way Interlis-D functions are printed with special indentation, to make them easier to read. Functions are pretty printed in the structure editor, DEdit (See Section 11.3, Page 11.4). You can pretty print uncompiled functions by calling the function PP with the function you would like to see as an argument, i.e. (PP function-name). For an example of this, see Figure 1.6.

A BRIEF GLOSSARY 1.5
1

A BRIEF GLOSSARY

Programmer’s Assistant The programmer’s assistant accesses the History List to allow you to FIX, U100, and/or REDO your previous expressions typed to the Interlis-D executive window. (See Chapter 6.)

Prompt window The skinny black window at the top of the screen. It displays system prompts, or prompts you have developed. (See Figure 1.7.)

Fqurø 1.7. Prompt window

property list A list of the form ( <property-name1> <property-value1>
<property-name2> <property-value2> ....) associated with an atom. It accessed by the functions GETPROP and PUTPROP.
record A record is a data-structure that consists of named "fields". Accessing elements of a record can be separated from the details of how the data structure is actually stored. This eliminates many programming details. A record definition establishes a record template, describing the form of a record. A record instance is an actual record storing data according to a particular record template. (See datatype, second definition.)

Right Button Default Window Menu This is the menu that appears when the mouse is in a window, and the right mouse button is pressed. It looks like the menu in Figure 1.8. If this menu does not appear when you depress the right button of the mouse and the mouse is in the window, move the mouse so that it is pointing to the title bar of the window, and press the right button.

Clone

Shrink

5-expression Short for "symbolic expression." In Lisp, this refers to any well-formed collection of left parffns, atoms, and right parens.

stack A pushdown list Whenever a function is entered, information about that specific function call is pushed onto (i.e. added to the front of) the stack; this information includes the variable names and their values associated with the function call. When the function is exited, that data is popped off the stack.

storage devices Information is stored for your Lisp machine on floppy disks, or on the hard disk. They are referred to as (FL ØPPY) and (DSK) respectively.

sysout A file containing all Lisp environment variables, namely, Interlis-O, everything the user defined or loaded into the environment, etc.

1.6 A ~N:EF GL ØSARY
I

A BRIEF GLOSSARY

windows that appeared on the screen, the amount of memory used, and 50 on. Everything is stored in the sysout file exactly as it was when the function SYST was called).

TFACE A function that creates a trace of the execution of another function. Each time the traced function is called, it prints out the values of the arguments it was called with, and prints out the value it returns upon completion.

Unbound Without value; an atom is unbound if a value has never been assigned to it

window A rectangular area of the screen that acts as the main display area for some Interlisp process,
6. TYPING SHORTCUTS

Once you have logged it, as per Chapters 3 or 4, you are in Interlis-D. The functions you type into the Interlis-D executive window will now execute, that is, perform the designated task. Please note that Interlis-D is case-sensitive; often it matters whether text is typed in capital- or lower-case letters. The shiftlock key is above the left shift key; when it is pressed (on the 1186, the red LED will be on; on the 1108, the key will be depressed), everything typed is in capital letters.

You must type all Interlis-D functions in parentheses. The Interlis-D interpreter will read from the left parenthesis to the closing right parenthesis to determine both the function you want to execute, and the arguments to that function. Executing this function is called evaluation. When the function is evaluated it returns a value, which is then printed in the Interlis-D executive window. This entire process is called the read-eval-print loop, and is how most LISP interpreters, including the one for Interlis-D, run.

The prompt in Interlis-D is a number followed by a left pointing arrow (see Figure 6.3). This number is the function’s position on the History List -- a list that stores your interactions with the Interlis-D interpreter. Type the function `(PLUS 3 4)`, and notice the number the History List assigns to the function (the number immediately to the left of the arrow). Interlis-D reads in the function and its arguments, evaluates the function, then prints the number 7.

In addition to this read-eval-print loop, there is also a programmer’s assistant. It is the programmer’s assistant that prints the number as part of the prompt in the Interlis-D executive window, and uses these numbers to reference the function calls typed after them.

When you issue commands to the programmer’s assistant, you will not use parentheses as you do with ordinary function calls. You simply type the command, and some specification that indicates which item on the history list the command refers to. Some programmer’s assistant commands are FIX, REDO, and UNDO. They are explained in detail below.

Programmer’s assistant commands are useful only at the Interlis-D top level, that is, when you are typing into the
Interlis-D executive window. They will not work in user-defined functions.

As an example use of the programmer’s assistant, use REDO to redo your function call (PLUS 3 4). Type REDO (Note: programmer’s assistant commands can be typed in either upper

TYPING 5H0RTCUTS 6 1

TYPING SHORTCUTS

or lower case) at the prompt, then specify the previous expression in one of the following ways:

(1) When you originally typed in the function you now want to refer to, there was a History List number to the left of the arrow in the prompt. Type this number after the programmer’s assistant command. This is the method illustrated in the following figure:

\[ \text{REDO } \text{PLUS } 3 4 \]
\[ \text{C} \text{5} \text{REOO } \text{24} \]
7
26,'`

Figure 6.1. Using the programmer’s assistant to REDO a function, when you know the its number on the history list

(2) A negative number will specify the function call typed in that number of prompts ago. in this example, you would type -1, the position immediately before the current position. This is shown in the following figure:

\[ \text{REDO } \text{PLUS } 3 4 \]
\[ \text{REOO } \text{24} \]
7
26,'`

Figure 6.2. Typing a negative number after the programmer’s assistant command will cause it use the function found on the History List that many positions before the current one.

(3) You can also specify the function for the programmer’s assistant with one of the items that was in that function call. The programmer’s assistant will search backwards in the History List, and use the first function it finds that includes that item. For example, type REDO PLUS to have the function (PLUS 3 4) reevaluated.

(4) If you type a Programmer’s Assistant command without specifying a function (i.e., simply typing the command, then a cr) the Programmer’s Assistant executes the command using the function entered at the previous prompt.
Here are a few more examples of using the programmer’s assistant:

Fqøuroø 6.3. Some Applications of the Programmer’s Assistant

6.1 If you make a Mistake

Editing in the Interlisp-D Executive Window is explained in Section 11.2, Page 11.2. In this section, only a few of the most useful commands will be repeated.

To move the caret to a new place in the command being typed, point the mouse cursor at the appropriate position, and press the left mouse button.

To move the caret back to the end of the command being typed, press CONTROL-X. (Hold the CONTROL key down, and type ø.X.’.)

The way you choose to delete an error may depend on the amount you need to remove. To delete:

The character behind the caret simply press the backspace key
The word behind the caret press CONTROL-W. (Hold the CONTROL key down, and rype ‘øWø.)

Any part of the command, first move the caret to the appropriate place in the command. Hold the right mouse button down and move the mouse cursor over the ten. All of the blackened tert between the caret and mouse cursor is deleted when you release the right mouse button.
TYPING SHORTCUTS 63

IF YOU MAKE A MISTAKE

The entire command press CONTROL-U. (Hold the CONTROL key down, and type in ".")
Deletions can be undone. Just press the UNDO key.
To add more text to the line, move the caret to the appropriate position, and just type. Whatever you type will appear at the caret.

6.4 TYPING SHORTCUTS

7. USING MENUS

The purpose of this chapter is to show you how to use menus.
Many things can be done more easily using menus, and there are many different menus provided in the Interlisp-D environment.
Some are "po-up" menus, that are only available until a selection is made, then disappear until they are needed again.
An example of one of these is the "background menu", that appears when the mouse is not in any window and the right mouse button is pressed. A background menu is shown in Figure 7.1. Yours may have different items in it.

SkGtL’h
LUop3 Icon
CHAT
F.lle0r-o-er
sav“VM
5nap

Figure 7.1. A background menu.

Another common pop-up menu is the right button default window menu. This menu is explained more in Section 10.4, Page 10.3.

Other menus are more permanent, such as the menu that is always available for use with the Interlisp-D Filebrowser. This menu is shown in figure Figure 7.2, and the specifics of its use with the filebrowser is explained in Chapter 9).

Dnjelsta
Rcnamr
Hor-”UpJ
-=‘ifl.e
MAKING A SELECTION FROM A MENU

7.1 Making a Selection from a Menu
To make a selection from a menu, point with the mouse to the item you would like to select. If one of the mouse buttons is already pressed, the menu item should blacken. If it is a permanent menu, you must press the left mouse button to blacken the item. When you release the button, the item will be chosen. Figure 7.3 shows a menu with the item "Undo" chosen.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig7_3.png}
\caption{A menu with the item "Undo" chosen}
\end{figure}

7.2 Explanations of Menu Items
Many menu items have explanations associated with them. If you are not sure what the consequences of choosing a particular menu item will be, blacken the menu item, and do not release the left button. If the menu item has an explanation associated with it, the explanation will be printed in the prompt window. Figure 7.4 shows the explanation associated with the item "Snap" from the background menu.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig7_4.png}
\caption{The explanation associated with the chosen item, Snap, is displayed in the prompt window}
\end{figure}

7.3 Submenus

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig7_5.png}
\caption{The menu that is available when using the Filebrowser}
\end{figure}
Some menus items have submenus associated with them. This means that, for these items, you can make even more precise choices if you would like to.

A submenu can also be found in one of two ways. One is to point to the item with the mouse cursor, and press the middle mouse button. If there is a submenu associated with that item, it will appear. (See Figure 7.5.)

Figure 7.5. The submenu associated with the menu item Exit It appeared when the mouse cursor pointed to the menu item and the middle mouse button was pressed.

A submenu can be indicated by a gray arrow to the right of the menu item, like the one to the right of the "Hardcopy" choice in Figure 7.1. To see the submenu, blacken the menu item, and move the mouse to follow the arrow. An example of this is shown in Figure 7.6. Choosing an item from a submenu is done in the same way as choosing an item from the menu. Any submenus that might be associated with the items in the submenu are indicated in the same way as the submenus associated with the items in the menu.

In summary, here are a few rules of thumb to remember about the interactions of the mouse, and system menus:

- Press the left mouse button to select an item of a menu
Press the middle mouse button to get more options - one of the ways to find a submenu

USING MENUS 73

SUBMENU 5

Press the right mouse button to see the default right button window menu, and the background menu

7.4 using menus

8. MOW TO USE FILES

8.1 Types of Files

A program file, or lisp file, contains a series of expressions that can be read and evaluated by the Interlisp-D interpreter. These expressions can include function or macro definitions, variables and their values, properties of variables, and soon. How to save Interlisp-D expressions on these files is explained in Section 11.6, Page 11.7. Loading a file is explained below, in Section 8.6, Page 8.4.

Not all files, however, have Interlisp-D expressions stored on them. For example, TEDit files (see Chapter 23) store text; sketches are stored on files made with the package Sketch (see Chapter 35), or can be incorporated into TEDit files. These files are not loaded directly into the environment, but are accessed with the package used to create them, such as TEDit or Sketch. When you name a file, there are conventions that you should follow. These conventions allow you to tell the type of a file by the extension to its name. If a file contains:

Interlisp-D expressions, it should not have an extension. For example, a file called "MYCODE" should contain Interlisp-D expressions;

compiled code, it should have the extension".DCOM". For example, a file called 'oMYCODE.DCOM" should contain compiled code;

a Sketch, then its extension should be "SKETCHo. For example, a file called 'oSKETCH" should contain a Sketch;

text, it should have the extension ".TEDITo. For example, a file called 'oREPORT.TEDIT" should contain text that can be edited with the editor TEDIT.

8.2 Directories
This section focuses on how you can find files, and how you can easily manipulate files. To see all the files listed on a device, use the function DIR. For example, to see what files are stored on the Y:ard disk, type

(DIR (DSK))

HOW TO USE FILES B1

DIRzG0R1E5

To see what files are stored on the floppy disk inside of the floppy drive, type

(DIR (FLOPPY))

Partial directory listings can be gotten by specifying a file name, rather than just a device name. The wildcard "ø'ø can be used to match any number of unknown characters. For example, the command

(DIR (DSK)Tø)

will list the names of all files stored on the hard disk that begin with the letter T. An example using the wildcard is shown in Figure 8.1

8.3 Directory Options

Various words can appear as extra arguments to the DIR command. These words give you extra information about the files.

(1) SIZE displays the size of each file in the directory. For example, type

(DIR (DSK) SIZE)

(2) DATE displays the creation date of each file in the directory. An example of this is shown in Figure 8.2

35~(DIR (DSK) DATE)

(3) DEL deletes all the files found by the directory command

G.a H0W TO USE FILES

SUøFILE DIREO0RIES
8.4 Subfile Directories

Subfile directories are very helpful for organizing files. A set of files that have a single purpose, for example all the external documentation files for a system, can be grouped together into a subfile directory.

To associate a subfile directory with a filename, simply include the desired subfile directory as part of the name of the file. Subfile directories are specified after the device name and before the simple filename. The first subfile directory should be between less-than and greater-than signs < >, with nested subdirectory names only followed by a greater-than sign >. For example:

[DSK]<D1rctory>SubD1rctory>Sm1SubD1rctory>..>fi1on~

8.5 To See What Files Are Loaded

If you type FILELST<CR>, the names of all the files you loaded will display.

Type SYSFILES<CR>, to see what files are loaded to create the SYSOUT.

8.6 Simple Commands for Manipulating Files

The following commands will work with the (FLOPPY) and other devices, but have been shown with (DSK) for simplicity. To have the contents of a file displayed in a window:

(SEE '[DSK)filenm)

To copy a file: (coPYFILE '[')oldfi1on~ '[DSF)ne,r,ilonrn)

An example of this is shown in Figure 8.3

(sOPvFILE 'T~0r,RZFc.TEDIT 'PF:IMEFRsEFOsTzzDITJ
t'Dcxl,(LIsPFILEs.PRIMp;0;PRIMEP.fiEFs.TEDIT;1

Figure 8.3. An example of the use of the function COPYFILE

To delete a file: (DEl.FIL 'L'AMPLE.TEPITJ

An example of this is shown in Figure 8.4.

φ ., OELFILż 'L’AMPLE.TEPITJ
φ . ∀. I’PHILE;""PRIMER?>AnPLE.TEPIT;1

FigureS.O. The function DELFILE

To rename a file: (RENI€FILE φ(osK)oldfi1onrn '((SF)ner,rl1on~)

HOW TO USE FILES 83

1

SIMPLE COMMANDS FOR MANIPULATING FILES

"LOAD" a file: Files that contain Interlisp-D expressions can be loaded into the environment. That means that the information on them is read, evaluated, and incorporated into the Interlisp-D environment.

To load a file, type:

(LUG '[DSF)filenm)

When using these functions, always be sure to specify the full filename, including subfile directories if appropriate.

8.7 Connecting to a Directory

Often, each person or project has a subdirectory where their files are stored. If this is your situation, you will want any files you
CONK is the Interlisp-D form that connects you to a directory. For example, COilKin the following figure:

```
- 1 l 11
29#(L'OlatN `CDv~K1.,LLv"PFILLES--\PP,IMER7IM\,!,1
 t'OS'96)cLiy'PFILzCv;:-PRlhlzR.--lM>
30#
```

Figure 8.5. COfllleaing to the subdirectory "PRIMERs srnbsu-i`edory ..lM"
connects you to the subsubdirectory iM, in the subdirectory PRIMER, in the directory LISPFILES, on the device D5K. This information, the device and the directory names down to the subdirectory you want to be connected to, is called the "path" to that subdirectory. co:: expects the path to a directory as an argument.

Once you are connected to a directory, the command DIR will assume that you want to see the files in that directory, or any of its subdirectories.

Other commands that require a filename as an argument (e.g., SEE, above) will assume, if there is no path specified with the filename, that the file is in the connected directory. This will often save you typing.

8.8 File Version Numbers

When stored, each file name is followed by a semicolon and a number.

```
fflILE.TEOIY;1
```

The number is the version number of the file. This is the system’s way of protecting your files from being overwritten. Each time the file is written, a new file is created with a version number one greater than the lost. This new file will have everything from your previous file, plus all of your changes.

In most cases, you can exclude the version number when referencing the file. When the version is not specified, and there is more than one version of the file on that particular directory, the System generally uses your most recent version. An exception is the function DELFILE, which deletes the oldest version (the one with the lowest version number) if none is specified.

HOW TO USE FILES as
TO THOSE WONDERFUL WINDOWS!

A window is a designated area on the screen. Every rectangular box on the screen is a window. While Interlisp-D supplies many of the windows (such as the Interlis-D executive window), you may also create your own. Among other things, you will type, draw pictures, and save portions of your screen with windows.

10.1 Windows provided by Interlisp-D
Two important windows are available as soon as you enter the Interlis-D environment. One is the Interlis-D executive window, the main window where you will run your functions. It is the window that the caret is in when you turn on your machine, and load Interlis-D. It is shown in Figure 10.1.

Figure 10.1. Interlisp-D Executive Window

The other window that is open when you enter Interlisp-D is the "Prompt Window". It is the long thin black window at the top of the screen. It displays system prompts, or prompts you have associated with your programs. (See Figure 10.2.)

Figure 10.2. Prompt Window

Other programs, such as the editors, also use windows. These windows appear when the program starts to run, and close (no longer appear on the screen) when the program is done running.

THOSE WONDERFUL WINDOWS’ 101

CREATING A WINDOW

10.2 Creating a window

To create a new window, type: (CREATE!l). The mouse cursor will change, and have a small square attached to it. (See Figure 10.3.)

Figure 10.3. The mouse cursor asking you to sweep out a window

There may be a prompt in the prompt window to create a window. Press and hold the left mouse button. Move the mouse around, and notice that it sweeps out a rectangle. When the rectangle is the size that you’d like your window to be, release the left mouse button. More specific information about the creation of windows, such as giving them titles and specifying their size and position on the screen when they are created, is given in Section 27.1.2, Page 27.2.

10.3 The Right Button Default Window Menu

Position the cursor inside the window you just created, and press and hold the right mouse button. A menu of commands should appear (do not release the right button!), like the one in figure 10.4. To execute one of the commands on this menu, choose the item. Making a choice from a menu is explained in Section 7.1, Page 7.2.
Bury
RoJisplay
Hardsopy~
Movc
’SShape
shrink

Figure 10.6 The Right Button Default Window Menu

As an example, select "Move" from this menu. The mouse cursor will become a ghost window (just an outline of a window, the same size as the one you are moving), with a square attached to one corner, like the one shown in Figure 10.5.

Move the mouse around. The ghost window will follow. Click the left mouse button to place the window in a new location.

10.1 TH0Sff w0NKQFUL WIH00–I

f

THE RIGHT 8Uff0N DEFAULT MN00– MFNU

Choose "Shape", and notice that you are prompted to sweep out another window. Your original window will have the shape of the window you sketch out.

10.4 An explanation of each menu item
The meaning of each right button default window menu item is explained below:

Close removes the window from the screen;
Snap copies a portion of the screen into a new window;
Paint allows drawing in a window;

Clear clears the window by erasing everything within the window boundaries;

Bury puts the window beneath all other windows that overlap it;
Redisplay redisplays the window contents;

Hardcopy sends the contents of the window to a printer or to a file;
Move allows the window to be moved to a new spot on the screen;
Shape repositions and/or reshapes the window;
Shrink reduces the window to a small black rectangle called an icon. (See Figure 10.6.)

Expand changes an icon back to its original window. Position the mouse cursor on the icon, depress the right button, and select Expand. Or, just button the icon with the middle mouse button.

These right-button default window menu selections are available in most windows, including the Interlis–D Executive window. When the right button has other functions in a window (as in an editor window), the right button default window menu should be accessible by pressing the Right button.
in the black border at the top of the window.

10.5 Scrollable Windows

Some windows in Interlisp-D are "scrollable". This means that you can move the contents of the window up and down, or side to side, to see anything that doesn’t fit in the window.

Point the mouse cursor to the left or bottom border of a window. If the window is scrollable, a "scroll bar" will appear.

THOSE WONDERFUL WINDOWS’ 103

SCROLLABLE WINDOWS

The mouse cursor will change to a double headed arrow. (See Figure 10.7.)

Figuro 10.7. The scrollbar of a scrollable window. The mouse cursor changes to a double headed arrow.

The scrollbar represents the full contents of the window. The example scrollbar is completely white because the window has nothing in it. When a part of the scrollbar is shaded, the amount shaded represents the amount of the window’s contents currently shown. If everything is showing, the scrollbar will be fully shaded. (See Figure 10.8.) The position of the shading is also important. It represents the relationship of the section currently displayed to the full contents of the window. For example, if the shaded section is at the bottom of the scrollbar, you are looking at the end of the file.

The amount of shading in the scrollbar represents the amount of the file shown in the window. Most of the file is visible. Because the shading is at the top of the scrollbar, you know you are looking at the top of the file.

Figure 10.1. The amount of shading in the scrollbar represents the amount of the file shown in the window. Most of the file is visible. Because the shading is at the top of the scrollbar, you know you are looking at the top of the file.

When the scrollbar is visible, you can control the section of the window’s contents displayed:

ø To move the contents higher in the window (scroll the contents up in the window), press the left button of the mouse, the mouse cursor changes to look like this:

Fun 10.1. upward scrolling cursor.

The contents of the window will scroll up, making the line that the cursor is beside the toppmost line in the window.

10.4 THo$a ~HOERFUL~w51
SCROLLASLE MN00-S

To move the contents lower in the window (scroll the contents down in the window), press the right button of the mouse, and the mouse cursor changes to look like this:

Figure 10.10. Oownwørd scrolling cursor

The contents of the window scroll down, moving the line that is the topmost line in the window to beside the cursor.

To show a specific section of the window’s contents, remember that the scroll bar represents the full contents of the window. Move the mouse cursor to the relative position of the section you want to see (e.g., to the top of the scroll bar if you want to see the top of the window’s contents.). Press the middle button of the mouse. The mouse cursor will look like this:

Figure 10.11. Proportional scrolling cursor.

When you release the middle mouse button, the window’s contents at that relative position will be displayed.

10.6 Other Window Functions

10.6.1 PROMPTPRINT

Prints an expression to the black prompt window.

For example, type

(P~PTPRIKT øTNIS SILL BE PRIKTED I* THE PAT UIKooS’)

The message will appear in the prompt window. (See Figure 10.12.)

1 . ø1 II

43 IpROMPTPRINT ‘THIS WILL BE PRINTED IN THE PROMPT WINDOW’)

Flurf 10.12. PROMPTPRINTing

THOSE WONDERFUL WINDOWS’ 10.5

OTHER WINDOW FUNCTIONS

10.6.2 WHICNW

Returns as a value the name of the window that the mouse cursor IS in.

(WHICHW) can be used as an argument to any function expecting a window, or to reclaim a window that has no name (that is not attached to some particular part of the program.).

10.6 THOil wONOERFUL~N00vn’
This chapter explains how to define functions, how to edit them, and how to save your work.

11.1 Defining Functions

DEFINEQ can be used to define new functions. The syntax for it is:

```
(HFIIffEQ (<tunctionname> (<parameterlist
  c~y-offrnnction>j>
```

New functions can be created with DEFINEQ by typing directly into the Interlis-D executive window. Once defined, a function is a part of the Interlis-D environment. For example, the function EXAMPLE-ADDER is defined in Figure 11.1.

```
(Figure 11.1. Defining the function EXAMPLE-ADDER

Now that the function is defined, it can be called from the Interlis-D executive window:

```
NIL
```

```
(Figure 11.1. After EXAMPLE-ADDER is defined, it can be executed
```

Functions can also be defined using the editor DEdit described above. To do this, simply type

```
(DF furttiorvnamej
```

EDITING AND SAVING

You will be asked whether you would like to edit a Dummy definition. A dummy definition is a standard template for your
function definition. Answer by typing Y for Yes, and you will be able to define the function in the editor. (See Figure 11.3. The use of the editor is explained in Section 11.3, Page 11.4.)

Figur 11.1 Using DEdit to define a function

II _ 2 _ Simple _ Editing _ in _ the _ Interlisp-D _ Executive Window
First, type in an example function to edit:
51-`(DEFxEQ (Y-R-FIRST-FuKTIrn (A B) (if (GREATERP A B
then THE FIRST IS GREATER
else THE SECOND IS GREATER)))
To run the function, type (YOUR-FIRST-FUflcTIoa 3 5). 52-`(Y-R-FIRST-Fu-TI 3 5) (THE SECOND IS GREATER)
Now, let’s alter this. Type:
53-`FIZ 51 cr
Notf that your original function is redisplayed, and ready to edit. (See Figure 11.4.)

53-`(DEFINEQ [YOUR-FIRST-FUNCTION (A B) (5 edited;
"~1-Dec-GB 19,"8") (IF (GREaTERP oA B) THEN (QUOTE (THE FiRST Is GREATER)) ELSE (QUOTE (THE SECOND IS GREATER))

ELSE (QUOTE (THE SECOND IS GREATER))

f-urSOI1.& Using FIX to editafundion

Move the text cursor to the appropriate place in the function by positioning the mouse cursor and pressing the Jeff mouse button.

Delete text by moving the caret to the beginning of the section to be deleted. Hold the right mouse button down and move the mouse cursor over the text. All of the blackened text between the caret and mouse cursor is deleted when you release the right mouse button.

If you make a mistake deletions can be undone. On an 1108, press the OPEN key to UNDO the deletion. On an 1108, press the UNDO key on the
keypad to the Jeff of the keyboard.
Now change GREATER to BIGGER:

1) Position the mouse cursor on the G of GREATER, and click the left mouse button. The text cursor is now where the mouse cursor is.

2) Next, press the right mouse button and hold it down. Notice that if you move the mouse cursor around, it will blacken the characters from the text cursor to the mouse cursor. Move the mouse so that the word "GREATER" is blackened.

3) Release the right mouse button and GREATER is deleted.

4) Without moving the cursor, type in BIGGER.

5) There are two ways to end the editing session and run the function. One is to type CONTROL-X. (Hold the CONTROL key down, and type "X".) Another is to move the text cursor to the end of the line and press 'Enter' In both cases, the function has been edited!

Try the new version of the function by typing:
58-(Y~FZRT-F~Tzrn 8 9)
(TNž sEc~ Is BIKER)

and get the new result, or you can type:
5~RE00 52cr
(TNE SEc~ Is BIKER)

EDITING AND SAVING 11.3

USING THE LIST STRUCTURE EDITOR

11.3 Using The List Structure Editor
If the function you want to edit is not readily available (i.e. the function is not in the Interlisp-D Executive window, and you can’t remember the history list number, or you simply have a lot of editing), use the List Structure Editor, often called DEdit. This editor is evoked with a call to OF:

81-(DF YWR-FIRST-f-TIa)

Your function will be displayed in an edit window, as in Figure 11.5.

If there is no edit window on the screen, you will be prompted to create a window. As before, hold the left mouse button down, move the mouse until it forms a rectangle of an acceptable size and shape, then release the button. Your function definition will automatically appear in this edit window.

!(L~nb&A IA Bj (* OIfi' øø:ø1øO:cw ‘-;‘ ‘ø -.tr-r (IF 113’RETEPP A B’il EqV;r~ THEN iOsuUUUE "THE ...:po'.T f ~Tr.GER),l cl,t’ ELSE 1-UUUE THE ..øE.ø N& j:. eluh'ER;J)) 4ep~:c /"’tCh

Figurø II.L An Edit Window

Many changes are easily done with the structure editor. Notice that by pressing the left mouse button, different expressions are underlined. Underline BIGGER as in Figure 11.5. Release the left mouse button.

To add an expression that doesn’t appear in the edit window, (i.e. it can’t simply be underlined), just type it in. Doing this will create an edit buffer below the DEdit window. For example, type LARGER and hit crø (Remember to cr! You won’t be able to do anything in the editor until you cr - this can fool you at first, so beware.) A new window opens up at the bottom for the new expression. (See Figure 11.6.)

LARGER now has the bold line underneath it, while BIGGER has a dotted line.

A

11.4 EDITING ~O ~VING

USING THE LIST STRUCTURE EDITOR

DEdit keeps track of items you have chosen by Using a stack. The underlines tell you the order of the items on the stack. The solid underline indicates the item on the top of the stack; the dotted underline indicates the second to the top. (lIIGGER was pushed on first. When LARGER was pushed on, BIGGER became the second element in the “stack”, and LARGER the first.)

Many commands operate with two items on the stack. Some of them are listed below:

After pops the stack, and adds this top item (in this example, LARGER) to the edit window after the second item on the stack (in this example, BIGGER). The item that was at the top of the stack, LARGER, will now appear in both the original and the new position.

Before pops the stack, and adds this top item (in this example, LARGER) to the edit window before the second item on the stack. (See Figure 11.7.)
Figure 11.7. The command Before is chosen; the word LARGER appears before the word BIGGER

Replace pops the stack, and substitutes this top item for the second item on the stack.

Sat tch changes the position of the first and second items on the stack in the edit window.

Find pops the stack, and searches this top expression for an occurrence of the second item on the stack. If the item is found, it is underlined with a solid line, that is, pushed on the stack. To find the next occurrence, simply choose "Find" again. If the expression is not found, the prompt window will blink, and a

EDITING AND SAVING 115

USING -E LIST STRUCTURE EDITOR

There are other editor commands which can be very useful. To learn about them, read the Interlisp-D Reference Manual, Volume 2, Section 16, on DEDIT.

11.5 File Variables

Certain system-defined global variables are used by the file package to keep track of the environment as it stands. You can get system information by checking the values of these variables. Two important variables follow.

FILELST evaluates to a list, all files that you have loaded into the Interlisp-D environment.

filenameCOMS (Each file loaded into the Lisp environment has associated with it a global variable, whose name is formed by appending "COMS" to the end of the filename.) This variable evaluates to a list of all the functions, variables, bitmaps, windows, and soon, that are stored on that particular file. For example, if you type:
the system will respond with something like:
FKS Your-FZReST-Function VARS)

11.6 Saving Interlisp-D on Files
The functions (FILES?) and (SAVEFILE ‘filename) are useful when it is time to save function, variables, windows, bitmaps, records and whatever else to files.

EDITING AND SAVING

USING THE LIST STRUCTURE EDITOR

message that the item was not found will appear. (See Figure 11.8 for an example of an item, the atom THIRD, not appearing in the function, YOUR-FIRST-FUNCTION.

ø1
L..lFB0-P-ø~T\P _ B! (,-J’1-J_x’P...n_l-
THEN ‘c1.lcTE _ ‘THE _ FIPT _ ~I_i”EP’]
ELSE 1stIJUTE _ HE _ ‘/E/()MIbD
Trrl,v Sr,i
El
ET.

Figwø 11.& The atom THIRD is not in the function being edited
Saap changes places, on the stack, of the first and second items on the stack. The edit window does not change, except that the expression that had a solid underline now has a dotted underline, and vice versa.

Delete works on only the top item of the stack. Delete removes the solid underlined expression from the edit window.
Undo undoes the last editor command.

Completing the example begun earlier, here’s how to have the word LARGER that you typed into the edit buffer appear in place of the BIGGER that you selected from the DEdit window: select the SWITCH command. Notice that the two items are switched, and the stack is popped. Now select EXIT and to leave the editor, and your function will again be redefined.

11.3.1 Commenting Functions

Tert can be marked as a comment by nesting it in a set of parentheses with a star immediately after the left parenthesis.
(ø This ii thø Von of ø c-rrt)

Inside an editor window, the comment will be printed in a smaller font and may be moved to the far right of the code.
Sometimes, however, centered comments are more appropriate.
To center a comment, type „ „ „ „ after the left parenthesis.
ø This co.oortt ø111 rtof bø rd to thø ?ør ri9ht of thø 
co5øø but ø111 bø coøtørd)

It is also possible to insert linebreaks within a comment. A dash should be placed in the comment wherever a carriage return is needed. Thit feoturø allows several comment1 to bø placed
saving interlisp.d on files

/files/ displays a list of variables that have values and are not already a part of any file, and then the functions that are not already part of any file.

Type:

/files/

the system will respond with something like:

variables: ~.VARiLe cURREKT.tuRTLe.. to be du:ed.
functions: Ri6HT LEFiT FOIAff iICK`Aa cLEAr-uREEin.. to be d--.

srit to s&y øbere thø abovø go?

If you type Y, the system will prompt with each item. There are three options:

1) To save the item, type the filename (unquoted) of the file where the item should be placed. (This can be a brand new file or an existing file.)

2) To skip the item, without removing it from consideration the next time (/FILES/) is called, type crø This will allow you to postpone the decision about where to save the item.

3) If the item should not be saved at all, type J. NoilQ re will appear after the item.

Part of an example interaction is shown in the following figure:

hil

u31~(FILES,)

Che variables: MY-`y'AR. To be di.imped.
the functions: MY-SeCuNO-FUtIJN,
YJUP-FIPøoT' FUNi)TIJN
to be dumped.

want to say where the .ibove 3ø ø? `ye'
(variables)
NY-VAR Nowhere
(functions)

NY-SElRnNO-FUN&'TION File name: E;~AMPl~

F~11.9. Part of an interaction using the function /FILES/ (FILES?) assembles the items by adding them to the appropriate file’s COMS variable. (See Section 11.5, Page 11.7.) (FILES?) does NOT write the file to secondary storage (disks or floppies). It only updates the global variables discussed in Section1.5.

(NAKEFILE `Tl lenaøe) actually writes the file to secondary storage. Files should only be written when the time is set. If the time is not set, you will run into problems, such as not being able to copy your file. To check
the time, typø
(riTE)
If the date is correct, yoU can safely use IRE FILE. If it is riot
correct, set the time with the function SETTIKE. To use it, type
(SETTIKE date), where datø isa string such as the one shown
inFigure1.10.

3. FLEXIBILITY AND FORGIVENESS:
CLISP AND DWIM

CLISP, (Conversational Lisp), and DWIM, (Do What Mean), are
two Interlisp utilities that make life easier.

13.1 CLISP

CLISP allows the machine to understand and execute commands
given in a non-standard way. For example, Figure 13.1 contains
an example expressi on (4 + 5).

NIL
b’4-iJ + 5;
9
85’

Figure 13.1. CLISP allows the use of infix notation

Without CLISP, you would need to type this using the notation
(PLUS 4 5). CLISP allows you to use expressions such as (4 + 5) for all arithmetic expressions.

CLISP also allows you to use more readable forms instead of
standard Lisp control structures. Expressions like IF-THEN-ELSE statements can replace COND statements. For example, instead of:

(CIO 1J6RE(APLTUESRPBA B (PLUS A 10))
10

the following can be used:

(if (A ~ B) then (A + 10) else (B + 10))

The system translates this CLISP code into Interlisp-D code. Setting flags will allow you to either save the CLISP code, or save the translation. One such flag is CLISPIFTRANFLG; if it is set to tfl, all the IF statements will be replaced with the equivalent CORD statements. This means that when you DEdit the function, the IF will be removed and replaced with the CORD. Typically, flags such as this one are set in your INlT file. These flags are discussed in the Interlisp-D Reference Manual in Volume 2, Section 21.

FLEXIBILITY AND FORGIVENESS. CLISP AND DWIM 13 I

OWIM

13.2 DWIM

DWIM tries to match unrecognized variable and function names to known ones. This allows Lisp to interpret minor typing errors or misspellings in a function, without causing a break. Line 87 of Figure 13.2 illustrates how the misspelled 0ANNANNA was replaced by 8ANANA before the expression was evaluated.

NIL

a7(8ETQø 8~øN.HA ‘FRUITj
FRUIT

38‘8nNN,~NNA
=8., ’H.,NA
FRUIT
39’

Figure 13.2. Examples of CLISP and DWIM features

Sometimes DWIM may alter an expression you didn’t want it to. This may occur if, for example, a hyphenated function name (eg. (NY-FUNCTION)) is misused. If the system doesn’t recognize it, it may think you are trying to subtract “FUN~lON” from “MY”. DWIM also takes the liberty of updating the function, so it will
have to be fixed. However, this is as much a blessing as a curse, since it points out the misused expression!

13.2 F-11UM AND ~ROVENESS$: cub AND OWN

----- End Forwarded Messages -----
F- 14. BREAKPACliGE

The Break Package is a part of Interlisp that makes debugging your programs much easier.

14.1 Break WindoNT

A break is a function either called by the programmer or by the system when an error has occurred. A separate window opens for each break. This window works much like the Interlisp-D Executive Window, except for extra menus unique to a break window. Inside a break window, you can examine variables, look at the call stack at the time of the break, or call the editor. Each successive break opens a new window, where you can execute functions without disturbing the original system stack. These windows disappear when you resolve the break and return to a higher level.

14.2 Break Package Example

This example illustrates the basic break package functions. A more complete explanation of the breaking functions, and the break package will follow.

The correct definition of FAGTORIAL is:

```
(DEFIKEQ (FACTORIAL (x) (if (<= x 1) 1 (ITIES x (FACTORIAL (- x 1))))))
```

To demonstrate the break package, we have edited in an error: DUMMY in the IF statement is an unbound atom, it lacks a value.

```
(DEFIKEQ (FACTORIAL (x) (if (<= x 1) 1 (ITIES x (FACTORIAL (- x 1))))))
```

The evaluated function

```
(FACTORIAL 4)
```

should return 24, but the above function has an error. DUMMY
is an unbound atom, an atom without an assigned value, so Lisp will "break". A break window appears (Figure 14.1), that has all the functionality of the typing Interlisp-D expressions into the Interlisp-D executive window (The top level), in addition to the break menu functions. Each consecutive break will move to another level "down".

Figure 14.3. Editing from the Break Window

Replace the unbound atom DUnNY with 1 φ Exit the editor with the EXIT command on the editor menu.

The function is fixed, and you can restart it from the last call on the stack (It does not have to be started again from the Top Level) To begin again from the last call on the stack, choose the last (top) FACTORIAL call in the BT menu. Select REVERT from the middle button break window, or type it into the window. The break window will close, and a new one will appear with the message: FACTORIAL broken.

To start execution with this last call to FACTORIAL, choose OK from the middle button break menu. The break window will disappear, and the correct answer, 24, will be returned to the top level.

14.3 _ Ways to _ Stop _ Execution _ from the _ Keyboard, called _ ”Breaking _ Lisp”

There are ways you can stop execution from the keyboard. They differ in terms of how much of the current operating state is saved:

Control-G provides you with a menu of processes to Interrupt. Your process will usually be φ ”EXEC”. Choose it to break your process. A break window will then appear.

Control-B causes your function to break, saves the stack, then displays a break window with all the usual break functions.

For information on other interrupt characters, see the Interlisp Reference Manual, volume 111, page 30.1.

BREAK PACKAGE 14.3

I

PROGRAMMING BREAKS AND DEBUGGING CODE

14.4 Programming Breaks and Debugging Code
PrOgramming breaks are put into code to cause a break when
that section of code is executed. This is very useful for debugging code. There are 2 basic ways to set program breaks:

(BREAK functionname) This function call made at the top level will cause a break at the start of the execution of "functionname". This is helpful in checking the values of parameters given to the function.

Setting a break in the editor Take the function that you want to break into the editor. Underline the expression that should break before it is evaluated. Choose BREAK on the editor command menu. Exit the editor. The function will break at this spot when it is executed.

Once the function is broken, an effective way to use the break window for debugging is to put it into the editor window. (See Section 14.2, Page 14.2.) All the local bindings still exist, so you can use the editor’s EVAL command to evaluate lists, variables, and expressions individually. Just underline the item in the usual way (move the mouse to the word or parenthesis and press the left mouse button), then choose EVAL from the command menu. (See Section 14.2 for more detail.)

Both kinds of programmed breaks can be undone using the (UNBREAK) function. Type (~KB RDF functionnm)

Calling (UNBREAK) without specifying a function name will unbreak all broken functions.

14.5 Break Menu

Move the mouse cursor into the break window. Hold the middle button down, and a new menu will pop up, like the one in Figure 14.4.

OK
BT
BY!
"a

Figure 14.4 The middle button menu in the Break window
Five of the selection are particularly important when just starting to use Interlisp-D:

8T Sack Trace displays the stack in a menu beside the break window. Back Trace is a very powerful debugging tool. Each function call is placed on the stack and removed when the execution of that function is complete. Choosing an item on the stack will open another window displaying that item’s local variables and their bindings. This is an inspector window that offers all the power of the inspector. (For details, see the section on the Inspector, Chapter 32).

? Before you use this menu option, display the stack by choosing 8T from this menu, and choose a function from it. Now, choose 7: It will display the current values of the arguments to the
function that has been chosen from the stack.

~ Move back to the previous break window, or if there is no other break window, back to the top level, the Interlisp-D Executive Window.

REVERT Move the point of execution back to a specified function call before the error. The function to revert back to is, by default, the last function call before the break. If, however, a different function call is chosen on the BT menu, revert will go back to the start of this function and open a new break window. The items on the stack above the new starting place will no longer exist. This is used in the tutorial example. (See Section 14.2, Page 14.1.)

OK Continue execution from the point of the break. This is useful if you have a simple error, i.e. an unbound variable or a nonnumeric argument to an arithmetic function. Reset the variable in the break window, then select OK. (See Section 14.2.) (Note: In addition to being available on the middle button menu of the break window, all of these functions can be typed directly into the window. Only ST behaves differently when typed. It types the stack into the trace window instead of opening a new window.)

14.6 Returning to Top Level

Typing Control-D will immediately take you to the top level from any break window. The functions called before the break will stop, but any side effects of the function that occurred before the break remain. For example, if a function set a global variable before it broke, the variable will still be set after typing Control-D.

27. WINDOWS AND REGIONS

27.1 Windows

Windows have two basic parts: an area of the screen containing a collection of pixels, and a property list. The window properties determine how the window looks, the menus that can be accessed from it, what should happen when the mouse is inside the window and a mouse button is pressed, and soon.

27.1.1 CREATEW

Some of the window’s properties can be specified when a
window is created with the function CREATEW. In particular, it is easy to specify the size and position of the window; its title; and the width of its borders.

(CREATEW region title borderw’idth)

Region is a record, named REGION, with the fields left, bottom, width, and height. A region describes a rectangular area on the screen, the window’s dimensions and position. The fields left and bottom refer to the position of the bottom left corner of the region on the screen. Vi dth and height refer to the width and height of the region. The usable space inside the window will be smaller than the width and height, because some of the window’s region is consumed by the title bar, and some is taken by the borders.

Title is a string that will be placed in the title bar of the window. Borderwvidfr is the width of the border around the exterior of the window, in number of pixels.

For example, typing:

(SETQ ~.WIN~ CREATEW
(CREAT RE6IS loo 150 300 200)
THIS Is ~ r"w illIN~ø )

produces a window with a default borderwidth. Note that you did not need to specify all the window’s properties. (See Figure 27.1.)

27.1.2 WINDDOWNPROP

The function to access or add to any property of a window’s property list is WINDDOWNPROP.

(WIN~PR0P window property <value>)

When you use WINDDOWNPROP with only two arguments - window and property - it returns the value of the window’s property. When you use wIKOOVPROP with all three arguments - window, property and value - it sets the value the window’s property to the value you inserted for the third argument.

For example, consider the window, NY WINDOW, created using (CREATEW). TITLE and REGION are both properties. Type

(iil*~PW ~.uI~ 'TITLE)

and the value of MY.WINDOW’s TITLE property is returned, “THIS IS MY OWN WINDOW”. To change the title, use the WINDDOWNPROP function, and give it the window, the property title, and the new title of the window.

(wiK~PW ~.uI~ 'TITLE øP FIRST iilK~ø)
automatically changes the title and automatically updates the window. Now the window looks like Figure 27.2.

27.1 WINDOWS AND REGIONS

WINDOWS

7ot’WINDOWPROP NV WINDOW TITLE)
IS NV OWN WINDOW"

s.(WINDOWPROP NY.WINDOW ‘qQY FIRST WINDOW”)
THIS IS M’ OWN WINDOW"
4’.

Figure 27.2. TITLE is a Window Property

Altering the region of the window, NY. VINDOV, is also be done with WINDOWPROP, in the same way you changed the title. (Note: changing either of the first two numbers of a region changes the position of the window on the screen. Changing either of the last two numbers changes the dimensions of the window itself.)

27.1.3 Getting windows to do things
Four basic window properties will be discussed here. They are CURSORINFN, CURSOROUTFN, CURSOROVERFN, and BUTTONEVENTFN.

A function can be stored as the value of the CURSORINFN property of a window. It is called when the mouse cursor is moved into that window.

Look at the following example:

(1) First, create a window called MY.WINDOW. Type:
(SETQ P.WINDQW
(CREATE1
(CREATERE6Ia 200 200 200 200)
"THIS WILLWII0W WILL IREMlø))
This creates a window.

(2) Now define the function SCREAMER. It will be stored on the property CURSORINFN. (Notice that this function has one argument, WINDOWNAME. All functions called from the property CURSORINFN are passed the window it was called from. So the value of MY. WINDOW is bound to WINDOWNAME. When it is called, SCREAMER simply rings bells.
(DEFINQ (SCREAMER (WINDOW--E)
Rii1BELLS)
PROIPTPRIIT TAT - IT WDFRSI")
RIKBELLS)))

(3) Now, alter that window’s CURSORINFN property, so that the system calls the function SCREAMER at the appropriate time. Type:

WINDow5 AND REGIONS 273

WINDOWS
After this, when you move the mouse cursor into MY.WINDOW, the CURSORINFN property’s function is called, and it rings bells twice.

CURSORINFN is one of the many window properties that come with each window - just as REGION and TITLE did. Other properties include:

CURSOROUTFN The function that is the value of this property is executed when the cursor is moved out of a window;

CURSORMOVEDFN the function that is the value of this property is executed when the cursor is moved while it is inside the window;

BUTTONEVENTFN the function that is the value of this property is executed when either the left or middle mouse buttons are pressed (or released).

Figure 27.3 shows MY.WINDOW’s properties. Notice that the CURSORINFN has the function SCREAMER stored in it. The properties were shown in this window using the function INSPECT. INSPECT is covered in Chapter 32.

You can define functions for the values of the properties CURSOROUTFN and CURSORMOVEDFN in much the same way as you did for CURSORINFN. The function that is the value of the property BUTTONEVENTFN, however, can be specialized to respond in different ways, depending on which mouse button is pressed. This is explained in the next section.

27.1.3.1 BUTTONEVENTFN
BUTTONEVENTFK is another property of a window. The function that is stored as the value of this property is called when the mouse is inside the window, and a mouse button is pressed. As an example of how to use this type:

```
27.1.4 Looking at a window’s properties
INSPECT is a function that displays a list of the properties of a window, and their values. Figure 27.3 shows the INSPECT function run with MY$WINDOW. Note the properties introduced in CREATEW: WBORDER is the window’s border, REG is the region, and WTITLE is the window’s title.

27.2 Regions
A region is a record, with the fields LEFT, BOTTOM, WIDTH, AND HEIGHT. LEFT and BOTTOM refer to where the bottom left hand corner of the region is positioned on the screen. WIDTH and HEIGHT refer to the width and height of the region. CREATERE6ION creates an instance of a record of type REGION.
```

```
(SETO ~.RE6lal (CREATERESIl 15 loo 200 450))
```
REGIONS

to create a record of type REGION that denotes a rectangle 200 pixels high, and 450 pixels wide, whose bottom left corner is at position (15, 100). This record instance can be passed to any function that requires a region as an argument, such as CREATEV, above.

28. WHAT ARE MENUS?

While Interlisp-D provides a number of menus of its own (see Section 7.1, Page 7.2), this section addresses the menus you wish to create. You will learn how to create a menu, display a menu, and define functions that make your menu useful.

Menu's are instances of records (see Chapter 24). There are 27 fields that determine the composition of every menu. Because Interlisp-O provides default values for most of these descriptive fields, you need to familiarize yourself with only a few that we describe in this section.

Two of these fields, the TITLE of your menu, and the ITEMS you wish it to contain, can be typed into the Interlisp-D Executive window as shown below:

NIL

33'(.ETO MY. MEN (cRE""TE ME/lb TITLE „PLE---SE CHCio8z ONE OF THE ITEMS"

ITEMS (0.LIIT NE.T-1)UE:STION NE:~TOPII SEE-TOPIC;5`JJJ ,rMEIU!,#c4, ij`w:`3JH

Figure 28.1. Creating a menu

Note that creating a menu does not display it. MY.MENU is set to an instance of a menu record that specifies how the menu will look, but the menu is not displayed.

28.1 Displaying Menus

Typing either the MENU or ADDMENU functions will display your menu on the screen. MENU implements pop-up menus, like the Background Menu or the Window Menu. ADDMENU puts menus
into a semi-permanent window on the screen, and lets you select items from it.

(MENU MENU POSITION) pops-up a menu at a particular position on the screen.
Type:

(*EKS MY.ffl KIL)

to position the menu at the end of the mouse cursor Note that the POSITION argument is NIL. In order to go on, you must either choose an item, or move outside the menu window and press a mouse button. When you do either, the menu will disappear. If you choose an item, then want to choose another, the menu must be redisplayed.

(ADONENU menu window position) positions a permanent menu on the screen, or on an existing window.
Type:

(ADIEKU P.*EI)

to display the menu as shown in Figure 28.2. This menu will remain active, (will stay on the screen) without stopping all the other processes. Because ADONElU can display a menu without stopping all other processes, it is very popular in users programs. If window is specified, the menu is displayed in that window. If window is not specified, a window the correct size for the menu is created, and the menu is displayed in that window.
If position is not specified, the menu appears at the current position of the mouse cursor.

Figure 28.2. A Simple Menu, displayed with AooNriU.

28.2 Getting Menus to DO Stuff
One way to make a menu do things is to specify more about the menu items. Instead of items simply being the strings or atoms that will appear in the menu, items can be lists, each list with three elements. (See Figure 28.3.) The first element of each list is what will appear in the menu; the second expression is what is evaluated, and the results of the evaluation returned, when the item is selected; and the third expression is the expression that should be printed in the Prompt window when a mouse button is held down while the mouse is pointing to that menu item. This third item should be thought of as help text for the user. If the third element of the list is NIL, the system responds with "Will select this item when you release the button".

WHAT ARE MENUS’ 283

GEHING MENUS TO DO STUFF

28.2.1 _ The WHENHŽLDFN _ and WNENSELŽCTEDFN fields of a _ menu
Another way to get a menu to do things is to define functions,
and make them the values of the menu’s WHENHELDFN and
WHENSElectedFN fields. As the value of the WHENHELDFN
field of a menu, the function you defined will be executed when
you press and hold a mouse button inside the menu. As the
value of the WHENSElŽCTEDFN field of a menu, the function you
defined will be executed when you choose a menu item. This
example has the same functionality as the previous example,
where each menu item was entered as a list of three items.
As an example, type in these two functions so that they can be executed when the menu is created and displayed:

```lisp
(DEFINEQ LSELECTED
  (SELECTED a: FROM BUTT: PRESSED)
QUIT (PROMPTPRINT CHOOSE THIS TO STOP))

NEXT-QUESTION (PROMPTPRINT CHOOSE THIS TO BE ASKED THE NEXT QUESTION)
NEXT-TOPIC PROMPTPRINT CHOOSE THIS TO MOO,E a TO THE NEXT SUBUIECT)
SEE-TOPICS PROMPTPRINT CHOOSE THIS TO SEE THE TOPICS NOT YET LEARNED)
ERROR (PROM TPRIKT NO ITCH FOUND))

(DEFINEQ WENSELECTED (ITEM.SELECTED MENU. FROM BUTT:.PRESSED)
QUIT (PRINT STOPPED)

NEXT-QUESTION "HERE IS THE NEXT QUESTION...)
NEXT-TOPIC "HERE IS THE NEXT TOPIC..."
SEE-TOPICS PRINT THE FOLLOWING HAVE NOT BEEN LEARNED...
ERROR (PROMPTPRINT NO ITCH FOUND))

Now, to create the menu, type:
(SETQ MY.MENU3 (CREATE MENU
  TITLE PLEASE CHOOSE :E OF THE ITEMS
  ITEK (QUIT NEXT-QUESTION NEXT-TOPIC SEE-TOPICS)
  WHENHELDFN (FUNCTION MY.MENU3.WHENHELDFN)
  WHENSELECTEDFN (FUNCTION MY.MENU3.WHENSELECTED)))

Type
(ADDMENU MY.MENU3)
to see your menu work.

NOW, due to executing the WHENHELDFN function, holding
down any mouse button while pointing to a menu item will
display an explanation of the item in the prompt window. The
screen will once again look like Figure 28.4 when the mouse
button is held when the mouse cursor is pointing to the item
NEXT-TOPIC.

Now due to executing the WHENSELECTEDFN function, releasing
the mouse button to select an item will cause the proper actions
for that item to be taken. The screen will once again look like
Figure 28.5 when the item NEXT-TOPIC is selected.
The crucial thing to note is that the functions you defined for
WHENHELDFN and WHENSELECTEDFN are automatically given
the following arguments:

(1) the item that was selected, ITEM. SELECTED;
(2) the menu it was selected from, MENU. FROM;
(3) and the mouse button that was pressed BUTTON PRESSED.
Hot: these functions, *Y.NENU3,fiENfiELO and
fiY.KEKUJ.iiHEKSELECTE, were quoted using FUKCIIOK
instead of QUOTE both for program readability and so that the

21.1 ~YAR1".NUs?

GETTING MENUS TO 00 STUFF

compiler con produce foster code when the program is compiled.
It is good style to quote functions in Intertisp by using the
function FUNCTION instead of QUOTE.
28.3 Looking at a menu's fields

`INSPECT` is a function that displays a list of the fields of a menu, and their values. The Figure 28.6 shows the various fields of `NY` when the function (`INSPECT NY`) was called. Notice the values that were assigned by the examples, and all the defaults.

29. lil/TMAPS

A bitmap is a rectangular array of dots. The dots are called pixels (for picture elements). Each dot, or pixel, is represented by a single bit. When a pixel or bit is turned on (i.e. that bit set to 1), a black dot is inserted into a bitmap. If you have a bitmap of a floppy on your screen, (Figure Figure 29.1), then all of the bits in the area that make up the floppy are turned on, and the surrounding bits are turned off.

FLOPPY
(Fa b~JwP-
~ ’.S.,Bh
(t-)o
Figure 29.1. Bitmap of a Floppy

BITMAPCREATE creates a bitmap, even though it can’t be seen.
(BITMAPCREATE width height)

If the width and height are not supplied, the system will prompt you for them.

EDZTBN edits the bitmap. The syntax of the function is:
(EDIT bitmapname)

Try the following to produce the results in Figure 29.4:
(EDIT bitmapname)

To draw in the bitmap, move the mouse into the gridded section of the bitmap editor, and press and hold the left mouse button. Move the mouse around to turn on the bits represented by the spaces in the grid. Notice that each space in the grid represents one pixel on the bitmap.

To erase, move the mouse into the gridded section of the bitmap editor, and press and hold the center mouse button. Move the mouse around to turn off the bits represented by the spaces in the gridded section of the bitmap editor.

To work on a different section, point with the mouse cursor to the picture of the actual bitmap (the upper left corner of the bitmap editor). Press and hold the left mouse button. A menu with the single item, move will appear. (See Figure 29.2.) Choose this item.

Figure 29.2. Move the mouse cursor to the picture of the bitmap. Press and hold the left mouse button, and the Move menu will appear.

You will be asked to position a ghost window over the bitmap. This ghost window represents the portion of the bitmap that you are currently editing. Place it over the section of the bitmap that you wish to edit. (See Figure 29.3.)

Figure 29.3. After you choose move, you will be asked to position a ghost window like this one. Position it by clicking the left mouse button when the ghost window is over the part of the picture of the bitmap you would like to edit. To end the session, ring the mouse cursor into the upper-right portion of the window (the grey area) and press the center button. Select OK from the menu to save your artwork.

29) .IY~
Figure 29.4. Editing a Bitmap

BITBLT is the primitive function for moving bits (or pixels) from one bitmap to another. It extracts bits from the source bitmap, and combines them in appropriate ways with those of the destination bitmap. The syntax of the function is:

(BITBLT sourcebitmap sourceleft sourcetop destinationbitmap destinationleft destinationbottom width height sourcetype operation texture clippingregion)

Here’s how it’s done - using MY.BITMAP as the sourcebitmap and MY.WINDOW as the destinationbitmap.

(BITBLT MY.BITMAP NIL NIL MY.WINDOW NIL NIL 10000 'INPUT 'REPLACE)

Note that the destination bitmap can be, and usually is, a window. Actually, it is the bitmap of a window, but the system handles that detail for you. Because of the NILs (meaning "use the default"), MY.BITMAP will be BITBLT’d into the lower right hand corner of MY.WINDOW. (See Figure 29.5.)

Figure 29.5. BITBLTng a Bitmap onto a Window

Here is what each of the BITBLT arguments to the function mean:

sourcebitmap the bitmap to be moved into the destinationbitmap
sourceleft a number, starting at O for the left edge of the sourcebitmap, that tells BITBLT where to start moving pixels from the sourcebitmap. For example, if the leftmost 10 pixels...
sourcebitmap were not to be moved, sourceleft should be 10
The default value is 0.

destinationbitmap the bitmap that will receive the sourcebitmap. This is often a
window (actually the bitmap of a window, but Interlisp-b takes
care of that for you).

destinationleft a number, starting at 0 for the left edge of the
destinationbitmap, that tells BITBLT where to start placing
pixels from the sourcebitmap. For example, to place the
sourcebitmap 10 pixels in from the left, destinationleft should be
10. The default value is 0.

destinationbottom a number, starting at 0 for the bottom edge of the
destinationbitmap, that tells BITBLT where to start placing
pixels from the sourcebitmap. For example, to place the
sourcebitmap 10 pixels up from the bottom, destinationbottom
should be 10. The default value is 0.

width how many pixels in each row of sourcebitmap should be moved.
The same amount of space is used in destinationbitmap to
receive the sourcebitmap. If this argument is NIL, it defaults to
the number of pixels from sourceleft to the end of the row of
sourcebitmap.

height how many rows of pixels of sourcebitmap should be moved. The
same amount of space is used in destinationbitmap to receive
the sourcebitmap. If this argument is NIL, it defaults to
the number of rows from sourcebottom to the top of the
sourcebitmap.

sourcebitmap refers to one of three ways to convert the sourcebitmap for
writing. For now, just use ‘INPUT.

OILMAPS

operation refers to how the sourcebitmap gets BITBLT’d on to the
destinationbitmap. ‘REPLACE will BLT the exact sourcebitmap.
Other operations allow you to AND, OR or XOR the bits from the
sourcebitmap onto the bits on the destinationbitmap.
texture Just use NIL for now.
croppingregion just use NIL for now.

Por more information on these operations, see the Interlisp-D

Source bitmap, sourceleft, sourcebottom, destinationbitmap,
destinationleft, destinationbottom, width and height are shown
in Figure 29.6.

BITMAPS 295

----- Next Message -----
Figure 30.1. The line drawn onto the displaystream, EXAMPLEWINDOW

DISPLAYSTREAMS 30

DRAWING ON A DISPLAYSTREAM

The syntax of DRAWLINE is

(DRAWLINE x1 y1 x2 y2 width operation stream)

The coordinates of the Jeff bottom corner of the displaystream are (0, 0).

x1 and y1 are the x and y coordinates of the beginning of the line;
x2 and y2 are the ending coordinates of the line;
width is the width of the line, in pixels

operation is the way the line is to be drawn. INVERT causes the line to invert the bits that are already in the displaystream. Drawing a line the second time using INVERT erases the line. For other operations, see the Interlis-D Reference Manual, Volume III, Page 27.15.

stream is the displaystream. In this case, you used a window.

30.1.2 DRAWTO

DRAWTO draws a line that begins at your current position in the displaystream. For example, type:

(DRAWTO 120 135 5 'INVERT E-LE.*IH-)

The results should look like this:

Figure 30.2. Another line drawn onto the displaystream, EXAMPLEWINDOW

The syntax of DRAWTO is

(DRAWTO x y width operation stream)

The line begins at the current position in the displaystream.
x is the x coordinate of the end of the line;
y is the y coordinate of the end of the line;
width is the width of the line

operation is the way the line is to be drawn. INVERT causes the line to invert the bits that are already in the displaystream. Drawing a line the second time using INVERT erases the line. For other operations, see the Interlis-D Reference Manual, Volume III, Page 27.15.

stream is the displaystream. In this case, you used a window.

30.2 DRAWSTRING

DRAWSTRING ON A DISPLAYSTREAM

30.1.3 DRAWCIRCLE

DRAWCIRCLE draws a circle on a displaystream. To use it, type:

(DRAWCIRCLE 150 100 50 'INVERT E-LE.*IH-)

Now your window, EXAMPLEWINDOW, should look like this:

Figure 30.3. The circle drawn onto the displaystream, EXAMPLEWINDOW

The syntax of DRAWCIRCLE is

(DRAWCIRCLE centerx centery radius brush dashing stream)

centerx is the x coordinate of the center of the circle
centery is the y coordinate of the center of the circle
radius is the radius of the circle in pixels
brush is a list. The first item of the list is the shape of the brush. Some of your options include ROUND, SQUARE, and VERTICAL. The second item of that list is the width of the brush in pixels.

dashing is a list of positive integers. The brush is "on" for the number of units indicated by the first element of the list, "off" for the number of units indicated by the second element of the list. The third element specifies how long it will be on again, and so forth. The sequence is repeated until the circle has been drawn.

stream is the displaystream. In this case, you used a window.

30.1.3.1 FILLCIRCLE

FILLCIRCLE draws a filled circle on a displaystream. To use it, type:

(FILLCIRCLE 200 150 10 6iY~DE ExlPLE.wll~)

EXAMPLE.WINDOW now looks like this:

DISPLAYSTREMS 303

DRAWING ON A DISPLAYSTREAM

Figure 30.1 A filled circle drawn onto the displaystream, EXAMPLE WINDOW

The syntax of FILLCIRCLE is

(FILLCIRCLE centerx centery radius texture stream)

centerx is the x coordinate of the center of the circle
centery is the y coordinate of the center of the circle
radius is the radius of the circle in pixels

texture is the shade that will be used to fill in the circle. Interlisp-D provides you with three shades, WHITESHADE, BLACKSHADE, and GRAYSHADE. You can also create your own shades. For more information on how to do this, see the Interlisp-D Reference Manual, Volume II, Page 27.7.

stream is the displaystream. In this case, you used a window. There are many other functions for drawing on a displaystream. Please refer to the Interlisp-D Reference Manual, Volume II, Chapter 27.

Text can also be placed into displaystreams. To do this, use printing functions such as PRIN1 and PRIN2, but supply the name of the displaystream as the "file" to print to. To place the ten in the proper position in the displaystream, see Section 30.2, Page 30.4.

30.2 Locating and Changing Your Position in a Displaystream

There are functions provided to locate, and to change your current position in a displaystream. This can help you place text, and other images where you want them in a displaystream. This primer will only discuss three of these. There are others, and they can be found in the Interlisp-D Reference Manual, Volume III, Chapter 27.

30.4 DISPLAYSTREAM

LOCATING AND CHANGING YOUR POSITION IN A DISPLAYSTREAM

30.2.1 DSPXPOSITION
DSPXPOSITION is a function that will either change the current x position in a displaystream, or simply report it. To have the function report the current x position in EXAMPLE.WINDOW, type:

(OSP*Position NIL EXAMPLE.WINDOW)

DSPXPOSITION expects two arguments. The first is the new x position. If this argument is NIL, the current position is not changed, merely reported. The second argument is the displaystream.

30.2.2 DSPYPOSITION

DSPYPOSITION is an analogous function, but it changes or reports the current y position in a displaystream. As with DSPXPOSITION, if the first argument is a number, the current y position will be changed to that position. If it is NIL, the current position is simply reported. To have the function report the current y position in EXAMPLE.WINDOW, type:

(DSPYPOSITION NIL EXAMPLE.WINDOW--)

30.2.3 MOVETO

The function MOVETO always changes your position in the displaystream. It expects three arguments:

(~ET0 xystream)

x is the new x position in the display stream

y is the new y position in the display stream

stream is the display stream. The examples so far have used a window.

DISPLAYSTREAMS 30.5

----- Next Message -----
function. These are only some of the fonts that are available in Interlisp-D.

In addition to the fonts that appear on your screen, Interlisp-D uses fonts for printers that are different than the ones used for the screen. The fonts used to print to the screen are called DISPLAYFONTS. The fonts used for printing are called INTERPRESSFONTS, or PRESSFONTS, depending on the type of printer.

3.1 What makes up a FONT?

Fonts are described by family, weight, slope, width, and size. This section discusses each of these, and describes how they affect the font you see on the screen.

Family is one way that fonts can differ. Here are some examples of how “family” affects the look of a font:

CLASSIC This family makes the word "Able" look like this: Able
MODERN This family makes the word "Able" look like this: Able
TERMINAL This family makes the word "Able" look like this: Able

Weight also determines the look of a font. Once again, "Able" will be used as an example, this time only with the Classic family.

A font’s weight can be:
BOLD and look like this: Able
MEDIUM or REGULAR and look like this: Able

The slope of a font is italic or regular. Using the Classic family font again, in a regular weight, the slope affects the font like this:

ITALIC looks like this: A file
REGULAR looks like this: Able

WHAT MAKES UP A FONT?

The width of a font is called its "expansion". It can be COMPRESSED, REGULAR, or EXPANDED.

Together, the weight, slope, and expansion of a font specifies the font’s "face". Specifically, the face of a font is a three element list:

(weight slope expansion)

To make it easier to type, when a function requires a font face as an argument, it can be abbreviated with a three character atom. The first specifies the weight, the second the slope, and the third character the expansion. For example, some common font faces are abbreviated:

MRR This is the usual face, MEDIUM, REGULAR, REGULAR;
MIR makes an italic font. It stands for: MEDIUM, ITALIC, REGULAR;
BRR makes a bold font. The abbreviation means: BOLD, REGULAR, REGULAR;

BIR means that the font should be both bold and italic. BIR stands for BOLD, ITALIC, REGULAR.

The above examples are used so often, that there are also more mnemonic abbreviations for them. They can also be used to
specify a font face for a function that requires a face as an argument. They are:

STANDARD This is the usual face: MEDIUM, REGULAR, REGULAR. It was abbreviated above, MRR;

ITALIC This was abbreviated above as MR, and specifies an italic font; BOLD of course, makes a bold font. It was abbreviated above, BRR; BOLDITALIC means that the font should be both bold and italic: BOLD, ITALIC, REGULAR. It was abbreviated above, BIR.

A font also has a size. It is a positive integer that specifies the height of the font in printers points. A point is, on an 1108 screen, about 1/72 of an inch. On the screen of an 1186, a point is 1/80 of an inch. The size of the font used in this chapter is 10. For comparison, here is an example of a TERMINAL, MRR, size 12 font: Able.

31.2 Fontdescriptors, and FONTCREATE
For InterlispD to use a font, it must have a fontdescriptor. A fontdescriptor is a data type in InterlispD that that holds all the information needed in order to use a particular font. When you print out a fontdescriptor, it looks like this:

Fontdescriptors are created by the function F0NTCREATE. For example,

(F~TCREATE 'flEL~ICA 12 '~)

J:

31.2 FONTDESCRIPTORS, AND F0NTCREATE

creates G fontdescriptor that, when used by other functions, prints in HELVETIEA BOLD size 12. Interlisp-D functions that work with fonts Gxpect a fontdescriptor produced with the FONTCREATE function.
The syntax of FONTCREATE is:
(F0KTCREATE family size face)

Remember from the previous section, face is either a three element list, (weight slope expansion), a three character atom abbreviation, e.g. MRR, or one of the mnemonic abbreviations, e.g. STANDARD.

If FONTCREATE is asked to create a fontdescriptor that aJready exists, the existing fontdescriptor is simply returned.

31.3 Display Fonts - Their files, and how to find them
Display fonts require files that contain the bitmaps used to print each character on the screen. All of these files have the extension .DISPLAYFONT. The file name itself describes the font style and size that uses its bitmaps. For example:

contains bitmaps for the font family MODERN in size 12 points. Initially, these files are on floppies. The files that are used most often should be copied onto a directory of your hard disk or fileserver. Usually, this directory is called FONTS.

Wherever you put your .DISPLAYFONT files, you should make this one of the values of the variable DISPLAYFONTDIRECTORIES. Its value is a list of directories to search for the bitmap files for
display fonts. Usually, it contains the "FONT" directory where you copied the bitmap files, the device (FLOPPY), and the current connected directory. The current connected directory is specified by the atom NIL. Here is an example value of DISPLAYFONTDIRECTORIES:

. . 11
NIL

r~:Pl:=pL"yFnNTDIP.ECDBP.IES
i!qo=‘. .=PFIL .-FnNT~." (D.-fr):!.LIT'.PFIL
fFLnPF"*)- NIL:!!
9!ø

Figure 31.1. A value for the atom DISPLAYFONTDIRECTORIES When looking for a DISPLAYFONT file, the system will check the FONT directory on the hard disk, then the top level directory on the hard disk, then the floppy, then the current connected directory.

FONTS 313

INTERPRESS FONT5 - THEIR FILES, AND HOW TO FIND THEM

31.4 Interpress Fonts - Their files, and how to find them
Interpress is the format that is used by Xerox laser printers. These printers normally have a resolution that is much higher than that of the screen: 300 points per inch.

In order to format files appropriately for output on such a printer, Interlisp must know the actual size for each character that is to be printed. This is done through the use of width files that contain font width information for fonts in Interpress format. Initially, these files (with extension .WD) are on floppies. The files should be copied onto a directory of your hard disk or fileserver.

For Interpress fonts, you should make the location of these files one of the values of the variable INTERPRESSFONToRFiles. Its value is a list of directories to search for the font widths files for Interpress fonts. Here is an example value of INTERPRESSFONToRFiles:

. . 11
1"!L

i?bdTEFPfiETø=.FnN7PIP:EcTnRIj~.,~
.i=~~.~
j~.;;

Figure 31.2. A value for the atom INTERPRESSFONToRFiles
When looking for a font widths file for an Interpress font, Interlisp-D will check the hard disk.

31.5 Functions for Using Fonts

31.5.1 FONTPROP Looking at Font Properties
It is possible to see the properties of a font descriptor. This is done with the function FONTPROP. For the following examples, the font descriptor used will be the one returned by the function (DEFAULTFONT 'DISPLAY). In other words, the font descriptor examined will be the default display font for the system.

There are many properties of a font that might be useful for you.
Some of these are:

FAfIlLy To see the family of a font descriptor, type:
\[ (\text{FKTP} \text{PiP} (\text{DEF} \text{AIL} \text{LTFoIT} \text{ ‘DISPLAY}) \text{ ‘-ILIY}) \]

SIZE As above, this is a positive integer that determines the height of the font in printer’s points. As an example, the SIZE of the current default font is:

31\ø ~n

FUNCTIONS FOR USING FONTS

.. 11
NII

Gi,ø(FnNTPROP (DEF~ULTFONT PI--PLAY)
‘.,ø::1ZE\}
is,

Figure 31.3. The value of (he font property SIZE of the default font
ASCE\N The value of this property is a positive integer, the maximum
height of any character in the specified font from the baseline
(bottom). The top of the tallest character in the font, then, will
be at (BASELINE # ASCE\VT - l). For example, the ASCENT of the
default font is:

ø 1 11
NII

Aø 4’ .. 1øFntNTPROP if OfF”’ ULI\NtNT øPI-,-PL-””,!”
‘-e-rENT:!
q.-

A,5:-:

Figure 31.& The value of the font property ASCENT of the default font
DESCENT The DESCENT is an integer that specifies the maximum number
of points that a character in the font descends below the
baseline (e.g. letters such as “p” and “g” have tails that descend
below the baseline.). The bottom of the lowest character in the
font will be at (BASELINE - DESCENT). To see the DESCENT of the
default font, type:

(FOKPROP (DEF\AULTFKTK ‘DISPLAY) ‘DESr:žKT)
HEIGHT HE IGHT is equal to t’DESCENT-ASCENT).
FACE The value of this property is a list of the form, (weight slope
expansion). These are the weight, slope, and expansion
described above. You can see each one separately, also. Use the
property that you are interested in, VEIGHT, SLOPE, or
EXPANSION, instead of FACE as the second argument to
FONTPROP.

For other font properties, see the Interli\np-D Reference Manual,
Volume III, Pages 27.27 - 27.28.

31.5.2 STRINGWIDTH

It is often useful to see how much space is required to print an
expression in a particular font. The function STRINGWIDTH
does this. For example, type:

(STR\N\WIDTH ‘NV theranø (‘L’N\C\RÆATž ‘UCli 10 ‘STAK\DARD))
The number returned IS how many left to right pixels would be
needed if the string were printed in this font. (Note that this

FUNCTIONS FOR USING FONTS

doesn’t just work for pixels on the screen, but for all kinds of
streams. For more information about streams, see Chapter 30.)
Compare the number returned from the example call with the
number returned when you change GACHA to TIMESROMAN.

31.5.3 DSPFONT - Changing the Font in One Window
The function DSPF0NT changes the font in a single window. As
an example of its use, first create a window to write in. Type:

```
(setq ~.font.window (create*))
```

in the Interlisp-D Executive window. Sweep out the window. To
print something in the default font, type:

```
(print 'hello ~.font.window)
```

in the Interlisp-D Executive window. Your window,
MY.FONT.WINDOW, will look something like this:

HELLO

Figure 31.5. HELLO, printed with the default font in MY.FONT.WINDOW
Now change the font in the window. Type:

```
(dspfont (fontcreate 'helvetica 12 'sold) *t.font.window)
```

The arguments to FONTCREATE can be changed to create any desired font. Now
retype the PRINT statement, and your window will look
something like this:

```
HELLO
```

Figure 31.6. The font in MY FONT WINDOW, changed
Notice the font has been changed!

J.

31.6 FONt

FUNCTIONS FOR USING FONTS

31.5.4 _ Globally Changing _ Fonts

There is a library package to globally change the fonts in all the
windows. To use it, first load BIG.DCOM. (See Section 8.6, Page
8.4 for how to load a file.)

To change fonts in 311 windows using the package BIG.DCOM,
type

```
(ke*font <ke-~>)~
```

There are four keywords for size of fonts to specify. They are
HUGE, BIG, STANDARD, and MEDIUM. For example:

`(*E*FKT 'BIG)`

sets the fonts in ALL the windows to be a larger size. Note: this package changes the fonts everywhere, including the editor window and system menus. It is particularly useful to change the size of the font for demos.

31.5.5 Personalizing Your Font Profile

Interlisp-D keeps a list of default font specifications. This list is used to set the font in all windows where the font is not specifically set by the user (Section 31.5.3). The value of the atom `FONTPROFILE` is this list. (See Figure 31.7.)

A `FONTPROFILE` is a list of font descriptions that certain system functions access when printing output. It contains specifications for big fonts (used when pretty printing a function to type the function name), small fonts (used for printing comments in the editor), and various other fonts.

`FONTS 317`

I

FUNCTIONS FOR USING FONTS

- - -

43-FJitITPRUF[LE
Figure 31.7. The value of the atom FONTPROFILE

The list is in the form of an association list. The font class names, (e.g. DEFAULTFONT, Or SOLDFONT) are the keywords of the association list. When a number follows the keyword, it is the font number for that font class.

The lists following the font class name or number are the font specifications, in a form that the function FONTCREATE can use. The first font specification list after a keyword is the specification for printing to windows. The list, (GACHA 10), in the figure above is an example of the default specification for the printing to windows. The last two font specification lists are for Press and Interpress file printing, respectively. For more information, see the Interlis-D Reference Manual, Volume 3, Chapter 27.

Now, to change your default font settings, change the value of the variable FONTPROFILE. Interlis-D has a list of profiles stored as the value of the atom FONTDEFS. Choose the profile to use, then install it as the default FONTPROFILE.

Evaluate the atom FONTDEFS and notice that each profile list begins with a keyword. (See Figure 31.8.) This keyword corresponds to the size of the fonts included. BIG, SMALL, and STANDARD are some of the keywords for profiles on this list - SMALL and STANDARD appear in Figure 31.8.

31.8 F0Htt

12. YOUR INIT FILE  

Interlisp-D has a number of global variables that control the environment of your 1108 or 1186. Global variables make it easy to customize the environment to fit your needs. One way to do this is to develop an 'INIT' file. This is a file that is loaded when you log on to your machine. You can use it to set variables, load files, define functions, and any other things that you want to do to make the Interlisp-D environment suit you.

Your init file could be called INIT, INIT.LISP, INIT.USER, or whatever the convention is at your site. There is no default name preferred by the system, it just looks for the files listed in the variable USERGREETFILES, (see below). Check to see what the preference is at your site. Put this file in your directory. Your directory name should be the same as your login name.

The INIT file is loaded by the function GREET. GREET is normally run when Interlisp-D is started. If this is not the case at your site, or you want to use the machine and Interlisp-D has already been started, you can run the function GREET yourself. If your user name was, for example, TURING, then you would type:

\( \text{(GREET 'TURK)} \)

This does a number of things, including undoing any previous greeting operation, loading the site init file, and loading your init file. Where GREET looks for your INIT file depends on the value of the variable USERGREETFILES. The value of this variable is set when the system’s SYSOUT file is made, so check its value at your site! For example, its value could be:

- - 11  
NIL

3'USERGREETFILES5  
\( \text{i iiiFD5hl,(.LISPFILES, USER :INIT,LISPJ} \)
\( t\text{frD5h},',.LISPFILES, >-INIT,LISPJ} \) 
\( t\text{'rFLoPPY",INIT,L15ZJ} \)
\( i\text{,rosh",',5LISPFILES\}, USER :INIT,USERJ} \)
\( ((O.h L FILE," .INIT.U.'ER' o} \)
As described in Section 11.5, Page 11.7, each Interlis-D program file has a global variable associated with it, whose name is formed by appending "COMS" to the end of the root filename. For any of the standard INIT file names, the variable INITCOMS is used. To set up an init file, begin by editing this variable. First, type:

```lisp
(setq *initcoms* '((vans))
```

Now, to edit the variable, type:

```lisp
(l z:sicn*>)
```

A DEdit window will appear. This DEdit window is the same as the one called with the function OF, and described in Section 11.3, Page 11.4. This chapter will assume that you know how to use the structure editor, DEdit.

The CONS variable is a list of lists. The first atom in each internal list specifies for the file package what types of items are in the list, and what it is to do with them. This section will deal with three types of lists: VARS, FILES, and P. Please read about others in the Interlis-D Reference Manual, Volume II, Chapter 17. The list that begins with "VARS'ø allows you to set the values of variables. For example, one global variable is called DEditLinger. Its default value is T, and means that the DEdit window won't close after you exit DEdit. If it is set to NIL, then the DEdit window will be closed when you exit DEdit. To set it to NIL in your INIT file, edit the VARS.list so that it looks like this:

```lisp
"...1 1 ...1
'(,'4r,$' iOEdirLinger NILi Her
B--are
G--lete
Replace
'3yvitch
()
```

(out
Undo
Find
5'tap
Reprint
Edit

EditCam
Break
Eva
Figurø 12J. Setting the variable DE<!putline in INITCONS.
Notice that inside the vars list, there is yet another list. The firtt
item in the list is the name of the variable. It is bound to the
value of the second item. There are many other variables that
you can set by adding them to the VARS list. Some of these
variables are described in Chapter 43, and many others can be
found in the Interlis-D Reference Manual.

If you want to automatically load files, that can be done in your
init file also. For example, if you always want to load the Library file SPY. DCOM, you can load it by editing the INITCONS variable
to list the appropriate file in the list starting with FILES:

12.1 YOUR INIT FILE

MAKING AN INIT FILE

```lisp
(VARS (DžditLingcr NIL')) After
FILES SPY) Betott Delete Replace Switch

()out Undo Find Swap Reprint Edit

EddCom Break Evol Exit

FluFe 12.3. INITCONS changed to load the file SPY.DCOM
Other files can also be added by simply adding their names to
this FILES list.

Another list that can appear in a COMS list begins with "P". This
list contains InterLisp-D expressions that are evaluated when the
file is loaded. Do not put DEFINEQ expressions in this list.
Define the function in the environment, and then save it on the
file in the usual way (see Section 11.6, Page 11.7). One type of expression you might want to see here, however, is a
FONTCREATE function (see Section 31.2, Page 31.2). For
example, if you want to use a Helvetica 12 BOLD font, and there
is not a font descriptor for it normally in your environment, the
appropriate call to FONTCREATE should be in the "pP" list. The
INITCONS would look like this:

```

```

((VARS (DžditLingcr NIL)) After
(FFILES SPY) Betott
(~ JOHTcREaTE (QUOTE Delcte HEL\"ETII,, Repace
~vyitch

1.- (~jooTE _ SOL") _ 1)) ('out
Undo Find

Find
Figure 12.4. The form will be evaluated when the INI file is loaded.

To quit, exit from DEdit in the usual way. When you run the function SAVEFILES (See Section 11.6, Page 11.7.), be sure that you are connected to the directory (see Section 8.7, Page 8.4) where the INIT file should appear. Now when GREET is run, your init file will be loaded.

YOUR INIT FILE 123

----- Next Message -----
stored on the file will be a part of the value of this variable.

A variety of commands are now possible, all referring to individual functions within the analyzed files. Substantial variation in exact wording is permitted. Some commands are:

- \*SHoN PATHS FRDN ANY T0 ANY
- \*EDIT WERE ANY CALLS functionname
- \*EDIT WERE ANY USES variablename
- \*Wo CALLS WDN

- \*Wo CALLS functionname
- \*BY WoN IS functionname CALLED
- \* WD USES variablename AS FIELD

Note that the function is being called to invoke each command. Refer to the /nterlis-D Reference Manual for commands not listed here.

Figure 33.2 shows the Interlis-D Executive Window after the commands \*Won CALLS GobbleDunp and \*vifo DOES JVLinScan CALL.

M ASTH COPE

Figure 33.2. Sample Masterscope Output

33.t The SHOW DATA command and GRAPHER
When the library package GRAPHER is loaded, (to load this package, type (FILESLOAD GRAPHER).) Masterscope’s SHOWPATHS command is modified. The command will be changed to generate a tree structure showing how the program’s functions interact instead of a tabular printout into the Interlis-D Executive window. For example, typing:

\* ~ PATHS FW Proces:sE.

produced the display shown in Figure 33.3.

Figure 33.3. SHOW PATHS Display Example
All the functions in the display are part of this analyzed file or a previously analyzed file. Boxed functions indicate that the function name has been duplicated in another place on the display.

Selecting any function name on the display will pretty print the function in a window. (See Figure 33.4.)

33.2 Databasefns: Automatic Construction and Upkeep of a Masterscope Database
DataBaseFns is a separate library package that allows you to automatically construct and maintain Masterscope databases of your files. The package is contained in the DATABASEFNS.DCOM file.

When DATABASEFNS.DCOM is loaded, a Masterscope database will be automatically maintained for every file whose DATABASE property has the value YES. If this property’s value is not set, you will be asked when you save the file “Do you want a Masterscope Database for this file?” Saying YES enables the DabaBaseFns to construct a Masterscope database of the file you are saving. Each time the function *AKEFILE is used on a file whose DATABASE property has a value YES, Masterscope will analyze your file and update its own database. Each file’s masterscope database is kept in a separate file whose name has the form FILE.DATABASE. Whenever you load a file with a YES value for its DATABASE property, you will be asked whether you also want the database file loaded.

Figure 34.2. The SPY window when SPY is being used.

To turn off SPY after the program has run, again click a mouse button in the SPY window. The eye closes, and you are asked to position another window. This window contains SPY’s results. An example of result window is shown in Figure 34.3.

WHERE DOES ALL THE TIME GO? SPY 341

HOW TO USE SPY WITH THE SPY WINDOW

- TIME

WHEN

WHERE

- REPE,,TE&L’,EV~rn EJ~rn ø1 EF.zUFE

Figure 34.3. The window produced after running SPY.

This window is scrollable in two directions horizontally, and vertically. This is useful, since the whole tree does not fit in the window. If a part that you want to see is not shown, then you can scroll the window to show the part you want to see.

34.2 How to use SPY from the Lisp Top Level

SPY can also be run while a specific function or system is being used. To do this, type the function WITH.SPY:

(SPYN,SPLY ( form ))

The expression used for form should be the call to begin running the function or system that SPY is to watch. If you watch the SPY window, the eye will blink! To see your results, run the function SPY.TREE. To do this, type:

(SPYN,TREE)

The results of the last running of SPY will be displayed. If you do this, and SPY.TREE returns (no SPY samples have been gathered), your function ran too fast for SPY to follow.

34.3 Interpreting SPY’s Results

Each node in the tree is a box that contains, first, the percentage of time spent running that particular function, and second, the function name. There are two modes that can be used to display this tree.

The default mode is cumulative. In this mode, each percentage is the amount of time that function spent on top of the stack, plus the amount of time spent by the functions it calls.

The second mode is individual. To change the mode to individual, point to the title bar of the window, and press the middle ‘n’ouse button. Choose Individual from the menu that appears. In this mode, the percentage shown is the amount of time that the function spent on the top of the stack.

34.2 WHERE 00E5 ALLTN5ylMff G0? spY

1
32. THE INSPECTOR

The Inspector is a window-oriented tool designed to examine data structures. Because Interlisp-D is such a powerful programming environment, many types of data structures would be difficult to see in any other way.

32.1 Calling the Inspector

Take as an example an object defined through a sequence of pointers (i.e. a bitmap on the property list of a window on the property list of an atom in a program.)

To inspect an object named NAME, type:

(IKSPECT ~)

If NAME has many possible interpretations, an option menu will appear. For example, in Interlisp-D, a litatom can refer to both an atom and a function. For example, if NAME was a record, had a function definition, and had properties on its property list, then the menu would appear as in Figure 32.1.

Figure 32.1. Option Window For Inspection of NAME

If NAME were a list, then the option menu shown in Figure 32.2 would appear. The options include:

ø calling the display editor on the list;
ø calling the ~ editor (the "Typing Shortcuts", Chapter 6);
ø seeing the list’s elements in a display window. If you choose this option, each element in the list will appear in the right column of the Inspector window. The left column of the Inspector window will be made up of numbers. (See Figure 32.3.)

ø inspecting the list as a record type (this last option would produce a menu of known record types). If you choose a record type, the items in the list will appear in the right column of the Inspector window. The left column of the Inspector window will be made up of the field names of the record.
Figure 32.2. Option Window For Inspection of Lirf

THE INSPECTOR 321

USING THE INSPECTOR

32.2 Using the Inspector

If you choose to display your data structure in an edit window, simply edit the structure and exit in the normal manner when done. If you choose to display the data structure in an inspect window, then follow these instructions:

ø To select an item, point the mouse cursor at it and press the left mouse button.

ø Items in the right column of an Inspector window can themselves be inspected. To do this, choose the item, and press the center mouse button.

ø Items in the right column of an Inspector window can be changed. To do this, choose the corresponding item in the left column, and press the center mouse button. You will be prompted for the new value, and the item will be changed. The sequence of steps is shown in Figure 32.3.

Figure 32.3. The sequence of steps involved in changing a value in the right column of an Inspector window.

32.3 Inspector Example

This example will use ideas discussed in Section 37.1. An example, ANIMALGItAPH, is created in that section. You do not need to know the details of how it was created, but the structure will be examined in this chapter.
If you type

(IKSPECT II-.6liPN)

and then choose the Inspect option from the menu, a display appears as shown in Figure 32.4. ANIMAL.G-PH is being

J

ro 34.WHERE DOES ALL THE TiME GO?  
spy  
spy is an InterlispøD library package that shows you where you spend your time when you run your system. It is easy to learn, and very useful when trying to make programs run faster.  

34.1 How to use Spy with the SPY Window  
The function SPY. BUTTON brings up a small window which you will be prompted to position. Using the mouse buttons in this window controls the action of the SPY program. When you are not using SPY, the window appears as in Figure 34.1.  

Figure 34.1. The SPY window when SPY is not being used.  
Ts use SPY, click either the left or middle mouse button with the mouse cursor in the SPY window. The window will appear as in Figure 34.2, and means that SPY is accumulating data about your program.  

spy  
Figure 34.2. The SPY window when SPY is being used  
To turn off SPY after the program has run, again click a mouse button in the SPY window. The eye closes, and you are asked to position another window. This window contains SPY’s results. An example of result window is shown in Figure 34.3.  

WHERE DOES ALL THE TiME Go’  SPY 341  

How TO USE SPY ‘KITH THE SPY WINDOW  

rp.ire?  
~L;";"~-.  
IrP.rpi=.E;'".;.  
sU Tl~REhpYfiZ&.  
J!!i .EV–fiʃf. ': ø ø1 FEPEA~OL.EU~rn -'1 EJ~J.l ER.GURE  
7 _ øøø.BN.ø.F i:f;iø.iU~. _ Fpi`cføø:ø11 .. j IPP,fl~.øhJri.øiN
Figure 34.3. The window produced after running SPY

This window is scrollable in two directions, horizontally, and vertically. This is useful, since the whole tree does not fit in the window. If a part that you want to see is not shown, then you can scroll the window to show the part you want to see.

34.2 How to use SPY from the Lisp Top Level
SPY can also be run while a specific function or system is being used. To do this, type the function WITH SPY:
(WITH.sPY form)

The expression used for form should be the call to begin running the function or system that SPY is to watch. If you watch the SPY window, the eye will blink! To see your results, run the function SPY.TREE. To do this, type:

(SPY.TREE)

The results of the last running of SPY will be displayed. If you do this, and SPY.TREE returns (no SPY samples have been gathered), your function ran too fast for SPY to follow.

34.3 Interpreting SPY’s Results
Each node in the tree is a box that contains, first, the percentage of time spent running that particular function, and second, the function name. There are two modes that can be used to display this tree.

The default mode is cumulative. In this mode, each percentage is the amount of time that function spent on top of the stack, plus the amount of time spent by the functions it calls. The second mode is individual. To change the mode to individual, point to the title bar of the window, and press the middle mouse button. Choose Individual from the menu that appears. In this mode, the percentage shown is the amount of time that the function spent on the top of the stack.

34.2 WHERE DOES ALL THE TIME GO? SPY

1

INTERPRET SPY’S RESULTS
To look at a single branch of the tree, point with the mouse cursor at one of the nodes of the tree, and press the right mouse button. From the menu that appears, choose the option SubTree. Another SPY window will appear, with just this branch of the tree in it.

Another way to focus within the tree is to remove branches from the tree. To do this, point to the node at the top of the branch you would like to delete. Press the middle mouse button, and choose Delete from the menu that appears.

There are also different amounts of "merging" of functions that can be done in the window. A function can be called by another function more than once. The amount of merging determines where the subfunction, and the functions that it calls, appear in the tree, and how often. (For a detailed explanation of merging, see the Lisp Library Packages Manual.)

WHERE DOES ALL THE TIME GO’ sPY 343

1
Free Menu is a library package that is even more flexible than the regular menu package. It allows you to create menus with different types of items in them, and will format them as you would like. Free menus are particularly useful when you want a "fill in the form" type interaction with the user.

Each menu item is described with a list of properties and values. The following example will give you an idea of the structure of the description list, and some of your options. The most commonly used properties, and each type of menu item will be described in Section 36.2 and Section 36.3.

36.1 An Example Free Menu

Free menus can be created and formatted automatically! It is done with the function FN. FORCNENEU This function takes one argument, a description of the menu. The description is a list of lists; each internal list describes of one row of the free menu. A free menu row can have more than one item in it, so there are really lists of lists of lists! It really isn’t hard, though, as you can see from the following example:

```lisp
(SETQ Example
  (F* FORliT*EMu
    '(( TYPE TITLE LABEL TitlesDonothing)
      ( TYPE EDITSTART LABEL PressToStartEditing
        ITEMS (EDIT*))
      (TYPE EDIT ID EDITEND LABEL øø))
    (*IKDDMPRAPS TITLE øEx~1e Dris Nothing))))
```

The first row has 2 items in it; one is a TITLE, and the second is a 3STATE item. The second row also has 2 items. The second, the EDIT item, is invisible, because its label is an empty string. The caret will appear for editing, however, if the EDITSTART item is chosen. Windowprops can appear as part of the description of the menu, because a menu is, after all, just a special window.

You can specify not only the title with WINDOWPROPS, but also the position of the free menu, using the "left" and "bottom" properties, and the width of the border in pixels, with the "border" property. Evaluating this expression will return a window. You can see the menu by using the function OPENW.

The following example illustrates this:
FREE MENUS 361

AN EXAMPLE FREE MENU

61.~T~ EM.Dlcldnij

T1r le.". OcNorhing E...:r~_1_ =_ o'..i~
Rrn. ':'", T,St.arrEdir,iri,

...

Figure 36.4 Free menu with the 3STATE item in its NIL state

If you would like to specify the layout yourself, you can do that too. See the Lisp Library Packages Manual for more information.

36.2 Parts of a Free Menu Item

There are 8 different types of items that you can use in a free menu. No matter what type, the menu item is easily described by a list of properties, and values. Some of the properties you will use most often are:

36.2 FREE MENUS

1

PARTS OF A FREE MENU ITEM
LABEL Required for every type of menu item. It is the atom, string, or bitmap that appears as a menu selection.

TYPE One of eight types of menu items. Each of these are described below.

MESSAGE The message that will appear in the prompt window if a mouse button is held down over the item.

ID An item’s unique identifier. An ID is needed for certain types of menu items.

ITEMS Used to list a series of choices for an NCHOOSE item, and to list the ID’s of the editable items for an EDITSTART item.

SELECTEDFN The name of the function to be called if the item is chosen.

36.3 Types of Free Menu Items
Each type of menu item is described in the following list, including an example description list for each one.

Momentary This is the familiar sort of menu item. When it is selected, the function stored with it is called. A description for the function that creates and formats the menu looks like this:
(TYPE WEKTARY
LABEL Blink-K-Rin9
*ES~6E øBlinks the screen and rings bellsø
s2LEcTEDFK RIKBELLS)

TOGGLE This menu item has two states, T and NIL. The default state is NIL, but choosing the item toggles its state. The following is an example description list, without code for the SELECTEDFN function, for this type of item:
(TYPE T~6LE
LABEL hi~isable
sLEcTEDFN changeIl*State)

3STATE This type of menu item has 3 states, NUIETRAL, T, AND NIL. Neutral is the default state. T is shown by highlighting the item, and NIL is shown with diagonal lines. The following is an example description list, without code for the SELECTEDFN function, for this type of item:
(TYPE 3STATE
LABEL correctprograøAllofflospelling
sLEcTEDFNli ToggleSpellingcorrection)

TITLE This menu item appears on the menu as dummy text. It does nothing when chosen. An example of its description:
(TYPE TITLE LABEL øChoices:"")

NWAY A group of items, only one of which can be chosen at a time. The items in the NWAøY group should all have an ID field, and the ID’s should be the same. For exam1Flle, to set up a menu that would allow the user to chose between Helvetica, Gacha, Modern, and Classic fonts, the descriptions might look like this (Once again, without the code for the SELECTEDFN):
(TYPE IAY ID F--Tc~Ic’
LABEL bivetica
sLEcTEDFN changeFont)

FREE MENUS 36)
TYPES OF FREE MENU ITEMS

(TYPE NVAY ID FOQTCKICE
LABEL Gacha
SELECTEDF

(TYPE IAY ID F05TliCriC0ha,~n8efont)
LABEL Modern
SELECTEDI Chan2eFont)
(TYPE KAY ID fONTCHOIC
LABEL Classic
SELECTEDFN Changefont)

NCHOOSE This type of menu item is like NWAY except that the choices are
given to the user in a submenu. The list to specify an NCHOOSE
menu item that is analogous to the NWAY item above might
look like this:
(TYPE MC~SF
LABEL FontChoices
ITEMS Helvotica Gacha Modern Classic)
SELECT DfK Changefont)

EDITSTART When this type of menu item is chosen, it activates another type
of item, an EDIT item. The EDIT item or items associated with an
EDITSTART item have their ID’s listed on the EDITSTART’s ITEMS
property. An example description list is:
(TYPE EDITSTART LABEL øFunction to add? ITEMS (Fn))
EDIT This type of menu item can actually be edited by you. It is often
associated with an EDITSTART item (see above), but the caret
that prompts for input will also appear if the item itself is chosen.
An EDIT item follows the same editing conventions as editing in
Interlisp-D Executive window:
Add Characters by typing them at the caret.
Move the caret by pointing the mouse at the new position, and
clicking the left button.
Delete Characters from the caret to the mouse by pressing the
right button of the mouse. Delete a character behind the caret
by pressing the back space key.
Stop editing by typing a carriage return, a Control-X, or by
choosing another item from the menu.
An example description list for this type of item is:
(TYPE EDIT ID Fn LABEL øø)

37. THEGRAPHER

37.1 Say it with Graphs

Grapher is a collection of functions for creating and displaying graphs, networks of nodes and links. Grapher also allows you to associate program behavior with mouse selection of graph nodes. To load this package, type

(FILESL~ GliPHER)

Figure 37.1 shows a simple graph.

```
Figure 37.1. A Simple Graph
```

In Figure 37.1 there are six nodes (ANIMAL, MAMMAL, DOG, LAT, FISH, and BIRD) connected by five links.

A GRAPH is a record containing several fields. Perhaps the most important field is GRAPHNODS - which is itself a list of GRAPHNODE records. Figure 37.2 illustrates these data structures. The window on top contains the fields from the simple graph. The window on the bottom is an inspection of the node, DOG.

NODE ID 300

Figure 37.2. Inspefing a Graph and a Node
The GRAPHNODE data structure is described by its text (NODEID), what goes into it (FROMNODES), what leaves it (TONODES), and other fields that specify its looks. The basic model of graph building is to create a bunch of nodes, then layout the nodes into a graph, and finally display the resultant graph. This can be done in a number of ways. One is to use the function NODECREATE to create the nodes, LAYOUTGRAPH to lay out the nodes, and SHOWGRAPH to display the graph. The primer shows you two simpler ways, but please see the Library Packages Manual for more information about these other functions. The primer’s first method is to use SHOWGRAPH to display a graph with no nodes or links, then interactively add them. The second is to use the function LAYOUTSEXPR, which does the appropriate NODECREATEs and a LAYOUTGRAPH, with a list. The function SHQWGRAPH displays graphs and allows you to edit them. The syntax of SHOWGRAPH is

```
(~liPH graph window lefbuttonfn middlebuttonfn
topjustifflg alloweditflg copybuttoneventfn)
```

Obviously the graph structure is very complex. Here’s the easiest way to create a graph.

```
~.6liPN III)
```

Figure 37.3. My Graph

37.2 THEGRAPHER.

SAY IT WITH GRAPHS

You will be prompted to create a small window as in Figure 37.3. This graph has the title My Graph. Hold down the right mouse button in the window. A menu of graph editing operations will appear as in Figure 37.4.

```
D:ier~ Link
&=h--n9e ib P.I
lbel g.nil--r
l&'bel l--ros--r
Dir--.ct-.i1
SldPg
~ BoiødP.r
'h;=d"
'Tr"P
```

Figure 37.4. A Menu of Graph Editing Operations

Here’s how to use this menu to:

Add a Node Start by selecting Add Node. Grapher will prompt you for the name of the node (See Figure 37.5.) and then its position.

Figure 37.5. Grapher prompts for the name of the node to add after Add Node is chosen from the graph editing menu.

Position the node by moving the mouse cursor to the desired location and clicking a mouse button. Figure 37.6 shows the graph with two nodes added using this menu.

```
~irstå-ri+-te
s~~`onndod~
```

Figure 37.6. Two nodes added to MY GRAPH using the graph edit menu.
AddA Link Select Add Link from the graph editing menu. The Prompt window will prompt you to select the two nodes to be linked. (See Figure 37.7.) Do this, and the link will be added.

Figure 37.7. The Prompt window will prompt you to select the two nodes to link.

THEGRAPHER 37.3

SAY IT WITH GRAPHS

DeleteALink Select Delete Link from the graph editing menu. The Prompt window will prompt you to select the two nodes that should no longer be linked. (See Figure 37.8.) Do this, and the link will be deleted.

Figure 37.8. The Prompt window will prompt you to select two nodes that should no longer be linked.

Delete A Node Select Delete Node from the graph editing menu. The Prompt window will prompt you to select the node to be deleted. (See Figure 37.9.) Do this, and the node will be deleted.

Figure 37.9. The prompt to delete a node.

Moving a Node Select "Delete Node" from the graph editing menu. Choose a node pointing to the it with the mouse cursor, and pressing and holding the left mouse button. When you move the mouse cursor, the node will be dragged along. When the node is at the new position, release the mouse button to deposit the node.

The commands in this menu are easy to learn. Experiment with them!

37.2 Making a Graph from a List

Typically, a graph is used to display one of your program’s data structures. Here is how that is done.

LATOUTSEXPR takes a list and returns a GRAPH record. The syntax of the function is

(UYWTSEXPR sexpr format ~xing font motherd penonald fam;lyd)

For example:

(u-T10Q AKlil.L.TREE ‘(MIIL (l’~ ~ CAT) BIIi FISH))
Aaiili.L.6iiN

37.4 THEGRAPHER

MAKING A GRAPH FROM A LIST

b~YouTSE*PR AKlil.L.TREE øHoRIZ0NTALi~)
(EII N AIIiL.GliPN øNj Grøpbø NIL KIL a T)
This is how Figure 37.1 was produced.

37.3 Incorporating Grapher into Your Program
The Grapher is designed to be built into other programs. It can call functions when, for example, a mouse button is clicked on a node. The function SHOWGRAPfh does this:

```lisp
(-liPH graph window leflbuttonfn middlebuttonfn
topjusti-Rg alloweditflg copybuttoneventfn)
```

For example, the third argument to SHOWGRAPH, leftbuttonfn, is a function that is called when the left mouse button is pressed in the graph window. Try this:

```lisp
(DEFUIKžQ (~.LEfT.BUTT0N.FUNCTIO*N
(TNE.6liPHNooE THE.GliPH.wIN~)
(INSPECT TNE.6liPNNooE)))
```

```lisp
(-liPH FİLY.61PN øInspect&bla fiilyø
(F~TIK N".LEFT.BUTTa.FuNCTIo*)
liIL NIL T)
```

In the example above, liT.LEFT.BUTTON. FUNCTION simply calls the inspector. Note that the function should be written assuming it will be passed a graphnode and the window that holds the graph. Try adding a function of your own.

37.4 More of Grapher

Some other Library packages make use of the Grapher. (Note: Grapher needs to be loaded with the packages to use these functions.)

ø NASTERSCOPE: The Browser package modifies the Masterscope command, .SHOW PATHS, so that its output is displayed as a graph (using Grapher) instead of simply printed.
ø GRAPHZOOM: allows a graph to be redisplayed larger or smaller automatically.

THEGRAPHER 375

----- Next Message -----
examples that could, if you aren’t careful, provide a few problems. Here are a few tips on how to prevent problems:
ø If you change the value of a system variable, for example, or connect to a directory other than
(DsK)<LlsPFILes>, write a function to reset the variable or
directory to its original value. Run this function when you are
finished working. This is especially important if you change any
of the system menus.
ø Don’t redefine Interlisp-D functions or CLISP words.
Remember, if you reset an atom’s value or function definition at
the top level (in the Interlisp-D Executive Window), the message
(Some.Crucial.Function. Or. Variable redefined), appears. If
this is not what you wanted, type UNDO immediately!
If, however, you reset the value or function definition of an atom
inside your program, a warning message will not be printed.
ø Make the atom names in your programs as unique as possible.
To do this without filling your program with unreadable names
that no one, including you, can remember, prefix your variable
names with the initials of your program. Even then, check to see
that they are not already being used with the function BOUNDP.
For example, type:
(~P øB&ckgroundhnu)
This atom is bound to the menu that appears when you press the
left mouse button when the mouse cursor is not in any window.
BOUKDP returns T. BOUNDP returns NIL if its argument does not
currently have a value.
ø Make your function names as unique as possible. Once again,
prefixing function names with the initials of your program can
be helpful in making them unique, but even so, check to see that
they are not already being used. GETD is the Interlisp-D function
that returns the function definition of an atom, if it has one. If
an atom has no function definition, GETO returns NIL. For
example, type:
(GEffl ‘CAR)
 RESOURCE MANAGEMENT 411
NAMING VARIABLES AND RECORDS
A non-NIL value i- returned. The atom CAR already has a
function definition.
ø Use complete record field names in record FETCHes and
REPLACEes when your code is not compiled. A Complete record
field name is a list Consisting of the record declaration name and
the field name. Consider the following example:
(RECORD N~ FIRST LAST))
SETQ Nyyfflrn create Nilz FIRST ‘John LAST ‘--ith))
FETCH (~ FIRST) OF Mylrn)
ø Avoid reusing names that are field names of Interlisp-D System
records. A few examples of system records follow. Do not reuse
these names.
(RECORD RE6IOI (LEFT RoTT0I WIDTH NEIGHT))
(RECORD POSITIK xc00RD
RECORD II6E~ BITIiYCP00RD)))
ø When you select a record name and field names for a new
Call the function RECLOOK, with your record name as an argument, in the Interlisp-D Executive Window. (See Figure 41.1.) If your record name is already a record, the record definition will be returned; otherwise the function will return NIL.

Call the function FIELDLOOK with your new field name in the Interlisp-D Executive Window. (See Figure 41.2.) If your field name is already a field name in another record, the record definition will be returned; otherwise the function will return NIL.

41.2 RESOURCE MANAGEMENT 01

NAMING VARIABLES AND RECORDS

In order for your program to run at maximum speed, you must efficiently use the space available on the system. The following section points out areas that you may not know are wasting valuable space, and tips on how to prevent this waste. Often programs are written so that new data structures are created each time the program is run. This is wasteful. Write your programs so that they only create new variables and other data structures conditionally. If a structure has already been created, use it instead of creating a new one.
Some time and space can be saved by changing your RECORD and TYPERECORD declarations to DATATYPE. DATATYPE is used the same way as the functions RECORD and TYPERECORD. (See Chapter 24.) In addition, the same FETCH and REPLACE commands can be used with the data structure DATATYPE creates. The difference is that the data structure DATATYPE creates cannot be treated as a list the way RECORDs and TYPERECORDs can.

41.2.1 Global Variables

Once defined, global variables remain until Interlisp-D is reloaded. Avoid using global variables if at all possible! One specific problem arises when programs use the function 6ENSYff. In program development, many atoms are created that may no longer be useful. Hints:

ø Use

(DELDEF atomname 'PKP)
to delete property lists, and
(DELDEF atomname 'vARS)

RESOURCE MANAGEMENT 413

----- Next Message -----
41.2.2 Circular Lists

If your program is creating circular lists, a lot of space may be wasted. (Note that many cross linked data structures end up having circularities.) Hints when using circular lists:
ø Write a function to remove pointers that make lists circular when you are through with the circular list.
ø If you are working with circular lists of windows, bind your main window to a unique global variable. Write window creation conditionally so that if the binding of that variable is already a window, use it, and only create a new window if that variable is unbound or NIL.

Here is an example that illustrates the problem. When several auxiliary windows are built, pointers to these windows are usually kept on the main window’s property list. Each auxiliary window also typically keeps a pointer to the main window on its property list. If the top level function creates windows rather than reusing existing ones, there will be many lists of useless windows cluttering the work space. Or, if such a main window is closed and will not be used again, you will have to break the links by deleting the relevant properties from both the main window and all of the auxiliary windows first. This is usually done by putting a special CLOSEFl on the main window and all of its auxiliary windows.

41.2.3 When You Run Out Of Space
Typically, if you generate a lot of structure that won’t get garbage collected, you will eventually run out of space. The important part is being able to track down those structures and

41.4 REsource MANAGEMENT
I

SOME SPACE AND TIME CONSIDERATIONS

the code that generates them in order to become more space efficient.

The Lisp Library Package GCHAX.DCOM can be used to track down pointers to data structures. The basic idea is that GCHAX will return the number of references to a particular data structure.

A special function exists that allows you to get a little extra space 50 that you can try to save your work when you get toward the edge (usually noted by a message indicating that you should save your work and sysin a fresh Lisp). The GAINSPACE function allows you to delete non-essential data structures. To use it, type:

(liikSPACE)

into the Interlisp-D Executive Window. Answer "N" to all questions except the following.
ø Delete edit history
ø Delete history list.
ø Delete values of old variables.
ø Delete your MASTERSCOPE database
ø Delete information for undoing your greeting.
Save your work and reload Lisp as soon as possible.
42. SIMPLE INTERACTIONS WITH
THE CURSOR, A BITMAP, AND A WINDOW

The purpose of this chapter is to show you how to build a moderately tricky interactive interface with the various Interlisp-D display facilities, in particular how to move a large bitmap (larger than 16 x 16 pixels) around inside a window. To do this, you will change the CURSORINFN and CURSOROUTFN properties of the window. If you would also like to then set the bitmap in place in the window, you must reset the BUTTOKEVENTFN. This chapter explains how to create the mobile bitmap.

42.1 An Example Function Using GETMOUSESTATE

One function that you will use to "trace the cursor" (have a bitmap follow the cursor around in a window) is GETMOUSESTATE. This function finds the current state of the mouse, and resets global system variables, such as LASTMOUSEX and LASTMOUSEY.

As an example of how this function works, create a window by typing

(SETQ EzMPLE.wIN~ (CREATEI))

into the Interlisp-D Executive window, and sweeping out a window. Now, type in the function

(DEFIKEQ (PRIKTC00RDS (V)
P~TPRI*T ø(ø ~TuoUSeX ., . US~EY ø)ø)ø)
BLocK)
6E~SESTATE)))

This function calls GETMOUSESTATE and then prints the new values of LASTMOUSEX and LASTMOUSEY in the prompt window. To use it, type

(WIKraoPrOPEXIPLE.iill*~ 'CURSDF~EDFK 'PRIaTC00RDS)
The window property CURSORHIOVEDFN, used in this example, will evaluate the function PRINTCOORDS each time the cursor is moved when it is inside the window. The position coordinates of the mouse cursor will appear in the prompt window. (See Figure 42.1.)
SIMPLE INTERACTIONS WITH THE CURSOR, A BITMAP, AND A WINDOW

AN EXAMPLE FUNCTION USING GETMOUSESTATE

Figure 42.1. The current position coordinates of the mouse cursor are shown in the prompt window.

42.2 Advising GETMOUSESTATE
For the bitmap to follow the moving mouse cursor, the function GETMOUSESTATE is advised. When you advise a function, you can add new commands to the function without knowing how it is actually implemented. The syntax for advise is

\[(RISE \text{ fn when where what})\]

fn is the name of the function to be augmented. when and where are optional arguments. when specifies whether the change should be made before, after, or around the body of the function. The values expected are BEFORE, AFTER, or AROUND.

what specifies the additional code.

In the example, the additional code, what, moves the bitmap to the position of the mouse cursor. The function GETMOUSESTATE will be ADVISEd when the mouse moves into the window. This will cause the bitmap to follow the mouse cursor. ADVISE will be undone when the mouse leaves the window or when a mouse button is pushed. The ADVISEing will be done and undone by changing the CURSORINFN, CURSOROUTFN, and BUTTONEVENTFN for the window.

42.3 Changing the Cursor

Of if last part of the example, to give the impression that a bitmap is dragged around a window, the original cursor should disappear. Try typing:

\[(CURSOR (CURSORCRZR (6I-PCREAtt 1 l) l 1 1) \text{ into the Interlis-D Executive Window}.\]

\[\text{This causes the original cursor to disappear. It reappears when you type (CURSOR T)}\]

When the cursor is invisible, and the bitmap moves as the cursor moves, the illusion is given that the bitmap is dragged around the window.

42.4 Functions for "Tracing the cursor"
To actually have a bitmap trace (follow) the cursor, the environment must be set up so that when the cursor enters the tracing region the trace is turned on, and when the cursor leaves the tracing region the trace is turned off. The function Establish/Trace/Data will do this. Type it in as it appears (note: including the comments will help you remember what the function does later).

\[(DEFIKEQ Establish/Trace/rata)\]
Establish/Trace/Data is collécted to establish the function to trace the döt of the tracing bitap. The cursor/right offset is the döt in which the tracing is to take place, the tracing hotspot is the cursor/right offset \(\text{cursor/right offset} \in \mathbb{R}_+\) which determine the hotspot of the tracing bitap. As the "cursor/height offset" set and \(\text{cursor/right offset}\) increase the cursor hotspot moves up and to the right.

If GCGA6P is non-NIL, GcGAC still be disabled.

(PROG NIL

(ATE PAINT]

That’s all the functions!

SIMPLE INTERAcTioNs NITH THE cuRsoR, A BITMAP, AND A WIND0W 42 S

P

RUNNING THE FuNcTlGh5

42.5 Running the Functions

To run the functions you just typed in, first set a variable to a window by typing something like
(SETQ EXMPLExW1N~ (CRžATEI))

into the Jnterlisp-D Executive window, and sweeping out a new window. No’rv, set a variable to a bitmap, by typing, perhaps, (SETQ ExlPLE.BTn (žDITl))
Type

(Establisfl’Trscë’Oo~ EXIPLE.WIN~ EXIPLE.BTK))

When you move the cursor into the window, the cursor will drag the bitmap.

(Note: If you want to be able to make menu selections while tracing the cursor, make sure that the hotspot of the cursor is set to the extreme right of the bitmap. Otherwise, the menu will be destroyed by the BITSLTs of the trace functions.)
To stop tracing, either

ø move the mouse cursor out of the window;
ø press the right mouse button;
ø call the function UNTRACE/CURS0R.

u.6 SIMPLE lNTEPACT~NS WITH THE CURSOR, A SITMAP, AND A W1N00W
Here are some references to works that will be useful to you in addition to this primer. Some of these you have already been referred to, such as:

- The Interlisp-D Reference Manual
- The Library Packages Manual
- The User’s Guide to SKETCH
- The Little Lisper by Daniel P. Friedman and Matthias Felleisen. The second edition of this book was published in 1986 by SRA Associates, Chicago. This book is a deceptively simple introduction to recursive programming and the flexible data structures provided by LISP.

In addition, you can learn more about LISP with the books:
- Essential LISP by John Anderson, Albert Corbett, and Brian Reiser. This book was published in 1986 by Addison Wesley Publishing Company, Reading, MA. It was informed by research on how beginners learn LISP.
- The Interlisp-D: The language and its usage by Steven H. Kaisler. This book was published in 1986 by John Wiley and Sons, NY.
- LISP by Patrick Winston and Berthold Horn. The second edition of this book was published in 1985 by the Addison Wesley Publishing Company, Reading, MA.

Finally, there are three articles about the Interlisp Programming environment:
Each of these articles was reprinted in the book Interactive Programming Environments by David R. Barstow, Howard E. Shrobe, and Erik Sandewall. This book was published in 1984 by McGraw Hill, NY. The first article can be found on pages 19 - 30, the second on pages 83 - 96, and the third on pages 31 - 80.

--- End Forwarded Messages ---

—End of message—
1. INTRODUCTION

Medley is an integrated programming environment, with support for the Interlisp and Common Lisp languages, an integrated windowing system, and a large collection of utilities and programs. It offers a mature and rich programming and development environment, as well as access to a large number of applications written for Interlisp, Interlisp-D, Common Lisp, and LOOPS.

Medley for the Sun Workstation has two versions, a Sun–3 version and a Sun–4 version, available on separate tapes. Medley 2.0 runs on the Sun–3 and Sun–4 workstations and the SPARCstation.

What Medley Requires

Hardware

Medley runs on Sun–3 and Sun–4 Workstations and the SPARCstation. It runs on both standalone workstations and diskless workstations linked to servers.

Medley on the Sun–3 Workstation requires the MC68881 floating-point coprocessor chip. On the Sun–4 Workstation, the Weitek 1164/1165 coprocessor is optional, but recommended.

For adequate performance, we recommend at least a 20 MHz 68020 (Sun 3/60 or 3/260), a 14 MHz SPARC (Sun 4/110 or 4/260), or a SPARCstation.

Except under X Windows, reasonable interactive performance can be expected with 8 megabytes (MB) or more of RAM. Smaller configurations of diskless workstations have been tested, but performance suffers. When using X Windows software, allow an additional 4 MB.

Naturally, larger applications will benefit from more memory. Medley’s maximum working set is approximately 40 MB.

Input/Output Devices

Medley provides access to the Sun’s input/output devices, such as display, keyboard, mouse, and file systems. It also provides access to PUP and XNS Ethernet services directly.

Bitmap Display

Medley supports all standard Sun displays and frame buffers.

Printers

You can print on Xerox Interpress printers using the XNS networking protocols. The FX80 printer also works via the RS232 port.

If you have a PostScript printer, you can use the LispUser modules PostScriptStream and UNIXPrint to direct output to your printer.
1. INTRODUCTION

Software Requirements

Medley on the Sun–3 Workstation requires SunOS versions 3.2, 3.4, 3.5, 4.0, or 4.0.3. On the Sun–4 Workstation, Medley requires SunOS version 4.0, 4.0.3, or 4.1.

If you plan to run Medley under X Windows, you will need X11, version 4, or Motif.

NOTE: Medley’s XNS Ethernet code will not work if you are running SunOS 3.5 configured for Kernel XNS Ethernet Support or Alpine.

Medley and Other Applications

Display Usage

When Medley is running alone, it takes over the entire display screen. When running under X, Medley uses one window as its screen; Medley maintains its own windows within that single window. Medley cannot run at the same time as Suntools or Open Windows.

Processor Usage

Medley runs its own process scheduler; as far as the UNIX scheduler is concerned, Medley is always running. For this reason, other heavy computational jobs on the same Sun Workstation will not get as good performance as they would competing with conventional UNIX interactive applications.

Similarly, Medley may not have adequate interactive performance if it is competing with other compute-bound tasks on the same machine.

For these reasons, we recommend that Medley be used on machines that are set up primarily for a single user.

System Components

Functionally, Medley consists of the following components:

emulator A SunOS-executable program, which performs several functions. It executes the Interlisp-D virtual machine instruction set compatibly with the microcode of the Xerox 1100 series workstations. (This instruction set allows memory-efficient representation of Interlisp and Common Lisp programs.) It also provides access to the host machine’s I/O (display, keyboard, file system), and executes some system functions directly.

sysout A virtual memory image (the sysout) containing both byte-code-compiled Lisp functions and data structures. The sysout provided can be used both on the Sun Workstation and on the Xerox 1100 series machines.

library Files of compiled Lisp code and data structures.

fonts Data describing the "looks" of printed characters used by Medley's graphics, windowing, and hardcopying subsystems. Font directories are in three groups: display fonts, InterPress printer fonts, and Press printer fonts.
checksum A script that reports inconsistent files, the correct checksum values for the files, and an error message. The checksum of individual files can be generated with the UNIX command `sum filename`. Use this when Medley installs correctly but does not run.

### Medley Device-Naming Conventions

Medley for the Sun Workstation lets you interact with SunOS file systems (including file systems mounted from other machines) by using host device names. The two device names are as follows:

{DSK} A host name which gives you access to the SunOS file system using Xerox workstation local disk conventions.

{UNIX} A host name which gives you access to the file system using normal SunOS conventions.

The {DSK} device name provides an interface to the Sun Workstation for users who want to maintain compatibility with existing development tools and applications originally developed on a Xerox workstation. The {UNIX} device name provides a way for new applications to interact naturally with UNIX. Chapter 5 explains, in greater detail, some important exceptions and restrictions to the {DSK} and {UNIX} device name.

### Notation Conventions

Text marked by a revision bar in the right margin contains information that was added or modified since the last release. Fonts, packages, and prompts have the following types of notation.

#### Fonts

**Bold text in TITAN font** indicates text you should type in exactly as printed.

Regular TITAN font text indicates what the system prints on your workstation screen. Lisp functions and variables and UNIX files and programs are also shown in TITAN FONT.

Text in Classic italics indicates variables or parameters that you should replace with the appropriate word or string.

#### Packages

Most Lisp symbols have a Lisp package qualifier; the INTERLISP package (IL:) is the default when no package qualifier is shown.

#### Prompts

All examples which include SunOS dialogues use the following conventions for the SunOS prompt.

A number sign (#), part of the system prompt, indicates that you are logged on as root or is running `su`; for example,
1. INTRODUCTION

A percent sign (%), part of the system prompt, indicates that a user other than root is logged on; for example,

prompt#

Compatibility

The Medley release on the Sun Workstation is designed for maximum compatibility with the Xerox workstation implementations. However, when moving applications to the Sun Workstation note the differences in end-of-line conventions and techniques for moving files.

Sysout Compatibility

Sysouts of the same version are compatible with all machine types. But a sysout generated on a Sun Workstation cannot be used on a Xerox workstation.

NOTE: You cannot mix different versions of sysouts and emulators.

Compiled-File Compatibility

Code compiled in a Medley 1.0, 1.1, 1.15 or 1.2 sysouts cannot be loaded into Medley 2.0 sysouts, nor can code compiled in Medley 2.0 be loaded onto earlier sysouts. Code compiled for Medley 2.0 on a Xerox workstation cannot be loaded into Medley running on a Sun. The opposite is not possible either.

End-of-Line Convention

Some care must be taken in moving files to and from Xerox workstations, since the default end-of-line convention in UNIX is to terminate lines with the line feed (LF) character, while, traditionally, Medley has terminated lines with the carriage return (CR) character. In particular, if you use some other file transfer mechanism, such as FTP or Kermit, be careful to transfer .TEDIT, .DFASL, and .LCOM files in binary mode.

In Medley on the Sun Workstation, the default end-of-line convention for all text files is line feed (LF). The default end-of-line convention for all binary files is carriage return (CR); this is because CR (ASCII 13) is used internally in the system.

Release Contents

The release distribution contains the following documentation and software.

Documentation

The Medley documentation kit for users moving from a Xerox workstation to a Sun Workstation contains:

- Lisp Library Modules, Medley Release
- Lisp Release Notes, Medley Release
- Medley For the Sun Workstation® User’s Guide
• Sun Type 3 and Type 4 keyboard templates.

New customers also receive the following:
• Interlisp-D Reference Manual, Volumes 1-3, Koto Release
• Xerox Common Lisp Implementation Notes, Lyric Release
• Lisp Documentation Tools, Lyric Release
• Guy Steele, Common Lisp, the Language, First Edition

All users can also purchase this document:
• LispUsers’ Modules, Medley Release

Software

The software release is available on either a ¼-inch tape cartridge or a ½-inch 9-track tape. The software release is specific to the Sun architecture (Sun 3 or 4) for which you purchased Medley, but contains multiple SunOS versions. This tar tape contains the directories listed below. (See Appendix C for details of the directory contents.)

./install-medley
./medley
./install.sunos3/
./install.sunos4/
./install.sunos4.1/
./lisplibrary
./checksumdir
./lispsysouts
./fonts/display
./fonts/interpress

LispUsers Modules

The Medley version of LispUsers Modules is a software supplement to Medley for the Sun Workstation. This is software written by our users which you may purchase separately. The support for these modules comes from each module’s author; Venue has no commitment to support LispUsers’ modules.

Two LispUsers Modules are particularly useful when you are running Medley on a Sun Workstation. For those users with Postscriptstream printers for output, the PostScript module is particularly useful. The LispUsers module RPC implements Sun remote procedure calls.

### Glossary

### Index
2. SOFTWARE INSTALLATION

This chapter describes how to install Medley on Sun Workstations.

To install the Medley Release on a Sun Workstation, you need the following:
- Release tape
- Medley documentation kit for the Sun Workstation.

Getting Ready to Install Medley

Medley includes a shell script for automatic installation. The script infers as much as it can about your host and network, but will prompt you for answers when needed. Once it has collected the necessary information, it installs only those parts of Medley that you really need.

Do not worry if you forget something. You can run the installation again, and pick up any items you missed.

Before installing Medley, you should gather some facts about the hardware and network environment on which you will be using Medley. The following checklist will help you.

- Do you have the correct release tape correct for the kind of machine on which you plan to run?
  The tape is labeled either Sun-3 or Sun-4/SPARCstation.
- Where is the tape drive you will be using?
  Does your Sun have a 1/4-inch tape drive? If not, you need a Sun with a 1/4-inch tape drive on your network. You will need to know the host name for that machine.
- Does your system have sufficient swap space (45 MB) for Medley?
  If you are not sure, see the section below for instructions.
- Are you installing Medley for a single user, or will several users be sharing this copy?
  If it is for shared use, you will want to install Medley on a public directory on a shared server. For that, we recommend using /usr/share/lde as the directory name. You will need to be running on the server when you do the installation, and you will probably need to log in as root. Check with your System Administrator for details.
- Do you have enough disk space free?
  You need to select a file system with enough disk space to install the software. A minimal installation requires approximately 12 MB, and a full installation will require up to 23 MB. Use the UNIX command df to find one.
- Have you selected an installation directory?
  The directory must be on a file system with enough space. For individual use, we recommend /usr/local/lde.
2. SOFTWARE INSTALLATION

---

**CAUTION**

If the installation directory contains a previously installed version of Medley, some of the older files will be replaced with new ones.

---

- Do you have write permission to create the installation directory and to write files into it?
- Will you be running on X Windows?
  - If you are, you will need X11 R4 or Motif. If you have X Windows installed, the utility will install the software necessary to run Medley under X11.
- Will you be running XNS (Xerox Network Services) or PUP protocols?
  - If so, you must be logged in as root during the installation.
  - If so, be sure you are not running SunOS 3.5 Kernel XNS Ethernet Code ("Alpine Kernel").
- If your host is networked, do you have XNS (Xerox Network Services) servers on it?
  - If so, you will want to install XNS-relevant software. Also, if you have XNS Print Services and InterPress printers on your network, you might want to install InterPress fonts, allowing you to use an InterPress printer from within Medley. The default is not to install any XNS-relevant software.
- Is this a new installation, or are you upgrading from an earlier version of Medley?
  - If you are upgrading, you only need to install the sysout, the appropriate emulator, and library files. If you are making a new installation, you will need at least the display fonts as well.

### Ensuring Adequate Swap Space

Medley requires 45 MB of swap space on top of the normal swap space requirements. Check swap space using the `pstat` command:

```
prompt% /etc/pstat -s
37176k used (3176k text), 12920k free, 1344k wasted, 0k missing
max process allocable = 10224k
avail: 5*2048k 1*512k 4*256k 3*128k 6*64k 7*32k 7*16k 40*1k
4800k allocated + 2520k reserved = 7320k used, 64672k available
```

If you need more swap space, consult the Sun Software Technical Bulletin, March 1988, pages 335-36, for information on increasing the amount of available swap space.

### Installing Medley for Shared Use

If several people will be using Medley on different machines, it probably makes sense to install one copy and have people share it.

You will need to find one machine—probably your main file server—with enough disk space. You will also want to have the directory look the same to every user. We recommend calling the installation directory `/usr/share/lde`. 

---

8 Medley for the Sun User's Guide, Release 2.0
Installing Medley Software

1. Log in under your username.
   
   ```
   login yourname
   ```

2. Put the tape in the tape drive. The script will allow you to install from a tape drive on a remote host. If you are performing a remote installation, put the tape in the tape drive of the host.

3. Retrieve the installation utility from the tape, as follows.
   
   - If the tape drive is on a different host, enter the following:
     
     ```
     rsh remote-host dd if=/dev/rst0 | tar xf -
     ```
     
     Replace `remote-host` with the name of the host on your network that has the tape drive you are using. This copies the file `install-medley` to your working directory.
   
   - If the tape drive is local to your machine, type the following:
     
     ```
     tar xf /dev/rst0
     ```
     
     This copies the file `install-medley` to your working directory.

   If you have any problems during this step of the installation, consult your local UNIX system administrator.

4. Run the installation utility:
   
   ```
   install-medley
   ```

   Each time you are prompted for information, the script will show you the default in brackets. Pressing the return key selects the default. To select a different option, type it.

   After installing Medley, the script will offer to update two files which must refer to the installation directory. We recommend this. The two files are:

   ```
   medley A script for running Medley easily
   site-init A sample site-init file
   ```

   You can stop the installation process at any time by typing `^C` (Control-C).

Using the Installation Script's Menu

To choose an option from the Installation Options Menu, type at least the first three characters of the selection. Most of the menu lists items you might want to install. Choosing one of these options works as a toggle switch, either selecting or deselecting, depending on its previous setting. The other menu items act as commands when you select them. "OS version" lets you pick the SunOS version(s) for which you will need matching emulators. "Directory" lets you specify where to install Medley. "!" lets you use UNIX commands if you need to.

In Figure 2-1, the user has selected for installation the Sysout, Monochrome and X Windows emulators for SunOS 4.1, Display fonts, and Library modules. The menu shows that you need 15052.8 KB of disk space to finish the installation, but only 13002 KB are available. At this point you can either deselect an option to decrease the disk space requirements, or change the installation directory to one that has sufficient disk space.
---------- Installation Options Menu ----------
----------------------------------------------

For one or several OS versions (At least one of monochrome, color or X11-version is required for new installations)

- Monochrome - 0.5 MByte
- X11-version - 0.6 MByte
- XNS - allows use of XNS protocols
- Object files - allows linking of Medley to other software
  OS version - Change versions. Selected: 4.1

-----------------------------------------------
- Fonts ----------------------------------------

- Display - 5.5 MByte (recommended)
- Interpress

-----------------------------
- Sysout, Library & Checksum files --------------

- Sysout - 5.1 MByte (required for new installations)
- Library modules - 3 MByte (recommended)
- Checksum files

-------------------------------
- Commands --------------------------

Directory - Change location of installation directory.
  -- Current: /usr/share/lde 13002 KB
  -- Disk-space(KByte) Available:13002 Needed:15052.8
  !<Unix command> - Execute a Unix command
  ? or Help - Show menu instructions
  Redraw - Redisplay this menu
  None - Unmark all options
  All - Mark all options
  Continue installation
  Quit installation

Select [Directory]:

Figure 2-1. Sample Installation Menu

Because of the disk space shortage, the script has offered [Directory] as the default next command. If that is what you want, just press Return. Otherwise, type some other command.

For example, to deselect Library modules, type:

Select [Directory]: lib

Alternately, to find a filesystem with enough disk space, issue the following command:

Select [Directory]: !df

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>kbytes</th>
<th>used</th>
<th>avail</th>
<th>capacity</th>
<th>Mounted on</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/sd0a</td>
<td>7548</td>
<td>4935</td>
<td>1858</td>
<td>73%</td>
<td>/</td>
</tr>
<tr>
<td>/dev/sd0g</td>
<td>75106</td>
<td>51704</td>
<td>15891</td>
<td>76%</td>
<td>/usr</td>
</tr>
<tr>
<td>/dev/sd1g</td>
<td>47999</td>
<td>21898</td>
<td>21301</td>
<td>51%</td>
<td>/home</td>
</tr>
<tr>
<td>king:/shared</td>
<td>416928</td>
<td>349202</td>
<td>26042</td>
<td>93%</td>
<td>/share</td>
</tr>
</tbody>
</table>

Select [Directory]:
To change the installation directory, type:

`Select [Directory]:` dir

At the new prompt, give the directory name:

`Where do you want to install Medley? [/usr/share/lde]:` /share/lde

If the directory does not exist, the script will attempt to create it.

---

**Getting a Copy Protection Key**

Before starting Medley, you must first obtain a host access key from Venue. This key enables the use of Medley on one workstation. The software cannot run without the key. You must have one key for each host on which you wish to run. Note that your current host access key will work if you move from one version of SunOS to another, or if you upgrade from an earlier version of Medley to Medley 2.0.

To obtain a key:

1. Get the host ID of the machine on which you intend to run Medley by typing on that machine

   ```
   prompt% hostid
   310002f6
   ```

2. Call Venue at 800-228-5325 between 9:00 a.m. and 4:30 p.m. PST. Outside the United States, call your local distributor.

3. Ask for a host access key, giving the Venue representative your host ID. Venue provides you with a host access key, which you need during software configuration, below.

4. If you plan to use the Medley startup script, you will be prompted for the key the first time you invoke it. The script will automatically save the key into a file for future reference.

---

**CAUTION**

Depending on your license agreement with Venue, your host access key may have an expiration date. After that date, your key is no longer valid.

---

**Changing Configurations or Adding Options**

If you forgot to install something or need to add a new emulator, you can rerun the installation, and select only the new things you need. The installation script does not remove things.

This need arises most often when you start running X Windows and need the new emulator.

First, decide what you need to install. Then type `install-medley`. When you get to the Installation Options Menu, select all the new things you need and deselect everything else. Continuing the installation from there just adds the new items.
If you have Sun-3s and you just got a SPARCstation, all you need from the new installation are the proper emulators. Everything else is the same.

3. GETTING STARTED

Getting Ready

To prepare your system to run Medley, use the following checklist:

1. Exit suntools or any other windowing system, unless you plan to run under X (in which case you can leave X running). Medley provides its own window system and must not run simultaneously with others.

2. Kill all your user processes (these have console as the control tty). Check to make sure you have killed any "selection_svc" process. If you do not perform this step, certain error messages from UNIX (e.g., file system full) cause those processes to print to the console, resulting in scrolling of the display.

3. Check for the directory for the software, and add it to your path, if necessary:

   ```
   prompt# set path = ($path /usr/share/lde/install.sunos)
   ``

   You can also add this to your .login file.

Running Medley

Running Medley Directly

Invoke Medley by typing the name of the program, e.g.,

   ```
   prompt% lde optional-sysout -k 'thishost-key' [-m memory-size]
   ``

If you are using either Xerox XNS or Xerox PUP Ethernet protocols, type instead

   ```
   prompt% ldeether optional-sysout -k 'thishost-key' [-m memory-size]
   ```

This, in turn, runs lde and lets it use the Ethernet directly.

optional-sysout is the name of a Lisp virtual memory image file (see the section Where Medley Looks for Your Sysout below). thishost-key is the key you obtained from Venue for the machine on which you are running.

If the sysout was created on a machine with a different size display, the image will appear garbled for several seconds. After Lisp starts running, it readjusts the display to the current size.

The -m flag lets you control the maximum amount of memory Medley will use. memory-size is a number in the range 8 through 32, in megabytes. (See the detailed explanation on page 25.)

Using the Medley Shell Script

The script will try to find a key, an appropriate emulator, and a sysout. The script relies on information about where the Medley software was initially installed on your system. (The installation script install-medley automatically updates this information for you.) The medley script assumes that you have not changed the installation subdirectory structure from when it was originally installed.
The script will first try to find a key in the file Installation directory/.medleyKey.hostname or in ~/.medleyKey.hostname. Installation directory is where Medley was originally installed on your system. hostname is the name of the host for which the license key was issued. If neither file is found, you will be prompted for a key.

```
medley [[emulator] sysout] [Command]
```

**emulator**

Given a pathname or a simple name, the command will search for emulator as follows:

- If `emulator` is a relative or absolute pathname, e.g., /share/medley/emulators/lde, it will only try that pathname.

- If `emulator` is a plain file name, e.g., lde, the script uses the regular UNIX search path to find it. If it cannot find it, the script looks in the installation directory for Medley at your site, e.g., /usr/share/lde/install.sunos4.1/lde.

- If you omit `emulator`, the script uses lde as the default value, searching for it in the same fashion as above.

**sysout**

The command will search for sysout as follows:

- If `sysout` is a relative or absolute pathname, e.g., ../applications/my.sysout, it will only try that path name.

- If `emulator` is a plain file name, e.g., my.sysout, it will look for it in the following order:
  1. Current working directory my.sysout
  2. Installation directory for Medley at your site, e.g., /usr/share/lde/lispsysouts/my.sysout.
  3. Your home directory, ~my.sysout
  4. The medley subdirectory in your home directory, ~/medley/my.sysout.

- If you omit `sysout`, the script looks for it as explained in the Where Medley Looks for Your Sysout section below.

**Examples**

```
prompt% medley
```

To start Medley 2.0, a host access key is required. Call Venue at (1-800-228-5325) for one, and be prepared to give them your workstations host ID# Your workstations host ID# is: 51006da3

Type in key or [^C] to abort: 8bf7723e 459aab34 73491feb

Saving key ‘8bf7723e 459aab34 73491feb’ into file ‘.medleyKey.hostname’...

Trying /usr/share/lde/.medleyKey.hostname ... Write protected!
3. GETTING STARTED

Trying home-directory/.medleyKey.hostname ... Done
Starting up Medley 2.0 ...
.................... Medley 2.0 starts ....................

If you had Medley installed in `/share/medley` on your system, it would try to run
the emulator `/share/medley/install.sunos4.1/lde`, using the `sysout`
`/share/medley/lispsysouts/LISP.SYSOUT`.

In this example you are prompted for a key, which is saved into the file: `home-
directory/.medleyKey.hostname`

The script tried to save the key into the installation directory but did not have write
access there. Instead it was put into your home directory (`~`). `hostname` is the name
of the host running medley.

The next time you use the script `medley`, you will not be prompted for the key.

• `prompt% medley application.sysout`

If you had `application.sysout` in your home directory, it would try running the
emulator `/share/medley/install.sunos4.1/lde` using
`~/application.sysout`.

Where Medley Looks for Your Sysout

If you run Medley directly, the system searches the following places, in order, for the
sysout to be used:

• command line

The name of the sysout file can be given on the command line when starting Medley;
for example,

`prompt% lde sysout -k 'thishost-key'

• LDRESRCESYSOUT

If no sysout file name is given on the command line, the value of the environment
variable `LDRESRCESYSOUT` is used as the name of the sysout file. For example:

`prompt% setenv LDRESRCESYSOUT my.sysout
prompt% lde -k 'thishost-key'

would run the host key my.sysout.

• ~/lisp.virtualmem

Finally, Medley looks for the file `lisp.virtualmem` on your home directory.

Where Medley Looks for Your Site Initialization File

When Medley starts, it reads in a Lisp site initialization file. This site initialization file
sets things like pathnames for fonts, site parameters, and the like.

Greeting and initialization are described in the Interlisp-D Reference Manual, Section
12.1.

Medley looks for a site initialization file in a number of locations:
3. GETTING STARTED

- **LDEINIT**
  
  If the environment variable `LDEINIT` is set to a complete Lisp file name, Lisp looks there first for the site initialization file:

  ```
  prompt% setenv LDEINIT /usr/lisp/my-site-init.lisp
  ```

- **/usr/share/lde/site-init.lisp**
  
  If `LDEINIT` is not set or there is no file with the name given, Lisp looks for a site initialization file called `/usr/share/lde/site-init.lisp`. The distribution tape contains a sample site initialization file in the Lisp library directory `/usr/share/lde/lisplibrary/site-init`. The system administrator should copy `site-init` into `/usr/share/lde/site-init.lisp` then customize it for the site. The comments in the sample `site-init.lisp` describe the parameters it sets and give guidelines for customizing it to your local conditions.

- `{DSK}INIT.DFASL, {DSK}INIT.LCOM, {DSK}INIT.LISP`
  
  Finally, Lisp looks for a site initialization file on your Medley home directory (`{DSK}`). Chapter 5, Medley File Systems, describes the `{DSK}` device.

---

**Medley and X Windows**

Medley 2.0-S supports the X Window System, Version 11 Release 4 (X11R4). Medley runs in a single X window; Medley's "screen" is displayed in that window, and you use Medley as usual.

**Starting X Windows**

Start the X server on your console. Use the `xinit` command.

If necessary, start a window manager as a client of X (`xinit` often starts a window manager). The window manager provides many window management functions, such as moving, resizing and iconifying the window. Medley has no window management function of its own.

**Running Medley Remotely**

You can run Medley on one machine, with the window on some other machine. To do so, perform these steps on the machine whose keyboard and display you will be using:

1. Add the host name to execute the Medley access control list:

   ```
   xhost + hostname
   ```

2. Open a new xterm and rlogin to the Sun Workstation on which Medley is to run. Set the environment variable `DISPLAY` to the host name of the server machine:

   ```
   setenv DISPLAY servername:0
   ```

3. Set the `LDEKBDTYPE` environment variable to tell Medley what kind of keyboard you will be using. Possible values are:

   ```
   type3   Sun Type 3 keyboard
   type4   Sun Type 4 keyboard
   rs6000  IBM RS/6000 or PS/2
   dec3100 DECstation 3100 or 5000
   ```
3. GETTING STARTED

If you don’t set $LDEKBDTYPE$, it will default to $X$. The advantage of specifying a specific keyboard lies in how Medley treats the special function keys. The specific keyboard maps maximize the usefulness of keys marked, e.g., "Find". The generic keyboard code cannot do that reliably.

4. Start up Medley.

A new window for Medley will appear on the X server’s screen.

The Medley Window

Normally, Medley uses the whose screen. Under X, Medley’s "screen" appears in a single X window. Medley’s screen is slightly smaller than the screen you are using to display it; if you make the X window full-screen-size, you see Medley’s entire screen. If it is smaller, you will need to scroll to see parts of the screen.

The scroll bars (at the right and bottom of the X window) control what parts of Medley’s screen appears in the window. Use the vertical scrollbar to scroll up and down, and the horizontal scrollbar to scroll left and right. The gravity buttons (at the lower right corner) set the bitgravity of the display window. Click the mouse button on one of these areas. The shade pattern is moved to the clicked area, and the bitgravity is set in the corresponding corner on the display window. The bitgravity determines how reshaping the X window affects what part of the Medley screen is visible.

Environment Variables

Medley on the Sun uses several environment variables. They can be set from the shell with the `setenv` UNIX command. By convention, environment variable names use uppercase rather than lowercase letters, e.g., $LDEDESTSYSOUT$. The Medley environment variables are listed below, with a reference to sections in this Guide where further information can be found.

- $LDEKBDTYPE$: See the Medley and X Windows or Sun Type 4 Keyboard sections in this chapter.
- $LDEINIT$: See the Site Initialization File section in Chapter 4.
- $LDESRCESYSOUT$: See the Where Medley Looks for Your Sysout section in this chapter.
- $LDEDESTSYSOUT$: See the Saving Your State section in Chapter 4.
- $LDESHELL$: See the UNIXCHAT section of the Lisp Library Modules.
- $LDEFILETIMEOUT$: See the File System Errors subsection in Chapter 5.

Keyboard Interpretation

This section describes how Medley interprets the Sun Type 3 and Type 4 keyboards. Except when running under X, Medley performs its own keyboard interpretation, taking raw up/down transitions directly from the keyboard. Medley uses its own key
numbering scheme; key numbers are used by Lisp functions such as \texttt{IL:KEYDOWNP} and \texttt{IL:KEYACTION}.

These key assignments were chosen to maximize compatibility with both the Xerox workstation keyboard and the normal Sun keyboards. You can attach a Sun Type 3 or Type 4 keyboard template, which also shows the Medley keyboard assignments, to your Sun Type 3 or Type 4 keyboard. Both templates are included with your Medley documentation set.

**Sun Type 3 Keyboard**

Figure 3-1 shows the key number assignments for the Sun Type 3 keyboard. Figures 3-2 through 3-4 show Medley's key assignments for the Sun Type 3 keypads.

**Figure 3-1. Sun Type 3 Key Numbering**

```
   61  62  63
   90  91  92

   14  15
   111

   11
```

**Figure 3-2. Sun Type 3 Left Key Pad**

```
Stop  Again
Help  Undo
Same  Move

7  Home  8  9  PgUP
4  5  6
1  End  2  3  PgDN
Ins  DOIT  Caps  Lock
```
3. GETTING STARTED

Sun Type 4 Keyboard

Figure 3-5 illustrates the keyboard interpretation for the Sun Type 4 keyboard. Figures 3-6 through 3-8 show the keyboard and the left and right key pads for the Sun Type 4 keyboard.

NOTES: In SunOS 4.0, the NEXT (ALT/GRAPH) key on the Type 4 keyboard is inaccessible. Later versions of SunOS fix this.

Medley cannot detect whether it is running on a workstation with a Type 4 keyboard when running SunOS 4.0, 4.0.1, or 4.1. To make it work correctly on your workstation, enter the following before you start running Medley:

```
setenv LDEKBDTYPE type4
```

This Guide describes Medley release 2.0 for the Sun–3 and Sun–4 workstations and the SPARCstation: the release contents, instructions for installing the release, and information on using it.

Audience

The Medley For the Sun Workstation® User’s Guide is intended for users familiar with the Medley environment who want to use it on the Sun–3 or Sun–4 workstations or the SPARCstation. The Guide assumes that the user is already familiar with UNIX and SunOS concepts. The system administrator of a Sun system or network should read this Guide to ensure the correct installation of the Medley software.

Chapter 1 of this manual gives an overview of the product and its internal architecture, and is of interest to all users of the system.

System administrators should read Chapter 2, Software Installation; and Chapter 3, Getting Started. These chapters guide the administrator through the process of installing Medley 2.0 and configuring it on the Sun Workstation. Experienced Lisp users may want to configure the software; this procedure is described in Chapter 4.

Users already familiar with the Lisp environment on Xerox workstations should find Chapter 1 and Chapters 3 through 6 useful. These chapters describe the operation of the system after it has been installed as well as those functions and operations which are specific to the Sun Workstation.

Using This Manual

Chapter 1, Introduction, describes the hardware, input/output devices, and software needed to run Medley on a Sun Workstation; describes Medley and how it works with other applications; lists the system components; introduces pertinent SunOS and UNIX conventions used throughout the Guide; explains Medley's compatibility; and lists the contents of the release.

Chapter 2, Software Installation, contains the installation and software configuration procedures.

Chapter 3, Getting Started, explains how to set up a site initialization file and install the X Windows System. It also shows the keyboard configuration and has instructions for getting started in Lisp on the Sun Workstation.

Chapter 4, Using Medley on the Sun Workstation, describes how specific Lisp functionality works on the Sun.

Chapter 5, Medley File Systems, discusses the file conventions that need to be followed when running in Medley on a Sun Workstation. Differences in Lisp file attributes and variables are also discussed.

Chapter 6, Error Recovery, describes the diagnostic error recovery program URAID. This chapter explains how to recover from fatal error conditions and lists specific Lisp errors that may be encountered when running Medley on the Sun.

Appendix A, Installation Hints, contains additional notes to help configure Medley, and includes a complete description of the installation script.
Appendix B, Verifying the Installation Tape’s Validity, tells how to validate the contents of the tar tape.

Appendix C, Layout of Installation Tape Files, includes a listing of the tar tape directories and the font directories.

Appendix D, Differences between Xerox Workstations and the UNIX Version of Medley, includes functions for controlling device-specific behavior of the Xerox 1100 series workstation disk drives. It also describes the library modules not supported on the Sun.

The Glossary provides definitions of SunOS, UNIX, and Lisp terms used in this Guide.

Medley is a Venue product which was built on the Xerox Lisp environment. It provides an integrated programming environment consisting of Interlisp-D and Common Lisp, a windowing system, and a set of programs and utilities. Users not already familiar with the Xerox Lisp environment should try to become somewhat familiar with it before attempting serious development work.

Supporting Documentation

The following reference documents are useful to have on hand during the installation process and when working in Medley on the Sun Workstation.

Sun References

This literature from the Sun documentation set is useful during the installation and when running Medley on a Sun Workstation.

- Installing UNIX on the Sun Workstation
- UNIX Interface Reference Manual
- SunOS Reference Manual

Venue Documentation

In addition to this Guide, the following documents describe the Medley system:

- Xerox Common Lisp Implementation Notes, Lyric Release
- Lisp Documentation Tools, Lyric Release
- Lisp Library Modules, Medley Release
- Lisp Release Notes, Medley Release
Templates for the Type 3 and Type 4 Sun keyboards are also part of the Medley documentation set.

New users of Medley receive, in the software kit, all the manuals listed above.

Users who are moving the Medley environment from a Xerox workstation to a Sun Workstation receive the following documentation in the software kit:

- Lisp Release Notes, Medley Release
- Lisp Library Modules, Medley Release
- Medley for the Sun Workstation® User’s Guide
- Sun Type 3 and Type 4 keyboard templates

The manual Lisp Users’ Modules, Medley Release, which may be purchased separately, supplements the Medley release.
[This page intentionally left blank]
4. USING MEDLEY ON THE SUN WORKSTATION

Once the system administrator has installed Medley software on the Sun, Lisp users can customize their Medley Lisp environments. This chapter provides basic information to get you started in the Medley environment on a Sun Workstation.

Setting Up a Site Init File

The users at a given site generally print to the same printers, load library files from the same directory, and so on. Medley uses variables to supply defaults for such things. The obvious place to set these variables is in one common initialization file. That is the Site Init File's role.

The Site Init File is a file of Lisp expressions that is loaded when you start Medley with a fresh LISP.SYSOUT.

The following Lisp symbols should be set in your site init file:

**IL:USERSGREETFILES** [Variable]
A list of templates to search for the place where individuals should find their personal init files. If this is not set in the site init file, no personal init file is used. The list should be similar to the following:

```
((file-server) < USER > LISP> INIT.LCOM)
((file-server) < USER > LISP> INIT)
((file-server) < USER > INIT.LISP))
```

**IL:DISPLAYFONTDIRECTORIES** [Variable]
A list of directories to search when the system is looking for display fonts. The site initialization file should set it to a list of strings, each containing a complete pathname for font files, e.g., "{UNIX}/usr/local/1de/fonts/display/presentation/".

**IL:INTERPRESSFONTDIRECTORIES** [Variable]
A list of directories to search when the system is looking for Interpress font widths.

**IL:DIRECTORIES** [Variable]
The list of paths to search for files that are not found in the current (Lisp) connected directory.

**IL:LISPUSERSDIRECTORIES** [Variable]
The list of paths to search for library and LispUsers' files. Remember that every path in this list should also be in DIRECTORIES.

**IL:DEFAULTPRINTINGHOST** [Variable]
A list of names of default printers.

**IL:DEFAULTPRINTERTYPE** [Variable]
The default printer type, e.g., POSTSCRIPT.
4. USING MEDLEY ON THE SUN WORKSTATION

XCL:*LONG-SITE-NAME*  [Variable]

The value of the function XCL:*LONG-SITE-NAME*, e.g., "Frobnitz, Baz and Lispers, Incorporated."

XCL:*SHORT-SITE-NAME*  [Variable]

The value of the Common Lisp function XCL:*SHORT-SITE-NAME*, e.g., "Froboz".

IL:\BeginDST  [Variable]

The day of the year on or before which Daylight Savings Time takes effect (i.e., the Sunday on or immediately preceding this day). Must be set to 98 in the USA if Lisp is to perform time computations correctly (subject, of course, to future legislation). If you are in a region where Daylight Savings Time is not observed, set the value to 367.

IL:\EndDST  [Variable]

The day of the year on or before which Daylight Savings Time ends. Must be set to 305 in the USA.

Setting Up a Personal Init File

Your personal init file keeps track of the location of your home directory and windows layout; it also remembers which library files you always load.

Your personal init file is a file of Lisp expressions that is loaded and run after the site init file. You can create it either as a text file, or have Medley's File Manager help you.

Your initialization file is normally ~/INIT.LCOM

Saving Your State

On the Sun, ide is an ordinary UNIX program that allocates a 45 MB data area, reads into that area several megabytes of data (the sysout), and modifies it there. Under UNIX, that program's data requirements (which include the sysout) are handled by UNIX; all Medley does is modify in "memory" a copy of your original sysout file. UNIX, transparently to Medley, handles all real memory swapping. This has several consequences related to starting, saving, and restarting sysouts.

On Xerox workstations, the virtual memory partition is updated periodically and used to store new pages as they are allocated or flushed from the real memory of the machine. For example, LOGOUT and SAVEVM write out only those pages of data which are different from what might already be in the virtual memory file.

On the Sun Workstation, however, the contents of virtual memory are only written to a file by an explicit call to SAVEVM, LOGOUT, SYSOUT, or MAKESYS. This file is an ordinary SunOS file (normally ~/lisp.virtualmem). The entire virtual memory, which may be many megabytes of data, is written out there.

On the Sun Workstation, starting anew from a saved virtual memory file requires reading it into memory. On the Xerox workstation, it is necessary to first copy the saved sysout to the virtual memory file and then read it in. Thus, restarting a saved sysout or virtual memory file is significantly faster on a Sun Workstation.
The file that LOGOUT and SAVEVM writes is normally ~/lisp.virtualmem (i.e., the file lisp.virtualmem on the user’s home directory). However, the environment variable LDEDESTSYSOUT can be used to override this default. For example, you might want to keep virtual memory images on /user/local. During a demonstration where you do not want the memory image saved, you can reset LDEDESTSYSOUT to /dev/null. You can use the C-Shell command `setenv` to do this, e.g.:

```bash
prompt% setenv LDEDESTSYSOUT "/dev/null"
```

Cursor tracking interferes with writing out the screen bitmap as part of the Medley memory image. For this reason, Medley takes the cursor down before saving a virtual memory image as part of LOGOUT, SAVEVM, SYSOUT, or MAKESYS. When this happens, the message

```
Saving VMem, taking mouse down
```

appears in the prompt window, and cursor tracking is disabled.

Because the virtual memory file need not already exist to run Medley, the functions LOGOUT and SAVEVM can signal the following file errors:

- **File-System-Resources-Exceeded**
- **Protection-Violation**
- **File-Wont-Open**

Even if some errors occur while saving a virtual memory, the old destination file is safe. Saving does not overwrite the old virtual memory file. The saving virtual memory file is named with "-temp", such as lisp.virtualmem-temp. The file is renamed to a specified name, such as lisp.virtualmem, at the last sequence of the save.

When the user does not have enough space to save the virtual memory, the old virtual memory file can be overwritten by setting `IL:LDEDESTOVERWRITE` to T. The initial value of `IL:LDEDESTOVERWRITE` is NIL. In some cases, even if the user tries to overwrite, there may still not be enough space.

In Medley, a "page" is 512 bytes. Under SunOS, the page size is variable; some Sun Workstations use 8 Kbyte pages. In general, Medley functions deal only in units of Medley pages, e.g., the `SIZE` attribute of files is in terms of 512-byte pages, `(VMEMSIZE)` returns the number of 512-byte pages in use.

**Function**

```lisp
(IL:LOGOUT FAST)
```

Lets you exit Medley cleanly. The parameter `FAST` indicates whether resumption of the same environment is desirable and in what fashion. Before exiting, disk buffers are written, and network connections subject to timeout are closed.

If `FAST` is NIL, LOGOUT first saves your virtual memory in a file. Change the file name by setting the UNIX environment variable `LDEDESTSYSOUT`. If this variable is not set, the file saved is ~/lisp.virtualmem (i.e., lisp.virtualmem on the user’s home directory).

If `FAST` is T, Medley stops without writing the virtual memory file. It is not possible to resume execution in the same image.

**Function**

```lisp
(IL:SAVEVM )
```

Saves your state, but does not exit. It causes the current virtual memory image to be written to the location specified by the environment variable `LDEDESTSYSOUT`, if this variable is set; otherwise it is written to ~/lisp.virtualmem. This allows Lisp to
4. USING MEDLEY ON THE SUN WORKSTATION

continue. Execution in Medley continues after memory is saved; thus, \texttt{SAVEVM} operates as a sort of checkpoint of the current working state. \texttt{SAVEVM} can cause the following error:

\texttt{File-System-Resources-Exceeded.}

\texttt{(IL:SYSOUT FILE)} [Function]

Performs the equivalent of \texttt{SAVEVM} and then copies the saved image to \texttt{FILE} for devices other than \{DSK\} and \{UNIX\} (e.g., XNS file servers). (See Chapter 5, Medley File Systems, for further information on \{DSK\} and \{UNIX\}.) \texttt{SYSOUT} can cause the following error:

\texttt{File-System-Resources-Exceeded.}

**Sun-Specific Environment Functions**

**System Environment Functions and Variables**

These functions, which interrogate the system environment, operate as described below when they are invoked on the Sun Workstation:

\texttt{(IL:REALMEMORYSIZE)} [Function]

On some machines, returns the total amount of real memory available; does not work on a Sun Workstation (i.e., returns a meaningless value).

\texttt{(CL:MACHINE-TYPE)} [Function]

Returns a string identifying the type of computer hardware the system is running under. On the Sun–3 workstation \texttt{MACHINE-TYPE} returns "mc68020". On a Sun–4 workstation, \texttt{MACHINE-TYPE} returns the string "sparc".

\texttt{(IL:MACHINETYPE)} [Function]

Identifies the generic type of Lisp machine in use. On the Sun Workstation, it returns the symbol \texttt{IL:MAIKO}.

\texttt{(CL:MACHINE-VERSION)} [Function]

Returns a string identifying the version of the emulator running; e.g., "Microcode version: 279, memory size: 16384".

\texttt{(CL:MACHINE-INSTANCE)} [Function]

Returns a string containing the workstation host ID (in hexadecimal) and the host name.

\texttt{IL:LISP-RELEASE-VERSION} [Variable]

Identifies the release number within a single major release name. In Medley 2.0, \texttt{IL:LISP-RELEASE-VERSION} is 2.0 While \texttt{IL:MAKESYSNAME} does not change, \texttt{IL:LISP-RELEASE-VERSION} always changes with each new sysout release. This variable did not exist in the Medley 1.0-S sysout.
IL:MY.NSADDRESS  [Variable]

Fills in the fields of the network address with the host ID if Medley is run without the Ethernet enabled. Programs that use the network address as a unique identifier should be aware that the value could vary from session to session depending on whether or not the Ethernet is enabled. (Refer to Chapter 14 of the Interlisp-D Reference Manual for further information.)

VM Functions

The biggest difference is a change in terminology. On Xerox 1100 series workstations, Lisp itself handles all virtual memory operations directly, so the terms "sysout" and "virtual memory image" can be used interchangeably. The running sysout resides in a reserved area on the workstation local disk (the virtual memory partition) that Lisp reads from and writes to as it needs to move pages into and out of physical memory.

(IL:VMEMSIZE)  [Function]

Returns the number of 512-byte pages of the Medley virtual memory that are in use. This number is a good estimate of the size of a SYSOUT, MAKESYS, or SAVEVM virtual memory file.

(IL:VMEM.PURE.STATE ON/OFF)  [Variable]

Has no effect on the Sun Workstation. The virtual memory file is not modified except by an explicit (LOGOUT) or (SAVEVM).

IL:BACKGROUNDPAGEFREQ  [Variable]

Has no effect on the Sun Workstation. The virtual memory file is not modified except by an explicit (LOGOUT) or (SAVEVM).

You can control how much virtual memory Medley uses by using the -m switch, as described below.

ldeether [:SYSOUT-name:] [-m<memory-size>] [other options]  [Command]

Allows you to specify an arbitrary virtual memory size for Medley.

-m    Specifies the memory size

memory-size 8 through 32 Mbytes

When you use -m, the value of IL:STORAGEFULLSTATE in the sysout you start should not be 3 or 4. Those values mean it already used more than the 8-Mbyte space in the sysout. Because of the Medley storage management architecture, the virtual memory size cannot be changed after IL:STORAGEFULLSTATE has been set to 3 or 4. This value can be examined just before (IL:LOGOUT) if you want to specify the virtual memory size during the next start-up.

Example: ldeether /usr/LISP.SYSOUT -m 16

This example means 16 Mbytes of virtual space will be assigned for Lisp.

Stopping Lisp Temporarily
**IL:SUSPEND-LISP**

Suspends, temporarily, the UNIX process running Medley. Using the `fg` C-Shell command, the Medley process can be continued from the C-Shell where it was started. **SUSPEND-LISP** has no effect on Xerox Lisp workstations. This function should not be used during I/O operations (file or network).
Login Functions

This section describes the interaction between the usernames and passwords in Medley and the SunOS usernames and passwords. The functions IL:USERNAME, IL:SETUSERNAME, IL:SETPASSWORD, and IL:LOGIN access the username/password database used by Medley in network operations. (For further information, see Chapter 24 of the Interlisp-D Reference Manual.) When Medley is started, this database contains only the SunOS username, with no password. Except for this, there is no interrelation between these Medley functions and SunOS usernames and passwords.

IL:USERNAME returns the SunOS login name under which the emulator was started. A subsequent IL:SETUSERNAME or IL:LOGIN changes IL:USERNAME, and the default login name for network access to XNS and PUP hosts. However, it does not change the SunOS login name or access capabilities for files on {DSK} or {UNIX}. (See Chapter 5, Medley File Systems, for detailed information on {DSK} and {UNIX}.) Because it doesn't change the SunOS login name, it won't change the author name on SunOS files created from Lisp.

The following functions apply to login activities.

(IL:UNIX-USERNAME) [Function]

Returns a string consisting of the username of the SunOS process running Medley. Returns NIL if one of the following conditions apply:

- You are not running under UNIX
- You do not have a full name entered in /etc/passwd or the NIS password map
- An error occurs.

(IL:UNIX-FULLNAME) [Function]

Returns a string containing the full name of the owner of the SunOS process running Medley. Returns NIL if the user is not running under UNIX or an error occurs.

(IL:LOGIN HOST FLG DIRECTORY MSG) [Function]

Attempts to maintain user IDs and passwords for network as well as local access. If HOST is NIL, this function attempts to perform the SunOS setuid operation. Unless you are running as root, this will not change your SunOS login.

Environment Inquiry

The following functions return the values of UNIX environment variables or machine parameters. They return NIL if run in Medley on Xerox 1100 series workstations.

(IL:UNIX-GETENV STRING) [Function]

Returns the value of the environment variable with the given name. The argument STRING should be the name of a UNIX environment variable. For example, (UNIX-GETENV "HOME") might return the user's home directory.

(IL:UNIX-GETPARM STRING) [Function]

Returns the value of one of a few built-in parameters. The argument STRING should be the name of one of the following UNIX environment variables:
### Display and Keyboard Functions and Variables

Some Medley display and keyboard functions and variables operate differently on the Sun Workstation.

The following functions have no effect on a Sun Workstation, and always return NIL:

- \texttt{IL:CHANGEBACKGROUNDBORDER}
- \texttt{IL:VIDEORATE}
- \texttt{IL:SETMAINTPANEL}
- \texttt{IL:VIDEOCOLOR}

The functions \texttt{IL:BEEPON}, \texttt{IL:BEEPOFF}, \texttt{IL:PLAYTUNE}, \texttt{IL:RINGBELLS} generate monotones.

\begin{itemize}
  \item \texttt{(IL:BEEPON FREQ)} \hspace{1cm} \textbf{[Function]}
  \item \texttt{(IL:BEEPOFF)} \hspace{1cm} \textbf{[Function]}
  \item \texttt{(IL:PLAYTUNE TUNEPAIRS)} \hspace{1cm} \textbf{[Function]}
  \item \texttt{(IL:RINGBELLS)} \hspace{1cm} \textbf{[Function]}
\end{itemize}

Timers and Clocks

UNIX is a timesharing operating system. When Medley is running, other programs can be running at the same time on the same workstation.

4. USING MEDLEY ON THE SUN WORKSTATION

On a Xerox workstation running Lisp, CPU time could be computed exactly from elapsed time after subtracting known system overhead. To allow older Interlisp-D programs to work unchanged, the timer functions were modified to allow programs that accounted for time on Xerox workstations to continue to run. Time is categorized as follows:

CPU time: The total amount of time spent executing Medley's process in user mode.

SWAP time: The total time spent running other processes (Elapsed time – (CPU time + Disk time)).

Disk I/O time: The total amount of time spent in the system executing on the behalf of Medley's process.

The Medley functions CLOCK, TIME, and the like get the time of day directly from SunOS. The function SETTIME has no effect on the Sun Workstation.

IL:\RCLKMILLISECOND [Variable]

The number of clock "ticks" in a millisecond. On the Sun Workstation, this value is always 1000. All of the timer functions that deal in clock ticks will do their computation in microseconds. Note, however, that the Sun Workstation does not have that accurate a clock resolution. While clock resolution varies from one operating system version to another, it often has a resolution no better than 1/60th of a second.

Miscellaneous Operational Differences

The stack and virtual memory handling functions on the Sun Workstation are implemented differently from the way they are on the Xerox workstations. For this reason, the "cursor bars" used on the Xerox workstations are not used on the Sun Workstation.

When working in Medley on a Sun workstation, you should periodically load a fresh sysout. Older Medley sysouts don't run as well as "fresh" sysouts due to a number of factors such as fragmentation of memory, increased working set, more objects taking up various spaces (e.g., gc tables), reduced symbol space.

On Xerox workstations, users are reminded to reload fresh sysouts, because they eventually fill up their sysout partition. With Sun workstations, there is no such limit reminder, so users' sysouts tend to grow to the maximum size (32 MB), and thus run slower and slower.

Console Messages

Under SunOS, various system processes and operations attempt to log information on the console. Since Medley takes over the screen, console messages are redirected (except when running under X); a background process in Medley causes them to appear in the prompt window.

However, when Medley is run remotely (i.e., not from the console), most console, or operating system, messages are printed in the prompt window. However, some messages may also appear in the middle of the Medley display screen or on the remote tty. This occurs because UNIX is often confused about where to send messages. Note that Medley is normally run remotely only for debugging purposes.
CAUTION

Critical UNIX system processes can hang if the buffer holding console messages fills. Medley uses a temporary file, /tmp/XXXX-lisp.log, where XXXX is the user's login name, to buffer console messages before printing them. Do not delete this log file while Medley is running. If the log file is deleted, console messages can no longer be printed in the Medley prompt window.
5. MEDLEY FILE SYSTEMS

This chapter discusses the conventions for using files from Medley.

File Naming Conventions

In Lisp, a file name (pathname) consists of a collection of fields: the host, directory, name, extension and version. These fields are optional. The standard Lisp syntax for these fields is:

{host}<directory>name.extension;version

The directory field can be a directory path consisting of a sequence of directory and subdirectory components. Slashes (/) and right angle brackets (>) can be used to delimit a directory name; there is no distinction made between them. Square brackets ([]) are not acceptable as directory delimiters.

Duplicated directory delimiters are treated as a single delimiter. Thus, the following two file names specify the same file:

{DSK}<LISP>USERS>FOO.;1
{DSK}</LISP/USERS/>FOO.;1

Hosts that Medley Supports

{CORE} Creates "files" in memory; useful for quick temporary files
{LPT} Creates files that are automatically sent to your printer
{NULL} Creates a file that does nothing

{DSK} and {UNIX} Give you access to the Sun's file systems; the rest of the chapter concentrates on them.

The above hosts are described in more detail in the IRM.

Using SunOS Files from Medley

You can access any mounted SunOS file system directly from Lisp. The mounted file system is available as an I/O device of the Lisp environment. This file system appears as the local disk of Lisp, even though it may be a remotely mounted file system of networked Sun file servers.

Many of the file devices to which the Medley environment can talk, including PUP, XNS file servers, the {CORE} device, and others, have facilities that are not directly supported by SunOS. For example, many file systems have file version numbers and case insensitive file search conventions.

Medley on the Sun Workstation has two distinct "host" names that can be used to access the SunOS file system. These host names are provided for compatibility with existing applications and tools. They also simultaneously allow natural interaction with the SunOS file system. The names are:
On the Xerox workstation, {DSK} gave you access to your local hard disk; to use {DSK}, you had to create a directory on each disk partition you wanted to use. On the Sun Workstation, in contrast, the {DSK} device lets you access the file system using similar conventions to those used for {DSK} on the Xerox workstation local disk devices. In particular, {DSK} files have version numbers; {DSK} file name recognition also ignores the case of letters.

The {UNIX} device lets you use the mounted file systems with the normal naming conventions of the SunOS file system. {UNIX} files do not have version numbers, and the file name recognition treats lowercase letters as distinct from their uppercase equivalents.

File streams can be opened or closed on both devices. The reason for having both devices is to more easily support the running of applications that were originally developed on a Xerox workstation, while still allowing new applications to interact more naturally with UNIX.

NOTE: Both {DSK} and {UNIX} work as filters. They act as pointers to a device. On 11xxs, {DSK}foo is the same as {DSK}<lispfiles>foo. On the Sun, {DSK}foo is the same as $HOME/foo -user/foo.

Common {DSK} and {UNIX} Naming Conventions

- To include a special character (e.g., > or ;) in a file name, precede it with a single quote (‘). To include a single quote in a file name, precede it with another single quote. You can quote any of these characters: <, >, ;, ~, and a period (.). The following examples show how the single quote notation on {DSK} and {UNIX} is used.

<table>
<thead>
<tr>
<th>{DSK} Name From Lisp</th>
<th>File Name From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo’&gt;bar.baz;1</td>
<td>foo&gt;bar.baz</td>
</tr>
<tr>
<td>foo’;bar.baz;1</td>
<td>foo;bar.baz</td>
</tr>
<tr>
<td>foo’’bar.baz;1</td>
<td>foo’bar.baz</td>
</tr>
</tbody>
</table>

- {DSK} and {UNIX} do not allow you to use either the slash (/) or the NUL character in file names. Thus, you cannot name files containing these characters.

- Both {DSK} and {UNIX} can handle the following characters, which were defined as special characters in Medley Release 1.1: backslash (\) and tilde (~).

- {DSK} and {UNIX} can distinguish between a file name with a period at the end (e.g., foo.) and a simple file name (e.g., foo). The final period is preceded with a single quote, as shown in the following example:

<table>
<thead>
<tr>
<th>{DSK} Name From Lisp</th>
<th>File Name From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo.;1</td>
<td>foo</td>
</tr>
<tr>
<td>foo’..;1</td>
<td>foo</td>
</tr>
</tbody>
</table>

- On {DSK} and {UNIX}, the C-Shell and SunOS directory notations (~, ., and ..) are supported in the Lisp directory specification. The tilde character (~) is allowed at the very beginning of the directory specification of a pathname. A combination of relative path specifiers (~, ., ..) is supported. The tilde character corresponds to the
user's home directory at login. The period (.) corresponds to the current working
directory. Two periods (..) indicates the parent of the current working directory.

- File names are returned by the system (e.g., INFILEP) in more canonical form. The
  function which returns the full file name returns it in the canonical form, as in
  \{DSK\}<usr>etc> rather than \{DSK\}/usr/etc/. This change will make some tools
  which depend on the conventional file name representation described in the Interlisp-
  D Reference Manual work correctly on the Medley file system (e.g., COPYFILES).

\{DSK\} Naming Conventions

The \{DSK\} device performs the following file name transformation when actually
accessing the SunOS file system:

- Mixed case letters are read as such.
- File name searches are done case-sensitive first; if a match is not found, the system
does a case-insensitive search.
- The left angle bracket character (<) is translated to a slash (/), the delimiter for the
  root directory.
- \{DSK\} supports relative pathnames. You can specify relative pathnames by omitting
  a slash (/) or left angle bracket (<) as the first character in the directory field. For
  example:

    \{DSK\}foo.fee and \{DSK\}~/foo.fee are relative to the user's UNIX home
directory (~/foo.fee).

    \{DSK\}.~/foo.fee is relative to the user's current working directory
    (SunOS./foo. fee).

    \{DSK\}../foo.fee is relative to the parent directory of the user's current UNIX
    working directory (../foo. fee).

The Medley 2.0-S \{DSK\} device supports the notation in which the three meta
characters ('‘, ‘.., and ‘~) are used together, as shown in the following example:

    \{DSK\}~../tom/foo.c

In this example, the \{DSK\} device interprets tom as one of the subdirectories of the
parent directory of the user's home directory.

\{DSK\} also supports the tilde-name (~name) convention. \{DSK\} interprets
\{DSK\}-tom/foo.c as a file named foo on tom's home directory. In this notation, the
user name is case-sensitive (e.g., -tom and -Tom are treated as different users).

Version Numbering

The UNIX file system does not support version numbers in file names; \{DSK\} emulates
versions with a naming convention. (GNU Emacs also uses this convention.) This
section explains how \{DSK\} version numbers are represented in the SunOS file system.

- When you create a completely new file, it appears in the SunOS file system without a
  version number.
When you create (from Medley) a file with a version other than 1, Medley adds version numbers to that file name, as a trailing number between tildes, e.g., “myfile.~12~” for the twelfth version of myfile.

The following shows some examples of equivalent file names in Lisp and SunOS.

<table>
<thead>
<tr>
<th>{DSK} Name From Lisp</th>
<th>File Name From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar.baz;1</td>
<td>bar.baz.<del>1</del></td>
</tr>
<tr>
<td>bar.baz;2</td>
<td>bar.baz.<del>2</del></td>
</tr>
<tr>
<td>bar.;23</td>
<td>bar.<del>23</del></td>
</tr>
</tbody>
</table>

Medley always maintains a versionless file which is hard-linked to the highest extant version of the file (i.e., they are two names for the very same file). This file name does not appear in the {DSK} directory listing.

<table>
<thead>
<tr>
<th>From {DSK}</th>
<th>From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo.c;15</td>
<td>foo.c (hard linked with foo.c.<del>23</del>)</td>
</tr>
<tr>
<td>foo.c;23</td>
<td>foo.c.<del>15</del></td>
</tr>
</tbody>
</table>

Similarly, a file created in UNIX with no version number is treated by {DSK} as the highest version.

When you create a new version of a file, the versionless–file link is broken, and the versionless file is hard–linked to the new highest version.

<table>
<thead>
<tr>
<th>From {DSK}</th>
<th>From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo.c;15</td>
<td>foo.c (hard linked with foo.c.<del>24</del>)</td>
</tr>
<tr>
<td>foo.c;22</td>
<td>foo.c.<del>15</del></td>
</tr>
<tr>
<td>foo.c;24 (new file)</td>
<td>foo.c.<del>22</del> (no link with foo.c)</td>
</tr>
<tr>
<td></td>
<td>foo.c.<del>24</del> (new file, link from foo.c)</td>
</tr>
</tbody>
</table>

When you delete the highest version of a file, the versionless file is also deleted. If any older versions of the file remain, a new link is created from the versionless name to the highest version extant. For example, if you have the files

<table>
<thead>
<tr>
<th>From {DSK}</th>
<th>From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo.c;1</td>
<td>foo.c (linked to foo.c.<del>2</del>)</td>
</tr>
<tr>
<td>foo.c;2</td>
<td>foo.c.<del>1</del></td>
</tr>
<tr>
<td>fee.c;1</td>
<td>foo.c.<del>2</del></td>
</tr>
<tr>
<td>fee.c;2</td>
<td>foo.c.<del>2</del></td>
</tr>
</tbody>
</table>

and you delete foo.c;2 from {DSK}, the resulting files are:

<table>
<thead>
<tr>
<th>From {DSK}</th>
<th>From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo.c;1</td>
<td>foo.c (linked to foo.c.<del>1</del>)</td>
</tr>
<tr>
<td>foo.c;2</td>
<td>foo.c.<del>1</del></td>
</tr>
</tbody>
</table>

When you rename a file, it works the same as deleting the file under the old name then creating it under the new name. For example, if you have the following {DSK} files

<table>
<thead>
<tr>
<th>From {DSK}</th>
<th>From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo.c;1</td>
<td>foo.c (linked to foo.c.<del>2</del>)</td>
</tr>
<tr>
<td>foo.c;2</td>
<td>foo.c.<del>1</del></td>
</tr>
<tr>
<td>fee.c;1</td>
<td>foo.c.<del>2</del></td>
</tr>
<tr>
<td>fee.c;2</td>
<td>foo.c (linked to fee.c.<del>2</del>)</td>
</tr>
</tbody>
</table>
5. MEDLEY FILE SYSTEMS

fee.c.-1-
fee.c.-2-
and you rename "foo.c" to "fee.c", your renamed {DSK} files and the linked SunOS files would appear as:

<table>
<thead>
<tr>
<th></th>
<th>From {DSK}</th>
<th>From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo.c:1</td>
<td>foo.c (linked to foo.c.~1-)</td>
<td></td>
</tr>
<tr>
<td>fee.c:1</td>
<td>foo.c.~1-</td>
<td></td>
</tr>
<tr>
<td>fee.c:2</td>
<td>fee.c (linked to fee.c.~3-)</td>
<td></td>
</tr>
<tr>
<td>fee.c:3</td>
<td>fee.c.~1-</td>
<td></td>
</tr>
<tr>
<td></td>
<td>fee.c.~2-</td>
<td></td>
</tr>
<tr>
<td></td>
<td>fee.c.~3- (renamed file)</td>
<td></td>
</tr>
</tbody>
</table>

- When a file has a name suffix that is not a valid version number (e.g., myfile.~12x~), the suffix is regarded as part of the file name.

<table>
<thead>
<tr>
<th></th>
<th>From {DSK}</th>
<th>From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>myfile.<del>12x</del>:1</td>
<td>myfile.<del>12x</del>-1</td>
<td></td>
</tr>
</tbody>
</table>

Pathnames

A pathname on {DSK} is always case insensitive. When the user specifies a file, the {DSK} device handler first searches for the file with the specified name. If no such file is found, it then searches for a file with the same spelling but different case.

Most Lisp functions, such as FINDFILE and INFILEP, which return pathnames return them with the original case when they are applied on files on {DSK} when IL:*DSK-UPPER-CASE-FILE-NAMES* is NIL. If IL:*UPPER-CASE-FILE-NAMES* is not NIL, these functions return only uppercase pathnames. The only exception is the function DIRECTORY, which returns a list of pathnames. The case of the pathnames is controlled by the global variable IL:*UPPER-CASE-FILE-NAMES* in a similar manner to IL:*DSK-UPPER-CASE-FILE-NAMES*.

If a pathname on {DSK} has no directory specification, a tilde-slash combination (~/) is used, i.e., the Lisp directory specification {DSK}foo is the equivalent of {UNIX}~/foo.

{UNIX} Naming Conventions

For the {UNIX} device, file name translation takes place only on the directory. An initial left angle bracket (<) is treated as if it were an initial slash (/); both signify a path relative to the SunOS file system root directory; if there is no initial left angle bracket or slash, the directory is relative to the current working directory. Initially this is the working directory where Lisp was started; you can change it using the CHDIR function, described below. Tilde (~) is translated to the user’s home directory.

For example, {UNIX}myfile/abc means the file abc on the ./myfile directory.

The {UNIX} device does not recognize version numbers, does not return them, and ignores them for recognition.

No case translation or recognition is done; upper- and lowercase letters are treated as distinct.
### Examples:

<table>
<thead>
<tr>
<th>Name From Lisp</th>
<th>File Name From SunOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;foo&gt;fee&gt;bar.baz;1</td>
<td>/foo/fee/bar.baz;1</td>
</tr>
<tr>
<td>&lt;foo&gt;fee/bar.;1</td>
<td>/foo/fee/bar.;1</td>
</tr>
<tr>
<td>&lt;foo/fee&gt;</td>
<td>/foo/fee/</td>
</tr>
<tr>
<td>&lt;/foo/fee/&gt;</td>
<td>/foo/fee/</td>
</tr>
<tr>
<td>/foo/fee/bar.-1-</td>
<td>/foo/fee/bar.-1-</td>
</tr>
<tr>
<td>/foo/fee/</td>
<td>/foo/fee/</td>
</tr>
</tbody>
</table>

In the first two examples the ;1 is treated as part of the file name, not the version number. In the last two examples that translation is not done.

### Directories

In places where Lisp expects a directory name, `{UNIX}` paths must end with a slash (/).

### Directory Enumeration

You cannot use the wildcard character, asterisk (*), in subdirectories for either `{DSK}` or `{UNIX}` devices. For example:

> `(DIRECTORY '{DSK}/users/x*/foo)`

NIL

Enumeration of files in directories differs between `{DSK}` and `{UNIX}` devices. On the `{DSK}` device, a versionless file which has a link to the highest version file is not enumerated in a directory.

On the `{UNIX}` device, all files are enumerated in a directory. For instance, if the following SunOS files linked with foo.c.-2- exist:

- foo.c
- foo.c.-1-
- foo.c.-2-

the `{DSK}` directory enumeration would look like this:

> `(DIRECTORY '{DSK}/users/venue/*)``

{DSK}/users/venue/foo.c;1
{DSK}/users/venue/foo.c;2)

The `{UNIX}` directory enumeration, on the other hand, would look like this:

> `(DIRECTORY '{UNIX}/users/venue/*)`

{UNIX}/users/venue/foo.c
{UNIX}/users/venue/foo.c.-1-
{UNIX}/users/venue/foo.c.-2-)

### Directory Creation

When you write a new file on `{DSK}`, if the directory named in a pathname does not exist, the `{DSK}` device handler creates the directory automatically. This feature is provided for compatibility with other Interlisp-D implementations.
If you try to “connect” to a nonexistent directory (using the CONN Exec command or the function IL:CNDIR), Medley returns the message

Nonexistent directory

The {UNIX} device does not support such directory creation. An attempt to create a file on a nonexistent directory results in an error.

{UNIX}/users/venue/foo.c.

Directory Deletion

Neither {UNIX} nor {DSK} support automatic directory deletion. To delete a directory you must use the SunOS C-Shell command rmdir.

Open File Limit

The number of simultaneously open {DSK} and {UNIX} files must fall within the SunOS limits for a process. For OS 3.4, this number of open files may be configured, with 30 as the maximum permissible number of open files per process. This means that it is not possible to have more than 30 files open for a process, minus whatever files Medley has open for its own use, at any one time in the Medley system. If you try to open too many files, the system call error number 24, Too many open files, appears in the prompt window.

For OS 4.0, the maximum number of files/processes that can be open at one time is 64, unless your kernel is configured otherwise.

Default Pathname

If no path is given, the {DSK} device defaults to the user’s home directory, tilde-slash (~). The {UNIX} device defaults to the current working directory. This current working directory can be changed with the CHDIR function. The current working directory is also used to resolve the interpretation of the period (.) and double period (..) specifications at the beginning of a {DSK} pathname.

(IL:CHDIR PATHNAME) [Function]

Changes the current working directory for the current invocation of Lisp. For example,

(CHDIR "{DSK}:~/subdir/")

(OPENSTREAM "{DSK}:/foo" ...)

opens the SunOS file ~/subdir/foo.

When PATHNAME does not end with a slash (/) or right angle bracket (>), the whole PATHNAME is treated as a directory name:

(CHDIR '{DSK}<users>local>)

> '{DSK}<users>local>

(CHDIR '{UNIX} /usr/local)

> '{UNIX}<usr>local>

If PATHNAME is NIL, CHDIR tries to change the current working directory to the current connected directory. If the directory is connected to devices other than {DSK} or {UNIX}, the error message

Bad Host Name

appears, followed by the host name of the current connected directory.
If the PATHNAME does not exist, the error message
   No-Such-Directory
appears followed by the system echo of the pathname.

File Attributes

This section describes how the various file attributes are treated by Lisp on the Sun
Workstation and what they translate to in SunOS.

GETFILEINFO obtains file attributes and SETFILEINFO sets the attributes.

**WRITEDATE and CREATIONDATE**  
[File Attributes]

Resets the date to the current time whenever the contents of a file are modified. This
only works for the owner of the file. Since UNIX does not naturally support more than
one date for file modification, the WRITEDATE and CREATIONDATE are treated
identically by Lisp functions OPENSTREAM, OPENFILE, GETFILEINFO, and by the \{DSK\}
and \{UNIX\} devices.

**TYPE**  
[File Attribute]

Sets the TYPE property of files; normally either TEXT or BINARY. However, UNIX does
not distinguish between TEXT and BINARY files. Normally, programs will infer the type
by the file extension, using the Lisp variables DEFAULTFILETYPE and
DEFAULTFILETYPELIST. This is the convention used by Medley. If no file extension is
given, the value in DEFAULTFILETYPE is used. SETFILEINFO cannot change the TYPE
attribute.

**EOL**  
[File Attribute]

Returns the end–of–line convention. Both the \{DSK\} device and \{UNIX\} use line feed
(LF) as the default EOL convention for text. The EOL for binary files is carriage return
(CR). EOL uses the TYPE property of files. (The TYPE property of a file depends on the
file extension and the DEFAULTFILETYPE and DEFAULTFILETYPELIST variables). If the
TYPE property of a file is TEXT, LF (=10) is used as EOL. If the TYPE property of a file is
BINARY, CR (=13) is used as EOL.

NOTE: EOL conventions on \{DSK\} are not compatible with those on Xerox
workstations.

**AUTHOR**  
[File Attribute]

Returns the author of the file, i.e., the login name of the user who created it. This
attribute cannot be changed.

**PROTECTION**  
[File Attribute]

Returns file protection attributes. The file protection attributes of files under the
SunOS cannot be directly manipulated from inside Lisp. It is necessary to use the UNIX
chmod command to change file protection bits.
5. MEDLEY FILE SYSTEMS

**SIZE**

[File Attribute]

Returns the file size. For compatibility with other Lisp environments running on Xerox workstations, the SIZE attribute is computed as the length of the file (in bytes) divided by 512 (rounded up).

**NOTE:** SETFILEINFO lets you change the SIZE attribute of I/O streams and output streams. However, a file cannot be expanded this way.

**File Variables**

This section discusses how certain file variables are used by Medley in SunOS.

**IL:FileTypeConfirmFlg**

[Variable]

The file–type attribute of a file on {DSK} or {UNIX} is decided from its extension, DEFAULTFILETYPELIST and DEFAULTFILETYPE. Extensions of binary files should be registered in DEFAULTFILETYPELIST. When this rule is broken, a hardcopy of files on {DSK} and {UNIX} may confuse the printers. So when you try to hardcopy a file whose extension is not registered in DEFAULTFILETYPELIST, a menu is invoked to confirm the file type. Text or binary can be selected. The invocation of this menu can be stopped by setting IL:FileTypeConfirmFlg to NIL. The default value of IL:FileTypeConfirmFlg is T.

When extensions of binary files are not registered in DEFAULTFILETYPELIST, copy or rename from a DSK/UNIX device to a non–DSK/UNIX device also may cause file type confusion. This type of copy or rename results in one of the following warning messages in the prompt window, as appropriate:

- Extension of {DSK}foo.fee;1 isn’t in DEFAULTFILETYPELIST. {CORE}foo.fee;1 was copied as TEXT.
- This message can be stopped by set FileTypeConfirmFlg to NIL.
- Extension of {DSK}foo.fee;1 isn’t in DEFAULTFILETYPELIST. {CORE}foo.fee;1 was renamed as TEXT.
- This message can be stopped by set FileTypeConfirmFlg to NIL.

Either of these messages can be stopped by setting IL:FileTypeConfirmFlg to NIL.

**IL:DEFAULTFILETYPE**

[Variable]

Initially set to TEXT. Used with the file attribute TYPE.

**DEFAULTFILETYPELIST**

[Variable]

Used with the file attribute TYPE. Binary files, such as Sketch files, InterPress files, or Press files, should have their extensions registered in DEFAULTFILETYPELIST. This is especially important because UNIX does not support file types.
File System Errors

Several types of errors may occur in the Medley file system.

When a remotely mounted file system or NFS service is down, or when network traffic is heavy, any attempt to access a file on that file system results in an error. The following error message is printed in the prompt window:

File access timed out

Medley will wait until the file system responds or until a timeout occurs. If the file system is mounted with the "hard" option, the timeout is controlled by the value of environment variable LDEFILETIMEOUT. If the file system is mounted with the "soft" option, the timeout depends on the NFS file system timeout time, and the value of LDEFILETIMEOUT. Medley will wait until the shorter of these two times is exceeded. The NFS file system timeout time, retry times, etc., are controlled by the UNIX command mount.

If LDEFILETIMEOUT is not set, the default value of 10 seconds is used. The variable is inspected at boot time, and a setting between 1 and 100 seconds is appropriate in most cases.

The following error messages may appear when there are Medley file errors:

- Not owner
- Device error:
- Protection-violation
- File-won’t-open
- Too-Many-Files-Open
- File too large
- File-System-Resources-Exceeded
- Connection timed out
- No-Such-Directory
- Bad Host Name
- FS-RENAMEFILE-SOURCE-COULDNT-DELETE

Another type of error occurs when the user has insufficient access to files. When this happens, Medley will print the following message:

File not found

The following message then appears in the SunOS prompt window:

System call error: open errno=13 Permission denied

See the UNIX Interface Reference Manual, Intro (2), for descriptions of all OS system call messages.
5. MEDLEY FILE SYSTEMS

[This page intentionally left blank]
6. ERROR RECOVERY

Medley on the Sun Workstation has an error handling system which includes the following:

- The Xerox Lisp error system, described in the IRM
- A diagnostic program, URAID, which handles emulator errors

Occasionally, you may encounter SunOS error messages. Refer to your Sun documentation set for recovery procedures when these errors occur. When running Medley on a Sun Workstation, previous Lisp error handling such as Teleraid and MP errors are no longer available. However, you can still use Teleraid from a Sun Workstation to debug a Xerox 1100 series workstation.

URAID

The Medley system normally operates as a self-contained environment. In some unusual circumstances Medley may encounter a situation from which it cannot recover. In this case, when an unrecoverable emulator error is encountered, the emulator halts and enters into a small debugger called URAID. URAID allows you to inspect memory, or to look inside the sysout file, and attempt to recover from the error.

If you produce the same type of error condition in Medley on a Sun Workstation as you did on a Xerox workstation, you get a URAID error instead of an MP error.

Entering URAID

Normally, the emulator automatically enters URAID when an unrecoverable emulator error occurs. However, there are two additional methods available when you want to enter URAID directly.

- Use the SHIFT-CTRL-DELETE key combinations to enter URAID between opcodes. Note that the DELETE key referred to here is in the L10 position on the left keypad of the Sun keyboards. This sequence allows you to return to Lisp later.
- Use SHIFT-CTRL-NEXT for emergency interrupts only. Note that the NEXT key is in the ALTERNATE key position on the regular Sun keyboard. These combinations are useful for exiting from an opcode infinite loop. SHIFT-CTRL-NEXT does not necessarily enter URAID between opcodes; once you are in URAID mode, another URAID command such as "f" could cause the emulator to crash. At this point it is unlikely that you could return to Lisp. USE WITH CAUTION!

Conventions

URAID uses these display conventions:

- Numbers are displayed in hexadecimal unless otherwise noted.
- The litatom should be an uppercase string when used with a package prefix (e.g., XCL:EVAL).
- Symbols are displayed with a package prefix, but with no escape character.
• Symbols in the Interlisp (IL:) package are case-sensitive (e.g., IL:\InterfacePage); symbols in other packages are case-insensitive (e.g., XCL:EVAL).
In addition, these input conventions apply:

- Symbols may only be qualified by their home package.

- A full package name may prefix an input symbol. URAID also supports approved abbreviations of package names (e.g., XCL:, SI:, CL:, XCLC:).

  A symbol without a prefix is treated as a symbol in the Interlisp package. For instance, \InterfacePage is the equivalent of IL:\InterfacePage.

- Type-in is uppercase for symbols in any package except the Interlisp package; type-in is in mixed case for IL: package symbols or symbols with no prefix.

### URAID Commands

URAID has a few simple commands which you can use to attempt diagnosis and error recovery. All URAID commands are case-sensitive.

- **h** Hard Reset. Attempts to recover by resetting the Lisp stack. Quits URAID and causes Lisp to resume execution. This command should not be used unless you are sure that execution can be resumed.
- **e** Exits to SunOS. Medley will end.
- **q** Quits URAID and returns to Lisp.

**NOTE:** An error may occur while the Medley system is running uninterruptibly. The following message signals this error:

```
Error in uninterruptable system code -- ^N to continue into error handler
```

Disregard the ^N command; it is not supported by URAID. Use the q command to continue.

### Displaying a Stack

For casual users, the l command followed by several f commands generally provides the most useful information. Many of the other commands require some knowledge of the internal representation of Lisp objects and stack frames.

- **c** Checks all user stack contents; stack inconsistency is displayed.
- **k type** Changes the stack link that precedes the l command to be type, which is either a (to follow ALinks) or c (to follow CLinks). The default is to trace ALinks. ALinks follow the chain of free variable access.
- **l type** Shows the stack as a back trace consisting of a numbered sequence of frame names. The default is the user stack. The argument type is a single letter denoting the stack to view. The system has a number of special contexts, which are areas of stack space used by certain system routines. Legal values of type are as follows:
  - **g** (garbage collect)
  - **k** (keyboard handler)
  - **m** (miscellaneous)
  - **p** (page fault)
  - **r** (reset)
  - **u** (user stack) - Default
type := g | k | m | p | r | u or nil

C  Checks the contents by scanning all stack space in the sysout. For example:

0x11880 BF,[ivar:0x1800]
0x11802: FX for CL:T [
0x11816 BF,[ivar:0x1816
0x11818: FX for IL:\TURN.ON.PROCESSES[

Viewing Frames From a Stack

After displaying a particular stack with the l command, the following commands view individual frames from that stack:

f number  Displays the contents of frame number (decimal) with its basic frame, IVars and PVars. The frame is printed in two parts, a basic frame containing the function's arguments and a frame extension containing control information, the function's local (PROG) variables, and dynamic values. On the left side of the printout are the hexadecimal contents of each cell of the frame, with an interpretation, usually as a Lisp value, on the right. The following message appears as you display a frame with the f command:

Press Return (To quit ESC and RET)

To abort the printing of a frame, first press the ESC key then the RETURN key. The URAID prompt "<" reappears.

<CR>  Displays the next frame (closer to the root, or bottom, of the stack). This is the same as f n+1, where n is the number of the frame most recently viewed. Immediately after an l command, n is zero, so <CR> views the first frame.

a litatom  Displays the top-level value of the litatom

d litatom  Displays the contents of definition cell for the litatom. If it is compiled code, this command prints a CCODEP hexadecimal address pointer; for example,

{CCODEP}0x14ccc4

Otherwise, it prints a Lisp definition; for instance, interpreted code returns

( LAMBDA () ...)

M  Displays TOS, CSP, PVar, IVar, PC.

m func1 func2  Moves the definition of func1 to func2.

t Xaddress  Displays the type of this object.

p litatom  Displays the contents of the litatom's property list.

w  Displays the current function name and PC.

x Xaddress[Xnum]  Prints Xnum word (16-bits) of the raw contents of the virtual memory starting at virtual address Xaddress. This is most useful for examining the contents of a datatype which other commands simply print as its virtual address.
@litatom[sn|I|T] Sets the TOPVAL of litatom to the specified value. 
  sn|I|T is a signed smallp number.

<Xaddress val> Sets the the contents of the word (16-bits) at the Xaddress to val.

Miscellaneous

`v filename` Saves the current virtual memory on the filename. This file can be examined using the functions READSYS and VRAID in the TeleRaid Lisp Library module, but cannot be used as a sysout file.

NOTE: This sysout cannot be restarted.

`s` Invokes a subshell.

(num) Sets the print level (default is 2).

`?` Displays this summary.

`!` Prints the error message passed from the emulator.

Other Fatal Error Conditions

Occasionally, other emulator, operating system, or system administration errors may occur from which the URAID program cannot recover. Such error conditions include the process dying, the emulator going into an infinite loop, the keyboard being lost, or the system freezing up.

If any of these emulator errors occur, use the UNIX `kill` command to kill the lde process.

Lisp Errors

Errors While Running Medley

The following Lisp errors may occur when running Medley on the Sun Workstation.

<table>
<thead>
<tr>
<th>ERROR MESSAGE</th>
<th>CAUSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>File access timed out</td>
<td>Occurs when you try to access a file when the remotely mounted file system or NFS service is down, or when network traffic is heavy. See the File System Errors subsection of Chapter 5.</td>
</tr>
<tr>
<td>File too large</td>
<td>Self-explanatory.</td>
</tr>
<tr>
<td>Too-Many-Files-Open</td>
<td>Occurs when you exceed one of the following:</td>
</tr>
<tr>
<td></td>
<td>- SunOS open file limit (see Chapter 5, Medley File Systems)</td>
</tr>
<tr>
<td></td>
<td>- System file resources while writing a sysout (using IL:SYSOUT)</td>
</tr>
</tbody>
</table>
Nonexistent directory

Occurs when you try to connect to a nonexistent directory using the \texttt{IL:CNDIR} function or the \texttt{CONN} command.

No-Such-Directory

\texttt{CHDIR}

Connection timed out

Self-explanatory.

Bad Host Name

Self-explanatory.

FS-RENAMEFILE-SOURCE-COULDNT-DELETE

Occurs when you try to rename a file which exists on a directory or which you do not have delete permission.

\section*{Xerox Workstation-Specific Errors}

These Xerox workstation-specific errors may occur if certain functions are inadvertently used on the Sun Workstation.

\begin{center}
\begin{tabular}{ll}
\textbf{ERROR MESSAGE} & \textbf{CAUSE} \\
Floppy: No floppy drive on this machine. & Self-explanatory. \\
Device error: \{FLOPPY\} & Occurs when the user tries to enter a Lisp floppy function while running on the Sun Workstation. \\
Wrong machinetype & Occurs when functions controlling Xerox disk drive device-specific behavior are entered while running in SunOS. \\
\end{tabular}
\end{center}

\section*{Virtual Memory Errors}

\begin{center}

\textbf{ERROR MESSAGE} & \textbf{LISP FUNCTION RESPONSIBLE} \\
File-System-Resources-Exceeded & \texttt{IL:SYSOUT, IL:LOGOUT, IL:SAVEVM} \\
Protection-Violation & \texttt{IL:SYSOUT, IL:LOGOUT, IL:SAVEVM} \\
File-Wont-Open & \texttt{IL:SYSOUT, IL:LOGOUT, IL:SAVEVM} \\
\end{tabular}
\end{center}
6. ERROR RECOVERY

[This page intentionally left blank]
APPENDIX A. INSTALLATION HINTS

Medley Shell Variables

The following is a fragment of a .cshrc file which you may want to adapt to your own needs. In this example Smythe works in Building 12b (bldg12b), and always wants a fresh sysout, containing Rooms, loaded.

```
# ============================================
# Set up various Medley variables.
setenv LDEDESTSYSOUT /user/smythe/sysouts/saved.virtualmem
setenv LDESRCESYSOUT /usr/share/lde/lispsysouts/ROOMS.SYSOUT
setenv LDEINIT       /usr/share/lde/site-files/bldg12b-init.lcom

# Assuming you are using UNIXChat and VTChat, configure the Chat window
if ($?LDESHELL == 1) then
    setenv TERM vt100
    stty erase ^H
endif

# ============================================
```

Running on Multiple Workstations

Installation for Sites with Sun–3 and Sun–4 Workstations

In Medley 2.0, the only differences between the Sun–3 and Sun–4 distributions are in the install.sunosX directories. Thus, during installation the common subdirectories (lispsysouts, lisplibrary, fonts, etc.) might be installed instead to a shared file system, saving 15 MB of unnecessary duplicated space. In the example below, /sharedserver is a remote file system mounted on the local machine.

```
prompt% mkdir /sharedserver/lde
prompt% cd /sharedserver/lde
prompt% tar xvf /dev/rxv0 126 ./lispsysouts ./lisplibrary ./fonts

If soft links are then left on /usr/share/lde, the installation can proceed as before.

prompt% ln -s /sharedserver/lde/lispsysouts
/usr/share/lde/lispsysouts
prompt% ln -s /sharedserver/lde/lisplibrary
/usr/share/lde/lisplibrary
prompt% ln -s /sharedserver/lde/fonts /usr/share/lde/fonts

Otherwise, the site initialization file needs to be changed appropriately.
```
APPENDIX A. INSTALLATION HINTS

The install directories are left on `/usr/share/lde`, since those directories are typically local to a particular processor architecture.

```
prompt% cd /usr/share/lde
prompt% tar xvfb /dev/rrx0 126 ./install.sunos4
```

Using a "runlde" on Multiple Workstations

The following is an example of a runlde script that might be used for running Medley on different machines.

```
# (invokes CSH)
# ==============================================================
# Usage: runlde optional-sysout
#
# The script below is for the following machines:
#
#       Host    HostID
#   ----    -----
#  timber   1700319b
#    gopher  17003016
#      tree  13003565
# ==============================================================

switch ("hostid")
  case '1700319b':
    ldeether $1 -k '99e8bfc6 92299f45 9199a409'
    breaksw
  case '17003016':
    ldeether $1 -k '70c5a8d8 7b0498cc 45e35500'
    breaksw
  case '13003565':
    ldeether $1 -k 'ce7627bf b5b61ac8 2f990cc0'
    breaksw
  default:
    echo "Sorry, host '"$hostname'" is not in this shell script"
endsw
```

Configuring the Software

The software comes in these two forms:

- An executable binary image for users who have not modified the Sun kernel too extensively
- An object file that can be relinked for your particular system.
If you want to use the executable that Venue supplies, skip to the Enabling PUP/XNS Ethernet subsection below.

Relinking

If you have tried the prelinked software and it doesn’t work, link the object code with the Sun libraries. To do this, you need the suntool, sunwindow, and pixrect libraries, and make, cc, etc., available on your search path. To configure the system, connect (cd) to the directory /usr/share/lde/install.sunosx (where x is the version of SunOS that you are running, e.g., SunOS 4.0 in the following), and type make.

```
prompt% cd /usr/share/lde/install.sunos4
prompt% rm lde ldeether; make
```

This procedure replaces the two executable programs, lde and ldeether. The program ldeether enables access to Xerox network protocols from Lisp.

Enabling PUP/XNS Ethernet

If you intend to use the PUP or XNS Ethernet directly from Medley, you need to change file ownership and permissions of ldeether. Note that you do this on the server where ldeether is actually residing (root permission must be on the server). Log in to the machine where ldeether resides. To find out where ldeether resides, type:

```
prompt% df filename
```

where filename is the pathname of ldeether. The system responds with the name of a file system (e.g., /dev/sd0g) for a local file, or with a machine name and directory (e.g., python:/user1) for an NFS file.

Now you can change the ldeether file ownership and permissions.

```
prompt% rlogin server
server% su
server# cd /usr/share/lde/install.sunos4
server#/etc/chown root ldeether
server#/etc/chmod 4755 ldeether
server# exit
```

If you are using the Ethernet, substitute ldeether whenever lde appears in the instructions below.

Using NIS to Manage the Keys for Multiple Workstations

Here is an example how to handle several Medley licenses on a network, by using the Sun Network Information Service (NIS).

Create a file containing an association list of hostnames vs. license keys, for each host that has a Medley license. For example:
NOTE that the following commands should all be run as `root`.

On your NIS master server, create an NIS database of hostname vs. Medley keys:

```
prompt% /usr/etc/yp/makedbm ./medley-keys.by-hostname \
   /var/yp/your-domain/medley-keys
```

Replace `your-domain` with the name of your NIS domain. The output is put in the directory containing your master NIS maps.

If you have NIS slave servers serving your domain, you will need to update each one manually the first time the map is created. Thereafter, they will be updated automatically. On each NIS slave server do the following:

```
% /usr/etc/yp/ypxfr -f -h your-NIS-master medley-keys
```

Replace `your-NIS-master` with the name your NIS master server.

After updating all NIS slave servers, you now need to propagate the NIS map to your NIS clients. On your NIS master, type:

```
% /usr/etc/yp/yppush medley-keys
```

From now on, any changes made to the `medley-keys.by-hostname` file will only require the propagation of the map to your NIS clients. The following steps are required:

1. Create a new NIS map using the `makedbm` command as described above.
2. Propagate the changes to your NIS clients using the `yppush` command as described above.

You can now use the newly created map. Below is an example of a `runlde` script that uses the newly created NIS map.

```
#! /bin/csh -f
# ==============================================================
# Usage : runlde [sysout]
#
# Script for running Venue Medley software.
#
# ==============================================================
if ($#argv > 1) then
    echo "Usage : runlde [sysout]"
endif

set SYSOUT = "$1"
set HOSTNAME = `/bin/hostname`
set KEY = `/bin/ypmatch $HOSTNAME medley-keys`
```
if ! $status then
    ideether $SYSOUT -k "$KEY"
endif

Consult the Sun Network and Communications Administration manual for more details about NIS and how to add the new map to the /var/yp/Makefile.
APPENDIX B. VERIFYING THE INSTALLATION TAPE’S VALIDITY

If you encounter inexplicable problems shortly after you install Medley, they may be due to files being corrupted — the release tape may have been damaged, errors may have occurred while the tape was being read, etc. If you have unexplained problems, we recommend that you verify the checksums of your installed files.

The script generates checksum files named *.check and compares them to the released *.sum residing in the /checksumdir subdirectory.

The checksum script reports inconsistent files, the correct checksum values for the files, and an error message. The checksum of individual files can be generated with the UNIX command sum filename.

```
ldechecksum [-cg] medleydir [ dir | dirgroup ] [Command]
```

- `c` Generates checksums for your installed files and compares them with correct values. This is the default action.
- `g` Generates checksums for the files specified.

`medleydir` Name of the Medley installation directory. Default is `/usr/share/lde`.

`dir` Any specific directory residing under `medleydir`. Only relative pathnames with respect to `medleydir` are accepted.

`dirgroup` The directory group, either all (the default) or lisp, which includes the X/install.xxxx, X/lisplibrary and X/lispsysouts directories.

Output

As it begins checking each directory, the script prints a message in the form:
```
Checking directory: /usr/share/lde/subdir
```

Error and warning messages may be in one of two forms:
```
< E > 32711 49 4045XLPSTREAM.DFASL
```
indicates that file 4045XLPSTREAM.DFASL is erroneous or does not exist in the directory. The correct checksum of 32711, together with the size (49 Kbytes) of the file, are shown.
```
< W > /usr/share/lde/fonts/display/chinese : Directory not installed
```
indicates that Chinese fonts were not installed or were removed after Medley was installed.

Examples

```
prompt% ldechecksum /usr/share/lde
```
All files in the installed Medley directories in `/usr/share/lde` are checked.
prompt% ldechecksum /usr/share/somedir/lde lisp

This example checks all files in:

/usr/share/somedir/lde/install.xxxx
/usr/share/somedir/lde/lisplibrary
/usr/share/somedir/lde/lispsysouts

prompt% cd/usr/share/lde

prompt% ldechecksum -c . fonts/display

This example checks only the display font directories. The period (.) is used because you are positioned under the current Medley installation directory.
[This page intentionally left blank]
APPENDIX C. LAYOUT OF INSTALLATION TAPE FILES

Layout of Installation Tape

Below follows the layout of the Medley Installation Tape with a description of the individual files.

<table>

</tbody>
</table>
Manually Extracting Files from the Installation Tape

You can manually extract individual files or directories from the Medley installation tape. For example, if you want to extract the X-window emulator `ldex` for SunOS release 4.1 from the tape do the following:

```
prompt% mt -f /dev/nrst0 rewind
```

Ensures that the tape is positioned at the beginning of the tape.

```
prompt% mt -f /dev/nrst0 fsf 2
```

Positions the tape at the beginning of the third file on the tape. The `n` in the `/dev/nrst0` makes sure the tape is not rewound after the command has been completed.

```
prompt% tar xvf /dev/nrst0 ./install.sunos4.1/ldex
```

Extracts `ldex` from the Medley installation tape and puts it in your current working directory.
APPENDIX D. DIFFERENCES BETWEEN XEROX WORKSTATIONS AND THE UNIX VERSION OF MEDLEY

Local Disk and Floppy Functions

The functions for controlling device-specific behavior of the Xerox 1100 series workstation disk drives are not supported. These functions signal the error

Wrong machinetype

if called when running under UNIX. These functions include

IL:PURGEDSKDIRECTORY
IL:CREATEDSKDIRECTORY
IL:VOLUMESIZE
IL:DISKFREEPAGES
IL:DISKPARTITION
IL:SCAVENGEDSKDIRECTORY
IL:FILENAMEFROMID

The following functions for controlling the Xerox 1100 series workstation floppy disk drive also signal an error under UNIX:

IL:FLOPPY.FORMAT, IL:FLOPPY.NAME, IL:FLOPPY.TO.FILE,
IL:FLOPPY.PROM.FILE, IL:FLOPPY.ARCHIVE, IL:FLOPPY.UNARCHIVE,
IL:FLOPPY.MODE, IL:FLOPPY.FREE.PAGES, IL:FLOPPY.CAN.READP,
IL:FLOPPY.CAN.WRITEP, IL:FLOPPY.WAIT.FOR.FLOPPY,
IL:FLOPPY.SCAVENGE

These functions signal the error

Floppy: No floppy drive on this machine. Device error: {FLOPPY}

The following functions have no effect and always return NIL on UNIX:

IL:VOLUMES
IL:LISPDIRECTORYP
IL:DSKDISPLAY

Library Modules Not Supported on the Sun

The following modules listed in the manual Lisp Library Modules, Medley Release, are not supported on the Sun Workstation running Medley.

TCP, TCPCHAT, etc.

Because SunOS supports TCP/IP directly, TCP packets cannot be routed to Medley. For this reason, the TCP library modules are not supported on the Sun Workstation.
**DLRS232C, DTTY**

The DLRS232C and DTTY library modules are specific to the hardware devices available on the Xerox 1100 series workstations. Serial lines and other devices can be accessed from Medley either through sub-shells, or by using the `{UNIX}` file device, e.g., writing to `{UNIX}`/dev/ttya or `{UNIX}`/dev/ttyb.

The following library modules are normally used with equipment attached to the Xerox 1186 RS232 serial lines:

- FX-80DRIVER
- 4045XLPSTREAM
- KERMIT
- RS232CHAT.

**KEYBOARDEDITOR, VIRTUALKEYBOARD**

Medley does not include versions of KEYBOARDEDITOR or VIRTUALKEYBOARD library modules that know about the Sun keyboards.

VIRTUALKEYBOARD lets you bring up keyboard images that give you access to special characters via the mouse. The keyboard itself is unaffected.
MEMORANDUM

FROM: John Sybalsky
DATE: September 15, 1991
RE: Release 2.0 of Medley for the Sun Workstation

Enclosed is the software and documentation for Release 2.0 of Medley for the Sun Workstation. The package consists of the following:

- Tape containing the revised software.
- Release Notes, providing warnings and information important to the successful running of the software, followed by fixed bugs.
- Medley for the Sun Workstation User’s Guide, encompassing release contents, instructions for installing Release 2.0, and information on using it. This Guide has been completely reorganized, and information about using the new installation script has been added.
- Lisp Library Modules revised pages, reflecting additions to the prior issue (replace the old sections with the corresponding new pages).
access permissions* Determines what operations can be performed on a file.

alias* A user-created C-Shell command defined in terms of other commands or programs. For example, if you type (or put in your .cshrc file)

```
alias runlde "lde ~/sysout -k xx"
```

then when you type runlde to the C-Shell, it acts as if you had typed

```
lde ~/sysout -k xx
```

backing store A Xerox 1100 series workstation file, the virtual memory partition. This file stores pages as they are allocated or flushed from real memory.

byte code emulator A byte-code instruction interpreter. Executes the Interlisp-D virtual machine instruction set compatibly with microcode for the Xerox workstations.

ch放* A program used to change access permissions of a file.

chown* A program used to change ownership of a file.

{DSK} A host device name allowing users to access the SunOS file system. Uses conventions (e.g., version numbers and file name recognition which ignores the case of letters) similar to those used by the Xerox 1100 series workstation local disk device (\{DSK\}).

environment variable* A name/value pair that is passed to subprocesses. Can be set from the shell with the setenv command. By convention, environment variable names use uppercase rather than lowercase letters, e.g., LDEDESTSYSOUT. The Medley environment variables are LDESRCESYSOUT, LDEDESTSYSOUT, LDEINIT, LDE SHELL.

home directory* The working directory when a user logs in.

host access key A special code which must be entered to Medley to run Medley software on the Sun Workstation.

lde Lisp development environment.

ldeether A program produced during the software startup procedure; runs lde after enabling access to Xerox network protocol.

.login* The name of a file in the home directory that is read by the shell when a user first logs in. Contains C-Shell commands.

Medley The Venue programming environment; also, the name of the release. Supports Common Lisp and Interlisp; a library of utilities, graphics packages, applications; a complete windowing system; network protocols. Runs on both Xerox and Sun workstations.
**NFS**  
Network File System; the way SunOS handles remote file systems.
**pathnames***: In UNIX, a position identifier of a file or directory within the file system tree structure.

An absolute pathname gives the position, beginning with the root directory, of the file or directory in the file system hierarchy. Each directory in the pathname is delimited by a slash (/).

A relative pathname locates the position of the desired file or directory from the working directory. Again, all directories in this pathname are delimited by the slash (/).

**root directory***: The root of the directory tree. Designated by a slash (/) at the beginning of an absolute pathname. Slashes elsewhere in a pathname are simply delimiters.

**shell***: Command interpreter (akin to the Medley Exec).

**shell script***: A file that contains shell commands. Can be run by typing the file name provided the user has execute permission on the file.

**site initialization file**: A Lisp file, used when Medley is started up. Contains standardized information about the site environment such as pointers to fonts and site parameters.

**SunOS**: Sun’s version of UNIX.

**suntools**: A Sun system window–based program tool. A program that allows all of the Sun window–based tools to run on the screen.

**tar**: A program for copying data to and from magnetic tape.

**{UNIX}**: A host device name allowing users to access the SunOS file system using UNIX naming conventions. Files on the {UNIX} device have no version numbers and file name recognition distinguishes between upper- and lowercase letters.

* Indicates a UNIX term. See UNIX documentation for full definition.

== IMINDEX ==

The file IMINDEX contains the functions used for creating and editing index image objects, and inserting them into a Tedit document. When a Tedit document containing index objects is formatted for printing, the index objects do not appear, but information about the index objects is put into an auxiliary "IMPTR" file. The functions in IMTOOLS can be used to take a set of IMPTR files, and generate an index.

Adding an Index Object to a Tedit Document

The simplest way of adding an index object to a Tedit document is to type ctrl-O while typing at Tedit, which will cause a window to pop up asking you to type a form to eval:

Form to eval:

Typing (IM.INDEX.CREATEOBJ) will create an empty index object, indexing the term NIL, inserted in the Tedit document at the caret. Index objects appear in the Tedit window as words with boxes around them:

* Text Editor Window

The following is an index object: NIL

Using the IM Index Menu

An easier way to put many index objects into a Tedit document is to type (IM.INDEX.MENU) at the lisp exec, which will prompt you to position a menu that looks like this:

* IM Index menu

Index Selection as Term
>>Add Type<<
>>Close Menu<<

If the caret is blinking in a Tedit window, selecting [Index Selection as Term] with the left button will create and insert an index object that indexes the selected string. For example:

Before: FOO and BAR

Selecting [Index Selection as Term] with the MIDDLE button will insert an index object that indexes the selected string, and then create an index object editing window, that can be used to edit the values of the fields in an index image object.
Editing an Index Object in a Tedit Document

If you select an index object, a menu will appear asking whether you want to edit the contents of the index object:

![Index Object Menu]

If you select [Edit Index], you will be prompted to position an index object editing window, which looks like the following:

![Index Object Editor]

This is a freemenu that allows you to edit the values of the fields in an index image object. Selecting [Store Props] stores the values in the editor into the object itself -- if the "Name:" field is changed, the Tedit window will change to show the new index name. Selecting [Close Window] will close the editor window. Note that any changes are lost if you close an index object editing window without storing the new property values.

Index Object Properties

There are more properties in an index object than show in the window initially; the window can be scrolled or reshaped to see and edit the other properties. The fields are interpreted as follows:

Note: The properties listed with "()", such as "Type()":, interpret their value as a list of take a list of items, delimited by spaces. The other properties interpret their value as an atom, including spaces.

Name: Value is the name used to sort and merge index entries. This should normally be all-uppercase. The [Index Selection as Term] item in the IM Index menu will automatically uppercase the selection if it is not all-uppercase, and put the real value in the "Text:" field. Examples:
Name: FOO
Name: BAR

Type(): Value is the type of object being indexed. If NIL, this stands for an English term. Other types are used for indexing lisp functions, variables, etc. Note that upper/lower case is important. Examples:
Type(): Function
Type(): Editor Command

Note: The special types CHAPTER and SUBSEC (all-uppercase) are used to create entries in the table of contents, as
described below. These cannot be used as index entry types.

Text: Value is the name actually printed in the index. If NIL, the value of the "Name:" property is used. This is usually used when indexing non-uppercase items. Another place where this is useful is when you want an item containing strange characters to appear in a different place in the index. For example, if Name: = FOO and Text: = *FOO*, the item "*FOO*" will appear in the index among the "F" items instead of the "*" items.

Info(): Value is a list of "information" words, that mean something to the indexing programs. There are a few info words likely to be used by IMINDEX users. One is the word *PRIMARY*, which indicates that this is a primary reference. In the index, primary index page numbers are printed first, in a bold font. Another is the word *NOPAGE*, which indicates an index entry that should not be printed with a page number. This can be used to generate entries such as "FOO, see BAR". Example: Info(): *PRIMARY*

SubSec(): Probably not much use for IMINDEX users. Value is a reverse list of nested subsection and chapter numbers. For example, SubSec(): 4 2 99 indicates subsection 4 inside subsection 2 inside chapter 99. This is not used with normal index entries, except that chapter numbers, if given, are used when generating the page number in the index. For example, if the index entry specified chapter 99, and it was on page 5, it would appear in the index as 99.5. Another use for this field is if you use IM index objects to generate a table of contents, by creating index objects with type of CHAPTER or SUBSEC, as described below. In this case, the SubSec field is used to specify the subsection numbers.

Page#: The value of this field is replaced with the page number when the Tedit textstream containing the index image object is hardcopied. Not much use to change, but it is possible.

SubName:
SubType():
SubText: Name, Type, and Text values for a sub-entry, if any, which appears under the main entry in the index.

SubSubName:
SubSubType():
SubSubText: Name, Type, and Text values for a sub-sub-entry, if any.

Adding New Types to the IM Index Menu

If all of the index entries in a document are terms, it is very easy to use the IM Index menu to index them. However, if there are a lot of Functions, variables, etc., you may need to edit each index entry to change the type. To make this easier, you can use the [>>Add Type<<] button in the IM Index menu to add new selections to the IM Index menu. If [>>Add Type<<] is selected, the system will prompt you to type a type name, and add a new item to the menu. For example, if you started with the initial menu, and added a new entry for the type "Function", the menu would be changed to look like the following:
If [Index Selection as Term] is selected, an index object will be created indexing the the current Tedit selection, with the type of Function.

**Saving and Retrieving Tedit Documents with IM Index Objects**

Tedit documents containing IM Index objects can be saved using the ordinary Tedit "Put" command, which will store all of the indexing information in the index objects. Note, however, that it is necessary to load the IMINDEX package before editing any Tedit documents containing IM Index objects -- otherwise Tedit will print the message "WARNING: Document contains unknown image objects", and all index objects will appear as the following:

```
Unknown IMAGEOBJ type
GETFN: IM_INDEX.GETFN
```

If this happens, it will not be possible to use these index image objects, or re-save the Tedit document. Close the Tedit window, load IMINDEX.DCOM, and call Tedit to edit the document again.

**Hardcopying a Tedit Document Containing Index Objects**

A Tedit document containing index objects can be hardcopied using the normal [Hardcopy] menu button, or from the Filebrowser. Index image objects will not appear in the final hardcopy. However, while the document is being formatted, the index objects will put indexing information in an auxiliary file with the extension "IMPTR". The first time an index object is formatted, it will try to open an imptr file on the connected directory, printing a message in the prompt window: "Opening index pointer file: {DSK}<LISPFILES>FOO.IMPTR...done". When the formatting is completed, another message will appear: "Closing index pointer file: {DSK}<LISPFILES>FOO.IMPTR;1...done".

The directory used for the imptr file is the currently-connected directory (which can be changed using the CONN command). The file name used if the file name of the Tedit file, if there is one. For example, if the Tedit file is XYZ.TEDIT, the imptr file would be XYZ.IMPTR. If the Tedit text stream doesn’t have a name (for instance, if the Tedit window has been brought up but never saved) the file name NONAME.IMPTR is used. The extension is always IMPTR.

For Hackers Only: If there is a need to use a different filename for the imptr file, it is possible to specify this programmatically by changing textstream properties of the Tedit textstream before the hardcopy operation. If the value of the textstream property IM_INDEX.PTRFILENAME is non-NIL, it is used as the file name for the IMPTR file. If the value of the textstream property IM_INDEX.PTRFILE is non-NIL, it is the stream used for the IMPTR information.

**Creating Indices and Tables of Contents From IMPTR Files**

The file IMTOOLS.DCOM contain the routines used to create indecies and tables of contents for documents in IM format. These will also produce indecies and tables of contents from IMPTR files created by IM index objects. Loading this file will automatically load IMINDEX.DCOM, if it is not already loaded. Note,
however, that you can load IMINDEX (for the purpose of editing Tedit documents with IM index objects) without loading IMTOOLS.

IMTOOLS contains the following useful functions:

(MAKE.IM.INDEX OUTFILE.FLG VOLUME.INFO IMPTR.FILES IMPTR.TYPES) [Function]

MAKE.IM.INDEX takes a number of IMPTR files, and produces an index, formatted like the one in the IRM. If OUTFILE.FLG is NIL, the output file is just sent to the default printer. If OUTFILE.FLG is T, the outfile textstream is simply returned. If OUTFILE.FLG = anything else, it is taken as a file name of an interpress file which is created <but not printed>.

VOLUME.INFO is a list of lists specifying which chapters are associated with which volumes in a large multi-volume document (like the IRM). For an example of the format, see the variable IM.MANUAL.VOLUMES in IMTOOLS. If NIL, no volume numbers are printed in the index.

IMPTR.FILES is a list of IMPTR files to be used to create this index. If NIL, any index info loaded in by explicitly calling GRAB.IMPTR is used (see IMTEDIT.TEDIT). When doing the IRM, all of the IMPTR files are loaded into global variables using GRAB.IMPTR, but users of IMINDEX probably want to specify the values specifically.

IMPTR.TYPES should be a list of IM index types to be included in the index, specified as lists. For example, if IMPTR.TYPES = ((Function)(Variable)), only function and variable entries would be listed in the index. If IMPTR.TYPES = NIL, all index entries in the IMPTR files are used.

(MAKE.IM.TOC OUTFILE.FLG CHAPTER.NUMBERS IMPTR.FILES) [Function]

MAKE.IM.TOC takes a number of IMPTR files, and produces a table of contents, formatted like the one in the IRM. All im index entries whose type is CHAPTER or SUBSEC are used as chapter and subsection pointers.

OUTFILE.FLG and IMPTR.FILES are interpreted similar to MAKE.IM.INDEX.

CHAPTER.NUMBERS is either: NIL, meaning to generate TOC of ALL data in the specified imptr files; a single number, meaning to generate a chapter TOC for that chapter; or a list of numbers, meaning to generate a TOC for those chapters.
****** The IMNAME Database Package ******

IM format is the text formatting language that the Interlisp Reference Manual is represented in. It is somewhat like TEX source code, in that there are keywords, and brackets are used to delimit text. However, IM format was specifically designed for representing the Interlisp Manual, so the "text objects" used are semantically meaningful objects within the manual, such as "function definition", "lisp code", "subsection".

IMNAME is a package designed to help people who may frequently need to modify IM format files. Usually, a large document (such as the Interlisp Manual) is stored in a number of separate files, and it is difficult to know which file contains a particular piece of information. IMNAME contains functions for analyzing a set of IM format files and building a database of "IM Names" (functions, variables, property names, etc) with pointers to the files where they are defined. Using this database, other functions allow the user to specify an IM name, and bring up a Tedit window on the appropriate file, with the cursor positioned at the right place. This tool has been very helpful to the people updating the Interlisp Reference Manual.

****** Using IMNAME to access IM format files. *****

The normal way of using an IMNAME database is by creating an "IM name inspector". This can be done using either of the following two functions:

(MAKE.IM.INSPECTOR hashFileName)
or
(IMNAME hashFileName)

hashFileName should be the name of the IMNAME database hashfile to use for this inspector. One can create multiple IM name inspectors point to the same hashfile, or to different hashfiles. Currently, I know of only two IMNAME hashfiles; the one for the Interlisp Manual and one for the Loops Manual. If hashFileName is the atom INTERLISP or LOOPS, this Inspector will point to the appropriate hashfile. If hashFileName is ommitted, it will assume that the Interlisp Manual hashfile is desired for people whose default host is Phylum, and the Loops Manual for people on Ivy. (Other people can set up their own default IMNAME hashfile by setting the global variable IM.NAME.DEFAULT.HASHFILE).

MAKE.IM.INSPECTOR sets up an "IM Inspector Window", which contains a menu. Initially, this contains the single selection "Type an IM name", which (when buttoned) prompts the user to type a name which will be looked up in the database. If an IM name is found in the hashfile, another window will appear below the first one, containing all of the "types" that the given name is known by. For example, a name may be known as both a variable and a function. If one of these types is selected, a third menu will appear below the second, listing references to the name in different files. Selecting one of the references will move the cursor in a TEDIT window (if there exists an active TEDIT window to the appropriate file), or create a new TEDIT window to the file. [Note: If a name is only known to be of one type, the "type menu" step is ommitted.]

Other functions:

(INSPECT.IM imname hashFileName)
This allows the searching for a single IM name, using several pop-up menus. In general, it is easier to use the IM name inspector.

(GET.IM.NAME.LIST hashFileName)
Returns a list of all of the IM names known within the specified hashFileName.

***** Updating an IMNAME database. *****

IMNAME works by referencing a hashfile database containing IM names and pointers to files where these names are referenced. As a set of files is modified, this information will become obsolete. In particular, simply adding a few characters to a file will invalidate all pointers to positions later in the file. This can be tolerated for awhile (it is rare that IM format files will be changed enough such that the pointers are totally off), but eventually, it is necessary to update the IMNAME database, using the following function:

(IMNAME.UPDATE.HASHFILE oldHashFileName addFileList deleteFileList flushDisappearedFlg)

This function updates an IMNAME database hashfile. First, it looks at the list of files referenced in the hashfile, and determines which of these files have been updated, by comparing version numbers. Next, every updated file is reanalyzed with IMTRAN, and updated index information is stored into an in-core hasharray. Finally, the entries in the old hashfile are read in, merged with the new info, and written out to a new hashfile.

oldHashFileName is the name of the hashfile to be updated (Note that this file must be named explicitly --- no file searches are done so that the user will not inadvertantly start updating the main manual database). The new hashfile will be created as the new version of the same file name. addFileList is a list of files that will be analyzed, and added to the database. deleteFileList is a list of files that will be deleted from the database. addFileList and deleteFileList can be used to "manage" a database, as new files are added to a document, and old ones are removed, split up, or renamed. flushDisappearedFlg determines what IMNAME.UPDATE.HASHFILE will do if it finds that some of the files in the database have disappeared (and they are not named on deleteFileList). If flushDisappearedFlg = T, the info for those files will simply be deleted. If flushDisappearedFlg = ERROR, IMNAME.UPDATE.HASHFILE will return without doing anything if files have disappeared. If flushDisappearedFlg = <anything else>, the info on the disappeared files will simply be retained.

To create a new IMNAME hashfile, pass a non-existant file name as oldHashFileName, and give a list of files as addFileList. In this case, a new hashfile will be created just from the internal hasharray info.
***** The IMTEDIT IM-to-TEDIT translation program. *****

author: Michael Sannella
file: IMTEDIT.DCOM
loads file: IMTRAN.DCOM
related files: IMTOOLS.DCOM

IM format is the text formatting language that the Interlisp Reference Manual is represented in. It is somewhat like TEX source code, in that there are keywords, and brackets are used to delimit text. However, IM format was specifically designed for representing the Interlisp Manual, so the "text objects" used are semantically meaningful objects within the manual, such as "function definition", "lisp code", "subsection". IM format is described in detail below.

IM format files are easy to edit using Tedit, but they don’t look very pretty. To produce the manual, use the function IM.TEDIT, which translates IM format files to formatted Tedit text streams. These text streams can be proofread and edited by the user, or automatically printed.

A useful feature of IM.TEDIT is that is very forgiving about errors in IM format, even misplaced bracket errors! This is not to say that the output will be pretty, but at least the translation program will not bomb out on you.

***** Formatting a File with IM.TEDIT *****

To translate an IM format file into a formatted Tedit text stream, use the following function:

(IM.TEDIT INFILE.NAME OUTFILE.FLG) [Function]

This function takes an IM format file, and produces a formatted Tedit text stream. INFILE.NAME is the name of an IM format file. OUTFILE.FLG determines what happens to the translated textstream. If OUTFILE.FLG = T, the Tedit textstream is returned by IM.TEDIT. A Tedit window showing the translated document can be created by typing (TEDIT (IM.TEDIT xxx T)). If OUTFILE.FLG = NIL, the document is immediately sent to the printer. If OUTFILE.FLG = anything else, it is taken as a file name for the Interpress file which is created <but not printed>.

As IM.TEDIT runs, it prints out warning messages. These messages are also saved in the file <infile>.IMERR.

Important note: It is necessary to understand that IM.TEDIT produces a totally separate document from the IM format original. Any edits to this document will NOT be reflected in the original. In general, all of the editing should be done to the IM format files, to insure that there are no inconsistencies.

Note: If IM.TEDIT is called with OUTFILE.FLG = T to produce a textstream, and IM.INDEX.FILE.FLG (below) is set to T to add index information to the textstream, the textstream cannot be stored or printed. IM.INDEX.FILE.FLG should only be set to T if IM.TEDIT is called with OUTFILE.FLG not T, so it automatically prints the document to a printer or interpress file.

***** Variables Affecting IM.TEDIT *****
The operation of IM.TEDIT affected by a number of variables:

**IM.NOTE.FLG** [Variable]
If T, notes will be printed out, otherwise they will be suppressed. Initially NIL. (Note: If this is T, the translation programs will print out a message to remind you that notes will be printed.)

**IM.DRAFT.FLG** [Variable]
If T, the output will have "--DRAFT--" and the date printed on the top and bottom of every page. Initially NIL.

**IM.CHECK.DEFS** [Variable]
If T, checks whether variables and functions are bound/defined in the current Interlisp environment, and prints a warning if not. For functions, will also check arg list consistancy. Initially NIL.

**IM.EVEN.FLG** [Variable]
If T, IM.TEDIT will add an extra page at the end of the file saying "[This page intentionally left blank]". This can be used if you need a document with an even number of pages (for double-sided copying). Initially NIL.

The following FLGs are only of interest when generating an index:

**IM.INDEX.FILE.FLG** [Variable]
If T, index information will be added to the formatted Tedit text stream, and the file <infile>.IMPTR will be generated containing index information when the formatted Tedit texstream is printed. Initially NIL.

**IM.REF.FLG** [Variable]
If T, the translation program will try to resolve cross-references by looking at various hash tables. Initially NIL.

**IM.SEND.IMPLICIT** [Variable]
If T, send "implicit references" for functions and variables (if not in index hash array). Initially NIL. {fn...} or {var...} objects generate "implicit references" if they are not contained in the index hash tables. This can be used to find variables and functions that are not formally defined, but only mentioned.

***** Producing an Index and Table of Contents *****

The file IMTOOLS.DCOM contains functions for gathering index information, generating an index and a table of contents, and using index information to resolve cross-references.

Currently, these tools are rather primitive. Eventually, it is hoped that they will be improved to make this process easier.

To produce an index and TOC:

(1) Evaluate (SETQ IM.INDEX.FILE.FLG T), which tells IM.TEDIT to create index pointer files <XX>.IMPTR.
(2) Run (IM.TEDIT <file> <ipfile>) on all files in the document

(3) Evaluate (INIT.INDEX.VARS) to clear the index.

(4) For each of the files in the document, load the index information by evaluating (GRAB.IMPTR xxx.IMPTR).

(5) Generate an index by evaluating (MAKE.IM.INDEX OUTFILE.FLG), where the argument OUTFILE.FLG is interpreted the same as in IM.TEDIT.

(6) Generate a table of contents by evaluating (MAKE.IM.TOC OUTFILE.FLG), where the argument OUTFILE.FLG is interpreted the same as in IM.TEDIT.

To generate formatted files with cross-references resolved, do the following:

(1) Evaluate (SETQ IM.INDEX.FILE.FLG T), which tells IM.TEDIT to create index pointer files <XX>.IMPTR.

(2) Run (IM.TEDIT <file> '{NULL}FOO.IP) on all files in the document

(3) Evaluate (INIT.INDEX.VARS) to clear the index.

(4) For each of the files in the document, load the index information by evaluating (GRAB.IMPTR xxx.IMPTR).

(5) Evaluate (SETQ IM.REF.FLG T), which tells IM.TEDIT to resolve cross references using the loaded index information.

(6) Format all of the files using (IM.TEDIT <file> <ipfile>).

Note that creating a formatted file with cross-references requires formatting the file twice.

The process of formatting a large set of documents such as the IRM can automated using the following function:

**DO.MANUAL**

CHAPNAMES MAKE.INDEX.FLG GET.REFS NO.IP.FLG

[Function]

Formats the IRM manual chapters specified by CHAPNAMES, producing Interpress files, "imptr" files (explained below), and error files. Uses the global variable IM.MANUAL.DIRECTORY (initially {erinyes}<lispmanual>) to indicate where the IRM files are taken from, and where the processed files should go.

Note: **DO.MANUAL** initially puts all files on {DSK}, and then copies them to the value of IM.MANUAL.DIRECTORY. Therefore, you should have at least 3000-4000 free pages on DSK.

"IMPR" files are files with the extension "IMPR" (such as ChapLitatoms.IMPTR), which contain index info, including the page number where each index appears. These are generated whenever a chapter is formatted. These must be read in to generate an index, or format a chapter resolving cross-references.
CHAPNAMES indicates which chapters should be processed. If CHAPNAMES = a list of chapter file names such as (ChapLitatoms ChapStack), only these chapters are formatted. If CHAPNAMES=T, all chapters in the IRM are formatted. If CHAPNAMES=NIL, all chapters that have been modified since the corresponding Interpress files were made are formatted. The global variable IM.MANUAL.CHAPTERS specifies all of the chapters, and all of the sub-files in each chapter, and the chapter numbers.

If MAKE.INDEX.FLG is non-NIL, after processing the chapters, the index, title pages, and many tables of contents are generated. Note that if this is done, all of the IMPTR files for all of the chapters are loaded again.

If GET.REFS is non-NIL, all of the IMPTR files are loaded before any of the chapters are processed, and all cross-references in the chapters are resolved.

If NO.IP.FLG is non-NIL, the chapters are formatted to the interpress file {NULL}FOO.IP, and thus not kept. This can be used when you simply want to generate all of the IMPTR files, but do not want the interpress files.

Ideally, all you should need to do to re-format the IRM is:

(DO.MANUAL T NIL NIL T)  --- to generate the IMPTR files

(DO.MANUAL T T T)  -- to generate the Interpress files, and the index.

If DO.MANUAL doesn’t do exactly what you want, the code is fairly self-explainatory.

*****  Modifying the dimensions of the formatted pages *****

Note on modifying the formatting tools for different paper sizes: All of the lengths that IMTEDIT uses (left margin size, page height, etc.) are stored in global variables, set in the filecoms of IMTEDIT. IMTEDITCOMS also includes comments documenting the meaning of each of these global variables. Modify these variables until you get what you want.

*****  Known problems with IMTEDIT *****

Currently, IM.TEDIT produces a good-looking document. However, there are some features that I was not able to provide, because Tedit did not provide the formatting capability. These are as follows:

(1) Footnotes. Tedit does not supply footnotes. Currently, I "fake" footnotes by positioning them in-line after the paragraph wherein they were created. They also will not appear within definitions, tables, or lisp code.

(2) Tables. Tedit doesn’t do table formatting. Currently, IM.TEDIT simply prints out the items in the table without formatting.

*****  IM Format Description *****
This is a complete description of the syntax and vocabulary of "IM format". The general syntax is not likely to change, but the vocabulary will probably be extended as the Interlisp Manual is edited, and we discover new text objects that we need.

IM Format Syntax  
************************

An IM-format file consists of a linear string of visible, editable characters (and Tedit image objects, which are treated like characters). No funny control characters are allowed. "Text" is defined to be a linear string of characters, organized into paragraphs (delimited by blank lines), interspersed with any number of "Text Objects". Text Objects are used to specify the meaning of various pieces of text, which may be processed and formatted in different ways.

Text Objects can be divided into two types: those that take a single unnamed argument, and those that take a number of labeled arguments. All of the 'arguments' to Text Objects can be arbitrary text, organized in paragraphs, and including sub-text-objects nested to any level.

Text Objects within a file and arguments within a text object are specified using the characters "{" and ""}". These characters are ALWAYS interpreted as Text Object delimiters or Text Object argument delimiters---there are special text objects for indicating that you really want a left or right bracket character as part of your text.

The format of Text Objects is:

- single argument TO

\{'<TOname> <TOarg>'\}

- multi-argument TO

\{'<TOname> {<TOargname1> <TOarg1>} {<TOargname2> <TOarg2>} .... \'}

Between a TOname or TOargname and its TOarg, and between named TOargs, there can be any combination of spaces, tabs, and CRs. These can be used to make your file look better.

In order to help with the problem of matching brackets in large TOs (such as SubSecs, which can extend over many pages), I have introduced a new piece of syntax: Begin and End:

"{Begin <TOname> <tag>}" is treated exactly like "{<TOname>"
"{End <TOname> <tag>}" is treated exactly like "}"

except that additional checks are made when the file is processed that the "Begin"s and "End"s match up. The (optional) "<tag>"s can be used as an additional check, to distinguish between different TOs of the same type. If you use a Begin TO, you should use a matching End TO.

Note that Begin and End TOs can be used with TOs that have labeled args, for example:

\{Begin SubSec <tag>\}
\{Title ----\}
\{Text
 .
 .
\}
\{End SubSec <tag>\}
In order to allow the IM format translation program to recover from errors (like missing brackets), information has been included in the program about what TOs "should" appear in other TOs. In general, "complex" TOs such as LabeledLists can only appear in other complex TOs. "Simple" TOs such as Lisp can appear within anything. These rules are defined on a per-argument basis for TOs with multiple labeled arguments --- for example, a LabeledList can appear within the "Text" argument of a FnDef, but not within the "Name" argument. This feature should not cause any problems, as long as TOs are used "reasonably."

Other rules followed by the translation program: FnDef’s, VarDef’s, Def’s, etc can only appear at the "top-level", or inside a SubSec or Chapter. (this rule is very useful, because it helps trap many bracket errors before they propagate too far) Footnotes may not be nested.

New feature <which may get changed>: If a TO name is unrecognized, it will be printed out surrounded by brackets. For example, {FOO} will actually print as "{FOO}". This allows simple expressions to be bracketed without actually using the "{bracket ...}" TO.

Text Objects currently defined:
***********************

(note: the order of arguments in multi-argument TOs IS significant.)

(note: No distinction is made between upper and lower case in the TO names and the argument names, or in Begin/End tags)

(note: Many TO names and argument names have synonyms. These are indicated below.)

************************** Plain Text Text objects *****

<paragraph>
   All plain text is organized into paragraphs, delimited by blank lines.

   {Chapter {number <number>} {title <title>} {text <text>} }
   Specifies the number, title, and text of a chapter. If the number is not specified, the IM format translator will ask you to supply a number.

   {subsec {title <title>} {text <text>} }
   This can be used to generate sections, subsections, etc. to any depth. Heirarchical numbering is done automatically.

   {Comment <text>}
   Used to insert comments (which won’t appear in the final formatted output).

   {Note <text>}
   Inserts comments that may be printed in the final formatted output, depending on the value of the variable IM.NOTE.FLG. Should be used for comments such as {Note I should write something about X here}
Generates a footnote. Footnotes may not occur within other footnotes. Currently, Tedit does not support footnotes, so these are just printed after the paragraph in which they appear. Synonyms: footnote -> foot

Subscripts <text>.

Superscripts <text>.

Used to italize pieces of text. Synonyms: italics, emphasize -> it

Used to print text in the default, "roman" font.

The text object for normal single-line references to lisp code. This is used for writing things like: "Obviously, {lisp (CONS 'A 'B)} evaluates to {lisp (A . B)}.”

The text object for multiline lisp code, which do not appear in the middle of text, and have to be formatted differently. Spaces, tabs, and carriage returns are significant within <text>.

************************** TOs for Interlisp manual objects ******

This is used to define all lisp system functions. It needs to know the name of the function, and the args, and the text of the function description. (If the function has 0 args, the {Args --} argument may be omitted.) {Type ...} is an optional argument used to specify the argument type of the function. If the keywords NLambda or NoSpread (case doesn’t matter) are included in <keywords>, the function is specified to have the corresponding argument type. Synonyms: FnName -> Name FnArgs -> Args FnType -> Type

Used to define system variables.

Used to define system variables.
Used to define property names.

{MacDef {Name <name>} {Args <args>} {Type <keywords>} {Text <text>} }
Like FnDef, but for macros.

{arg <name>}
Used to talk about an abstract argument to a function, such as "x" or "y" or "number". It is used primarily within function definitions.

{fn <name>}
Used to talk about the name of a function. i.e.: "...it calls {fn CONS} to do something."

{var <name>}
Used to talk about a system variable.

{prop <name>}
Used to talk about a property name.

{Mac <name>}
Like Fn, but for macros.

{EditCom <name>}
Used to talk about an edit command.

{BreakCom <name>}
Used to talk about a break command.

{PACom <name>}
Used to talk about a programmer’s assistant command.

{FileCom <name>}
Used to talk about a file package command.

******************************************************************** Indexing Text objects *****

The following TOs (for indexing, defining, and referencing) all deal with objects with specific "object-types." The Interlisp Manual contains a very large number of names (CONS, NIL, FOO, etc). It is not enough just to list the name in the index --- it is also important to indicate WHAT the name is (a function, a variable, an error message, etc.) An "object-type" is essentially the description that would be printed in the index to describe a particular name. In IM format, such a description is given by a list of words, within parenthesis. [note upper/lower case are NOT distinguished in "object-types"] For example:
Some commonly-used object-types may be abbreviated with single words:

- FN -> (Function)
- Var -> (Variable)
- Prop -> (Property Name)
- BreakCom -> (Break Command)
- EditCom -> (Editor Command)
- PACom -> (Prog. Asst. Command)
- FileCom -> (File Package Command)
- Error -> (Error Message)
- Litatom ---> (Litatom)

[Note: In {PageRef ...} and {SectionRef ...}, the word TAG can be used to refer to tags, as specified below. The word FIGURE is a synonym for TAG; this can be used to refer to a figure tag. The word TERM can be used in {index ...} to index an English term.]

{index <text>}

Creates an index reference. Some of the text objects (such as function definitions) will automatically create an index reference, but it is useful to be able to create one explicitly. This should have the format:

{index  <keywords>   <object>  <object type>}

- <keywords> (optional) can be any combination of the words *BEGIN*, *END*, *PRIMARY*
- <object> can be any number of words.
- <object type> should be an object-type as specified above.
  If this is omitted (<text> does not end with ")" and the last word in <text> is not one of the special object-type words), then this is the index of a term.
  This can also be specified by using the word TERM.

Examples:

{index *PRIMAR Y* BLOBB Y (Transor Command)}
{index SELF-DESTRUCT SEQUENCE INITIATED Error)
{index *BEGIN* *PRIMAR Y* file names)

{indexX {name <name>} {type <type>} {info <info words>} {text <text>}
{subtype <type>} {text <text>}
{subsubname <name>} {subsubtype <type>} {subsubtext <text>}

Used for creating special index references whose printname is different from the "index name", or who have sub-index entries, or should not have page numbers in the index. <name> is the index name, used for referencing the object, and alphabetizing the index entry. <type> is the object type. <info words> (optional) can contain one or more of the keywords *BEGIN*, *END*, *PRIMAR Y*, <text> is the text printed in the index for this index entry.
Example: {indexX {name +} {type (Infix Operator)} {text {lisp {arg X}+{arg Y}}}} could be used to index "+" as an infix operator so that it would appear in the index alphabetized near other "+"s, but printing as "A+B". 

The arguments \{subname <name>\} \{subtype <type>\} \{subtext <text>\} \{subsubname <name>\} \{subsubtype <type>\} \{subsubtext <text>\} are all optional. These are used to specify 1st and 2nd level subentries in the index. The subentry can have their own type and text definition, although these are mostly terms.

If <info terms> includes *NOPAGE*, this indicates that the index entry should not have a page number associated with it. This can be used with subentries to create "See also..." notes. Within a list of subentries, the *NOPAGE* entries will always be listed last.

Example: The following set of indexx commands:

\{indexX \{name FOO\} \{type (Big Command)\} \{text {lisp /FOO/}\}\}
\{indexX \{name FOO\} \{type (Big Command)\} \{subname ZZZ\}\}
\{indexX \{name FOO\} \{type (Big Command)\} \{subname BAZ\}\}
\{indexX \{index *NOPAGE*\} \{name FOO\} \{type (Big Command)\} \{subname See also BAR\}\}
\{indexX \{name FOO\} \{type (Big Command)\} \{subname BAZ\} \{subsubname QWERTY\} \{subsubtype VAR\}\}

Would produce the index entries:

/FOO/ (Big Command) x.xx
BAZ x.xx
 QWERTY (Variable) x.xx
ZZZ x.xx
See also BAR

\{Def \{type <type>\} \{name <name>\} \{printname <pname>\} \{args <args>\} \{parens\} \{noparens\} \{text <text>\}\}

May be used to specify the definition of anything. <type> should be an object-type, as specified above. <name> should be the name of the object, ideally a single word. If \{printname <pname>\} (optional) is given, it will be used for printing the object in the top line of the definition and in the index. If \{printname <pname>\} is not given, the printed name is specified by \{name <name>\}, \{args <args>\}, \{parens\}, and \{noparens\}. \{args\} should be the "arguments" of this object. \{\{args <args>\}\} is optional.] Normally, \{Def will put parenthesis around the object if and only if \{Args <args>\} is given. \{parens\} and \{noparens\} (if given) can be used to change this default behavior. Examples:

\{Def \{Type (Blobby Command)\} \{Name DOBLOB\} \{Args A B\} \{Text ....\}\}
\{Def \{Type (CLISP Character)\} \{Name +\} \{PrintName \{lisp \{arg X\}+\{arg Y\}\}\} \{Text ....\}\}

\{Tag <tag>\}

This may be used to associate <tag>, a single word (upper/lower case doesn’t matter), with a particular place in the text. This can be referenced by \{SectionRef and \{PageRef as described below.

\{SectionRef <object-type> <object>\}
\{PageRef <object-type> <object>\}

These TOs are used to provide a cross-reference facility. \{SectionRef will print "section " and the section that the "main" occurrence of the object with the given type occurs. <"main"
shall remain undefined for now>  {PageRef prints "page " and the appropriate page number. If
<object-type> is "Tag", these TOs can refer to tags generated with {Tag <tag>}. Examples:
{SectionRef Fn CONS} could print "section 3.1.1"
{PageRef (File Package Type) Expressions} could print "page 14.34"
{PageRef Tag CompilingCLISP} could print "page 20.42"

Note:  {PageRef...} and {SectionRef...} can only be used to reference 1st level index references.
They cannot be used to reference subentries generated with {indexx...}

{Term <text>}  
Prints <text> exactly as given, and also puts it into the index. Equivalent to
"<text>{index <text> Term}".

{Figure {tag <tag>} {text <text>} {caption <text>} }  
Prints a simple "figure", with figure text and caption as specified by the "text" and
"caption" arguments.  "{tag <tag>}" is an optional argument which, if specified, generates a tag
at the beginning of the figure. This tag can be used to refer to the page or section that this figure
appears on (using {PageRef Figure <tag>} or {SectionRef Figure <tag>}), or to refer to the
figure number (using {FigureRef <tag>})

{FigureRef <tag>}  
Prints "figure" and the figure number of the figure with the specified tag.

**************************************** Complex Text objects *****

{numberedlist {item <text>} {item <text>} {item <text>} ...}  
Used for making numbered lists of items.
Synonyms:  Text  ->  Item

{unnumberedlist {item <text>} {item <text>} {item <text>} ...}  
Like {numberedlist ...}, except that it uses bullets to mark each item in the list.
Synonyms:  UnlabeledList  ->  Unnumberedlist
Text  ->  Item

{labeledlist {name <text>} {item <text>} {name <text>} {item <text>} ...}  
Used for making a table associating a set of labels with descriptions of their meanings.
The argument {LName <text>} can be used to add a label left-justified on the page.
Either an LName or a Name, or both, can appear as labels for an item. If an LName is supposed
to be on the same line as a Name, it should appear first: {Labeledlist {LName xx} {Name yy}
{item zz} ...}  
Synonyms:  Label  ->  Name
Text  ->  Item

{Table {Column} ... {Column} {First <text>} {Next <text>} {Next <text>} ... {First <text>} ... }  
Used for formatting multi-column tables. The number of {Column}’s before the first
{First or {Next indicates how many columns the table should have. If no {Column}’s are given,
the default is three columns. There are other formatting arguments, but they will probably change. <<<Note: This is not currently supported in Tedit. Currently, this TO only prints out the values of each {First} or {Next} argument, without formatting. Do not use tables>>>

**************************** Other Text objects ******

{Include <filename>}
Used to include the text of one file within another. Files may be nested arbitrarily deep.

{Lbracket}
{Rbracket}
{bracket <text>}
These are used to insert the curly-bracket symbol into the text. {Lbracket} and {Rbracket} insert left and right brackets, and {bracket <text>} puts brackets around the given piece of text.

The following TOs are used to specify certain non-typeable characters.
{CRsymbol} or {cr} - carriage return symbol (currently a superscripted 'CR')
{pi} - Greek letter pi
{plusminus} - Plus or Minus ("+" + "+")
{GE} - greater than or equal (">" + "+")
{LE} - less than or equal ("<" + "+")
{NE} - not equal ("=" + "+")
{endash} - short dash
{emdash} - long dash
{ellipsis} - ellipsis (...)
{bullet} - bullet
{anonarg} - long dash (should be used in the argument list of a function definition to specify the "unspecified arguments" specified in the current manual with a dash)
FORMATTING AN INDEX

Creating a properly formatted index takes a certain amount of work (about 2 hours).

- Type in your Executive (TEDIT (MAKE.IM.INDEX T NIL ‘(filenames) NIL))

- Save the resulting file in {ERIS}<Doc>LoopsBeta>Ref>RefIndex-Raw.tedit.

- Now start dithering. The task is the change all the separators in the file. For example, the index program returns pages in the form 1.2; 10.5,38; 18.3-4. The Index format we use is in the form 1-2; 10-5; 10-38; 18-3. Unfortunately, you can’t make all the necessary changes in a global substitute, since many of the separators are also in the text and the comma requires that you repeat the chapter number. Here goes:

  -- Fix the commas. Do a Find on a comma (,). Everyhwere a comma occurs in a page number, change it to a semicolon (;) and repeat the chapter number and a dot before the page number. For example, 10.5,38 becomes 10-5; 10-38.

  -- Fix the dashes. Do a Find on a dash (-). Everyhwere a dash occurs in a page number, delete it and the following page number.

  -- Fix the period. Except for he form #., you can use a global substitute from a period to a dash (. to -). This takes about 20-30 minutes, as there about 700 substitutions.

  I really recommend saving the file at this point.

- Hardcopy the index. Make whatever page breaks and other changes you feel are necessary. Make a final hardcopy and save the file.
ARCLEANUP Package --- Michael Sannella
(and augmented by Susana Wessling, 26-mar-87)

The file \{eris\]<lispcore>internal>library>ARCLEANUP.LCOM contains a few functions used to update the AR database and to print summaries.

(AR.CLEANUP UPDATE.FLG INDEX.LOCAL.DIR SUMMARY.FLG SUMMARY.LOCAL.DIR )

This is the main function, which should be run every few days, preferably just as you go out the door (so your machine can crunch on it overnight). If UPDATE.FLG is non-NIL, all of the ARs that have been touched since the last update are scanned, and the AR database is updated. If SUMMARY.FLG is non-NIL, a set of summaries is generated on \{eris\}<lispars>summaries and press-fied.

INDEX.LOCAL.DIR and SUMMARY.LOCAL.DIR are used if you want the AR index and/or the summary reports to be cached on a local disk. This speeds up the prosess considerably, along with reducing ethernet load. If non-NIL, each of these should be a host/directory pair, which will be PACKed on the front of a filename to generate the caching filename. These are not just flags, with caching defaulting to \{DSK\}, so that I can use multiple partitions for caching. The issue is space: Sometimes the local disk does not have enough room for two copies of the AR index, or for both the txt and press version of the grang summary.

Example:

AR.CLEANUP (T NIL T NIL)
-- does cleanup with no caching

AR.CLEANUP (T \{DSK\} T \{DSK2\})
--- caches index on \{DSK\}, and the summaries on \{DSK2\}

AR.CLEANUP (T \{DSK\})
--- just does index update, caching on \{DSK\}.

Another useful function:

AR.CLEANUP.REDO.SUMMARIES: just generates summaries, does not do a new cleanup.
The AREDIT Interlisp bug database system

author: Michael Sannella
files: {eris}<lispcore>library>AREDIT.DCOM
doc: {eris}<lispcore>library>AREDIT.TEDIT
uses: All Tedit files

The file AREDIT.DCOM contains a number of tools useful for examining, editing, and submitting ARs ("Action Requests") related to the Interlisp-D system. These tools are loosely based on the "Adobe" tools in the Tajo environment. The Interlisp-D support group uses this system to keep track of the state of outstanding bug reports. There are currently over 2000 ARs in the database.

These tools can be used from any machine running Interlisp-D which can establish a leaf connection to the Phylex: file server, where the database files are currently stored, and the ERIS file server.

After loading AREDIT.DCOM, the user can create two types of windows: AR edit forms and AR Query forms.

The AR Edit Form

An AR edit form is used to examine, edit, and submit ARs. To create an AR Edit Form, evaluate (AR.FORM). Interlisp will prompt you to specify a region for the form window -- the best size to give it is one about half the width of the screen and at least half the height of the screen. The form window which will appear contains three subwindows: (1) On the top is the message subwindow, where prompts and status messages are printed; (2) in the middle is the command subwindow, a menu of commands for editing / submitting ARs; (3) on the bottom is the form subwindow, where the information in an AR is displayed.

The command subwindow contains the following commands:

**New** -- Buttoning this word clears the fields of the AR in the form subwindow. Some fields (Source, Submitter, Status) are initialized to appropriate values for a new AR.

**Get** -- Buttoning this retrieves the AR whose number follows "Number:" in the command subwindow.

**Put** -- Buttoning this will either store an edited AR, or submit a new AR. Which one (submit new or store old) depends on whether the last operation was "New" or "Get". If the current AR displayed was retrieved with "Get", then "Put" will store it as the old AR. If this AR was built up from scratch after buttoning "New", then "Get" will submit it as a new AR. The title of the form subwindow gives an indication of what state the form is in: if it says "New Bug Report", then "Put" will submit it. If it says "Editing AR xxx", then "Put" will store it. [There are plans to improve this interface]

**Number:** -- This is a text field just like text fields in the form window (see below) used to specify the number used by "Get". Buttoning the word "Number:" will pending-delete-select the value of the field, so you can delete it and insert a new number. If the character carriage-return is typed, then a "Get" is automatically done on the value of this field. This is faster than typing a number, and buttoning "Get".

The form subwindow contains a large number of fields. The meaning of these fields is described in XXX. The value of these fields can be edited as follows:

"Enumerated fields" can only contain certain values. These are indicated in the form subwindow by field names followed by curly-braces "{}". To change the value of one of these fields, button the field name; a menu of permissible values will appear; select a value; it will be inserted between the braces.

[Note: Some of the enumerated field values are dependent on other fields. For example, the values of "Subsystem:" depend on the value of "System:" -- if the "System:" value is changed, the "Subsystem:" value is automatically set to NIL. The fields with this relationship are System/Subsystem: and Machine/Disk:]
"Text fields" can contain arbitrary text. These fields do not have braces after the field name. The text can be edited using normal Tedit editing. Buttoning the field name will pending-delete-select the entire field value, which allows the whole field to be easily deleted.

[note: Currently, stored ARs only contain straight text. Any tedit formatting information put into an AR will be lost when the AR is stored. Image objects (like bitmaps) are also not stored.]

[note: A few of the text fields, like "Number:“, are read only -- they cannot be edited by the user.]

[note: in older versions of AREEDIT, some text fields (such as "Attn:“) could only contain a certain number of characters. The user could type as many characters as he wanted, but an error would occur when the "Put" command was executed. This has now been changed --- any text field can contain an arbitrary number of characters.]

The AR Query Form

An AR Query Form is used to search the AR database for all ARs with particular characteristics. One can search for all ARs with a given name in the "Attn:“ field, all ARs which have Status: = Open, etc. These ARs can be sorted, and a summary of the selected ARs can be printed into a file.

To create an AR query form, evaluate (AR.QFORM.CREATE). Interlisp will prompt for a region (the default size is ok), and create a window with three subwindows: (1) on top, a message subwindow, for printing prompts and messages; (2) in the middle, a browser subwindow, used for displaying the ARs selected by a query; (3) on the bottom, the AR query command subwindow, containing a number of commands and fields.

The Ar Query command subwindow contains the following fields/commands:

**Query List:** -- This field is used to specify which ARs the "Query" command will search for. This field should be filled with an AR query spec, which has one of the following forms:

- `(<field> HAS <val>)` searches for all ARs whose text field `<field>` contains `<val>`. `<string>` may either be an Interlisp string or an atom. The search is case-independent: foo matches Foo matches FOO.

- `(<field> IS <val>)` searches for all ARs whose enumerated field `<field>` has the value `<val>`.

- `(AND <spec1> <spec2> ... <specN>)` returns all ARs satisfying ALL of the given specs.

- `(OR <spec1> <spec2> ... <specN>)` returns all ARs satisfying ANY of the given specs.

[Note: an implicit (AND) is wrapped around the value of the "Query List:" field, so just giving a number of specs will AND them together.]

Not every AR field can be searched for in the same way: some can only be searched with HAS, some can only be searched with IS, and some (like the Description: field) cannot be searched at all. To find out the possible query specs, button the words "Query List:" --- this will put up a menu of all of the permitted searching options. Some of these menu items have submenus. When one of the options is selected, it is added at the end of the value of this field.

Examples:

**Query List:** (Subject: HAS foo)
Searches for all ARs whose subject contains the string "foo".

**Query List:** (Status: IS Open) (Attn: HAS sannella)
Searches for all open ARs which have "sannella" in the Attn: field.

**Query List:** (OR (Status: IS Declined) (Status: IS Superceded) )
Searches for all ARs with Status: either Declined or Superceded.
Sort List: -- This field determines how the Query-ed ARs will be sorted. Currently, ARs can only be sorted by the values of enumerated fields. Buttoning the words "Sort List:" will put up a menu of the permitted field names -- selecting one will add it to the value of this field.

Example:

Sort List: Status: Priority:
This will sort first by the Status: field, and then by the Priority: field.

[Note: After sorting by all given fields, if two ARs are the same, they are sorted by AR number. Therefore, if this field is left blank, the queried ARs will be in numerical order]

Query -- Buttoning this command will initiate the query specified by the "Query List:" field, and sort it according to the value of the "Sort List:" field. While the query is in progress, the AR query command subwindow is greyed-out. When the query is completed, the numbers, subjects, etc of the ARs which have been found are displayed in the AR query browser subwindow. This window can be scrolled both vertically and horizontally.

Print File: -- This field can be filled in with a file name, which is used to specify the file that the Print command should store a report. If left blank, a window will pop up on the screen, and the information will be displayed there.

Print -- This prints a detailed summary of all of the ARs from the last Query into the file given in the Print File: field.

To generate and print a summary of a selected group of ARs, fill in the Query List: and Sort List: fields, select Query and wait for the query to complete, fill in the Print File: field, and select Print. The summary is rather wide -- it may be a good idea to use the LANDPRESS package to print it out sideways on a printer.

The AR query browser window:

This window shows a short summary (one line each) of the ARs that have been queried. Left-buttoning one of the AR lines will call AR.SHOW on that AR, to display it. Middle-buttoning an AR line will "Get" that AR into a specified AR edit form window.

Background menu commands:

When AREEDIT is loaded, the item "AREEDIT" is added to the background menu, with a number of subitems. These are interpreted as follows:

AREEDIT -- Creates a new AR edit form, initially cleared.

New AR Form -- Same as AREEDIT

Load AR Form -- prompts the user for a number, and creates a new AR edit form, with the specified AR number loaded initially.

AR.SHOW -- prompts the user for a number, and calls AR.SHOW, an old version of AREEDIT which quickly displays the contents of a given AR. It prompts for a window region the first time it is used -- thereafter it uses the same window.

AR Query Form -- Creates a new AR query form.

Auxiliary AR edit form commands.
Pressing the left mouse button in the title bar of the AR Edit form command subwindow will bring up a menu of less-used commands:

Clear -- Clears ALL the fields of the current AR. Similar to New, except that none of the fields like Source:, etc., are filled in. This is useful when you are submitting an AR for someone else.

New
Get
Put -- the same as the Commands in the edit command subwindow.

Put&Get -- prompts the user for a number, Puts the current AR, and Gets the given numbered AR. Useful when scanning through a number of ARs.

GetFromFile -- Prompts the user for a file name, and loads the information from that file into the AR edit form subwindow. If this file is not in the right format, an error will be generated.

PutToFile -- Prompts the user for a file name, and stores the information from the AR into that file.

**Locally caching the AR index.**

All AR query operations use the information in the "AR Index" file. This file, which is updated every few days, is stored as {eris}<lispars>AR.INDEX. To speed up Query operations, this file can be copied to a local file server, or the local hard disk. Warning: this file is currently ~700 IFS pages long, and it will undoubtedly get larger. Also, it is the responsibility of the user to make sure that they update their local version of AR.INDEX when the master copy is updated.

To use a local version of AR.INDEX, give the file name as an argument to AR.QFORM.CREATE:

(AR.QFORM.CREATE '{DSK}AR.INDEX).

**Global Variables that control AREDIT**

The following are global variables that can be set to alter the operation of AREDIT. These are the only global variables that it is safe to change.

AR.ENTRY.LIST.WINDOW.FIELDS -- Controls which fields are displayed in the AR query browser window, along with the widths of the fields.

AR.ENTRY.LIST.PRINT.FIELDS -- Controls the fields displayed by the Print command of the AR query form.

AR.ENTRY.LIST.PRINT.MULTILINE.FLAG -- if non-NIL, the Print command of the AR query form will print all of the characters in each field, using multiple lines for those field values bigger than the field width allowed. If NIL, each AR will use only one line, truncating any field values that are too big.
DATEPATCH

By: Bill van Melle
(vanMelle.pa@Xerox.com)

DATEPATCH fixes some bugs and extends the functionality of the date functions DATE, GDATE and IDATE.

Date Parsing

The date parser (IDATE) now handles all dates legal in RFC822 syntax (except the silly single-digit military time zones). In addition, it handles months spelled out, months abbreviated with a period, and ignores initial strings of the form ”[letter]*,” assuming these to be specifying a day, as in ”Monday, May 1, 1989”. In addition to the official time zone specifications, it also recognizes any in the list TIME.ZONES, whose format has changed slightly:

TIME.ZONES

An association list whose elements are of the form (offset regzone dstzone), where offset is the number of hours west of GMT (note that this, unfortunately, is opposite in sign to the RFC822 standard, but is strictly an internal matter), regzone is a string specifying the time zone normally, and dstzone is a string specifying the zone when daylight savings time is in effect. If dstzone is omitted, then there is no representation for that zone in daylight savings time, and DATE is forced to use absolute syntax (e.g., +0400).

The initial value of TIME.ZONES is

```lisp
((8 "PST" "PDT")
 (7 "MST" "MDT")
 (6 "CST" "CDT")
 (5 "EST" "EDT")
 (0 "GMT" "BST")
 (0 "UT")
 (-1 "MET" "MET DST")
 (-2 "EET" "EET DST"))
```

IDATE also accepts an optional argument DEFAULTTIME, which is interpreted as a number of seconds past midnight. If the date string does not contain a time, DEFAULTTIME is used; if DEFAULTTIME is NIL, IDATE returns NIL in this case (as it always has).

Date Output

The date printers (DATE and GDATE) now produce appropriate time zones outside of the U.S. Given a choice of time zones, they take the first entry found in TIME.ZONES. In addition, they support a few more DATEFORMAT options:

MONTH.LONG

Provides for full names of months rather than the first three characters. For instance, (DATE (DATEFORMAT MONTH.LONG SPACES NO.TIME)) might produce ”20 February 87”.

MONTH.LEADING

[DateFormat Option]

Causes the month to be produced as a word before the day and the day to be followed by a comma. For instance, (DATE (DATEFORMAT MONTH.LEADING MONTH.LONG YEAR.LONG NO.TIME)) might produce "February 20, 1987". MONTH.LEADING implies SPACES and inhibits NUMBER.OF.MONTH.

CIVILIAN.TIME

[DateFormat Option]

Specifies 12-hour time instead of 24-hour (military) time. For instance, (DATE (DATEFORMAT CIVILIAN.TIME NO.DATE NO.SECONDS)) might produce "11:34pm".

For completeness, listed below are all the DATEFORMAT options currently supported.

Those affecting the date portion:

NO.DATE Omit the date portion (month, day, year, day of week).

NUMBER.OF.MONTH Use a number for the month instead of spelling it.

MONTH.LONG Spell the month out instead of abbreviating it.

MONTH.LEADING Month before day, spelled out, comma after day.

YEAR.LONG Use 4 digits for year instead of 2.

DAY.OF.WEEK Include day of week (it appears at the end of the string, in parentheses).

DAY.SHORT Use 3-letter abbreviation for day.

SLASHES Separate parts of date with slashes instead of hyphens.

SPACES Separate parts of date with spaces instead of hyphens.

NO.LEADING.SPACES Omit leading spaces (default is a fixed format that always "lines up"). This also affects the hour when CIVILIAN.TIME is specified.

Those affecting the time portion:

NO.TIME Omit the time portion (hour, minutes, seconds, zone).

NO.SECONDS Omit seconds.

CIVILIAN.TIME 12-hour instead of 24-hour time.

TIME.ZONE Include time zone specification.
Basic Functions

(DOFILEBANGER Destination Length NoBreak)

Starts a new file banger in its own process. The device and directory specified by Destination will be where the test files are created during the testing. Each file will be Length bytes long. The file banger performs consistency checks on all the files it creates after each operation. If those consistency checks fail, it will print a message indicating what it found wrong, and if NoBreak is NIL will open a break window.

To stop the file banger process, one may (KILL.PROCESS 'FILEBANGER), provided that only a single file banger is in operation.

(FILEBANGER TestFile Destination MakeWindow NoBreak InParms OutParms)

Enters a loop of creating, manipulating, and deleting files, making consistency checks after each pass. TestFile may be the name of a file (whose contents are used as the contents of the test files), or an integer, in which case a test file of that many random bytes is created. Destination is the device and directory to be tested (normally this should be (DSK)<LispFiles>). MakeWindow, if T, causes a fresh window to be created; that window is used for progress messages as the test runs. If MakeWindow is NIL, the regular TTY window for the process is used (and created, if need be). If the test's consistency checks fail, FILEBANGER will print a message in the status window; if NoBreak is NIL, it'll also stop and open a break window. If you are interested in really stressing the file system, you may specify PARAMETERS arguments to be given to OPENSTREAM when files are opened. InParms is used when opening for input, and OutParms when opening for output. We don't recommend the use of these arguments.

Generally speaking, the test file should be of a good length (5000 bytes or more), to assure that the files spread out to cover the disk volume you’re testing.

FILEBANGER continues to run until interrupted from the outside somehow. The easiest way to arrange that is to run it in its own process (using DOFILEBANGER) and use KILL.PROCESS.

Recommended Operation

(DOFILEBANGER '(DSK)<LispFiles> 5000 NIL)

This will open a TTY window for the FILEBANGER process, and print small ongoing status messages there; you will need to do something to prevent the scrolling from hanging things up when the TTY window is full (either type ahead some spaces in that window, or arrange for the window not to pause when it fills up). To stop the file banger when it has run long enough, do (KILL.PROCESS 'FILEBANGER) in the top-level TTY window.

Likely Error Messages

HARD DISK ERROR
The low-level disk code hit a hard error on the disk, and was able to complete its operation to the extent of recognizing the error. Indicates a bad spot on the disk.

**VERIFY ERROR**

The disk-page label checking code found an inconsistency. While this might be software, it is most likely to be controller trouble or a bad spot on the disk.

**(infinite uninterruptible loop)**

The low-level disk code hit a snag so severe that it could never complete the disk operation at all. This should never happen. If it does, suspect IOP trouble.

**File1 and File2 differ at byte xxx**

Two files should have been identical but weren’t. Suspect software problems, unless the error follows a particular drive, processor, or IOP.

**File1 has length xxx, but File2 has length yyy.**

Two files should have been identical but weren’t. Suspect software problems, unless the error follows a particular drive, processor, or IOP.
Files in this directory /usr/local/lde/internal/
where copied from {eris}<lispcore>internal>library>
31-Jan-90
This document describes Lisp Diagnostics program for Xerox 1108 and Xerox 1109 workstations.

To start it, load LISPDIAGNOSTICS.DCOM from the Lisp Library.

As soon as it finishes loading the file, a menu will appear. You will have 2 choices, i.e. : Start Exercise and Stop Exercise.

If the file has previously been loaded, you’ll only have to type : (MAKEDIAGNOSTICSMENU) to make the menu appear.

When you select Start Exercise, the following message will appear on the Top level typescript window :

Legend

! -> Completed !DIAGNOSE of MACROTEST
@ -> Completed TANSPEED benchmark
# -> Completed BROWSE benchmark
$ -> Found a Clearing House on the Ethernet
- -> Looked, but failed to find a Clearing House
[xxx] -> Tried 32 retrievals from CH and got xxx failures
{xxx} -> Copied and deleted xxx copies of the Disk file
(XXX) -> Finished with xxx’th run of the EMUPROC loop
GDATE on new line marks release of working set pages

In addition to that, a window appears on top of the menu, it describes
the current activity indicated by a black rectangular cursor.
They are :
1. Swap out working set.
2. Ethernet activity.
3. Disk Activity.
4. Benchmark.

To stop the diagnostics, simply click the Stop Exercise selection.

(This package was superficially tested on Intermezzo>Full.sysout on 05 - 21 - 1985 by G. Santosa)
INTRODUCTION

The module NSMAIL implements the protocols to allow Lafite to be used to send and retrieve Xerox NS Mail. Load the file NSMAIL.LCOM. To run this in Lyric, you must have loaded the LispUsers module NSRANDOM as well (q.v. for important loading information). If you don’t have NSRANDOM loaded, you can’t use the “Put to file” command described below.

If you have both Grapevine and NSMAIL implementations loaded, you must set Lafite’s mode to NS. Use the “NS Mode” subitem underneath Lafite’s Quit command, or call (LAFITEMODE ‘NS). You must also be a registered NS user, and have a mailbox.

ATTACHMENTS

The main difference between this and earlier versions of NSMAIL is that “attachments” are no longer left in your mailbox to be read later with, for example, Viewpoint. Instead, Lafite retrieves the entire attachment and encapsulates it into an image object that is enclosed as part of the text message, immediately following the header. A typical attachment appears in a mail message as:

```
Attachment: Viewpoint Document
```

If you click inside the object with any mouse button, you are offered a menu of things you can do with the attachment. The choices vary according to the type of attachment:

- **View as text**: This brings up a window in which is displayed the raw content of the attachment as ascii bytes. Runs of non-ascii bytes are replaced by nulls to reduce the amount of garbage. Some attachments are utter gibberish, but some, such as Viewpoint documents and Interpress masters, contain sections that are plain text. With this command, you may be able to decide whether you care to do anything further with the attachment. (Sorry, there is no Viewpoint to TEdit converter, nor are there plans for one.)

- **Put to file**: This prompts you for a file name, and creates a file to contain the attachment. The file must be on an NS file server for this command to be very useful; otherwise, information will be lost. Once the file is so stored, you can retrieve it from Viewpoint and manipulate it just as if you had originally retrieved it as mail in Viewpoint.
Send to Printer

This command is only available for attachments that are in the form of an Interpress master. The command prompts you for a printer (must be one that accepts Interpress, of course), and sends the attachment to it for printing.

Expand folder

This command is only available for attachments that are in the form of a "folder". A folder is a mechanism for collecting several objects into a single one. The Expand folder command splits the attachment up into its component objects, each of which can be manipulated in the same way as a top-level attachment. For example, if the folder contains an Interpress master, you can print it.

If you use the Put to file command on a folder, the name component of the file name you type will be treated as the name of a new subdirectory, and the components of the folder will appear as files in that subdirectory. For other types of attachments, Put to file (usually) produces an ordinary (non-directory) file.

Messages containing attachments are otherwise just like formatted messages—you can move them to other folders, and you can forward them (assuming the mail is received by another Lafite recipient and did not have to pass through a mail gateway).

There is currently no mechanism for creating your own attachments to send to other users.

MISCELLANY

If you prefer the old behavior of leaving the attachments behind in the mailbox, set the variable NSMAIL.LEAVE.ATTACHMENTS to T, but this use is discouraged. You must take care to regularly retrieve your mail from somewhere (such as Viewpoint) that will flush out all the mail; otherwise, the mail with attachments, whether you want them or not, accumulate on the server.

When in NS mode, Lafite will want your NS login identity. Normally, if your NS password differs from your default password, you will be prompted to login. You can also call (LOGIN 'NS::) yourself to set your NS login.

You can freely intermix Grapevine and NS mail in the same mail folder if you like, but the Answer command always treats the selected message as if it were one in the current mode. So if you try to answer a Grapevine message while in NS mode, some confusion may result. Also, the status window always shows you mail status only of the current mode.
SOURCELOOKUP

INTRODUCTION

This module provides a mechanism to locate the source file and floppy in which a particular system function is defined. It is designed for use with the set of Xerox LISP source files distributed on floppy with the Lyric release. This module uses the WHEREIS module distributed with Lisp Library documented in Section 23 of the Interlisp Reference Manual.

LOADING THE MODULE

SOURCELOOKUP requires WHEREIS.DCOM and HASH.DCOM to be loaded. The variable WHEREIS.HASH must be set to the hash file LYRICSOURCES.WHEREIS. All these files are distributed on the floppy labeled Lyric Sources #10. The hash file must reside on a random access device. To use the hash file on FLOPPY do the following:

(SETQ WHEREIS.HASH '((FLOPPY)LYRICSOURCES.WHEREIS))

The variable LyricSourceIndex will be set to a list where each element is a list whose CAR is the name of a Lyric Source floppy and CDR is the list of files contained on the floppy.

USER FUNCTION

(LOCATE.FUNCTION function)

If function is defined in a distributed source file prints out the appropriate file name and floppy and returns the file name; else prints "function not found" and returns NIL.

EXAMPLES

(LOCATE.FUNCTION 'SETQ)
The function SETQ is defined in the file LLINTERP located on floppy Lyric Source #5.

(LOCATE.FUNCTION 'UNDEFINED)
UNDEFINED not found.

NIL
INTRODUCTION

UNIXMAIL is a new mail sending and receiving mode for Lafite. It sends mail via Unix hosts using the SMTP mail transfer protocol and can receive mail either by reading a Unix mail spool file or by calling the Berkeley mail program.

INSTALLATION

Turn Lafite off, load the file UNIXMAIL, make sure UNIXMAIL is configured appropriately (check the settings of the variables below, and make sure any other modules UNIXMAIL m
SETUP instructions for
PC Emulation virtual hard disk and real PC floppy disk access

1. Make sure all of the normal PCE .DCOM files are loaded to run PCE:
   (PCEWINDOW, PCE, PCEERD, PCEDISPLAY, PCEKEYBOARD).
2. Select PC Emulation on the background MENU. This may take a while to load
   the PC fonts.
4. If the PCE boots ok, then select QUIT in the the command window.
5. Now we will make a virtual hard disk for the PCE.

   From LISP do the following:
   1_(PCE.CREATE.ERDFILE 'PCE.DISK 50)
       (* this will make a lisp file PCE.DISK which is nearly 2
        megabytes big - make sure you have enough disk space)
6. Reboot the PCE (BOOT command) and make sure configuration has the right
   file name PCE.DISK for the ERDFILE using the CONFIG command.
7. From the PC window:
   -FDISK
       (* create DOS partition using all of the disk )
   -FORMAT C:/V/S
       (* format the rigid disk, put a system on it, and label)
   -COPY A:*.* C:
       (* copies all of the system files from floppy to ERD)
8. Select QUIT from the COMMAND window.
9. You may now boot from the ERD (emulated rigid disk) by selecting FIXED DISK
   as boot device and Set-Config from the configuration window.
10. From LISP exec:
    2_ LOAD(VPCDISK.DCOM)
        (* loads in LISP virtual PC disk/floppy and real PC floppy
         access)
    3_ (VPCDISK.CREATE.DEVICE 'PCDISK 'PCE.DISK T)
        (* associates ERDFILE PCE.DISK with a device name PCDISK)
    4_ DIR {PCDISK}PCDISK:*
        (* directory listing of the PC DISK)
    5_(SETQ PC.TEXTFILE.EXTENSIONS '(TXT PAS BAS 1 2 3]
        (* list of PC file extensions which are treated as TEXT type
         files)
    6_(VPCDISK.CREATE.DEVICE 'PCFLOPPY '{PCFLOPPY})
        (* associates real PC floppy driver with {PCDISK} device
        PCFLOPPY)
        (* make sure real floppy is in the disk drive when you
         execute this)
    7_DIR {PCDISK}PCFLOPPY:*
        (* directory listing of the real floppy)
11. At this point you are set up to do any LISP commands you want such as Filebrowser, Hardcopy, TEdit, etc. using the \{PCDISK\}PCDISK: for the virtual hard disk, and \{PCDISK\}PCFLOPPY: for real PC floppies.

12. Try using Filebrowser and then selecting a textfile that has one of the extension names you setup in PC.TEXTFILE.EXTENSIONS above, and selecting HARDCOPY.

13. Try using TEDIT on a floppy file such as \{PCDISK\}PCFLOPPY:README.1 and then editing the file and writing (PUT) it back. and then reselect it from filebrowser and selecting hardcopy. (Make sure floppy is not write-protected.)

14. You may also access files on sub-directories. IE, \{PCDISK\}PCDISK:<DIR>FILE - However, you cannot delete or create directories from LISP. You have to do this from the PC window.

Subject: New Lispcore>Library package: MesaTypes
To: Lispcore^, Lispsupport, Sheil, Cooper, Purcell

Announcing a new Lispcore>Library package: MesaTypes

By Tayloe Stansbury with help from Richard Burton.

This package introduces three new clisprecordtypes which allow you to describe any block of bits with an arbitrarily nested datatype. You can define multidimensional, nonstandardly indexed arrays with multi-word elements; records with multi-word fields; and multi-word types. Special accessfns cover up the necessary \BLTs and LOCFs. Appropriate create methods are automatically provided. The package also provides a number of macros for manipulating instances of such types.

Anyone who wants to use graceful datatypes to describe some arbitrary chunk of memory (e.g. ethernet, rs232, nsfiling, any file system) will probably find this package useful; most of the 1108 file system now depends on it. People translating Mesa system code into Lisp will find it particularly useful.

This message is stored as Lispcore>Library>MesaTypes.tedit. Proper external documentation of this package will follow release of the 1108 file system. Extensive examples of its use can be found in the first few pages of stansbury>newdlionfs>dlionfs.

-- Tayloe.
Common Lisp package code and symbol conversions
Ron Fischer

[This document is for developers only. It is not intended to be part of any external software release.]

The package code can behave mightily strangely if not operated "just so." Please read this document carefully.

Loading

The package code is now loaded in the full.sysout. It lives in {Eris}<LispCore>Library> on
CMLSYMBOL.DCOM
CMLPACKAGE.DCOM

Initializing

Packages, as you might expect, must be bootstrapped carefully. At its simplest, initialization is accomplished by
calling just one function:

(package-init t)

simple startup

(package-init &optional (convert? nil))  [Function]
Clear, make structures of, initialize & convert symbols (if convert? is t) to, and enable use of the symbol
package system. On a DandeTiger this takes about 25 minutes.

The bootstrap actually takes place in three steps. The first one creates all the package structure needed. The second
passes over all the atoms in the sysout to "tag" them with packages. The third enables the package world.

step 1: make system packages

(package-make)  [Function]
Create, but do not fill with symbols, the base packages that need to exist. Also enables the package qualifier
characters in the readtables and saves the old definitions of \READ.SYMBOL and \MKATOM.

step 2: convert existing symbols

(package-hierarchy-init &optional (convert? nil))  [Function]
Fill all the initial system packages with their proper symbols, moving litatoms into appropriate places and such. If
convert? is non-nil then symbols whose pnames have fake package qualifiers, like cl:length, will be converted IN
PLACE to remove the qualifier. If conversion takes place you cannot fully disable the package system.

step 3: enable package system, remove old hacks

The third part of the bootstrap enables the use of packages by the reader, printer and friends. This involves
redefining \MKATOM and \READ.SYMBOL. Also, if *package* is set to nil things will not go well. Please use
package-enable and package-disable to start and stop, as these fellows know what they’re doing. These
faithful functions are available on a menu by calling package-menu.

(package-enable &optional (package *interlisp-package*))  [Function]
Turn on the package system, making package the current one and redefining \READ.SYMBOL and \MKATOM
appropriately.

(package-disable)  [Function]
Turn off the package system and restore the old definitions of \READ.SYMBOL and \MKATOM. After disabling,
symbols interned under the package system will not be eq to symbols of the same name reread.

(package-menu)  [Function]
Make a menu that allows turning the package system on or off without using the reader.

(package-hacks-disable)  [Function]
Eliminates package simulation hacks when loading over an old sysout. These hacks cannot be re-enabled.
(pkgconvert-enable) [Function]
Enables a change in the behavior of the function \READ.SYMBOL (using the function check-symbol-namestring), which converts symbols being read based on their "looking like" a package prefixed symbol name. "Looking like" is defined by a table in the global litatom-package-conversion-table.

litatom-package-conversion-table [Variable]
a global variable containing a list of clauses used by the functions package-hierarchy-init and check-symbol-namestring to determine if a symbol "looks like" is trying to be package qualified. The list contains clauses with the following structure:

(prefix-string list-of-exception-strings package-name-string where)

prefix-string - string containing the prefix of symbols which this clause converts, eg "CL:
list-of-exception-strings - list of strings naming symbols which this clause should leave alone, eg ("CL:FLG")
package-name-string - string containing the name of the package that symbols converted by this clause should wind up in, eg "LISP"
where - either :INTERNAL or :EXTERNAL, indicates whether symbols converted by this clause should be external or internal in their package.

The initial value of this variable is:

  "LISP":external)
 (":": nil "KEYWORD":external)
)

Notes & cautions
The read functions may return strings if you use package qualifier syntax and *package* does not contain a package. This is part of debugging code that Bill put into them. Beware especially of making *package* NIL without calling package-disable.

The list of conversion clauses is searched linearly, hence longer prefixes should come before shorter ones with the same chars in them, ie put a clause for "CL::" before one for "CL:".

Missing features
Cannot be placed early into loadup due to dependancies on CL files.

Apropos (and other Interlisp litatom functions) are not redefined to operate with packages.

Performance
There have been some small improvements since these timings were taken.

 {ERIS}<LISPCORE>CML>LAB>CMLPACKAGES.;129))

Testing symbol / litatom creation. Old array package. There are 6 random symbols made (new ones). intern is a factor of 16 slower, conses heavily, makes 3 strings for each call.

Read and Print state profile

There are a large number of special variables that control reading and printing. Taken together these comprise a "mode of operation" for the reader and printer. Because there are a fair number of such variables a method for capturing and restoring their state has been provided.

(xcl:make-read-print-profile &key (readtable *readtable*) (read-base *read-base*) (read-suppress *read-suppress*) (package *package*) (read-default-float-format *read-default-float-format*) (print-escape *print-escape*) (print-pretty *print-pretty*) (print-circle *print-circle*) (print-base *print-base*) (print-radix *print-radix*) (print-case *print-case*) (print-gensym *print-gensym*) (print-level *print-level*) (print-length *print-length*))

[Function]

Creates a read-print-profile object. The default values of its components are taken from the current special bindings of the variables shown in the argument list above.

(xcl:copy-read-print-profile profile)[Function]

Creates a new read-print-profile object and copies the values in the slots of profile into the new one.

(xcl:read-print-profile-p object) [Function]
Returns true if the object is a read-print-profile, otherwise false.

(xcl:read-print-profile-readtable profile) [Function]
(xcl:read-print-profile-read-base profile) [Function]
(xcl:read-print-profile-read-suppress profile) [Function]
(xcl:read-print-profile-package profile) [Function]
(xcl:read-print-profile-read-default-float-format profile) [Function]
(xcl:read-print-profile-print-escape profile) [Function]
(xcl:read-print-profile-print-pretty profile) [Function]
(xcl:read-print-profile-print-circle profile) [Function]
(xcl:read-print-profile-print-base profile) [Function]
(xcl:read-print-profile-print-radix profile) [Function]
(xcl:read-print-profile-print-case profile) [Function]
(xcl:read-print-profile-print-gensym profile) [Function]
(xcl:read-print-profile-print-level profile) [Function]
(xcl:read-print-profile-print-length profile) [Function]
(xcl:read-print-profile-print-array profile) [Function]
(xcl:read-print-profile-print-structure profile) [Function]

profile must be a read-print-profile object. Returns the named slot of the read-print-profile. A corresponding setf method is provided for each slot.

(xcl:save-read-print-profile profile) [Function]

Capture bindings of special read & print variables into the profile. Returns profile.

(xcl:with-read-print-profile profile-form &body forms) [Macro]

Binds all the special read & print variables to the values in the profile and executes the body forms as in a let. Returns the value of the last of the forms.

(xcl:restore-read-print-profile profile) [Function]

Restore values of special read & print bindings from profile. Sets current bindings. Returns T.

xcl:*default-read-print-profile* [Variable]

Holds a simple default read-print-profile. When possible programs should default to the current settings of the read-print variables by capturing them with save-read-print-profile instead.

(xcl:find-read-print-profile name) [Function]

Since read-print-profiles enclose readtables and packages, which are available by name, named read-print-profiles
are also available.

This function will retrieve one of the following "standard" read-print-profiles:

LISP:  LISP readtable and USER package, others nominal.
XCL:   XCL readtable and XCL-USER package, ditto above.
INTERLISP: INTERLISP readtable and INTERLISP package, ditto.

This function is case insensitive. It returns NIL if a profile by that name is not found.

(xcl:list-all-read-print-profile-names)  [Function]

Returns a list of strings containing the names of all available read-print-profiles.
The WHEREIS package extends the function WHEREIS such that, when asked about a given name as a function, WHEREIS will consult not only the commands of files that have been noticed by the file packages, but also one or more hash file data bases that associate function names with file names.

\[
(\text{WHEREIS } \text{NAME TYPE FILES FN}) \quad \text{[Function]}
\]

Behaves exactly like the standard WHEREIS function (see the Interlisp-D Reference Manual) unless \text{TYPE}=FNS (or NIL) and \text{FILES}=T. In this case, WHEREIS will consult, in addition to the files on FILELST, the hash files that are on the value of WHEREIS.HASH. Note: normally the user will just enter the full name of a file onto WHEREIS.HASH, but as WHEREIS begins to use it, it will convert the entry into a cons of the name and the hash file handle.

Many system functions, such as the editors, call WHEREIS with \text{FILES}=T, so loading this package automatically makes any information contained in the WHEREIS data base files available throughout the system.

Creating a Where Is Data Base

Information may be added to an existing WHEREIS hash file, or by creating new data bases. It is often useful to have a separate data base for large user systems, explicitly calling the following function:

\[
(\text{WHEREISNOTICE FILEGROUP NEWFLG DATABASEFILE}) \quad \text{[Function]}
\]

Inserts the information about all of the functions on the files in \text{FILEGROUP} into the WHEREIS data base contained on \text{DATABASEFILE}. If \text{DATABASEFILE} is NIL, the first entry on WHEREIS.HASH is used.

\text{FILEGROUP} may be simply a list of files, in which case each file thereon is handled directly; but it may also be a pattern to be given as a file group argument to DIRECTORY, so \text{*} may be used.

If \text{NEWFLG} is non-NIL, a new version of \text{DATABASEFILE} will be created containing the data base for the functions specified in \text{FILEGROUP}. If \text{NEWFLG} is a number, the hash file will be created with \text{NEWFLG} entries. Otherwise, it will be created to allow 20,000 entries.

Example:

The following sequence of actions will cause all of the files on the \text{PROJECT} directory to be noticed by the WHEREIS package.

\[
(\text{WHEREISNOTICE}'<\text{PROJECT}>'*. T '<\text{PROJECT}>\text{PROJECTWHEREIS.HASH})
\]

\[
(\text{push WHEREIS.HASH}
(\text{FINDFILE}'<\text{PROJECT}>\text{PROJECTWHEREIS.HASH}))
\]
library/CLIPBOARD

Written by Ron Kaplan, 2020-2021

A small package that implements copy and paste to the system clipboard.

It arms meta-C for copy to the clipboard from the current selection of an application that has been armed (Tedit, Sedit), and also meta-X for extraction (copy followed by delete).

Meta-V is defined as an interrupt character that pastes the current clipboard contents into whatever process current has input focus.

The information in the clipboard can be provided from or provided to external (non-Medley) applications (mail, emacs, etc.) in the usual way. For example, a form cselected in SEDIT can be copied to the clipboard and pasted into an email message.

It assumes that the external format of the clipboard is determined by (SYSTEM-EXTERNALFORMAT, and characters will be converted to and from the Medley internal character encoding.

The name of the clipboard stream may differ from platform to platform. On the Mac, the paste stream is "pbpaste" and the copy stream is "pbcopy". Those names are used if "darwin" is a substring of (UNIX-GETENV "ostype"). Otherwise both stream-names default to "xclip". The functions CLIPBOARD-COPY-STREAM and CLIPBOARD-PASTE-STREAM perform this selection.
Introduction

This document describes software for driving color displays. In order to run COLOR, you need either a Sun (3 or 4) with CG4 color hardware and display, a Dorado (Xerox 1132) with attached color display, or a Dandelion (Xerox 1108) with attached BusMaster and color display.

The color software which is distributed among a number of files can be divided into a machine independent group of files that all users can usefully load and a machine dependent group containing files that work for particular combinations of hardware.

The machine independent color graphics code is stored in the library files LLCOLOR.LCOM and COLOR.LCOM. LOADing COLOR.LCOM causes LLCOLOR.LCOM to be LOADed.

The machine dependent portions of Xerox Lisp color software is stored in files such as MAIKOCOLOR.LCOM, DORADOCOLOR.LCOM, or COLORNNCC.LCOM. The user LOADs one of these files according to what kind of machine and color card the user is using.

The Sun color driver resides in the file MAIKOCOLOR.LCOM which loads LLCOLOR.LCOM and COLOR.LCOM. The CG4 device supports 8 bpp at 1152 by 900 resolution. The user must be running ldecolor, the special color capable emulator. The physical display monitor is shared by both the monochrome and color screens (described below).

The Dorado color driver resides in the file DORADOCOLOR.LCOM which loads LLCOLOR.LCOM and COLOR.LCOM. The Dorado color board supports four or eight bits per pixel (bpp) at 640 by 480 resolution. (The board supports 24 bpp also, but Xerox Lisp doesn’t yet.)

The Dandelion color drivers reside in the files DANDELIONUFO.LCOM, DANDELIONUFO4096.LCOM, and COLORNNCC.LCOM, one package for each of three different kinds of boards. The user should load one of these packages on a Dandelion attached to a BusMaster and color display. The DANDELIONUFO and DANDELIONUFO4096 packages drive 4 bpp at 640 by 400 resolution color boards used inside Xerox which have been made obsolete by COLORNNCC. The COLORNNCC package drives an 8 bpp color at 512 by 480 resolution board, the Revolution 512 x 8, made by Number Nine Computer Corporation. The Revolution 512 x 8 is available both inside and outside Xerox through Number Nine.
Hardware Displays and Software Screens

On some workstations (such as the Dorado and Dandelion), there may be physically two separate displays. On most Suns, there is a single physical display, which additionally may be shared by two Unix devices. One device is monochrome (b/w), and the other is color.

To support the various hardware configurations and external display devices, the software has a special datatype, a "screen". There are two distinct instances of screens, a b/w screen, and a color screen. A screen represents and controls a physical hardware display, and contains windows, icons, and tracks the mouse.

On workstations with physically two separate hardware displays, each display is represented by a corresponding screen data structure. On workstations with a single hardware display, the display is shared by both the b/w screen and the color screen.

In all cases, before initialization only the b/w screen (and thus display) is visible and active. After initialization both screens are active (can contain screen images), although on single displays, only one screen is visible at a time. Since each screen logically controls a display, we will henceforth use the terms 'screen' and "display" interchangeably. Screens are discussed in greater detail below.

Turning the Color Display Software On and Off

The color display software can be turned on and off. While the color display software is on, the memory used for the color display screen bitmap is locked down, and a small amount of processing time is used to drive the color display.

\((\text{COLOORDISPLAYP})\) [Function]

returns T if the color display is on; otherwise it returns NIL.

\((\text{COLOORDISPLAY \text{\textsc{onoff type}}})\) [Function]

turns off the color display if \text{\textsc{onoff}} is 'OFF. If \text{\textsc{onoff}} is 'ON, it turns on the color display allocating memory for the color screen bitmap. \text{\textsc{type}} should be one of 'MAIKOCOLOR, 'DORADOCOLOR, 'DANDELIONUFO, 'DANDELIONUFO4096, or 'COLORNNCC. The usual sequence of events for the user is to LOAD the software needed to drive a particular color card and then to call COLOORDISPLAY with the appropriate \text{\textsc{type}} to turn the software on. For example,

\((\text{LOAD 'COLOR.LCOM})\)

\((\text{LOAD 'COLORNNCC.LCOM})\)

\((\text{COLOORDISPLAY 'ON 'REV512X8})\)

will turn on the software needed to drive the Number Nine Computer Corporation's Revolution 512 x 8 card with 1108 and BusMaster.

Besides initializing or reinitializing a color card that has been powered off, COLOORDISPLAY allocates memory for the color screen bitmap. Turning on the color display requires allocating and locking down the memory necessary to hold the color display screen bitmap. Turning off the color display frees this memory.
Colors

The number of bits per pixel determines the number of different colors that can be displayed at one time. When there are 4 bpp, 16 colors can be displayed at once. When there are 8 bpp, 256 colors can be displayed at once. A table called a color map determines what color actually appears for each pixel value. A color map gives the color in terms of how much of the three primary colors (red, green, and blue) is displayed on the screen for each possible pixel value.

A color can be represented as a number, an atom, or a triple of numbers. Colors are ultimately given their final interpretation into how much red, blue, and green they represent through a color map.

A color map maps a color number ([0 . . . \(2^{nbits}-1\)]) into the intensities of the three color guns (primary colors red, green, and blue). Each entry in the color map has eight bits for each of the primary colors, allowing 256 levels per primary or \(2^{24}\) possible colors (not all of which are distinct to the human eye). Within Xerox Lisp programs, colors can be manipulated as numbers, red-green-blue triples, names, or hue-lightness-saturation triples. Any function that takes a color accepts any of the different representations.

If a number is given, it is the color number used in the operation. It must be valid for the color bitmap used in the operation. (Since all of the routines that use a color need to determine its number, it is fastest to use numbers for colors. COLORNUMBERP, described below, provides a way to translate into numbers from the other representations.)

Red Green Blue Triples

A red green blue (RGB) triple is a list of three numbers between 0 and 255. The first element gives the intensity for red, the second for green, and the third for blue. When an RGB triple is used, the current color map is searched to find the color with the correct intensities. If none is found, an error is generated. (That is, no attempt is made by the system to assign color numbers to intensities automatically.) An example of an RGB triple is (255 255 255), which gives the color white.

RGB [Record]

is a record that is defined as (RED GREEN BLUE); it can be used to manipulate RGB triples.

COLORNAMES [Association list]

maps names into colors. The CDR of the color name's entry is used as the color corresponding to the color name. This can be any of the other representations. (Note: It can even be another color name. Loops in the name space such as would be caused by putting `(RED . CRIMSON) and `(CRIMSON . RED) on COLORNAMES are not checked for by the system.) Some color names are available in the initial system and are intended to allow color programs written by different users to coexist. These are:
COLOR

<table>
<thead>
<tr>
<th>Name</th>
<th>RGB</th>
<th>Number in default color maps</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLACK</td>
<td>(0 0 0)</td>
<td>15</td>

</tbody>
</table>

**Hue Lightness Saturation Triples**

A hue lightness saturation triple is a list of three numbers. The first number (HUE) is an integer between 0 and 355 and indicates a position in degrees on a color wheel (blue at 0, red at 120, and green at 240). The second (LIGHTNESS) is a real number between zero and one that indicates how much total intensity is in the color. The third (SATURATION) is a real number between zero and one that indicates how disparate the three primary levels are.

**HLS**

is a record defined as (HUE LIGHTNESS SATURATION); it is provided to manipulate HLS triples. Example: the color blue is represented in HLS notation by (0 .5 1.0).

**(COLORNUMBERP COLOR BITSPERPIXEL NOERRFLG)**

returns the color number (offset into the screen color map) of COLOR. COLOR is one of the following:

- A positive number less than the maximum number of colors,
- A color name,
- An RGB triple, or
- An HLS triple.

If COLOR is one of the above and is found in the screen color map, its color number in the screen color map is returned. If not, an error is generated unless NOERRFLG is non-NIL, in which case NIL is returned.

**(RGBP X)**

returns X if X is an RGB triple; NIL otherwise.

**(HLSP X)**

returns X if X is an HLS triple; NIL otherwise.

**Color Maps**

The screen color map holds the information about what color is displayed on the color screen for each pixel value in the color screen bitmap. The values in the current screen color map may be changed, and this change is reflected in the colors displayed at the
next vertical retrace (approximately 1/30 of a second). The color map can be changed to obtain dramatic effects.

(SCREENCOLORMAP NEWCOLORMAP) [Function]

reads and sets the color map that is used by the color display. If NEWCOLORMAP is non-NIL, it should be a color map, and SCREENCOLORMAP sets the system color map to be that color map. The value returned is the value of the screen color map before SCREENCOLORMAP was called. If NEWCOLORMAP is NIL, the current screen color map is returned without change.

(CMYCOLORMAP CYANBITS MAGENTABITS YELLOWBITS BITSPERPIXEL) [Function]

Returns a color map that assumes the BITSPERPIXEL bits are to be treated as three separate color planes with CYANBITS bits being in the cyan plane, MAGENTABITS bits being in the magenta plane, and YELLOWBITS bits being in the yellow plane. Within each plane, the colors are uniformly distributed over the intensity range 0 to 255. White is 0 and black is 255.

(RGBCOLORMAP REDBITS GREENBITS BLUEBITS BITSPERPIXEL) [Function]

Returns a color map that assumes the BITSPERPIXEL bits are to be treated as three separate color planes with REDBITS bits being in the red plane, GREENBITS bits being in the green plane, and BLUEBITS bits being in the blue plane. Within each plane, the colors are uniformly distributed over the intensity range 0 to 255. White is 255 and black is 0.

(GRAYCOLORMAP BITSPERPIXEL) [Function]

Returns a color map containing shades of gray. White is 0 and black is 255.

(COLORMAPCREATE INTENSITIES BITSPERPIXEL) [Function]

creates a color map for a screen that has BITSPERPIXEL bits per pixel. If BITSPERPIXEL is NIL, the number of bits per pixel is taken from the current color display setting. INTENSITIES specifies the initial colors that should be in the map. If INTENSITIES is not NIL, it should be a list of color specifications other than color numbers, e.g., the list of RGB triples returned by the function INTENSITIESFROMCOLORMAP.

(INTENSITIESFROMCOLORMAP COLORMAP) [Function]

returns a list of the intensity levels of COLORMAP (default is (SCREENCOLORMAP)) in a form accepted by COLORMAPCREATE. This list can be written on file and thus provides a way of saving color map specifications.

(COLORMAPCOPY COLORMAP BITSPERPIXEL) [Function]

returns a color map that contains the same color intensities as COLORMAP if COLORMAP is a color map. Otherwise, it returns a color map with default color values.

(MAPOFACOLOR PRIMARIES) [Function]

returns a color map that is different shades of one or more of the primary colors. For example, (MAPOFACOLOR 'RED GREEN BLUE) gives a color map of different shades of gray; (MAPOFACOLOR 'RED) gives different shades of red.
Changing Color Maps

The following functions are provided to access and change the intensity levels in a color map.

(SETCOLORINTENSITY COLORMAP COLORNUMBER COLORSPEC) [Function]
sets the primary intensities of color number COLORNUMBER in the color map COLORMAP to the ones specified by COLORSPEC. COLORSPEC can be either an RGB triple, an HLS triple, or a color name. The value returned is NIL.

(COLORLEVEL COLORMAP COLORNUMBER PRIMARY NEWLEVEL) [Function]
sets and reads the intensity level of the primary color PRIMARY (RED, GREEN, or BLUE) for the color number COLORNUMBER in the color map COLORMAP. If NEWLEVEL is a number between 0 and 255, it is set. The previous value of the intensity of PRIMARY is returned.

(ADJUSTCOLORMAP PRIMARY DELTA COLORMAP) [Function]
adds DELTA to the intensity of the PRIMARY color value (RED, GREEN, or BLUE) for every color number in COLORMAP.

(ROTATECOLORMAP STARTCOLOR THRUCOLOR) [Function]
rotates a sequence of colors in the SCREENCOLORMAP. The rotation moves the intensity values of color number STARTCOLOR into color number STARTCOLOR+1, the intensity values of color number STARTCOLOR+1 into color number STARTCOLOR+2, etc., and THRUCOLOR’s values into STARTCOLOR.

(EDITCOLORMAP VAR NOQFLG) [Function]
allows interactive editing of a color map. If VAR is an atom whose value is a color map, its value is edited. Otherwise a new color map is created and edited. The color map being edited is made the screen color map while the editing takes place so that its effects can be observed. The edited color map is returned as the value. If NOQFLG is NIL and the color display is on, you are asked if you want a test pattern of colors. A yes response causes the function SHOWCOLORTESTPATTERN to be called, which displays a test pattern with blocks of each of the possible colors.

You are prompted for the location of a color control window to be placed on the black-and-white display. This window allows the value of any of the colors to be changed. The number of the color being edited is in the upper left part of the window. Six bars are displayed. The right three bars give the color intensities for the three primary colors of the current color number. The left three bars give the value of the color’s Hue, Lightness, and Saturation parameters. These levels can be changed by positioning the mouse cursor in one of the bars and pressing the left mouse button. While the left button is down, the value of that parameter tracks the Y position of the cursor. When the left button is released, the color tracking stops. The color being edited is changed by pressing the middle mouse button while the cursor is in the interior of the edit window. This brings up a menu of color numbers. Selecting one sets the current color to the selected color.

The color being edited can also be changed by selecting the menu item “PickPt.” This switches the cursor onto the color screen and allows you to select a point from the color screen. It then edits the color of the selected point.
To stop the editing, move the cursor into the title of the editing window and press the middle button. This brings up a menu. Select Stop to quit.

## Color Bitmaps

A color bitmap is actually a bitmap that has more than one bit per pixel. To test whether a bitmap is a color bitmap, the function `BITSPERPIXEL` can be used.

```
(BitPerPixel BitMap)  [Function]
```

returns the bits per pixel of `BitMap`; if this does not equal one, `BitMap` is a color bitmap.

In multiple-bit-per-pixel bitmaps, the bits that represent a pixel are stored contiguously. `BITMAPCREATE` is passed a `BITSPERPIXEL` argument to create multiple-bit-per-pixel bitmaps.

```
(BitMapCreate Width Height BitPerPixel)  [Function]
```

creates a color bitmap that is `Width` pixels wide by `Height` pixels high allowing `BitPerPixel` bits per pixel. Currently any value of `BitPerPixel` except one, four, eight, or NIL (defaults to one) causes an error.

A four-bit-per-pixel color screen bitmap uses approximately 76K words of storage, and an eight-bit-per-pixel one uses approximately 153K words. There is only one such bitmap. The following function provides access to it.

```
(ColorScreenBitmap)  [Function]
```

returns the bitmap that is being or will be displayed on the color display. This is NIL if the color display has never been turned on (see `COLORDISPLAY` below).

## Screens, Screenpositions, and Screenregions

In addition to positions and regions, the user needs to be aware of screens, screenpositions, and screenregions in the presence of multiple screens.

### Screens

```
Screen  [Datatype]
```

There are generally two screen datatype instances in existence when working with color. This is because the user is attached to two displays, a black and white display and a color display.

```
(MainScreen)  [Function]
```

returns the screen datatype instance that represents the black and white screen. This will be something like `[SCREEN]#74,24740.`

```
(ColorScreen)  [Function]
```

returns the screen datatype instance that represents the color screen. Screens appear as part of screenpositions and screenregions, serving as the extra information needed to make...
clear whether a particular position or region should be viewed as lying on the black and white display or the color display.

**SCREENBITMAP** (SCREEN) [Function]
returns the bitmap destination of SCREEN. If SCREEN=NIL, returns the black and white screen bitmap.

## Screenpositions

**SCREENPOSITION** [Record]

Somewhat like a position, a screenposition denotes a point in an X,Y coordinate system on a particular screen. Screenpositions have been defined according to the following record declaration:

(RECORD SCREENPOSITION (SCREEN . POSITION)
  (SUBRECORD POSITION))

A SCREENPOSITION is an instance of a record with fields XCOORD, YCOORD, and SCREEN and is manipulated with the standard record package facilities. For example, (create SCREENPOSITION XCOORD _ 10 YCOORD _ 20 SCREEN _ (COLORSCREEN)) creates a screenposition representing the point (10,20) on the color display. The user can extract the position of a screenposition by fetching its POSITION. For example, (fetch SCREENPOSITION POSITION) of SP12).

## Screenregions

**SCREENREGION** [Record]

Somewhat like a region, a screenregion denotes a rectangular area in a coordinate system. Screenregions have been defined according to the following record declaration:

(RECORD SCREENREGION (SCREEN . REGION)
  (SUBRECORD REGION))

Screenregions are characterized by the coordinates of their bottom left corner and their width and height. A SCREENREGION is a record with fields LEFT, BOTTOM, WIDTH, HEIGHT, and SCREEN. It can be manipulated with the standard record package facilities. There are access functions for the REGION record that return the TOP and RIGHT of the region. The user can extract the region of a screenregion by fetching its REGION. For example, (fetch SCREENREGION REGION) of SR8).

## Screenposition and Screenregion Prompting

The following functions can be used by programs to allow the user to interactively specify screenpositions or screenregions on a display screen.

**GETSCREENPOSITION** (WINDOW CURSOR) [Function]

Similar to GETPOSITION. Returns a SCREENPOSITION that is specified by the user. GETSCREENPOSITION waits for the user to press and release the left button of the mouse and returns the cursor screenposition at the time of release. If WINDOW is a WINDOW, the screenposition will be on the same screen as WINDOW and in the coordinate system of WINDOW's display stream. If WINDOW is NIL, the position will be in screen coordinates.
(GETBOXSCREENPOSITION \textit{BOXWIDTH} \textit{BOXHEIGHT} \textit{ORGX} \textit{ORGY} \textit{WINDOW} \textit{PROMPTMSG}) [Function]

Similar to \textit{GETBOXPOSITION}. Returns a \textit{SCREENPOSITION} that is specified by the user. Allows the user to position a "ghost" region of size \textit{BOXWIDTH} by \textit{BOXHEIGHT} on a screen, and returns the \textit{SCREENPOSITION} of the lower left corner of the screenregion chosen. A ghost region is locked to the cursor so that if the cursor is moved, the ghost region moves with it. The user can change to another corner by holding down the right button. With the right button down, the cursor can be moved across a screen or to other screens without effect on the ghost region frame. When the right button is released, the mouse will snap to the nearest corner, which will then become locked to the cursor. (The held corner can be changed after the left or middle button is down by holding both the original button and the right button down while the cursor is moved to the desired new corner, then letting up just the right button.) When the left or middle button is pressed and released, the lower left corner of the screenregion chosen at the time of release is returned. If \textit{WINDOW} is a \textit{WINDOW}, the screenposition will be on the same screen as \textit{WINDOW} and in the coordinate system of \textit{WINDOW}'s display stream. If \textit{WINDOW} is \textit{NIL}, the position will be in screen coordinates.

\textit{NEWREGION} \textit{MINWIDTH} \textit{MINHEIGHT} \textit{OLDREGION} \textit{NEWREGIONFN} \textit{NEWREGIONFNARG} \textit{INITCORNERS} [Function]

Similar to \textit{GETREGION}. Returns a \textit{SCREENREGION} that is specified by the user. Lets the user specify a new screenregion and returns that screenregion. \textit{GETSCREENREGION} prompts for a screenregion by displaying a four-pronged box next to the cursor arrow at one corner of a "ghost" region: \includegraphics[width=0.1\textwidth]{ghost-box}. If the user presses the left button, the corner of a "ghost" screenregion opposite the cursor is locked where it is. Once one corner has been fixed, the ghost screenregion expands as the cursor moves.

To specify a screenregion: (1) Move the ghost box so that the corner opposite the cursor is at one corner of the intended screenregion. (2) Press the left button. (3) Move the cursor to the screenposition of the opposite corner of the intended screenregion while holding down the left button. (4) Release the left button.

Before one corner has been fixed, one can switch the cursor to another corner of the ghost screenregion by holding down the right button. With the right button down, the cursor changes to a "forceps" (\includegraphics[width=0.1\textwidth]{forceps}) and the cursor can be moved across a screen or to other screens without effect on the ghost screenregion frame. When the right button is released, the cursor will snap to the nearest corner of the ghost screenregion.

After one corner has been fixed, one can still switch to another corner. To change to another corner, continue to hold down the left button and hold down the right button also. With both buttons down, the cursor can be moved across a screen or to other screens without effect on the ghost screenregion frame. When the right button is released, the cursor will snap to the nearest corner, which will become the moving corner. In this way, the screenregion may be moved all over a screen and to other screens, before its size and screenposition is finalized.

The size of the initial ghost screenregion is controlled by the \textit{MINWIDTH}, \textit{MINHEIGHT}, \textit{OLDREGION}, and \textit{INITCORNERS} arguments.
(GETBOXSCREENREGION WIDTH HEIGHT ORGX ORGY WINDOW PROMPTMSG)

[Function]
Similar to GETBOXREGION. Returns a SCREENREGION that is specified by the user. Performs the same prompting as GETBOXSCREENPOSITION and returns the SCREENREGION specified by the user instead of the SCREENPOSITION of its lower left corner.

Color Windows and Menus

The Xerox Lisp window system provides both interactive and programmatic constructs for creating, moving, reshaping, overlapping, and destroying windows in such a way that a program can use a window in a relatively transparent fashion (see page XXX). Menus are a special type of window provided by the window system, used for displaying a set of items to the user, and having the user select one using the mouse and cursor. The menu facility also allows users to create and use menus in interactive programs (see page XXX). As of the LUTE release of Xerox Lisp, it is possible for the user to create and use windows and menus on the color display.

(CREATEW REGION TITLE BORDERSIZE NOOPENFLG)

[Function]
Creates a new window. REGION indicates where and how large the window should be by specifying the exterior screenregion of the window. In a user environment with multiple screens, such as a black and white screen and color screen both connected to the same machine, there is a new special problem in indicating which screen the REGION is supposed to be a region of. This problem is solved by allowing CREATEW to take screenregion arguments as REGION. For example,

(setq foo (createw (create screenregion
                    (colorscreen)
                    left _ 20
                    bottom _ 210
                    width _ 290
                    height _ 170)
                    "foo window")))

creates a window titled "FOO WINDOW" on the color screen. To create a window on the black and white screen, the user should use SCREEN _ (MAINSCREEN) in the CREATE SCREENREGION expression. Note that it is still perfectly legal to pass in a REGION that is a region, not a screenregion, to CREATEW, but it is preferable to be passing screenregions rather than regions to CREATEW. This is because when REGION is a region, RÉGION is disambiguated in a somewhat arbitrary manner that may not always turn out to be what the user was hoping for.

When REGION is a region, REGION is disambiguated by coercing REGION to be a screenregion on the screen which currently contains the cursor. This is so that software calling CREATEW with regions instead of screenregions tends to do the right thing in a user environment with multiple screens.
(WINDOWPROP WINDOW PROP NEWVALUE) [NoSpread Function]

If PROP='SCREEN, then WINDOWPROP returns the screen WINDOW is on. If NEWVALUE is given, (even if given as NIL), with PROP='SCREEN, then WINDOWPROP will generate an error. Any other PROP name is handled in the usual way.

(OPENWINDOWS SCREEN) [Function]

Returns a list of all open windows on SCREEN if SCREEN is a screen datatype such as (MAINSCREEN) or (COLORSCREEN). If SCREEN=NIL, then SCREEN will default to the screen containing the cursor. If SCREEN=T, then a list of all open windows on all screens is returned.

Color Fonts

The user can create color fonts and specify in the font profile that certain color fonts be used when printing in color.

Color Font Creation

The user can create and manipulate color fonts through the same functions that are used to create and manipulate black and white fonts. This is made possible in some cases by there being new ways to call familiar font functions.

(FONTCREATE FAMILY SIZE FACE ROTATION DEVICE NOERRORFLG CHARSET) [Function]

In addition to creating black and white fonts, FONTCREATE can be used to create color fonts. For example,

(FONTCREATE 'GACHA 10
  '(BOLD REGULAR REGULAR YELLOW BLUE)
  0 '8DISPLAY)

will create an 8 bit per pixel font with blue letters on a yellow background. The user indicates the color and bits per pixel of the font by the FACE and DEVICE arguments passed to FONTCREATE. DEVICE='8DISPLAY means to create an 8bpp font and DEVICE='4DISPLAY means to create a 4bpp font. A color font face is a 5 tuple,

(WEIGHT SLOPE EXPANSION BACKCOLOR FORECOLOR)

whereas a black and white font face is just a 3 tuple,

(WEIGHT SLOPE EXPANSION)

The FORECOLOR is the color of the characters of the font and the BACKCOLOR is the color of the background behind the characters that gets printed along with the characters. Both BACKCOLOR and FORECOLOR are allowed to a color name, color number, or any other legal color representation. A color font face can also be represented as a LITATOM. A three character atom such as MRR or any of the special atoms STANDARD, ITALIC, BOLD, BOLDITALIC can optionally be continued by hyphenating on BACKCOLOR and FORECOLOR suffixes. For example,
COLOR

MR-R-YELLOW-BLUE
BOLD-YELLOW-RED
ITALIC-90-200
BRR-100-53

are acceptable color font faces. Hence,

(FONTCREATE 'GACHA 10 'BOLD-YELLOW-BLUE 0 '8DISPLAY)

will create a color font. LITATOM FACE arguments fall into one of
the following patterns:

- wse                        wse-backcolor-forecolor
- STANDARD       STANDARD-backcolor-forecolor
- ITALIC                  ITALIC-backcolor-forecolor
- BOLD                    BOLD-backcolor-forecolor
- BOLDITALIC     BOLDITALIC-backcolor-forecolor

where w=B, M, or L; s=I or R; e=R, C, or E; backcolor=a color name
or color number; and forecolor=a color name or color number.

(FONTPROP FONT PROP)

[Function]

Returns the value of the PROP property of font FONT. Besides
black and white font properties, the following font properties are
recognized:

FORECOLOR  The color of the characters of the font, represented as a color
number. This is the color in which the characters of the font will
print.

BACKCOLOR  The color of the background of the characters of the font,
represented as a color number. This is the color in which the the
background of characters of the font will print. A font with red
characters on a yellow background would have a red FORECOLOR
and a yellow BACKCOLOR.

Color Font Profiles

Font profiles are the facility PRETTYPRINT uses to print different
elements (user functions, system functions, clisp words, comments,
etc.) in different fonts to emphasize (or deemphasize) their
importance, and in general to provide for a more pleasing
appearance. The user can specify that different colors of fonts be
used for different kinds of elements when printing in color. A well
chosen font profile will allows user to DEDIT functions, PP
functions, and SEE source files in color, for example. A
FONTPROFILE such as

(((DEFAULTFONT 1 (GACHA 10)
  (GACHA 8)
  (TERMINAL 8)
  (4DISPLAY (GACHA 10 MRR-WHITE-RED))
  (8DISPLAY (GACHA 10 MRR-WHITE-RED)))

(BOLDFONT 2 (HELVETICA 10 BRR)
  (HELVETICA 8 BRR)
  (MODERN 8 BRR)
  (4DISPLAY (HELVETICA 10 BRR-WHITE-MAGENTA)))

KALEIDOSCOPE MANUAL - 16-JAN-89 - Dev. Draft
would have comments print in green and clisp words print in blue while ordinary atoms would print in red.

Not all combinations of fonts will be aesthetically pleasing and the user may have to experiment to find a compatible set.

The user should indicate what font is to be used for each font class by calling the function FONTPROFILE:

\[
\text{(FONTPROFILE PROFILE)}
\]

Sets up the font classes as determined by \text{PROFILE}, a list of elements which defines the correspondence between font classes and specific fonts. Each element of \text{PROFILE} is a list of the form:

\[
\left(\text{FONTCLASS FONT\# DISPLAYFONT PRESSFONT INTERPRESSFONT (OTHERDEVICE1 OTHERFONT1) ... (OTHERDEVICEn OTHERFONTn)}\right)
\]

\text{FONTCLASS} is the font class name and \text{FONT\#} is the font number for that class. \text{DISPLAYFONT}, \text{PRESSFONT}, and \text{INTERPRESSFONT} are font specifications (of the form accepted by \text{FONTCREATE}) for the fonts to use when printing to the black and white display and to Press and Interpress printers respectively. The appearance of color fonts can be affected by including an \text{(OTHERDEVICEi OTHERFONTi)} entry where \text{OTHERDEVICEi} is either \text{4DISPLAY} or \text{8DISPLAY} for a 4 bits per pixel or 8 bits per pixel color font and \text{OTHERFONTi} is a color font specification such as \text{(GACHA 10 MRR-WHITE-RED)}.

\text{FONTPROFILE [Variable]}  

This is the \text{variable} used to store the current font profile, in the form accepted by the \text{function FONTPROFILE}. Note that simply editing this value will not change the fonts used for the various font classes; it is necessary to execute \text{(FONTPROFILE FONTPROFILE)} to install the value of this variable.
Using Color

The current color implementation allows display streams to operate on color bitmaps. The two functions DSPCOLOR and DSPBACKCOLOR set the color in which a stream draws when the user defaults a color argument to a drawing function.

\[(DSPCOLOR COLOR STREAM)\] [Function]

sets the foreground color of a stream. It returns the previous foreground color. If \(COLOR\) is NIL, it returns the current foreground color without changing anything. The default foreground color is MINIMUMCOLOR=0, which is white in the default color maps.

\[(DSPBACKCOLOR COLOR STREAM)\] [Function]

sets the background color of a stream. It returns the previous background color. If \(COLOR\) is NIL, it returns the current background color without changing anything. The default background color is (MAXIMUMCOLOR BITSPERPIXEL)=15 or 255, which is black in the default color maps.

The BITBLT, line-drawing routines, and curve-drawing routines routines know how to operate on a color-capable stream. Following are some notes about them.

BITBLTing in Color

If BITBLTing from a color bitmap onto another color bitmap of the same bpp, the operations PAINT, INVERT, and ERASE are done on a bit level, not on a pixel level. Thus painting color 3 onto color 10 results in color 11.

If BITBLTing from a black-and-white bitmap onto a color bitmap, the one bits appear in the DSPCOLOR, and the zero bits in DSPBACKCOLOR. BLTing from black-and-white to color is fairly expensive; if the same bitmap is going to be put up several times in the same color, it is faster to create a color copy and then BLT the color copy.

If the source type is TEXTURE and the destination bitmap is a color bitmap, the Texture argument is taken to be a color. Thus to fill an area with the color BLUE assuming COLORSTR is a stream whose destination is the color screen, use (BITBLT NIL NIL NIL COLORSTR 50 75 100 200 'TEXTURE 'REPLACE 'BLUE).

Drawing Curves and Lines in Color

For the functions DRAWCIRCLE, DRAWELLIPSE, and DRAWCURVE, the notion of a brush has been extended to include a color. A BRUSH is now (BRUSHSHAPE BRUSHSIZE BRUSHCOLOR). Also, a brush can be a bitmap (which can be a color bitmap).

Line-drawing routines take a color argument which is the color the line is to appear in if the destination of the display stream is a color bitmap.
(DRAWLINE X1 Y1 X2 Y2 WIDTH OPERATION
STREAM COLOR) [Function]

(DRAWTO X Y WIDTH OPERATION STREAM COLOR)[Function]

(RELDRAWTO X Y WIDTH OPERATION
STREAM COLOR) [Function]

(DRAWBETWEEN POS1 POS2 WIDTH OPERATION
STREAM COLOR) [Function]

If the COLOR argument is NIL, the DSPCOLOR of the stream is used.

**Printing in Color**

Printing only works in REPLACE mode. The characters have a background color and a foreground color determined by the font face of the font the characters are being printed with.

Example of printing to an 8bpp color screen:

```
(SETQ FOO (CREATEW (CREATE SCREENREGION

(COLORSCREEN)

LEFT _ 20
BOTTOM _ 210
WIDTH _ 290
HEIGHT _ 170)

"FOO WINDOW")

(DSPFONT (FONTCREATE 'GACHA

10

'MRR-YELLOW-GREEN

0

'8DISPLAY)

FOO)

(PRINT 'HELLO FOO) ; will print in green against a yellow background.
```
Operating the Cursor on the Color Screen

The cursor can be moved to the color screen. The cursor can be moved to the color screen by sliding the cursor off the left or right edge of the black and white screen on to the color screen or by calling function CURSORPOSITION or CURSORSCREEN.

**(CURSORPOSITION NEWPOSITION - -)**  [Function]

NEWPOSITION can be a position or a screenposition.

**(CURSORSCREEN SCREEN XCOORD YCOORD)**  [Function]

Moves the cursor to the screenposition determined by SCREEN, XCOORD, and YCOORD. SCREEN should be the value of either (COLORSCREEN) or (MAINSCREEN).

While on the color screen, the cursor is placed by doing BITBLTs in software rather than with microcode and hardware as with the black and white cursor. It is automatically taken down whenever an operation is performed that changes any bits on the color screen. The speed of the color cursor compares well with that of the black and white cursor but there can be a noticeable flicker when there is much input/output to the color screen. While the cursor is on the color screen, the black-and-white cursor is cleared giving the appearance that there is never more than one cursor at a given time.

Miscellaneous Color Functions

**(COLORIZEBITMAP BITMAP 0COLOR 1COLOR BITSPERPIXEL)**  [Function]

creates a color bitmap from a black and white bitmap. The returned bitmap has color number 1COLOR in those pixels of BITMAP that were one and 0COLOR in those pixels of BITMAP that were zero. This provides a way of producing a color bitmap from a black and white bitmap.

**(UNCOLORIZEBITMAP BITMAP COLORMAP)**  [Function]

creates a black and white bitmap from a color bitmap.

**(SHOWCOLORTESTPATTERN BARSIZE)**  [Function]

displays a pattern of colors on the color display. This is useful when editing a color map. The pattern has squares of the 16 possible colors laid out in two rows at the top of the screen. Colors 0 through 7 are in the top row, and colors 8 through 15 are in the next row. The bottom part of the screen is filled with bars of BARSIZE width with consecutive color numbers. The pattern is designed so that every color has a border with every other color (unless BARSIZE is too large to allow room for every color—about 20).
In the list below, rank (between 1 and 5, 1 highest to 5 lowest) the priority of each item or feature you would be interested in. OR feel free to add to the list of things you might like to see.

Immediate bare-bones capabilities
(versus) Not so immediate richer capabilities
Flood fill
INTRODUCTION

As the name suggests, LAFITEABBREV gives you the ability to refer to mail addresses using personal, easy to remember abbreviations. If you define (say) "Joe" to stand for "John Doe:Xyzzy North:ACME Corporation", then all you need to type to send a message to Joe is Joe. If you don’t want to be bothered with his long address even when you read messages from him, you can optionally let the abbreviation apply both ways. When receiving messages from him (or where you both are recipients), his full address will be replaced by your abbreviation and thus only show as simple Joe in all header lines and the Lafite browsers.

In addition to this rather straightforward string-to-string text substitution, LAFITEABBREV will also do pattern matching using multiple wildcards in both the abbreviation and fully expanded strings. This is of course particularly useful for cases when many people share the same substring in their addresses, such as the NS domain. Say for example that Jane Doe worked at the same place as her brother. Then we could abbreviate "*:Xyzzy North:ACME Corporation" as "*:X:ACME" and refer to John as "John Doe:X:ACME" and Jane as "Jane Doe:X:ACME". In fact, we could even create the abbreviation "* Doe" => "* Doe:Xyzzy North:ACME Corporation" and refer to our friends as just "John Doe" and "Jane Doe" with the obvious expansions.

Abbreviations are purely personal; all other recipients of the message will see the real, expanded addresses. The abbreviations are on a strictly one-to-one mapping basis, i.e. you can’t implement private DLs by making an abbreviation expand into more than one address. As is the case with normal mail addresses, all abbreviations and expansions are case-insensitive.

EXAMPLES

An individual abbreviation: Sir => Tom Moran:EuroPARC:RX
A group abbreviation: * (APU) => *@MRC-APU.CAM.AC.UK:GV:Xerox
Hiding the local domain: * => *:EuroPARC:RX
Hiding gateway syntax: *@.EDU => *%*:EDU:Xerox
MODULE EXPLANATION

LAFITEABBREV advises the Lafite NSMAIL routines that encode and decode string addresses to NSNAMEs. It operates transparently and automatically with respect to the rest of the mail system while being controlled by the variables mentioned below. The most central of these is the list of abbreviations itself, LAFITE.ABBREVS:

LAFITE.ABBREVS [Variable]

This variable contains all abbreviations and their corresponding real addresses. It is formed as a list of translations, where each translation is a list of (up to) four elements: the abbreviation, the full address, an optional direction, and an optional comment. Both the abbreviation and full address should be strings; the direction may be either of :IN, :OUT, :BOTH, :NONE, or left empty in which case it defaults to :BOTH. Finally, the comment, if present, should be in normal Interlisp format, i.e. (* text). It has no functional purpose and serves only as a memory aid. A full translation thus looks like:

(abbreviation full-address direction comment)

eg: ("Pete" "Piotr Kropotkin:RusskiPARK:ZeRoks" :OUT (* ; "Old chap"))

which means that an address of Pete will be expanded to Piotr Kropotkin:RusskiPARK:ZeRoks whenever you send a message to him, but his full address will always be presented as such when receiving mail from him or whenever his address is mentioned in the header lines of a message you receive. For an explanation on translation directions, read more below.

The default list of translations is:

*@* "@"*:GV:Xerox :IN
*@* "%"*:GV:Xerox
*@*.* "%"*:Xerox :IN
*.pa "pa":PA:Xerox

This will present most ARPA Internet addresses in their proper form and also allow you to see Palo Alto Grapevine addresses as if you were on Grapevine. Note that the first rule above is necessary because some external GV addresses are being enclosed in double quotes by the GV/XNS Mail Gateway (for no apparent reason, one might add, since there exist no common conventions for parsing such constructs and it technically is malforming the address).

LAFITE.ABBREV.DIRECTIONS [Variable]

This variable controls the overall behaviour of LAFITEABBREV. It can take either of the following values:

:IN Translate full addresses to abbreviations when receiving messages.
:OUT Translate abbreviations to full addresses when sending messages.
:BOTH Both of the above.
:NONE Neither of the above, i.e. don’t ever do any translations at all.

The setting of LAFITE.ABBREV.DIRECTIONS limits the scope of individual translation rules, so if you for example set LAFITE.ABBREV.DIRECTIONS to :OUT, no translations will ever be done on incoming messages, not even if a rule has an explicit direction of :IN or :BOTH.

The default value of LAFITE.ABBREV.DIRECTIONS is :BOTH.
LAFITE.ABBREV.MOVE.GAZE.RIGHT

A quite handy application of LAFITE.ABBREV is to present ARPA Internet (RFC-822) addresses in their proper form, ie. translating addresses like Jakobsson%Score.Stanford:EDU:Xerox to Jakobsson@Score.Stanford.EDU and vice versa. Unfortunately, since the pattern matching algorithm uses a strict left-to-right order, an address like user%host%foo.bar:EDU:Xerox would end up translated as user@host%foo.bar.EDU, which is not quite what was intended. However, if LAFITE.ABBREV.MOVE.GAZE.RIGHT is set to a non-NIL value, translations resulting in a percent sign coming anywhere after an atsign will be automatically changed so that the rightmost percent sign is substituted for an atsign instead. Don’t worry too much if you didn’t understand any of the above; just think of it as applied magic (aka a kludge).

The default value of LAFITE.ABBREV.MOVE.GAZE.RIGHT is T.

LAFITE.ABBREV.TRACE

Set this variable to T or a window of your choice (eg the PROMPTWINDOW) to trace all translations that are done for you. Reset to NIL to stop tracing.

The default value of LAFITE.ABBREV.TRACE is NIL.

(LAFITE.ABBREV ADDRESS DIRECTION)

This is the function that does the actual translations; it is used automatically by LAFITE.ABBREV’s advices, but mentioned here if you want to test it manually or use it elsewhere. The address should be the string to expand/abbreviate and the direction either of :IN or :OUT, indicating whether this address is about to be sent or received. The result is the translated address.

(LAFITE.ABBREV.MATCH PATTERN STRING TEMPLATE)

This is a small, case insensitive pattern matching algorithm supporting multiple wildcards on both the pattern and the template side. Asterisks will match substrings of zero or more characters, anything else has to match literally for the comparison to succeed. The result is constructed using the template, if supplied. Some examples:

<table>
<thead>
<tr>
<th>PATTERN</th>
<th>STRING</th>
<th>TEMPLATE</th>
<th>RESULT</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Foo&quot;</td>
<td>&quot;FOO&quot;</td>
<td>NIL</td>
<td>&quot;FOO&quot;</td>
</tr>
<tr>
<td>&quot;Foo&quot;</td>
<td>&quot;FOO&quot;</td>
<td>&quot;Bar&quot;</td>
<td>&quot;Bar&quot;</td>
</tr>
<tr>
<td>&quot;Foo*Bar&quot;</td>
<td>&quot;FOOBAZBAR&quot;</td>
<td>NIL</td>
<td>&quot;FOOBAZBAR&quot;</td>
</tr>
<tr>
<td>&quot;Foo*Bar&quot;</td>
<td>&quot;FOOBAZBAR&quot;</td>
<td>&quot;1*2&quot;</td>
<td>&quot;1BAZ2&quot;</td>
</tr>
<tr>
<td>&quot;Foo<em>B</em>ar&quot;</td>
<td>&quot;FOOBAZBAR&quot;</td>
<td>&quot;1<em>2</em>3&quot;</td>
<td>&quot;12AZB3&quot;</td>
</tr>
<tr>
<td>&quot;Foo<em>B</em>ar&quot;</td>
<td>&quot;FOOBAZBA&quot;</td>
<td>&quot;1<em>2</em>3&quot;</td>
<td>NIL</td>
</tr>
</tbody>
</table>

BUGS

Only XNS is supported (ie. GV addresses aren’t touched). Messages from you won’t be presented as "To: <Recipients>" in the browser if you abbreviate your own name. No nice’n’cuddly user interface included.
This document last edited December 3, 1987.

INTRODUCTION

It is common practice in conversations conducted via electronic mail to include bits and pieces of previous messages in reply messages. The included text is indented to set it apart visually from the main body of the message. LAFITE-INDENT provides some support for this style of e-mail use.

USING LAFITE-INDENT

LAFITE-INDENT adds the item "Indent" to the default TEdit menu. Selecting the "Indent" item indents the current selection. In addition, it inserts carriage–returns in the text to ensure that no line in the selection is too long. The particular method of indentation is controlled by global variables described below. The "Indent" menu item also contains a number of subitems described below.

Indent [TEdit menu item]

This item will indent the current selection by prepending (the value of) *TEDIT-INDENT-STRING* to each line. To ensure that resulting text is properly formatted, lines will be broken to contain no more than *TEDIT-INDENT-LINE-LENGTH* characters. Existing carriage returns in the current selection may be replaced by spaces. For example the result of indenting the highlighted text below:

Date: 9 Sep 86 13:34:12
Subject: Eat?
To: JFrench
From: Wu

Hi Jane!
I was wondering if you might be able to make it over to our house tonight for dinner. Carol’s got a turkey that she wants to BBQ. Hank is coming over with a couple of bottle of his home brew beer, and Diane’s got a salad fresh from her garden.

Even if you can’t make it for dinner, you might want to stop by to visit. Remember Crazy Tom from Berkeley? He’s in the area on a job interview and he’ll be there.

Let me know soon...

Date: 9 Sep 86 13:34:12
Subject: Eat?

From: Wu

Hi Jane! I was wondering if you might be able to make it over to our house tonight for dinner. Carol’s got a turkey that she wants to BBQ. Hank is coming over with a couple of bottle of his home brew beer, and Diane’s got a salad fresh from her garden.
Even if you can’t make it for dinner, you might want to stop by to visit. Remember Crazy Tom from Berkeley? He’s in the area on a job interview and he’ll be there.

Let me know soon...

---

**Example 1: Before and after "Indent"**

**Indent & keep lines**

Like Indent, Indent & keep lines will indent the current selection. Unlike Indent, returns in the current selection are kept. This can be useful when indenting the headers of mail messages. For example the result of "Indent & keep lines" on the following text:

```
Date: 9 Sep 86 13:34:12
Subject: Eat?
To: JFrench
From: Wu

Hi Jane!
```

```
Date: 9 Sep 86 13:34:12
Subject: Eat?
To: JFrench
From: Wu

Hi Jane!
```

---

**Example 2: Before and after "Indent & keep lines"**

If Indent had been used instead of "Indent & keep lines", the lines would have been run together, resulting in:

```
Date: 9 Sep 86 13:34:12 Subject: Eat? To: JFrench From: Wu

Hi Jane! I was wondering if you might be able to make it over to our house tonight for dinner. Carol’s got a turkey that she wants to BBQ, Hank is coming over with a couple of bottle of his home brew beer, and Diane’s got a salad fresh from her garden.

Even if you can’t make it for dinner, you might want to stop by to visit. Remember Crazy Tom from Berkeley? He’s in the area on a job interview and he’ll be there.

Let me know soon...
```
Hi Jane! I was wondering if you might be able to make it over to our house tonight for dinner. Carol’s got a turkey that she wants to BBQ, Hank is coming over with a couple of bottle of his home brew beer, and Diane’s got a salad fresh from her garden.

Even if you can’t make it for dinner, you might want to stop by to visit. Remember Crazy Tom from Berkeley? He’s in the area on a job interview and he’ll be there.

Let me know soon...

Example 3: Before and after "Unindent"

Open line [TEdit menu item]

"Open line" will open a blank line at the current position in the textstream. Text following the current position maintain its distance from the left margin. For example:

Hi Jane! I was wondering if you might be able to make it over to our house tonight for dinner. Carol’s got a turkey that she wants to BBQ, Hank is coming over with a couple of bottle of his home brew beer, and Diane’s got a salad fresh from her garden.

Example 4: Before and after "Open line"

Insert <RETURN>s [TEdit menu item]

This will replace TEdit’s line breaks with real carriage returns (in the current selection). This way you know what line breaks recipients of your message will see.

Break long lines [TEdit menu item]

This item inserts <RETURN>s in the text, making sure that no line contains more than "TEDIT-INDENT-LINE-LENGTH" characters. Functionally, this is just like the "Indent" item, but without the indentation.

VARIABLES

The following variables can be changed to tailor how text is indented. They are defined as INITVARS in LAFITE-INDENT, so they can be given different values before or after loading the LAFITE-INDENT.
*TEDIT-INDENT-STRING* [GlobalVar]
This is the string that is used to indent each line of text. The default value is (the value of) (ALLOCSTRING 4 " "); a string consisting of four spaces.

*TEDIT-INDENT-LINE-LENGTH* [GlobalVar]
This is the maximum number of characters on a line that the indentation will allow. Extra line breaks will be added to ensure that no line has more than *TEDIT-INDENT-LINE-LENGTH* characters. The default value is 72.

**BUGS**
Unfortunately, these operations are not (always) UNDOable.
INTRODUCTION

The package LafiteTimedDelete allows users to specify expiration dates on their mail messages as they read them. After a message has expired, it will be marked for deletion the next time the user invokes the command “Delete Expired Msgs”. The package is useful for specifying deletion dates on dated information such as announcements of talks. It can also be used as a “sunset” clause on certain messages, saying in effect that if a message hasn’t been acted on by this date, mark it for deletion. Since the command for deleting expired messages only marks them for deletion and doesn’t actually delete them, the user can always intervene and save the message from deletion.

SETTING EXPIRATION DATES

To set an expiration date, simply select the message(s) that you wish to have deleted at some future time, and then click the “Delete” command on the Lafite browser with the middle button. This will produce a menu of durations like this:

<table>
<thead>
<tr>
<th>Expiration date</th>
</tr>
</thead>
<tbody>
<tr>
<td>now</td>
</tr>
<tr>
<td>one day</td>
</tr>
<tr>
<td>two days</td>
</tr>
<tr>
<td>four days</td>
</tr>
<tr>
<td>one week</td>
</tr>
<tr>
<td>two weeks</td>
</tr>
<tr>
<td>one month</td>
</tr>
<tr>
<td>two months</td>
</tr>
<tr>
<td>four months</td>
</tr>
<tr>
<td>eight months</td>
</tr>
<tr>
<td>forever</td>
</tr>
</tbody>
</table>
Selecting a duration will determine how long until the message(s) expire, measured from the current day. If no selection is made, then the operation is aborted.

When a message is marked for future deletion, a number from 1 to 9 will appear in the mark field to the left of the message id. This number indicates how long until the message should expire, measured from the date of the message. The number is approximately the logarithm of the number of days until the message expires. Thus "1" means 1 day, "2" means 2 days, "3" means 4 days, "4" means 1 week, "5" means 2 weeks, "6" means 1 month, "7" means 2 months, "8" means 4 months, and "9" means 8 months.

Selecting the duration "now" is equivalent to normal deletion. Selecting the duration "forever" is equivalent to undeletion, with the side effect that all expiration marks are removed.

DELETING EXPIRED MESSAGES

To delete all of the messages that have expired, invoke the "Delete Expired Msgs" command in the browser’s middle button menu. (The middle button menu is obtained by holding down the middle button while over the black bar in the mail folder.) The program will then examine all of the messages in that folder, looking for messages that have expired. When it finds a message that has expired, it will mark it to be deleted. Finally, it will print in the browser’s prompt window the number of messages that it marked for deletion.

Messages expire at 12 noon on the Nth day from the date given in the date field of browser. Thus if on Wednesday, October 7th you mark a message sent that day to be deleted in two days, then the message would be deletable after 12 noon on Friday, October 9th. However, the messages don’t actually get marked for deletion until you invoke the command "Delete Expired Msgs". You usually only need to invoke this command once per day since no new messages will expire later on, so if you are unhappy with 12 noon as an expiration time, you can move it by only invoking the command after the day is over (or early in the morning the next day.)

CAVEATS

Since LAFITETIMEDELETES uses the mark field of the message header to save the information about how long until the message expires, you may run into conflicts with other uses of the mark field. For instance, if you set the expiration date on a message and then forward it, you will lose the expiration information because the forwarder puts an "f" in the mark field. If you notice this, you can restore the mark manually by clicking the mark field and typing a new number.

Also, since LAFITETIMEDELETES is limited in the number of distinctions that it can make in the time until expiration, it may set the expiration of a message to a time much later than you might want. For instance, suppose that you are reading a message that was mailed yesterday and you want to set its expiration date to one week from today. Since it can only record expirations from the date of the message and not from the current date, it must set the message to expire in eight days. If the program used the one week expiration mark, then the message would expire in seven days, or six days from
today. Since that might expire the message before you intend, the program plays it safe and uses the
two week expiration mark. A six day expiration might be OK with the user, but it would be awkward to
ask him, especially if there were multiple messages selected. If the user is dissatisfied with the mark,
he can always change it manually as described above.

Please send all comments, questions, and bug reports to Maxwell.pa.
MAILSCAVENGE
For Scavenging Mail Folders

The Lisp Library package MAILSCAVENGE is used to rebuild the internal pointers in a mail file that has been damaged. Lafite generally reports “Can’t parse file” and terminates its Browse command when it detects damage in a file. The simplest remedy is to call MAILSCAVENGE, then browse the file again.

```
(MAILSCAVENGE FILENAME ERRORMSGSTREAM TEMPDIR)  [Function]
```

This function scavenges the file named FILENAME. FILENAME defaults to extension MAIL and your Lafite directory, exactly as with Lafite’s Browse command. If ERRORMSGSTREAM is specified, it is a stream on which MAILSCAVENGE writes information about what it is doing to correct the file. TEMPDIR is a host/directory specification for where MAILSCAVENGE should write its intermediate file. TEMPDIR defaults to {DSK}, unless you are on an 1108 without a local disk file system, in which case it defaults to the same directory as FILENAME.

When MAILSCAVENGE finishes, it asks if you want to replace the original file with the scavenged file. If you reply "No", MAILSCAVENGE returns the name of the temporary file it wrote, which you can then rename or delete as you wish. Ordinarily, you should reply "Yes", unless you find the report of what MAILSCAVENGE had to correct to be suspicious.

```
(MAILSCAVENGE.IN.PLACE FILENAME ERRORMSGSTREAM)  [Function]
```

This is similar to MAILSCAVENGE, but destructively scavenges the file in-place. This is faster than MAILSCAVENGE, but you have to be brave and assume MAILSCAVENGE is not overwriting anything valuable as it scans the file.

This file recognizes and decodes email messages that conform to the MIME internet standard. It interfaces to Lafite so that it can parse the MIME headers and recognize various kinds of attachments. The attachments are represented in the message display window as an image-object box. Clicking on that box will let you extract the attachment and write it to a file on a directory which is obtained by evaluating the value of ATTACHMENTDIR. This is initialized to

(CONCAT "{dsk}/tilde/" (L-CASE (USERNAME)) "/attachments")

which, for example, would evaluate to "{dsk}/tilde/kaplan/attachments".

The MIME package tries to show text attachments in-line, and it offers a Print option for attachments (or even just included text) that it recognizes as Postscript.

The extracted files can be accessed by standard PC software packages. For certain Mac-derived application types, it tries to provide the appropriate PC extension so that double clicking will launch the appropriate application.
INTRODUCTION

The module NSMAIL implements the protocols to allow Lafite to be used to send and retrieve Xerox NS Mail. Load the file NSMAIL.LCOM. To run this in Lyric, you must have loaded the LispUsers module NSRANDOM as well (q.v. for important loading information). If you don't have NSRANDOM loaded, you can't use the "Put to file" command described below.

If you have both Grapevine and NSMAIL implementations loaded, you must set Lafite's mode to NS. Use the "NS Mode" subitem underneath Lafite's Quit command, or call (LAFITEMODE 'NS). You must also be a registered NS user, and have a mailbox.

ATTACHMENTS

The main difference between this and earlier versions of NSMAIL is that "attachments" are no longer left in your mailbox to be read later with, for example, Viewpoint. Instead, Lafite retrieves the entire attachment and encapsulates it into an image object that is enclosed as part of the text message, immediately following the header. A typical attachment appears in a mail message as:

![Attachment: Viewpoint Document]

If you click inside the object with any mouse button, you are offered a menu of things you can do with the attachment. The choices vary according to the type of attachment:

- **View as text**: This brings up a window in which is displayed the raw content of the attachment as ascii bytes. Runs of non-ascii bytes are replaced by nulls to reduce the amount of garbage. Some attachments are utter gibberish, but some, such as Viewpoint documents and Interpress masters, contain sections that are plain text. With this command, you may be able to decide whether you care to do anything further with the attachment. (Sorry, there is no Viewpoint to TEdit converter, nor are there plans for one.)

- **Put to file**: This prompts you for a file name, and creates a file to contain the attachment. The file must be on an NS file server for this command to be very useful; otherwise, information will be lost. Once the file is so stored, you can retrieve it from Viewpoint and manipulate it just as if you had originally retrieved it as mail in Viewpoint.
Send to Printer  This command is only available for attachments that are in the form of an Interpress master. The command prompts you for a printer (must be one that accepts Interpress, of course), and sends the attachment to it for printing.

Expand folder   This command is only available for attachments that are in the form of a "folder". A folder is a mechanism for collecting several objects into a single one. The Expand folder command splits the attachment up into its component objects, each of which can be manipulated in the same way as a top-level attachment. For example, if the folder contains an Interpress master, you can print it.

If you use the Put to file command on a folder, the name component of the file name you type will be treated as the name of a new subdirectory, and the components of the folder will appear as files in that subdirectory. For other types of attachments, Put to file (usually) produces an ordinary (non-directory) file.

Messages containing attachments are otherwise just like formatted messages—you can move them to other folders, and you can forward them (assuming the mail is received by another Lafite recipient and did not have to pass through a mail gateway).

There is currently no mechanism for creating your own attachments to send to other users.

MISCELLANY

If you prefer the old behavior of leaving the attachments behind in the mailbox, set the variable NSMAIL.LEAVE.ATTACHMENTS to T, but this use is discouraged. You must take care to regularly retrieve your mail from somewhere (such as Viewpoint) that will flush out all the mail; otherwise, the mail with attachments, whether you want them or not, accumulate on the server.

When in NS mode, Lafite will want your NS login identity. Normally, if your NS password differs from your default password, you will be prompted to login. You can also call (LOGIN '|NS::|) yourself to set your NS login.

You can freely intermix Grapevine and NS mail in the same mail folder if you like, but the Answer command always treats the selected message as if it were one in the current mode. So if you try to answer a Grapevine message while in NS mode, some confusion may result. Also, the status window always shows you mail status only of the current mode.
UNIXMAIL

By: Bob Bane (Bane.mv@envos.Xerox.com)

INTRODUCTION

UNIXMAIL is a new mail sending and receiving mode for Lafite. It sends mail via Unix hosts using the SMTP mail transfer protocol and can receive mail either by reading a Unix mail spool file or by calling the Berkeley mail program.

INSTALLATION

Turn Lafite off, load the file UNIXMAIL, make sure UNIXMAIL is configured appropriately (check the settings of the variables below, and make sure any other modules UNIXMAIL may need are loaded), then restart Lafite. If you are running Lafite on a machine that is isolated from the Xerox mail environment, you will probably want to set the variable LAFITE.USE.ALL.MODES to NIL and call (LAFITEMODE 'UNIX) before you turn Lafite back on.

CONFIGURING

See SENDING MAIL and RECEIVING MAIL below for the exact meanings of the variables you will be asked to set.

D-machines:
UNIXMAIL.SEND.MODE must be set to SOCKET and UNIXMAIL.SEND.HOST must be set to the name of a TCP host that will accept SMTP connections. UNIXMAIL.RECEIVE.MODE must be set to SPOOL and UNIXMAIL.SPOOL.FILE must be set to the pathname of your Unix mail spool file.

Unix-based emulators:
The default values of UNIXMAIL.SEND.MODE and UNIXMAIL.RECEIVE.MODE (PROCESS and SPOOL, respectively) will work if you normally send and receive mail from the machine where Medley is running.

OTHER MODULES YOU MAY NEED

UNIXMAIL may need other library modules to work. The modules needed vary depending on what hardware you are using:

D-machines:
TCP is mandatory for Unix sending and may be used for Unix receiving, NFS is optional for Unix receiving

Unix-based emulators:
one of TCPOPS or UNIXCOMM is mandatory for sending

SENDING MAIL

UNIXMAIL can send mail in one of two ways, depending on the setting of UNIXMAIL.SEND.MODE:

UNIXMAIL.SEND.MODE [Variable]

If its value is the atom PROCESS, UNIXMAIL will send mail by doing SMTP with a Unix process-stream, normally running /usr/etc/mconnect. This option only works on Medley running one of the Unix-based emulators.

If its value is the atom SOCKET, UNIXMAIL will send mail by doing SMTP with a TCP host. For this to work, an appropriate version of TCP must be loaded: either the TCP library module for D-machines or the TCPOPS library module for emulators that support it.
UNIXMAIL.SEND.MODE defaults to PROCESS.

Each of these send modes can be configured as well:

**UNIXMAIL.SEND.PROCESS** [Variable]

When UNIXMAIL.SEND.MODE is PROCESS, the value of this variable is the program run to create the SMTP process-stream. Initially the string "/usr/etc/mconnect"

**UNIXMAIL.SEND.HOST** [Variable]

When UNIXMAIL.SEND.MODE is SOCKET, the value of this variable is the name of the host UNIXMAIL will attempt to contact via TCP to open an SMTP stream over socket 25. Initially NIL; on a Unix-based emulator this means to try the machine Medley is running on. This variable must be set when running on a D-machine.

**UNIXMAIL.WRAP.LINES** [Variable]

This flag controls whether or not outgoing mail has its lines word-wrapped to a fixed length. It defaults to T, meaning word-wrapping is done. UNIXMAIL patches the Change Mode menu entry of the standard Lafite message form, adding an entry for toggling UNIXMAIL.WRAP.LINES:

```
Mail mode
Change Mode
Line wrap On
```

**UNIXMAIL.WRAP-LIMIT** [Variable]

If UNIXMAIL.WRAP.LINES is true, this variable is the length in characters to which lines are wrapped. Default value is 72.

**UNIXMAIL.TABWIDTH** [Variable]

If UNIXMAIL.WRAP.LINES is true, this variable is the width tab characters are assumed to expand into for word-wrapping purposes. Default value is 8.

**UNIXMAIL.RECIPIENT.PATTERNS** [Variable]

This variable is a list of patterns that are applied to outgoing UNIXMAIL addresses; it can be used to catch bogus addresses and modify them before sending. List entries are of the form (pattern . function) where pattern is a list of arguments that will be passed along with the address to STRPOS; if STRPOS returns non-NIL, function is called with the address and the result replaces the address. For example, if mail from UUCP host black-silicon is arriving via path mimsy!black-silicon, but the address in its headers is missing the mimsy, this entry on UNIXMAIL.RECIPIENT.PATTERNS will add it back:

```
(("black-silicon!" NIL NIL T) LAMBDA (R) (CONCAT "mimsy!" R))
```

This means that whenever (STRPOS "black-silicon!" address NIL NIL T) returns non-NIL, address will have "mimsy!" prepended before the message is sent.

**RECEIVING MAIL**

UNIXMAIL can receive mail in one of two ways, depending on the setting of UNIXMAIL.RECEIVE.MODE:

**UNIXMAIL.RECEIVE.MODE** [Variable]

If its value is the atom SPOOL, UNIXMAIL will receive mail by reading a Unix mail spool file.

If its value is the atom MAILER, UNIXMAIL will receive mail by running a Berkeley mailer as a Unix process-stream, normally /usr/ucb/mail. This option only works on Medley running one of the
Unix-based emulators, and is a bit slower than SPOOL mode; it is primarily useful when you wish to occasionally switch between Lafite and the Berkeley mailer.

UNIXMAIL.RECEIVE.MODE defaults to SPOOL.

Each of these receive modes can be configured as well:

UNIXMAIL.RECEIVE.PROCESS [Variable]
When UNIXMAIL.RECEIVE.MODE is MAILER, the value of this variable is the program run to create the SMTP process-stream. Initially the string "/usr/ucb/mail -N"; the -N means to not print any banner or read any initialization file on starting the mailer.

UNIXMAIL.DONT.RECEIVE.STATUS [Variable]
When UNIXMAIL.RECEIVE.MODE is MAILER, the value of this variable is a set of message status letters; UNIXMAIL will leave behind any message whose status is included. Initially " ", which means to read all messages regardless of status; another useful value would be "O" which means leave old messages behind.

UNIXMAIL.SPOOL.FILE [Variable]
When UNIXMAIL.RECEIVE.MODE is SPOOL, the value of this variable is the file UNIXMAIL will receive mail from. Any time this file has characters in it, Lafite will say you have new mail; when Lafite gets mail from this file, it will read all messages in the file and then set its size to zero. Initially NIL; on a Unix-based emulator this means to try the file "/{UNIX}/usr/spool/mail/username", where username is the value of (UNIX-USERNAME). To access a Unix mail spool file from a D-machine, it will probably be necessary to load and configure either the TCP or NFS modules and then set UNIXMAIL.SPOOL.FILE appropriately.
MAIKOCOLOR

Introduction

This module is the Envos Lisp software driver for running the COLOR module under Maiko (Maiko is the MACHINETYPE of Medley running on the Sun workstations). The machine independent functionality is provided by and documented with the COLOR module. There are no MAIKOCOLOR functions that the user needs to call directly. The user calls functions described in the COLOR documentation.

Requirements

In order to run COLOR, you need a Sun 3 or Sun 4 with a color display (CG 4), plus a color emulator (lde). COLOR will *not* run on a non-color emulator, attempting to use color capabilities will cause an error trap into URaid. You additionally need:

COLOR
LLCOLOR

Installation

MAIKOCOLOR may be loaded into a sysout running on any D-Machine (or non-color emulator), as long as color is not initialized. Thus an initial sysout can be made which runs on all systems, by loading COLOR, and then writing the sysout.

To install, simply (FILESLOAD 'MAIKOCOLOR), which will load all the additional files necessary for running color.

Initialization

To actually use color, the user must be running on a color capable emulator (lde).

To Initialize color running under Maiko, simply type

(COLORDISPLAY 'ON 'MAIKOCOLOR)
Lisp will permanently allocate a color "screen", and will attempt to map the color frame buffer to that screen.

At this point, the user should refer to the documentation for COLOR.

**Known Bugs**

NOTE: As this is currently unreleased software undergoing active development, this list of bugs should not be construed as being a limitation or defect of the final product. This list is only included to point out the current state of affairs of the software.

1. Color screen is never GC'ed
2. Color TEdit slower than B/W TEdit
3. Can’t create big color windows
INTRODUCTION

The PostScript package defines a set of imageops for printers which understand the PostScript page description language by Adobe. At Beckman we have successfully used TEdit, Sketch, LISTFILES, and HARDCOPYW to an Apple LaserWriter and an AST TurboLaser PS. The PostScript imagestream driver installs itself when it is loaded. All symbols in the PostScript driver are located in the INTERLISP: package.

VARIABLES

POSTSCRIPT.FONT.ALIST [InitVariable]

POSTSCRIPT.FONT.ALIST is an ALIST mapping Xerox Lisp font names into the root names of PostScript font files. It is also used for font family coercions. The default value should be acceptable for any of the fonts which are built into the Apple Laserwriter.

POSTSCRIPTFONTDIRECTORIES [InitVariable]

POSTSCRIPTFONTDIRECTORIES is the list of directories where the PostScript .PSCFONT font files can be found. The default value is: ("{DSK}/usr/local/lde/fonts/postscript") on a Sun or IBM workstation and ("{DSK}<LISPFILES>FONTS>PSC>") for other cases.

POSTSCRIPT.DEFAULT.PAGEREGION [InitVariable]

POSTSCRIPT.DEFAULT.PAGEREGION indicates the area of the page to use for text file listings (i.e. LISTFILES). It is in units of 100'ths of points. The default value is: (4800 4800 52800 70800), which gives left and bottom margins of 0.75 inch and top and right margins of 0.5 inch on 8.5 x 11 paper.

POSTSCRIPT.PAGEREGIONS [InitVariable]

POSTSCRIPT.PAGEREGIONS is an ALIST mapping pagetypes into paper size and actual imageable area on the page. By default, it knows about LETTER, LEGAL, and NOTE pagetypes, and the corresponding sizes and imageable areas for the Apple Laserwriter. Others can be defined by the user by adding the appropriate entries onto this ALIST.

POSTSCRIPT.PAGETYPE [InitVariable]

POSTSCRIPT.PAGETYPE is used by OPENIMAGESTREAM to lookup the paper size and actual imageable area of the page in POSTSCRIPT.PAGEREGIONS to determine the initial margins. This value can be overridden with the PAGETYPE or PAPERTYPE options in the OPENIMAGESTREAM call. The name of the type of page selected is NOT passed through to the PostScript output.
\POSTSCRIPT.MAX.WILD.FONTSIZE [InitVariable]

\POSTSCRIPT.MAX.WILD.FONTSIZE indicates the maximum point size that should be returned from FONTSAVAILABLE when the SIZE argument is wild (i.e. *). All integer point sizes from 1 to \POSTSCRIPT.MAX.WILD.FONTSIZE will be indicated as available. The default value is: 72.

POSTSCRIPT.PREFER.LANDSCAPE [InitVariable]

POSTSCRIPT.PREFER.LANDSCAPE indicates if the OPENIMAGESTREAM method should default the orientation of output files to LANDSCAPE. It can have one of three values: NIL, T, or ASK. NIL means prefer portrait orientation output, T means prefer landscape, and ASK says to bring up a menu to ask the preferred orientation if it wasn’t explicitly indicated in the OPENIMAGESTREAM call (with the ROTATION option). The default value is: NIL. An item (PS Orientation) is added to the Background Menu to let you change the value of this variable.

POSTSCRIPT.TEXTFILE.LANDSCAPE [InitVariable]

POSTSCRIPT.TEXTFILE.LANDSCAPE indicates if the printing of TEXT files (e.g. LISTFILES, ...) should force the orientation of output files to LANDSCAPE. When it is non-NIL the orientation of output files is forced to LANDSCAPE. (There is no ASK option here.) The default value is: NIL.

POSTSCRIPT.BITMAP.SCALE [InitVariable]

POSTSCRIPT.BITMAP.SCALE specifies an independent scale factor for display of bitmap images (e.g. window hardcopies). Values less than 1 will reduce the image size. (I.e. a value of 0.5 will give a half size bitmap image.) The position of the scaled bitmap will still have the SAME lower-left corner (i.e. the scaled bitmap is not centered in the region of the full size bitmap image). The default value is: 1.

**HINT**

Setting POSTSCRIPT.BITMAP.SCALE to 0.96, instead of 1, will give cleaner BITMAP images on a 300 dpi printer. (This corrects for the 72 ppi imagentream vs. the 75 dpi printer, using 4x4 device dots per bitmap pixel.) Also, values of 0.24, 0.48 and 0.72, instead of 0.25, 0.5 and 0.75, will also give cleaner images for reduced size output. In general, use integer multiples of 0.24 for a 300 dpi printer.

POSTSCRIPT.TEXTURE.SCALE [InitVariable]

POSTSCRIPT.TEXTURE.SCALE specifies an independent scale for the display of bitmap textures. The value represents the number of device space units per texture unit (bitmap bit). The default value is 4, which represents each bit of the texture as a 4x4 block, so that textures are approximately the same resolution as on the screen (for 300 dpi output devices, such as the Apple Laserwriter).

The PostScript package extends the allowed representations of a texture, beyond 16-bit FIXP and 16x16 bitmap, to ANY square bitmap. (If the bitmap is not square, its longer edge is truncated from the top or right to make it square.) Use this feature with caution, as large bitmap textures, or sizes other
than multiples of 16 bits square, require large amounts of storage in the PostScript interpreter (in the printer controller), and can cause limitcheck errors when actually printing.

Anywhere that a texture or color can be used on an imagestream or in the specification of a BRUSH, you can instead give a FLOATP between 0.0 and 1.0 (inclusive) to represent a PostScript halftone gray shade. (0.0 is black and 1.0 is white. Specifically, the value sets the brightness of the shade.) The value you specify will not be range checked, and will be passed directly through to the PostScript setgray operator. (E.g. you can pass 0.33 as the color to DRAWLINE to get a dark gray line with approximately 67% of the pixels in the line black.)

**POSTSCRIPT.IMAGESIZEFACTOR**

POSTSCRIPT.IMAGESIZEFACTOR specifies an independent factor to change the overall size of the printed image. This re-sizing affects the entire printed output (specifically, it superimposes its effects upon those of POSTSCRIPT.BITMAP.SCALE and POSTSCRIPT.TEXTURE.SCALE). Values greater than 1 enlarge the printed image, and values less than 1 reduce it. An invalid POSTSCRIPT.IMAGESIZEFACTOR (i.e. not a positive, non-zero number) will use a value of 1. The BITMAPSCALE function for the POSTSCRIPT printer type does NOT consider the POSTSCRIPT.IMAGESIZEFACTOR when determining the scale factor for a bitmap.

**MISCELLANEOUS**

The SCALE of a PostScript imagestream is 100. This is to allow enough resolution in the width information for fonts to enable TEdit to correctly fill and justify text.

The first time any PostScript imagestream is created (even if only to hardcopy a bitmap or window) the DEFAULTFONT is instantiated (unless a FONTS option was given to the OPENIMAGESTREAM, in which case the initial font for the imagestream will be set to that font, or to the CAR if a list).

The PostScript imagestream method for FILLPOLYGON uses the global variable FILL.WRULE as the default value for the WINDINGNUMBER argument. (This is the same variable which is used by the DISPLAY imagestream method for FILLPOLYGON.)

The PostScript imagestream method for OPENIMAGESTREAM (and, therefore, SEND.FILE.TO.PRINTER), supports an IMAGESIZEFACTOR option to change the size of the printed image. The IMAGESIZEFACTOR re-sizing is combined with the POSTSCRIPT.IMAGESIZEFACTOR to produce an overall re-sizing of the printed image. A HEADING option is also supported to give a running header on each page of output. The value of the HEADING option is printed at the top left of the page, followed by "Page " and the appropriate page number. They are printed in the DEFAULTFONT (unless a FONTS option was given to the OPENIMAGESTREAM, in which case it will be that font, or to the CAR if a list).

The PostScript package is contained in the files: POSTSCRIPTSTREAM.LCOM & PS-SEND.LCOM, with the source in the files: POSTSCRIPTSTREAM & PS-SEND. The module PS-SEND.LCOM is required and will be loaded automatically when POSTSCRIPTSTREAM.LCOM is loaded. It contains the function which is called by SEND.FILE.TO.PRINTER to actually transmit the file to the printer. It is, by its nature, quite site specific, so it is in a separate file to make modifying it for any site relatively
simple. System record declarations required to compile POSTSCRIPTSTREAM can be found in EXPORTS.ALL.

Including Other PostScript Operations

If you wish to insert your own specific PostScript operations into a PostScript imagestream, you can do so with the following functions:

\(\text{POSTSCRIPT.OUTSTR} \quad \text{STREAM} \quad \text{STRING}\)  \[\text{Function}\]

POSTSCRIPT.OUTSTR outputs a string or value to the imagestream. \(\text{STREAM}\) must be an open PostScript imagestream. \(\text{STRING}\) is the value to output (STRINGP and LITATOM are most efficient, but any value can be output (its PRIN1 pname is used)).

\(\text{POSTSCRIPT.PUTCOMMAND} \quad \text{STREAM} \quad \text{STRING}_1 \ldots \text{STRING}_n\)  \[\text{NoSpread Function}\]

POSTSCRIPT.PUTCOMMAND is more general for sequences of commands and values. It calls POSTSCRIPT.OUTSTR repeatedly to output each of the \(\text{STRING}_i\) arguments to \(\text{STREAM}\).

\(\text{\textbackslash POSTSCRIPT.OUTCHARFN} \quad \text{STREAM} \quad \text{CHAR}\)  \[\text{Function}\]

\(\text{\textbackslash POSTSCRIPT.OUTCHARFN}\) is used to output the characters forming the text of a PostScript string (e.g. the argument to a show or charpath operator). \(\text{STREAM}\) is the open PostScript imagestream to output to, and \(\text{CHAR}\) is the CHARCODE of the character to output. The / (slash), ( and ) (parenthesis) characters will be quoted with /, and characters with ASCII values less than 32 (space) or greater than 126 (tilde) will be output as /nnn (in octal). \(\text{\textbackslash POSTSCRIPT.OUTCHARFN}\) will output the ( character to open the string, if necessary. Use POSTSCRIPT.CLOSESTRING (below) to close the string.

\(\text{POSTSCRIPT.CLOSESTRING} \quad \text{STREAM}\)  \[\text{Function}\]

POSTSCRIPT.CLOSESTRING closes a PostScript string (e.g. the argument to a show or charpath operator). \(\text{STREAM}\) is the open PostScript imagestream. It is important to use POSTSCRIPT.CLOSESTRING to output the ) character to close the string, because it also clears the stream state flag that indicates that a string is in progress (otherwise, the next POSTSCRIPT.PUTCOMMAND would output the commands to close the string and show it).

Warning

Do not attempt to create a PostScript font larger than about 600 points, as much of Interlisp’s font information is stored in SMALLP integers, and too large a font would overflow the font’s height, or the width for any of the wider characters. (I know that 600 points is a ridiculously large limit (about 8.3 inches), but I thought I’d better mention it, or someone might try it!)

Changes from the Initial Medley Release
This second Medley release of the PostScript imagestream driver includes some performance enhancements when writing bitmaps to the output, some SUN-specific code (from Will Snow of envos), implementation of the SCALEDBITBLT, DSPROTECT, and DSPTRANSLATE operations, and a lot of performance enhancements (many thanks to Tom Lipkis of Savoir).

Changes from the Lyric Release

The Medley release of this PostScript imagestream driver changed the default value of POSTSCRIPT.TEXTFILE.LANDSCAPE from T to NIL. It also added the support for the HEADING option.

Known Problems/Limitations

The output generated for a PostScript imagestream is rather brute force. It isn’t particularly careful to generate the smallest output file for a given sequence of operations. Specifically, it often generates extra end-of-lines between PostScript operator sequences (this has no effect on the printed output, only on the file size).

Using BITMAPs or Functions as BRUSH arguments to the curve drawing functions is not supported, nor is using a non-ROUND BRUSH with DRAWCIRCLE or DRAWELLIPSE.

The implementation of DSPROTECT accepts ROTATION argument values of 0 and 90 (any non-NIL, non-zero value is converted to 90). A value of 0 converts the page orientation to Portrait, and 90 converts the page orientation to Landscape. These conversions perform the translations necessary to keep the clipping region on the page. (This may or may not be the right thing to do, but since DSPROTECT is undocumented in what it should do, this is what the PostScript driver does).

There is no support for NS character sets other than 0, and there is no translation of the character code values from NS encoding to PostScript encoding.

There is no support for color.

\POSTSCRIPT.OUTCHARFN is pretty wimpy in its handling of TAB characters. It just moves to the next multiple of (eight times the average character width of the current font) from the current left margin.

I haven’t yet documented how to build the .PSCFONT files from .AFM files for new fonts that become available.
This file describes the UNICODE Lisp Library package.

Contributed by Ron Kaplan, August 2020.

The UNICODE library package defines external file formats that enable Medley to read and write files where 16 bit character codes are represented as UTF8 byte sequences or big-endian UTF16 byte-pairs. It also provides for character codes to be converted (on reading) from Unicode codes to equivalent codes in the Medley-internal Xerox Character Code Standard (XCCS) and (on writing) from XCCS codes to equivalent Unicode codes.

Four external formats are defined when the package is loaded:

:UTF8          codes are represented as UTF8 byte sequences and XCCS/Unicode character conversion takes place.

:UTF16BE       codes are represented as 2-byte pairs, with the high order by appearing first in the file, and characters are converted.

The two other external formats translate byte sequences into codes, but do not translate the codes. These allow Medley to see and process characters in their native encoding.

:UTF8-RAW      codes are represented as UTF8 byte sequences, but character conversion does not take place.

:UTF16BE-RAW   codes are represented as big-ending 2-byte pairs but there is no conversion.

These formats all define the end-of-line convention (mostly for writing) for the external files according to the variable EXTERNALEOL (LF, CR, CRLF), with LF the default.

The external format can be specified as a parameter when a stream is opened:

```
(OPENSTREAM 'foo.txt 'INPUT 'OLD '((EXTERNALFORMAT :UTF8)))
```

```
(CL:OPEN 'foo.txt :DIRECTION :INPUT :EXTERNAL-FORMAT :UTF8)
```

The function STREAMPROP obtains or changes the external format of an open stream:

```
(STREAMPROP stream 'EXTERNALFORMAT)  -> :XCCS

(STREAMPROP stream 'EXTERNALFORMAT :UTF8) -> :XCCS
```

In the latter case, the stream’s format is changed to :UTF8 and the previous value is returned, in this example it is Medley’s historical default format :XCCS.

Entries can be placed on the variable *DEFAULT-EXTERNALFORMATS* to change the external format that is set by default when a file is opened on a particular device. Loading UNICODE executes

```
(PUSH *DEFAULT-EXTERNALFORMATS* ' (UNIX :UTF8))
```

so that all files opened (by OPENSTREAM, CL:OPEN, etc.) on the UNIX file device will be initialized with :UTF8. Note that the UNIX and DSK file devices reference the same files (although some caution is needed because {UNIX} does not simulate Medley versioning), but the device name in a file
name ({UNIX}/Users/... vs. {DSK}/Users/...) selects one or the other. The default setting above applies only to files specified with {UNIX}; a separate default entry for DSK must be established to change its default from :XCCS.

The user can also specify the external format on a per-stream basis by putting a function on the list STREAM-AFTER-OPEN-FNS. After OPENSTREAM opens a stream and just before it is returned to the calling function, the functions on that list are applied in order to arguments STREAM, ACCESS, PARAMETERS. They can examine and/or change the properties of the stream, in particular, by calling STREAMPROP to change the external format from its device default.

The XCCS/Unicode mapping tables are defined by the code-mapping files for particular XCCS character sets. These are typically located in the Library sister directory

    ../Unicode/Xerox/

and the variable UNICODEDIRECTORIES is initialized with a globally valid reference to that path. The global reference is constructed by prepending the value of the Unix environment-variable "MEDLEYDIR" to the suffix

    /Unicode/Xerox/. MEDLEYDIR should be set by the Medley start-up shell script (e.g. /Users/kaplan/local/medley3.5/lispcore/)

The mapping files have conventional names of the form XCCS-<charsetnum>=<charsetname>.TXT, for example, XCCS-0=LATIN.TXT, XCCS-357=Ssymbols4.TXT. The translations used by the external formats are read from these files by the function

    (READ-UNICODE-MAPPING FILESPEC NOPRINT NOERROR)

where FILESPEC can be a list of files, charset octal strings ("0" "357"), or XCCS charset names (LATIN EXTENDED-LATIN). Reading will be silent if NOPRINT, and the process will not abort if an error occurs and NOERROR. The value is a flat list of the mappings for all the character sets, with elements of the form (XCCC-code Unicode-code).

When UNICODE is loaded the mappings for the character sets specified in the variable DEFAULT-XCCS-CHARSETS are installed. This is initialized to

    (LATIN SYMBOLS1 SYMBOLS2 EXTENDED-LATIN FORMS SYMBOLS3 SYMBOLS4 ACCENTED-LATIN GREEK)

but DEFAULT-XCCS-CHARSETS can be set to a different collection before UNICODE is loaded.

The internal translation tables used by the external formats are constructed from a list of correspondence pairs by the function

    (MAKE-UNICODE-TRANSLATION-TABLES MAPPING [FROM-XCCS-VAR] [TO-XCCS-VAR])

This returns a list of two arrays (XCCS-to-Unicode Unicode-to-XCCS) containing the relevant translation information organized for rapid access. If the optional from/to-variables arguments are provide, they are the names of variables whose top-level values will be set to these arrays, for convenience. For the external formats defined above, these variables are *XCCSTOUNICODE* and *UNICODETOXCCS*.

The macro

    (UNICODE.TRANSLATE CODE TRANSLATION-TABLE)

is used by the external formats to perform the mappings described by the translation-tables.
The following utilities are provided for lower-level manipulation of codes and strings

(XTOUCODE XCCSCODE) -> corresponding Unicode
(UTOXCODE UNICODE) -> corresponding XCCS code
(NUTF8CODEBYTES N) -> number of bytes in the UTF8 representation of N
(NUTF8STRINGBYTES STRING RAWFLG) -> number of UTF8 bytes in the UTF8 representation of STRING, translating XCCS to Unicode unless RAWFLG.
(XTOUSTRING XCCSSTRING RAWFLG) -> The string of bytes in the UTF8 representation of the characters in XCCSSTRING (= the bytes in its UTF8 file encoding)
(HEXSTRING N WIDTH) -> the hex string for N, padded to WIDTH

The UNICODE file also contains a function for writing a mapping file given a list of mapping pairs. The function

(WRITE-TRANSLATION-TABLE MAPPING [INCLUDEDCHARSETS] [FILE])

produces one or more mapping files for the mapping-pairs in mapping. If the optional FILE argument is provided, then a single file with that name will be produced and contain all the mappings for all the character sets in MAPPING. If FILE and INCLUDEDCHARSETS are not provided, then all of the mappings will again go to a single file with a composite name XCCS-csn1,csn2,csn3.TXT. Each cs may be a single charset number, or a range of adjacent charset numbers. For example, if the mappings contain entries for characters in charset LATIN, SYMBOLS1, SYMBOLS2, and SYMBOLS3, the file name will be XCCS-0,41-43.TXT.

If INCLUDEDCHARSETS is provided, it specifies possibly a subset of the mappings in MAPPING for which files should be produced. This provides an implicit subsetting capability.

Finally, if FILE is not provided and INCLUDEDCHARSETS is T, then a separate file will be produced for each of the character sets, essentially a way of splitting a collection of character-set mappings into separate canonically named files (e.g. XCCS-357=SYMBOLS4.TXT).
UnixPrint lets you arrange to have hardcopy sent directly to a PostScript printer via a UNIX print command. You can set your default printing host so that it happens automatically.

**Installation**

Load UNIXPRINT.DFASL. Customize UNIXPRINTCOMMAND.

Then set the two control variables appropriately, as described below:

**DEFAULTPRINTINGHOST**

[Variable]

This is a list of printer names, described in the *Interlisp Reference Manual* (refer to the IRM for a general description). To add a PostScript printer to the list, add an entry in the form `(POSTSCRIPT printername)`. To continue the example above, `DEFAULTPRINTINGHOST` should have a value like the following:

```lisp
(SEQT DEFAULTPRINTINGHOST
 '('- - (POSTSCRIPT daisy) --'))
```

**UnixPrinterName**

[Variable]

A string or symbol, the name of the UNIX printer to which you want output sent. This should be the name that you would give in the `lpr` command. For example, if you normally print files by entering:

```
lpr -Pdaisy...
```

then you should `(SEQT UnixPrinterName "daisy")`. If you do not normally specify a printer name, set `UnixPrinterName` to `NIL`.

**Customization**

You can get UNIXPRINT to use `lp` or `lpr` by modifying the function `UnixPrintCommand`. Your site may have a printing program other than `lpr`. For further information about printing on your system, please refer to your system manual.

```
(UnixPrintCommand PRINTER COPIES NAME TMPNAME)     [function]
```

Returns a string that is used by `/bin/sh` in the printing of the postscript code. The arguments are `PRINTER`, `COPIES`, `NAME` and `TMPNAME`. `PRINTER` is the name of the printer. `COPIES` is `NIL` or a `fixp` specifying how many copies to print. `NAME` is the string printed on the banner page of your hardcopy. `TMPNAME` is the name of the temporary file used to store the postscript code for your job.
A call to (UnixPrintCommand "daisy" 1 "Erik" "/tmp/foot") should return something like the string "/usr/ucb/lpr -Pdaisy -#1 -JErik -r -s /tmp/foot".

The source code of the function UnixPrintCommand is supplied with Medley. You are encouraged to write your own versions of this function depending on the site he or she uses. The function UnixPrintCommand is included in UNIXPRINT.DFASL. Sources and examples for different versions of UnixPrintCommand are included in the file UNIXPRINTCOMMAND.
Before you can print the Medley LispUsers' tedit files you must do the following:

1. If you aren't running in Lispcore you need to load {eris}<tedit>tedithcpy.lcom
2. In IL:"ASCIIITONS change entry 183 so that it reads 183 instead of what it normally reads.

Doing these two things causes the Envos logo to print correctly. To print some of the LispUsers' modules you must have some functions loaded. The following table shows what you must have loaded to print certain LispUsers' modules:

<table>
<thead>

LISPUSERS.TEDIT Short package summaries
I received this inquiry today:

------------------
Date: 16 Dec 86 12:38 PST
From: bloomberg.pa
Subject: Lispusers packages (updates)
To: wessling.pa
cc: bloomberg.pa

When I replace text or documentation of a Lispusers package with new versions, should I message you so that you can do the appropriate thing(s) vis-a-vis phylum?

--Dan
------------------

...and I thought this would be a good time to just give an update on how to handle the lispusers packages.

--- Directories:

{eris}<lisp>koto>lispusers> is where the frozen, released packages for Koto were put.
{eris}<lispusers>koto> is where the Koto packages that have been changed since release should be put.
{eris}<lispusers>lispcore> is where new packages that run in LispCore and updates of old packages that are updated to Lispcore should be kept.

--- Creating new packages:

if you create a new package that runs in LispCore, i.e. to be release with Lyric, write it onto {eris}<lispusers>lispcore>.

--- Editing old packages:

if you want to change a package that was released with Koto, make changes to the latest version (if it hasn’t changed since release this is on {eris}<lisp>koto>lispusers> or if it has been updated, it should have been put on {eris}<lispusers>koto>) and copy it to:
{eris}<lispusers>koto> if it only still runs in Koto
{eris}<lispusers>Lispcore> if you know it runs in Lyric.

--- What should be included:

No package will be released from LispUsers without:
- Source file
- Compiled file
- Documentation

Documentation can be made through the template
({eris}<lispusers>LispCore>easytemplate.tedit) or by using the new lispusers package,
DOCUMENT ( on {eris}<lispusers>koto>).

--- for more information:

{eris}<lispusers>lispcore>LispUsers-rules.tedit, LispUsers-Summary.tedit, LispUsers-
dependencies.tedit. I will store this on {eris}<lispusers>lispcore>lispusers-info-msg.tedit.

--- Nice things to do:

When you create a new package, please:
- send a note to LispUsers^ announcing it.
- add it to LispUsers-summary.tedit (a list of all the lispusers packages)
- add it to LispUsers-dependencies.tedit, which is a list of all the lispusers packages and
which files they need to run.
- Edit LispUsers-dependencies.tedit to reflect the current state of Lispcore lispusers files
(right now it is just the info from Koto).

If you created a package for Koto, please try to update it to Lispcore and store it onto
<lispusers>Lispcore>. If the package is un-updatable or useless in LispCore, please take it off of
the aforementioned lists and/or message me about it.

--- and to answer the question that started all this:

Just put your packages on the directories mentioned. Any copying will be done.

Thank you very much for your cooperation....

Susana...
NOTICE: If you are either a user or a creator/maintainer or ANY LispUsers module, please please please do not delete this message. I am sick of resending information...

All files that existed on {eris}<lispusers>lispcore> as of NOW have been moved to {eris}<LispUsers>Lyric>.

From now on, follow these rules for storing new or changed LispUsers modules:

- If the module was created or changed in Koto, please store it under {eris}<lispusers>koto>.
- If the module was created or changed in the {eris}<lyric>basics> sysout, please store it on {eris}<lispusers>lyric>.
- If the module was created or changed in the {eris}<lispcore>next> sysout, please store it on {eris}<lispusers>lispcore>.

Though this may seem a bit complicated, it will help us to keep track of which modules are assured of working where.

******************************************************************************
RULES:
AND NOW... I am once again going to remind you of how you can make our lives a bit easier when interacting with LispUsers:

All modules that are stored on ANY of the aforementioned directories MUST have:

- source file
- compiled file (.LCOM or .DFASL for Lyric, .DCOM for Koto)
- documentation

If you do not store any of the above with your module, it WILL NOT be released.

In writing documentation, you can use EasyTemplate.tedit (stored on any/all LU directories) to make life easier. For a long version, see DocumentationTemplate.tedit. Please please please note in your documentation:

- any dependencies between modules
- if the module is for internal use only

For further and more detailed rules, see Lispusers-rules.tedit.

If you are nice, I would appreciate your updating all of the <lispusers>lispusers* files. These files contain information about releasable modules that is very important. You should look into these files if

- your module requires other modules to be loaded with it.
- your module is for internal release only
- your module is new

******************************************************************************
QUESTIONS/REMINDERS:
It has been brought to my attention that there are some modules that are stored on [eris]<lispusers>lyric> that are definitely NOT lyric compatible. Please do not do this. It will not make anyone’s job easier. Such modules should go on <lispusers>koto>. Please move them if you are responsible for such horrific actions!

If you are responsible for or just have a vested interest in some module that is in <lispusers>koto> but has not been updated, please see to getting it updated and put into <lyric> or <lispcore>. If it is not done, it will not go out with Lyric.

For those who are anxiously waiting for an NS LispUsers directory... I’m working on it. I will send out further information if it happens.

*****************************************************************
THAT’S ALL FOLKS...
*****************************************************************

Sorry for the long message, but these things just had to be said....

Susana

—End of message—
LISP USERS' RULES

This document describes the rules and procedures for Xerox Lisp "Lisp Users'" modules. This document is mainly for Lisp Users' module writers, but users should also understand the rules. The deadline for Medley Lisp Users' module submissions is August 5, 1988.

DEVELOPING A LISP USERS' MODULE

A Lisp Users' module is a useful program made available to the general Xerox Lisp programming community. Neither the author nor the custodian of the Lisp Users' directory imputes any warranty of suitability or responsibility for errors.

Lisp Users' modules should be easily distinguishable from released library modules. In particular, this means that a Lisp Users' module may not have the same name as a Library module and should be visibly different. Lisp Users' modules derived from released software should be announced to the public only after communicating with the organization responsible for that released software.

Testing is important. If you make significant changes to a Lisp Users' module, enlist developers at your site as alpha testers. Avoid having to rerelease a package within hours of its announcement because of fatal bugs. A Lisp Users' module is not shoddy software; it is software made available outside the regular release channels.

Try not to flood your user community with a constant flow of new versions (or messages) so your messages can be appreciated rather than discarded without reading. If your module is undergoing continual changes, adopt a release strategy of regularly spaced, well tested releases. Your users will thank you.

LISP USERS' MODULE OWNERSHIP

A module submitted for Lisp Users' remains the "property" of the submitter. Others may not make changes, except for their own private use, without negotiating with the owner (who may already be making similar or incompatible changes).

As the owner of a module, you are not required to fix bugs, but if not, you must be willing to transfer ownership (permanently) to someone who volunteers to fix them. Ownership may pass back and forth among several people as long as they agree.

Like all software developed at Xerox, Lisp Users' modules are officially the property of Xerox. You should run with the COPYRIGHT option set to produce an appropriate Xerox copyright in the source.

A Lisp Users' module may become so useful that it becomes part of a standard Xerox Lisp release and is thereafter supported. Ownership then passes to the Xerox product organization.

SUBMITTING LISP USERS' MODULES

If you are not an internal user, you should submit your new module to Xerox either through e-mail or on a floppy. External users should make sure that they include all relevant information, such as documentation containing an e-mail or US mail address where he/she can be reached. External users are also held responsible for the support of their modules.

SUBMITTING FILES TO LISP USERS'

As with released software, it is important to submit not just the resulting product, but all the files needed to build and maintain a Lisp Users' module:
1. the runnable compiled file (.LCOM or .dfasl)
2. documentation describing it, following the set formatting rules (see below)
3. a source file that can be released (optional)
4. data files, if needed

Packages submitted once are released once. Do not assume that a package submitted in one release will be automatically released in subsequent releases.

DOCUMENTATION

Documentation, essential to any module being used effectively, should be put on the submitted floppy. No modules will be released without documentation. Documentation can be as simple as a paragraph describing what the module does and how to use it, or it can be as extensive as a dozen-page user manual. All modules should have a file with a .TEDIT extension. Formatting should be done according to the rules outlined in the appropriate (standalone or networked user) Lisp Users’ Template. All users, external users included, should follow the Lisp Users’ Template rules. If the documentation is large and formatting time consuming, you can also produce an interpress file (with the .ip extension), as well as submitting a .TEdit file. (Be sure to update the interpress file if you update the documentation!) Documentation should include the full electronic mail address of the submitter.

COMPATIBILITY WITH LISP USERS’

Any submitted Lisp Users’ files should be compilable in a “vanilla” environment. The file itself should load in any auxiliary modules under a suitable (DECLARE: EVAL@COMPILE -- ) when necessary.

Thanks for your cooperation.
## Lispusers Summary

A one-line description of (most) LispUsers packages.

All files listed here should be in `{eris}<lispusers>lispcore` If you want to look at the list for Koto files, see `{lispusers>koto}`, the same file. Please add any new files you create to this list.

---NO TEDIT FILE means that no documentation is needed.
---UNSUPPORTED means that there is no author or the author is unreachable.
---an asterisk before a file means its part of the previous package.
---INTERNAL means that it is not for release outside of Xerox
---SOURCE means that you load the source & not the DCOM
---Two dashes (--) before it means that it exists in Koto but hasn't been updated for lyric yet.

INTRODUCTION

This paragraph should be replaced by an overview of your module. The attached Lisp Users' Template explains the documentation conventions to be used for each Lisp Users' modules.

MODULE EXPLANATIONS

Functions, Variables, and Lisp Code Examples

It is usual to first give the name of a function, then describe its purpose and each of its arguments. When the name of a function is first given, it is set off like this:

(IMAGENFSCREATE DISPLAYFN IMAGEBOXFN PUTFN GETFN COPYFN) [Function]

The function name is in 10-point regular Modern, all caps. Arguments are in 10-point italic Modern, in all caps, mixed case, or lowercase, as they appear in the system. Variables look like functions, except that the word “Variable,” enclosed in square brackets, follows the variable name. Please note that these are the characters [], not the parentheses.

This is an example of code. It is in 10-point Terminal font.

Function names, commands, file names, and the like are in 10-point modern.

Be sure to include the following information in any module explanations:

- any file dependencies
- definitions of all arguments
- module, function variable, etc. limitations
- a liberal number of examples for all functions, variables, etc.
This document provides a template and instructions for formatting the Lisp Users’ module documentation. This template applies primarily to standalone workstation users. Using the Lisp Library module TEdit, and this document, you should be able to create a standard Lisp Users’ module for the Lisp Users’ manual. This document gives you the written specifications for formatting your document. The specifications are given in the order in which you would most likely use them to format a document, with the basic text and margins described first, then the various levels of headings, then special elements such as page numbers.

RULES FOR CONTENT

Documentation should always include the name of the module, the name of the author (and Xerox, Arpanet, CSNET or other electronic mailing address, when available—otherwise US mail address), the names of all other Lisp Users’ modules required, the names of all files which are part of the module (data files, other Lisp files, etc.), and enough detail to allow someone to effectively use it. A sample Lisp Users’ template appears at the end of this document.

BASIC SPECIFICATIONS

It is wise to apply the specifications for the body text, headings, functions, variables, and page numbers as you write the document.

Font, Type Size, Leading, and Margins

For the text, choose a 10-point Modern font and Apply it to the appropriate text using the Character Looks menu.

<table>
<thead>
<tr>
<th>Character Looks Menu</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLY SHOW NEUTRAL</td>
</tr>
<tr>
<td>Prop: Bold Italic Underline StrikeThru Overbar</td>
</tr>
<tr>
<td>TimesRoman Helvetica Gacha Modern Classic</td>
</tr>
<tr>
<td>Terminal Other</td>
</tr>
<tr>
<td>Size: {10} Normal Superscript Subscript distance: {}</td>
</tr>
</tbody>
</table>

Then, in the Paragraph Looks menu, set the leading, the spacing between lines of type; the justification; and the left and right margin settings. Set line leading to 1 point and paragraph leading to 7 points. Apply all paragraph looks to the appropriate text.
Finally, in the Page Layout menu, set the left margin to 7 picas, the right margin to 6, and the top and bottom margins to 8. Apply these to all types of pages (first, other left, and other right).

Functions, Variables, and Lisp Code Examples

It is usual to first give the name of a function, then describe its purpose and each of its arguments. When the name of a function is first given, it is set off like this:

(INIMAGEFNSCREATE DISPLAYFN IMAGEBOXFN PUTFN GETFN COPYFN) [Function]

The Paragraph Looks menu for a function is set up like this:
The function name is in 10-point regular Modern, all caps. Arguments are in 10-point italic Modern, in all caps, mixed case, or lowercase, as they appear in the system.

If the function description is more than one line long, the runover arguments should be indented under the function name and the word [Function] placed on the last line of the argument list, like this:

```lisp
(MAKE-ARRAY INDICESLIST &KEY :ELEMENT-TYPE: 
  INITIAL-ELEMENT :INITIAL-CONTENTS :ADJUSTABLE: 
  FILL-POINTER :DISPLACED-TO :DISPLACED-INDEX-OFFSET) [Function]
```

The Paragraph Looks menu should be set as follows to produce this type of argument format:

Long function descriptions should have two points leading between lines. To space them correctly, hold down the meta key when typing the carriage returns so that TEdit breaks the lines without creating separate paragraphs.

Parentheses are in 10-point regular Modern type. The type of definition is in 10-point Modern, caps and lowercase, enclosed in square brackets, and flushed right with a right tab set to 38.0. Note that tabs are used to indent the second and third lines of arguments.

Variables look like functions, except that the word "Variable," enclosed in square brackets, follows the variable name.

Examples of code should be in 10-point Terminal font (but not function names, commands, file names, and the like). If 10-point Terminal is not available on your printer, use 8-point Terminal. Code examples should have two points line leading and no paragraph leading.
Quotation Marks, Bullets, and Dashes

We recommend using TEdit's "expanded abbreviations" to produce professional-looking quotation marks, bullets, em-dashes—used to separate text phrases—and en-dashes (used to indicate inclusive numbers, as in "pages 3–6").

- To produce a bullet, type a lowercase b, select it, and type Control-X.
- To produce an em-dash, type a lowercase m, select it, and type Control-X.
- To produce an en-dash, type a lowercase n, select it, and type Control-X.

HEADS

There are four levels of heads in the Lisp Users' documentation: chapter (level 1) heads, level 2, level 3, and level 4 heads.

Note: A head that falls at the bottom of a page (a "widow") is undesirable. You eliminate a widow by selecting it, then applying the Before option of the New Page command in the Paragraph Looks menu.

The Chapter Head

The chapter head appears at the beginning of the document and identifies it. The heading "Lisp Users' Template," above, is a correctly formatted Lisp Users' chapter head.

When submitting a Lisp Users' module on floppy disk format the chapter head as follows:

Module Name: your Lisp Users' Module (all caps, 12-point bold Modern)
Your name and ARPANET address (if you have one) in 10-point Modern

The Level 2 Head

Level 2 heads identify major sections of a document. The level 2 heads for the Lisp Users' documentation are in 10-point bold Modern, all caps.

The Level 3 Head

Level 3 heads identify subsections of a document. For the Lisp Users' manual, they are in 10-point bold Modern, caps and lowercase.

The Level 4 Head

Level 4 heads identify the lowest level of subsection in the Lisp Users' documentation. They are in 10-point regular Modern, caps and lowercase, underlined.

PAGE NUMBERS

Page numbers are specified and applied in the Page Layout menu. First, specify the alignment of the page numbers to be centered, with the X position being 26.5 picas and the Y position 3.5. Then specify the character looks to be 10-point regular Modern. Finally, apply the page numbers to the First(&Default) pages.
After you submit your document, XEROX AIS will add running heads, put in additional formatting, and provide final page numbering to assemble it into the Lisp Users' manual.

**MANUAL TEMPLATE**

The following page has a sample template for the information required in a Lisp Users' module. Use this template to produce your module documentation.
Module Name:

>>MODULE NAME<<

By: >>Your Name<< (>>Your net address<<)

Uses: >>Other modules necessary to run this one<<

>>Type INTERNAL here if the file is for Internal Use Only<<

This document last edited on >>DATE<<.

INTRODUCTION

>>This paragraph should be replaced by an overview of your module. The information on the previous pages explains the documentation conventions to be used for each Lisp Users' module.<<

MODULE EXPLANATIONS

>>Functions, Variables, and Lisp Code Examples<<

It is usual to first give the name of a function, then describe its purpose and each of its arguments.

Module explanations may have several level headings.

Be sure to include the following information in any module explanations:

• any file dependencies
• definitions of all arguments
• module, function variable, etc. limitations
• a liberal number of examples for all functions, variables, etc.
This document provides a template and instructions for formatting the Lisp Users’ module documentation. This template applies primarily to standalone workstation users. Using the Lisp Library module TEdit, and this document, you should be able to create a standard Lisp Users’ module for the Lisp Users’ manual. This document gives you the written specifications for formatting your document. The specifications are given in the order in which you would most likely use them to format a document, with the basic text and margins described first, then the various levels of headings, then special elements such as page numbers.

RULES FOR CONTENT

Documentation should always include the name of the module, the name of the author (and Xerox, Arpanet, CSNET or other electronic mailing address, when available—otherwise US mail address), the names of all other Lisp Users’ modules required, the names of all files which are part of the module (data files, other Lisp files, etc.), and enough detail to allow someone to effectively use it. A sample Lisp Users’ template appears at the end of this document.

BASIC SPECIFICATIONS

It is wise to apply the specifications for the body text, headings, functions, variables, and page numbers as you write the document.

Font, Type Size, Leading, and Margins

For the text, choose a 10-point Modern font and Apply it to the appropriate text using the Character Looks menu.

```
<table>
<thead>
<tr>
<th>Character Looks Menu</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLY SHOW NEUTRAL</td>
</tr>
<tr>

</tr>
<tr>
<td>Times Roman Helvetica Gacha Modern Classic</td>
</tr>
<tr>
<td>Terminal Other otherfont: {}</td>
</tr>
<tr>
<td>Size; {10} Normal Superscript Subscript distance: {}</td>
</tr>
</tbody>
</table>
```

Then, in the Paragraph Looks menu, set the leading, the spacing between lines of type; the justification; and the left and right margin settings. Set line leading to 1 point and paragraph leading to 7 points. Apply all paragraph looks to the appropriate text.
Finally, in the Page Layout menu, set the left margin to 7 pica,s the right margin to 6, and the top and bottom margins to 8. Apply these to all types of pages (first, other left, and other right).

Functions, Variables, and Lisp Code Examples

It is usual to first give the name of a function, then describe its purpose and each of its arguments. When the name of a function is first given, it is set off like this:

```
(IMAGENSCREATE  DISPLAYFN IMAGEBOXFN PUTFN GETFN COPYFN)  
```

[Function]

The Paragraph Looks menu for a function is set up like this:
The function name is in 10-point regular Modern, all caps. Arguments are in 10-point italic Modern, in all caps, mixed case, or lowercase, as they appear in the system.

If the function description is more than one line long, the runover arguments should be indented under the function name and the word [Function] placed on the last line of the argument list, like this:

The Paragraph Looks menu should be set as follows to produce this type of argument format:

Long function descriptions should have two points leading between lines. To space them correctly, hold down the meta key when typing the carriage returns so that TEdit breaks the lines without creating separate paragraphs.

Parentheses are in 10-point regular Modern type. The type of definition is in 10-point Modern, caps and lowercase, enclosed in square brackets, and flushed right with a right tab set to 38.0. Note that tabs are used to indent the second and third lines of arguments.

Variables look like functions, except that the word "Variable," enclosed in square brackets, follows the variable name.

Examples of code should be in 10-point Terminal font (but not function names, commands, file names, and the like). If 10-point Terminal is not available on your printer, use 8-point Terminal. Code examples should have two points line leading and no paragraph leading.
Quotation Marks, Bullets, and Dashes

We recommend using TEdit’s “expanded abbreviations” to produce professional-looking quotation marks, bullets, em-dashes—used to separate text phrases—and en-dashes (used to indicate inclusive numbers, as in “pages 3–6”).

· To produce a bullet, type a lowercase b, select it, and type Control-X.
· To produce an em-dash, type a lowercase m, select it, and type Control-X.
· To produce an en-dash, type a lowercase n, select it, and type Control-X.

Animation Compiler and Environment

Introduction

ACE is a system for computer-assisted animation. It is based on the traditional cel-oriented animation process with the computer taking over many of the tedious jobs. You enter a succession of frames which represent a sequence. The system then plays back your frames to create the animated effect. It lets you draw pictures, enter text, and edit your work. The animated images you make are displayed on the screen in real-time. The two main parts of ACE system are a frame compiler and an environment. The environment provides the editing tools, frame manipulation, and display capabilities. The compiler operates automatically to produce a compressed-storage representation for frames.

You can also use the graphic editing features in ACE to make individual pictures, whether or not they're intended to be used for animation. Finally, you can use the compiler directly to compress any bitmap image so that it take up less space on your disk.

The majority of the code for ACE was originally written by Paul Turner, a student at the University of Rochester. I am currently maintaining the system. Please send all bug reports, comments, and suggestions directly to me, Denber.WBST, or Denber.WBST@Xerox.COM (Arpanet). This document describes the features available in ACE version 2.1.

Background

In this document: holding the mouse on a menu selection means to press down a mouse button on a menu item (inverting the item) and keeping it down for about 1.5 seconds (at this point, you can release the button or move to another selection). Clicking the mouse means pressing a mouse button down and releasing it. Unless otherwise stated, the left mouse button is used for selecting items from menus and to click at objects.

In addition to the mouse, ACE supports a graphics tablet (Summagraphics MM1201). [LMM: The graphics tablet hasn't been tested in Medley.] The tablet is more convenient for doing free-hand drawing; in fact, most commercial animation systems include a graphics tablet. The pen has two buttons: the stylus tip (which is activated by pressing down on it) and a blue button on the barrel of the pen (activated by pressing with the forefinger). We have adopted a convention with regard to the tablet: the stylus button acts like the left button on the mouse and the barrel button acts like the middle button on the mouse.
Terms and System Organization

A region is simply a rectangular area.

A frame is a region that contains one complete "picture" in an animation sequence; it is a rectangular bitmap with a fixed width and height.

A sequence is a collection of frames defining one complete animated segment.

The current frame is the frame in a sequence to which operations will be applied. As all the frames in any given sequence are the same size, you may say that one characteristic of a sequence is a region of a particular size. Frames are referred to by number for convenience; the numbering is from 1 to n.

There are two principal windows used in ACE. The sequence window is the window on the screen where a particular sequence will be created, edited and displayed. Typically, you define the shape of the sequence window to give you just the area you want to work in, although a sequence can also be edited and displayed in any existing window.

The ACE Control Window holds a menu of commands and displays animation state, prompt, and help information. The upper left region in the control window, referred to as the status region, tells which frame is currently being displayed (which frame is the current frame); which device (mouse or tablet) is being used in line art and painting operations; what operation is currently being performed; and, the size of a region (width, height) or the location (x, y) of the cursor within the sequence. The upper right portion of the control window is the prompt region; it is used to get user input and display helpful information. The bottom part of the control window is a menu of animation functions.

GETTING STARTED

Load ACE.LCOM from your lispusers directory (e.g., (FILESLOAD (SYSLOAD) ACE). When this is complete, type:

(ACE)

At this point an Ace control window will appear by the cursor. You can place it wherever you wish on the screen. The window initially contains a prompt "Animation Directory?" asking for a default directory to use for storing and retrieving animation files (The default selection is your login directory. Just press the return key to accept the default.) The control window can be moved around just like any other window. While you never need to "quit" from ACE, if you close the control window with the right mouse button menu it permanently aborts ACE; if you then re-type (ACE), the animation system will be restarted from scratch.
ACE Commands

Main Menu

The menu selections from the control window will now be described; an example of using ACE is given in the next section. The main menu is divided into three columns. The left-most one contains commands that affect the entire sequence, the middle column operates on frames, and the right-most column contains utility commands.

<table>
<thead>
<tr>
<th>Get Sequence</th>
<th>Edit Frame</th>
<th>Run Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Put Sequence</td>
<td>New Frame</td>
<td>Increment Frame</td>
</tr>
<tr>
<td>New Sequence</td>
<td>Delete Frame</td>
<td>Decrement Frame</td>
</tr>
<tr>
<td>Reset Sequence</td>
<td>Adjust Timing Delays</td>
<td>Initialize MM1201 Tablet</td>
</tr>
<tr>
<td>Change compression %</td>
<td>Change Input Device</td>
<td>Quit</td>
</tr>
</tbody>
</table>

Sequence commands (left column)

Get Sequence Loads a sequence-file from a file server or local disk. You are prompted for the name of the file; incomplete file names will be completed from the directory given as the default ACE directory. You will then be prompted for a window specification. Unless you want to display the sequence in a particular window, select ‘create window automatically’.

Put Sequence Saves the current sequence to a file. You will be asked for a file name and given the option to overwrite the existing version of the file (if any) or create a new version.

New Sequence Discards the current sequence (if any), and prompts you for a new sequence by requesting a size for the new sequence. Dragging out a rectangular region with the mouse; the exact size of the region is displayed in the status region of the control window. A blank first frame is created, ready for editing.

Reset Sequence "Rewinds" the current sequence to the beginning (i.e. there is no current frame and the next frame to be displayed will be the first frame).

Change compression % This can be used to change the amount of space compression performed by the animation compiler. For general use, there is no need to ever call this command.

Frame commands (middle column)
**Edit Frame**  Allows editing on the current frame.  Brings up a menu of editing options, described in the next section.

**New Frame**  Inserts a new frame after the current frame (ie. before the next frame).  The frame editor is then automatically invoked.

**Delete Frame**  Deletes the current frame.  The current frame is removed and the previous frame become the current frame.  The first frame can not be deleted.

**Adjust Timing Delays**  Lets you set the amount of time (in milliseconds) that any particular frame is displayed; for example, a delay of 50 on the 5th frame would mean that the 5th frame will be visible for 50 milliseconds before the 6th frame is put up.  You can change the entire sequence or a single frame at a time.  For individual frame setting, you get a menu of frames and their current delays.  Holding down a selection will display that particular frame in the sequence window (this is also a convenient way to rapidly move to an arbitrary frame); if you select a frame you will be prompted for a new delay value.  When new frames are created, they always get a default delay time of 0.

**Change Input Device**  Lets you select either ‘mouse’ or ‘tablet’ from a menu.  This sets the device to be used for line art and painting operations.  The status (upper left) region of the control window always shows which device is active.  All menu selections have to be done with the mouse, even when the tablet is being used for drawing.

**Utility commands (right column)**

**Run Sequence**  Runs the *remainder* of the sequence.  To run the entire sequence, select Reset Sequence before Run.  This command has a submenu with two additional commands:

- **Loop**  Runs the entire sequence in a continuous loop.  To stop the loop, hold down the space bar.  This is checked only at the end of the sequence, so just tapping the space bar may not stop the loop.

  **Loop part**  Runs a portion of the sequence in a continuous loop.  You can specify the starting and ending frame numbers.  To stop the loop, hold down the space bar, as in Loop above.

- **Increment Frame**  Displays the next frame and makes it the current frame.

- **Decrement Frame**  Goes back to the preceeding frame and makes it the current frame.

- **Initialize MM1201 Tablet**  This performs the necessary RS232 port initializing, sets the baud rate, activates the tablet, etc.  This must be called after the tablet is plugged in and before it is used.  If your tablet doesn’t seem to be responding, it may need to be reinitialized.

**Edit Frame Submenu**

For the commands described below, it is sometimes useful to know the exact coordinates at which a drawing operation will take place.  If you hold the T key down, ACE will put the current coordinates in the status window.  Release the key to stop this function.

When you select **Edit Frame**, a sub-menu of editing options appears.  Their functions are as follows:

- **Paint**  This lets you to paint on and erase bits from the current frame.  The painting operation is the standard Interlisp-D window paint command.  Either the mouse or tablet can be used (which ever device is currently selected).  Pressing the left mouse button or pen stylus draws; the middle mouse or pen barrel button erases.  Pressing the left shift key brings up a menu.  From this menu, you can quit painting, change the brush size or shape, and the color or texture of the "paint brush".  Note: selecting items from this menu requires using the mouse (unfortunately, the tablet cannot be used for menu selecting).  For more information on the paint command, please see page 19.20 in the Interlisp manual.
**Line Art**  This lets you add straight lines to a frame by selecting one vertex, dragging out a line, and then selecting another vertex. In this way, an arbitrary string of connected line segments can be created. The left mouse button or pen stylus will "put down" vertices, the middle mouse button or pen barrel stops the line dragging. The right mouse button brings up a menu of line art options (paint or invert drawing; several line width choices); as with all menus, the menu selection must be made with the mouse.

**Edit Bits**  This lets you use the Interlisp-D bitmap editor on the selected frame. The mouse is used to turn specific bits on or off (the tablet is not used as it isn’t helpful for this application). A complete description of the the bitmap editor is given in the Interlisp Reference Manual. Always exit the editor by selecting OK.

**Text**  Lets you put text into a frame. After selecting the 'Text' option, you will be prompted for font characteristics. Then you point (with the mouse) to where the text should begin and click the left mouse button. You may now type in text from the keyboard and it will show up in the frame. A press of the return key ends text entering (the return is NOT included in the text).

**Move Region**  Lets you move an arbitrary rectangular region in the current frame. You first drag out the region to be moved, then you will be asked what to do with the old image (i.e. leave it alone, erase it). At this point, a ghost image will attached to the cursor and you can position the image in its new location. Clicking the mouse will set the position for the image and then you will be asked how to combine the image (i.e. paint it in, exclusive-or it in).

**Combine Region**  This is similar to move region, except that you can select any region on the screen (not just inside the current frame). After selecting the region, bringing the mouse within the sequence window will show a ghost image; the rest of the procedure is the same as for Move Region. This command is extremely useful for bringing images created elsewhere into your frame. For example, you might have a drawing made using Sketch or an AIS file.

**Texture Area Fill**  This lets you fill in an arbitrary closed curve with a texture pattern. You are first prompted to select a bounding region. This represents a maximum area beyond which texturing will not occur, in the event that the texture "spills" outside the region being shaded. Next, select a starting point anywhere inside the desired region. You will then be offered a menu of predefined textures. You can choose one of these, or create your own by selecting * Other *. The area is then filled with that texture. You can then confirm that the right thing happened by clicking left. Click any other button to undo the operation.

**Texture Region Fill**  This is like Texture Area Fill, except that it is used to create filled-in rectangular boxes, rather than arbitrary areas.

**Scale Region**  Lets you change the size of any rectangular area. You first select a region, and then indicate the shape of the scaled area by sweeping it out on the frame. Useful if you know how big you want the result to look but not what percent of the original it is. This command has a submenu:

- **To a new region**  Same as the top level Scale Region.
- **In x and y**  You first select a region as in To a new region, and then indicate the percentage of the original size to scale by, much like selecting reduction or enlargement on a copier. You can set the x and y scale factors independently.
  - **In x only**  Use this if you only want to scale in the x direction, leaving y unchanged.
  - **In y only**  Use this if you only want to scale in the y direction, leaving x unchanged.
**Clear Region**  For clearing regions to white quickly. If you select a region within the sequence, it is immediately erased. There is no UNDO for this operation.

**Quit - Compile**  This is the usual way of exiting the editor. This keeps the changes made to the frame and calls the compiler, resulting in adding the frame to the current sequence.

**Quit - ABORT**  Exits the editor but does not update the frame. The sequence will be as it was before you selected Edit. Any changes made to this frame are lost.

**CONCLUSION**

**Examples**

You might want to see an existing animation before creating one of your own. There are several animation demos included in the Lispusers distribution of ACE: ACE-APPLEDEMO, ACE-BOUNCINGBALL, AND ACE-FOUETTE. The simplest one, BOUNCINGBALL, contains five frames showing a bouncing ball. To see this, start ACE running and select Get Sequence from the main menu. Type the name of the file, including the file server and directory if they are different from your current animation directory. Once the file is loaded ACE will let you position the sequence window. Then select Run Sequence. The system will display the five frames and then stop. To see the ball bounce continuously, select LOOP from the submenu on the Run Sequence command. The ball will now bounce until you hold the space bar down.

The file ACE-APPLEDEMO is a 125 frame sequence which shows an apple getting shot. ACE-FOUETTE is a six frame cycle of a ballet dancer performing a fouette turn.

**Animation Hints**

Remember that ACE is just a tool - it will not do any animating for you. Our goals were to provide a system that simplified the frame creation process and let you create animation on the computer without having to learn a special animation programming language. However, animation is an art form in itself. Experience is gained only through practice and experimentation.

Avoid moving objects too far between frames or the motion will appear jerky. The D machines screens are designed to minimize flicker through the use of a long persistence phosphor. Unfortunately, this results in trailing streaks of light behind rapidly moving objects. Sometimes you can use this to artistic effect. It can be reduced by moving dark objects over a light background, rather than the reverse.

Sometimes you can simplify the animation process by creating frames out of order, especially for cyclic animation. For example, the bouncing ball was created by drawing frame 1 and then making a new frame (which is by default a copy of frame 1). Then we backed up to frame 1 and added a new frame between 1 and 2, showing the ball half-way down. Then this frame was copied, yielding four frames. Backing up again and adding the middle frame gave a symmetrical bounce sequence with frames 1, 5 and 2, 4 being identical.

It’s often convenient to keep a snapshot of the object you’re animating handy in a window next to the sequence window. It can then be brought into the frame whenever needed, for example in the case where it is being modified in some way. You are not limited to editing images with the ACE editor. In particular, you may want to use the Sketch editor (an Interlisp-D library package) to modify images, and then bring them into the sequence window for compilation.

**References**

INTRODUCTION
This document is intended for programmers who intend to fix, update or otherwise significantly modify the ACE code. A general description and several specific points about the Animation Compiler and Environment will be brought out. This is neither a user’s guide nor a guide for animation. A user’s guide may be found filed under {ICE}<TURNER>ACE>ACE-USERS-GUIDE; a technical document is filed under {ICE}<WHOKNOWS>ACE>WHOKNOWS.

OVERVIEW
The Animation Compiler and Environment is a program for creating, editing, displaying and storing/retrieving frame-oriented animations. It is based on traditional animation principals; successive frames (each frame usually slightly different from the previous frame) are displayed at a rate fast enough to create the illusion of motion (at least 10 frames/second; usually more). To the user, the ACE system presents a sequence of whole frames (represented as bitmaps with the same width and height); the analogy being a stack of paper. In reality, however, the program maintains virtual frames. This decreases the storage requirements and allows the very rapid display of frames.

VIRTUAL REPRESENTATION
The virtual frames maintained by ACE are differential frames; that is, a frame only contains the information that is different from the previous frame. By this mechanism, the first frame is a complete frame (complete bitmap) providing the initial information. The second frame, then, is just the differences that exist between the first frame and a hypothetical complete second frame (i.e. just the differences between two bitmaps). And so on with all successive frames. The details of data structures and the compilation process are given below.

TRILLIUM vs STAND-ALONE
Currently, ACE is designed to operate as either a stand-alone program or in the Trillium environment. Conceptually, as a stand-alone, ACE should be considered more procedure oriented. When ACE is called (top level fn: (ACE)), a control window (ACE.CONTROL.WINDOW) is brought up which contains a menu. This window and menu remain up and stay active; once ACE is activated, it becomes a part of the user’s current environment. In Trillium, ACE operates more functionally; that is, ACE is called as a one-time function which returns a value (although, of course, it produces side-effects). The control window and menu are only active during the function call and are taken away when the ACE session is concluded. Also, a special animation-run-time function is provided for Trillium to use outside of ACE to run animation item types. At present, Trillium expects all editing (and most loading and storing) of animation sequences to be performed inside ACE.

ORGANIZATION
ACE is organized in a top-down fashion which allows a general to specific description of it. What the components do and how (where appropriate) will now be outlined.

FILES: There are four files to the ACE system (and one utility: RS232): ACE, ACE-MAIN, ACE-EDIT and ACE-PRIM. The divisions exist partly for organizational purposes and partly for ease in locating and working with segments. The ACE file contains some macros and variables, but exists primarily to load in all the necessary files. ACE-MAIN contains all the functions necessary to define, manipulate, run and load/store animations. ACE-EDIT contains all the editing functions (including interfacing to the MM1201 graphics tablet). ACE-PRIM contains the compiler functions; it is only concerned with compiling two frames to create a virtual frame.

ACE-MAIN
This is the guts of the animation environment. There are four main divisions in MAIN (you can see them by looking at the file coms): Top level fns, Trillium-gearied fns, I/O fns, and “helper” fns. In addition, there are several macros and a GLOBALVARS declaration. All the main functions that work with animation sequences are in the first division (including the startup fn: ACE). The I/O section is just for reading and writing files; user input and output fns are in the helper fns section. Control window operation and clipping region fns are also located in the helper fns section.

ACE-EDIT
This segment also consists of four parts (again, note the file coms). The first section provides
entry/interfacing to MAIN and calls to the actual editing routines. LINEART contains all the major fns for line art drawing. The third part contains all the other editing fns (e.g. painting, text, moving, etc.). The last part consists of tablet access fns and helper fns (all MM1201 code is located in this section and the code to read the current input device). The RS232 package is used by ACE-EDIT to read the MM1201 Summagraphics tablet. At present, the RS232 package (RS232.DCOM) is loaded by the ACE file. However, the maintainer should keep aware of changes in this package and its whereabouts.

ACE-PRIM: How the Compiler Operates:
The compilation process is concerned only with compiling two frames at one time (MAIN and EDIT take care of administration). The entry function is ACE.COMPILE.FRAME with arguments: BM.ORIG (the first or original bitmap), BM.CHANGED (the successor bitmap), VERTICAL.BLOCK (defines the height in scanlines for primitive regions of change; the horizontal component is 16 so as to take advantage of the 11xx series word size), and THRESHOLD (the percent as an integer representing the minimum amount of "changed area" allowable in a combination; more on this later). Take note that there are two variables defined in PRIM: ACE.PIXPERWORD (16, just the 11xx word size) and ACE.BITMAP.MASK (a mask used for ignoring extra bits in the last raster word of a bitmap).

The compiler works by comparing each word in BM.ORIG to BM.CHANGED (NOTE: these bitmaps must have the same dimensions) VERTICAL.BLOCK words at a time. If a changed word is found, a region specification is entered on list denoting this "region of change". After the whole area of the bitmaps is checked, the compiler attempts to merge these smallish changed-regions (see ACE.MAX.REGIONS). The algorithm first attempts to combine regions which result in no space wastage (this is always desirable). When no more 100% regions can be formed, the algorithm tests all pairings of primitive regions to find the highest efficiency (i.e. least space waste). If this efficiency is greater than or equal to THRESHOLD, the two regions are combined, otherwise, the algorithm terminates. The region merging process is the slowest aspect of ACE; the problem of merging regions is thought to be NP-complete.

DATA STRUCTURES
- A sequence is of the form: (FRAME FRAME FRAME ...).
- A FRAME is of the form: (DELAY BLITS).
- A DELAY is an integer representing a time delay in milliseconds.
- BLITS is a list: (BLIT BLIT BLIT ...).
- A BLIT is of the form: (BITMAP XCOOR . YCOOR).

A BLIT is essentially a small changed area with information on where it should be placed (relative to the animation). The record definitions for the above structures are in the file ACE. The compiler uses the structures: REGION : (LEFT BOTTOM WIDTH HEIGHT); a modified REGION : (REGION . AREA) for merging; and lists or both of these types.

GLOBALVARS
The following are important global variables with explanations where needed.

- ACE.CONTROL.WINDOW contains the top-level menu and status information.
- ACE.DIRECTORY is a default directory used to store/retrieve files.
- ACE.SEQ.WINDOW the current window where animations are displayed.
- ACE.SEQ.WIDTH and ACE.SEQ.HEIGHT refer to the current sequence.
- ACE.SEQ.WINDOW.XOFF and ACE.SEQ.YOFF the offset in the ACE.SEQ.WINDOW.
- ACE.CURRENT.SEQUENCE points to data which is the current animation sequence.
- ACE.CURRENT.SEQUENCE.NAME for retaining file name information.
- ACE.FRAME.TAIL tail of frames starting one after the current frame.
- ACE.CURRENT.FRAME a tail of frames starting with the current frame.
- ACE.VERTICAL.BLOCK value to use when compiling (see above on compiler).
- ACE.AREA.THRESHOLD for compiling.
- ACE.RUNNING.UNDER.TRILLIUM T if ACE was called by Trillium.
- Various CURSORs are just cursors.

There are also a GLOBALVARS list of menus in MAIN and EDIT. The approach on menus was that they should be created only once to save both time and space.
INTRODUCTION

The ADDRESSBOOK package provides quick and easy access to on–line address books or phone directories. It allows you to copy (shift select) from entries found in the book, for example, for use as a letter or electronic mail address. When you load the ADDRESSBOOK package, the icon shown above will appear on your screen. Opening this icon will provide a window interface to a simple search process. To find an entry containing any string in one of your *AddressBookFiles*, type the string followed by a return. The ADDRESSBOOK program will quickly search through the files and show you an occurrence of the string typed. The located string is shown in inverse video. The title of the window will contain the name of the file in which the entry was found. You can use a name, part of the address or any keywords to locate the appropriate part of the text. The search ignores case; e.g. "bobrow" matches "Bobrow". The text of the document is scrollable, and any portion can be shift selected into another document.

Type carriage return, ^X, or click on Next Occurrence to search further in the files for the same string. If no (further) occurrences are found, the text window will display a message indicating the failure. Searching again after failure will start the search from the beginning of all the files, using the same lookup string. Typing a new string can be repeated as many times as you like. When you are done, just SHRINK the window back to its icon by using the Shrink selection in the title bar.
Required Files

This package automatically loads LOOKUPINFILES.

Variables

*AddressBookFiles*  [Variable]

*AddressBookFiles* is a list of files that contain entries to be searched. This is usually set in the INIT.LISP file. In the ADDRESSBOOK package it is initially set to PHONELISTFILES, to make it backwards compatible with PHONE-DIRECTORY. The *AddressBookFiles* can be any unformatted or TEDIT formatted files, with any number of lines per entry. A typical value for PARC users (as defined for PHONELISTFILES in PARC-INIT) is

\[
\left\{\text{PHYLUM} < \text{REGISTRAR} \text{PARCPHONELIST.TXT} \right\}
\left\{\text{INDIGO} < \text{REGISTRAR} \text{ISDPHONELIST.TXT} \right\}
\]

*Address-Book-Pos*  [Variable]

*Address-Book-Pos* is the initial POSITION for the ADDRESSBOOK icon. This is defined as an INITVAR in the file, so you can set it before loading the file. The default value is

\[
\text{(create \ POSITION \ XCOORD} \leftarrow \text{970)}
\text{YCOORD} \leftarrow \text{(DIFFERENCE \ SCREENHEIGHT \ 90))}
\]

This places the icon in the upper right corner of the screen.
*Address-Book-Region* [Variable]

*Address-Book-Region* is the initial REGION for the ADDRESSBOOK window. This is defined as an INITVAR in the file, so you can set it before loading the file. The default value is

\[
\text{CREATEREGION 300 (DIFFERENCE SCREENHEIGHT 500)
400 200).}
\]

This places the window in the middle of the screen.

Notes

Starting or Restarting Address Book

Evaluating (MakeAddressBook) will create an address book window and process. This may be useful if you accidentally close the window.

Caching Files

When you first open the ADDRESSBOOK window, the program will copy the *AddressBookFiles* to {CORE}, significantly speeding up queries. Bugging in the title of the ADDRESSBOOK window with the left or middle mouse button will produce a menu with an option to recache the files on *AddressBookFiles*.

Editing Your Files

To edit the file in which an entry is found, click middle button in the title of the ADDRESSBOOK window, and select the option "Edit file named in window title". A TEDIT process editing the file will be set up. This process is independent of the lookup process. To select the file to be edited, rolloff the above item, and select "Select file to edit". A menu of files used by the Lookup process will be presented to you. Selecting one will cause that file to be edited.

To make editing changes visible to the lookup process, PUT the file in TEDIT; when it is done, recache the file in core. To recache just the file edited, (the one specified in the title bar of the window), select the option "Recache file named in window title" in the middle button title bar menu. You can recache all files by selecting the option "Recache all files" in the title menu (a subselection of the item "Recache file named in window title").

Adding to the List of Files
To add to the list of files being used for lookup, select the option "Add new file" in the title bar menu. This file will be added, and cached in core.

Deleting a file from the List of Files

To delete from the list of files being used for lookup, select the option "Delete file from list" in the title bar menu. This file will be deleted from the list of files to be searched.
INTRODUCTION

The purpose of this package is to provide menu-like operations on irregularly shaped regions within a
window and make available general functions that allow users to create their own applications using
irregularly shaped active regions. An added feature of AIRegions is that multiple IREGIONs may be
activated by selecting the intersecting area of those IREGIONs. (Throughout this document an
irregularly shaped region will be referred to as an IREGION).

DESCRIPTION

Virtually all of the features of menu selection have been implemented in this package: ease of menu
creation, item-selected shading, quick response to selection, and execution of an associated function.
Yet, this package adds one additional feature without any degradation to the quality and efficiency of
menu implementation: the selection of any irregularly shaped region from any point within that region,
and without any unsightly cosmetic change.

In describing the package by means of an example, picture a map of the world, or better yet, of a
particular country broken up into its individual states and/or provinces. Suffice it to say that these
regions are not square but irregular in shape and that they are bordered by solid lines, as they are on a
common map. Unlike the menu package or ACTIVEREGIONS package, AIRegions allows you to
select any of these pre-set states/provinces just as if your are making a menu selection of an item.
One of the nice aspects of this package lies in the fact that the package does NOT make any cosmetic
changes to the irregularly shaped region, like providing some small box within the region to button in.
Simply button your mouse within the solidly bordered region, anywhere in the region, and it will shade it
to your particular shade and execute your defined function.

Functionality provided:

The functions in this package allow the user to work with familiar concepts: creating and implementing
windows and menus. The examples provided within this documentation should be sufficient for the
user to begin setting up irregularly shaped regions.

(CREATEIR window shade buttoneventfn helpstring region poslist) [Function]

window: the window which will contain the irregular region.

shade: can be either a number between 0 and 65535 for a 4 by 4 shading or a 16 by 16 bitmap (if
shade is NIL then the default is black, 65535).
buttoneventfn: the function called when the region is selected. The arguments that are passed to the function are: the window containing the IREGION, the IREGION record itself, and the button which selected the IREGION.

helpstring: the string that is placed in the PROMPTWINDOW when the mouse is held over the item for a few seconds.

region: if specified, will be the region relative to window in which the IREGION can be found. (If region is NIL, the user will be prompted to sweep out a region within window.)

poslist: If specified, will be either a position or list of positions relative to window that are the starting points for the FILLREGION routine (i.e. a point within the desired IREGION). (if poslist is NIL, the user will be prompted for a position until he/she selects outside of region.)

Description of use: This is the first function that is called when actually setting up an irregularly shaped region to become sensitive to button activity. If the region argument is not set, then the cursor changes its shape and prompts for a region to completely surround the IREGION within the desired active window. (Note: That it is best to surround the desired IREGION as close as possible since this will save on execution time and memory usage.) A thin box will appear temporarily where the IREGION was scanned. If poslist is NIL, then the cursor changes into a TARGET symbol. The user should left-button mouse within desired active IREGION. Note: the IREGION must be surrounded by a border that FILLREGION can use to define the active area. Any gaps in the IREGION will cause the next routine to fill the region and anything outside with the shade provided. Mistakes can be corrected by using the REMOVEIREGION function described below and PAINTing in the gap to retry. After left-buttoning within the desired active IREGION, the cursor continues to remain in its TARGET state. If the IREGION is split up into many different parts, those parts may be selected with the left-button also making them all active concurrently. However, when one is finished activating that one IREGION, then she/he should left-button outside of region. This function must be called for each desired IREGION.

Examples:

(CREATEIR window 21930 'myfunction "This is the helpstring")

(CREATEIR (WHICHW) 1234 'MYSELECTED.FN "This is the helpstring" '(0 0 20 30) '((12 . 15) (2 . 29))

(SURROUNDIR window shade buttoneventfn helpstring poslist inside.pos) [Function]

window: the window which will contain the irregular region.

shade: can be either a number between 0 and 65535 for a 4 by 4 shading or a 16 by 16 bitmap (if shade is NIL then the default is black, 65535).

buttoneventfn: the function called when the region is selected. The arguments that are passed to the function are: the window containing the IREGION, the IREGION record itself, and the button which selected the IREGION.

helpstring: the string that is placed in the PROMPTWINDOW when the mouse is held over the item for a few seconds.

poslist: If specified, a list of positions relative to window that are the edge points for the FILLREGION routine. If NIL, the user will be prompted to define the outer border of the region desired to be active. Holding the SHIFT key will define the last point used in defining the edge. If this field is non-nil, Inside.pos must be specified.
Inside.pos: If specified, this would be the inside position in which the Fillregion routine would begin filling from. If poslist is non-nil, then this field must be specified.

Description of use: Like the CREATEIR function, this function creates IREGIONS. However, the functionality of this routine is quite different. There are times when you do not care what is within a particular region. Say, for example, you have a map of some country and you wish to surround a particular region of the country with an IREGION as you wish to denote an area rich in some mineral deposit or some other characteristic. Such a characteristic is oblivious of the borders of the country’s states or provinces, streams, rivers, etc., yet you would like to make active a very general area. Upon calling this function, you are prompted to button around the area of interest. And so, in viewing the crosshairs cursor, you begin buttoning about specifying the border of the area you wish to make active, independent of what is inside it. To stop being prompted for the next edge, simply hold the SHIFT key on the keyboard, (either one will do), as you make your last button selection. At this point, the lisp DRAWCURVE function will take effect and draw the closed region you’ve defined. Note that the first and last points do not have to touch as the DRAWCURVE routine will connect them for you. You will also be prompted to button within the region you’ve marked. It is here that the Fillregion routine will begin filling your region from. When complete, this function adds the IREGION to the window and returns the irezion added.

Examples:
(SURROUNDIR window 21930 ‘myfunction "This is the helpstring")
(SURROUNDIR (WHICHW) 1234 ‘MY.SELECTED.FN "This is the helpstring" ‘((5 . 5) (6 . 50) (50 . 50) (50 . 7)) ‘(10 . 10))

(ADD.IREGION window irezion) [Function]

window: the window to which the irezion is to be added.
irezion: the IREGION to be added to window.

Description: This function will add irezion to window which will then allow mouse selection of that IREGION.

(REMOVE.IREGION window irezion) [Function]

window: the window in which the irezion exists.
irezion: the IREGION you wish to remove from window.

Description: This function removes the region from a list of active irregular regions which is stored as a window property of the window. The list of irregular active regions can be found by evaluating: (ALL.IREGIONS window)).

(INTERSECTING.IREGIONS? window flg) [Function]

window: a window.
flg: either T or NIL

Description: This function sets up window to allow selection of intersecting iregions. If two or more iregions overlap and this function had been called with flg = T, then when the overlapping region is selected, all of those iregions will be high-lighted and each IREGIONs BUTTONEVENTFN will be called. If flg is set to NIL, then the last IREGION created in that intersection of iregions will be selected. (Please be aware that intersecting iregions might generate effects that you do not wish to have. That is, if you leave the iregion "ON" (the exact same thing you see when you hold the
mouse button down on the iregion, done by inverting that iregion) and create another iregion intersecting with the first, then the mask of the second would have a partial image of the first. At this point, buttoning in an area where both regions intersect might show everything but the intersection of those regions. Sometimes, it all depends on the order that they are created and what iregion’s mask is left on or off. Shades that are “negatives” or “equals” of one another might make matters more complex than necessary when they are intersected. It is recommend that you play with this function in order to understand how it actually works so that when you work it into your application you’ll have a better idea of the functionality and end-results). If this becomes a problem, an EDIT.MASK function has been provided so that you may edit the mask of the iregion by hand. Currently, there are no programmatic methods for doing this.

(ALL.IREGIONS window) (Function)

window: a window containing IREGIONS.

Description: This function returns a list of all the IREGIONS attached to window.

(DOSELECTED.IREGION window iregion button) (Function)

window: the window associated with iregion.
iregion: the iregion to be activated
button: the button which selected iregion.

Description: Applied iregions BUTTONEVENTFN to window, iregion and button. This provides a programmatic way of activating a given IREGION. This does not invert the iregion.

(EDIT.MASK iregion) (Function)

iregion: the IREGION whose mask you want to edit.

Description: This function is provided for buttoning in places where the MASK is not set. More explicitly, TARGETing a region (while creating the regions) specifies the places where the FILLREGION routine is to create a mask. For example, if a US state contains many rivers one pixel wide, the FILLREGION routine will fill around the river, but not the river itself. This means that when the mouse is positioned on the river, the region will not shade because the mask does not have that bit turned on. However, if the mask is edited and the rivers filled in, buttoning on those rivers will activate the IREGION.

(INVERT.IREGION window iregion) (Function)

window: the window in which the iregion exists.
iregion: the IREGION targeted for shading.

Description: This will highlight the iregion with that iregions shade. Calling it a second time will low-light it.
(IREGIONP  iregion)               (Function)

  iregion: the IREGION to be tested.

  Description: This function returns NIL if iregion is not an IREGION datatype and returns iregion if it is an IREGION.

(IREGIONPROP  iregion  prop  newvalue)               (Function)

  iregion: the region of which you are setting/requesting the property.

  prop: the property in which you are interested.

  newvalue: the new value to be assigned to prop.

  Description: As with WINDOWPROP, if newvalue is not specified, it will return the current value of the iregion’s property. If newvalue is specified, then the property will be reassigned with that value. If a prop name is not one of the fields of an IREGION record, it will be stored in property-list format on the USERDATA field of the iregion record.

IREGION fields:
  BUTTONEVENTFN - function called when iregion is selected.
  USERDATA - property list format for user properties (similar to WINDOWPROP).
  REGION - region relative to the window that surrounds the iregion.
  MASK - a bitmap the same size of REGION that is blackened where the iregion is active.
  SHADE - the shade number or bitmap used to shade the region.
  HELPSTRING - the string that is printed in the PROMPTWINDOW when a region is held.

Examples:

(IREDIONPROP  iregion  'SHADE)  -- returns shade of iregion
(IREDIONPROP  iregion  'SHADE  21930) - assigns new shade to iregion.

(SHOW.ALL.IREGIONS  window  shade  delay)               (Function)

  window: the window in which the IREGIONs exist.

  shade: the shade with which the iregions will be shown.

  delay: the time (in milliseconds) between which each IREGION is displayed. (if delay is NIL, then a default of 500 is used.)

  Description: This function will shade and unshade in shade (black is used if shade is NIL), each IREGION that has been created in the particular window. This is especially useful when the user has lost track of the number of IREGIONS within a window.

(WHICH.IREGIONS  window  posorx  y)               (Function)

  window: the window in which the IREGIONs lie. (if window is NIL, default is window to which mouse points).

  posorx, y: the location within the window where the IREGIONs can be found. These points must be local to the window’s coordinates...not the screen. (if posorx is a position, then it will be used, otherwise if x or y are not numbers then the current mouse position is used.)

  Description: Will return either NIL or the list of IREGIONs found in window and specified by posorx, y.
Examples:

(WHICH.IREGIONS)
(WHICH.IREGIONS MY.WINDOW 50 23)
(WHICH.IREGIONS MY.WINDOW '(50 . 23))

Saving IRegions

IREGIONS can be saved on a file by setting a variable to be the value returned by ALL.IREGIONS. This variable can be saved by using the file package command, UGLYVARS.

Example:

(SETQ IRS (ALL.IREGIONS (WHICHW)))
(SETQ SAVEIRSCOMS '((UGLYVARS IRS)))
(MAKEFILE 'SAVEIRS)

The file SAVEIRS can be loaded and IRS will be set. You can then add IRS to a window by doing:

(WINDOWPROP (WHICHW) 'IREGIONSLIST IRS)
(WINDOWPROP (WHICHW) 'BUTTONEVENTFN 'IN.CURSOR.REGION)

Caution: Some properties on the USERDATA field of an IREGION might not be saved correctly such as a window which can not be saved on a file.

Window images can be saved on a file by creating a bitmap the same size as the window, BITBLT from the window to the bitmap, and then saving the bitmap with the file package command VARS.

Example use of the AIRegions package:
1. Open a window...about 1/4 of a screen.
2. Use the paint function provided when you right-button in the window and paint a picture.

3. With your mouse in this painted window, type in:
   (CREATEIR (WHICHW) 21930)

4. The cursor changes shape and prompts for creating a region similar to the prompt for creating a window. In this case, span a region that contains California.

5. When you are done, and the mouse button is released, the region spanned will remain temporarily on the screen. The cursor changes into a target and now prompts for a left-button within the region.
Select somewhere in California. When done, left-button the mouse outside and away from the temporarily blocked off region. (If you want to continue selecting areas of the same irregular region, in this example, the upper left corner of California, then button that area within the squared off region. As you can see, your irregular region does not necessarily have to be connected).

6. To test it out, simply button anywhere in California and it will fill to a nice shade of grey, as we have just set it up to do:

![Image of California]

7. To create more active irregularly shaped regions, follow steps 3 through 5 above. If you want to set the selection of one of the regions to activate the execution of some function that calls RINGBELLS, and have the region shade to black upon selection, type in the following in the top level typescript window keeping the mouse within the painted window.

```
(CREATEIR (WHICHW) 65535 'IR.TESTFN)

(DEFINEQ (IR.TESTFN (LAMBDA (WINDOW IREGION BUTTON)
  (If (EQ (QUOTE LEFT) BUTTON)
   then (RINGBELLS 2))))
```

Span the cursor out over another state/region and repeat steps 3-5 above. When you button in this IREGION, the IREGION will temporarily shade black, and call the RINGBELLS function. Note that like menu selection, the function is called only when you release the button within the region. If the mouse button is held down and you move over the created IREGIONs, they will shade and unshade as you enter and exit them.

Note: if you wish to create your own shades but don’t know what shades correspond to which numbers, call the function (EDITSHADE) and begin selecting points that you want shaded. When you are done, the function will return the appropriate shade number. You can also use 16x16 bitmaps for the shade of an IREGION (try (EDITBM (BITMAPCREATE 16 16)))

DEMO PACKAGE: To run the demo package, load AIRegions-Demo.

**Intersecting Iregions**

1. Create a window and paint in the following:
2. Now call CREATEIR passing in this window and a shade of 4747 and surround the left circle and select inside that circle and also in the intersecting area for the area fill. Repeat this for the right circle but use a different shade (say 42405).

3. Now, with your mouse in the window, call the function (INTERSECTING.IREGIONS? (WHICHW) T). When you button in the intersection of the two circles, you should get:

4. When the mouse is released inside of the intersecting region, both IREGIONs BUTTONEVENTFN will be called.

Comments and suggestions are welcome.

INTRODUCTION

The AISBLT module provides a fast(er) interface for reading AIS format files into Lisp bitmaps. It does not provide all the arcane features found in the READAIS module.

CLIENT INTERFACE

The functions provided by the AISBLT module which are intended to be used by clients are

(AISBLT.BITMAP FILE SOURCE-LEFT SOURCE-BOTTOM DESTINATION DESTINATION-LEFT DESTINATION-BOTTOM WIDTH HEIGHT HOW FILTER)  [Function]

The SOURCE-LEFT, SOURCE-BOTTOM, DESTINATION, DESTINATION-LEFT, DESTINATION-BOTTOM, WIDTH, and HEIGHT arguments are interpreted in the same way as the corresponding arguments to BITBLT. FILE is either an open stream, or a filename. If a filename is provided it will be passed to FINDFILE, which searches the directories specified by the special variable AISDIRECTORIES [Variable] which should be a list of directories where the AIS file is likely to be found.

The argument HOW should be one of the atoms FSA, :FSA, TRUNCATE, :TRUNCATE. HOW is only applicable in the cases where the source and destination are a different number of bits per pixel (source bpp > destination bpp). If HOW is not specified, it defaults to FSA. FSA indicates that the source should be reduced to the bits per pixel of the destination by applying the Floyd-Steinberg dithering algorithm, as described in Newman & Sproull, Principles of Interactive Computer Graphics, pg. 226. TRUNCATE indicates that only the high order bit(s) of the source should be used.

The function

(AISFILEHEADER STREAM)  [Function]

Can be used to determine whether a file has a well formed AIS header, and what the attributes indicated in the header are. The result of the function is a property list describing the AIS attributes:

:RASTER  [Key]

The :RASTER property will always be present. The value is also a property list

:SCAN-COUNT  [Key]

An integer value indicating the number of scan lines in the image

:SCAN-LENGTH  [Key]

An integer value indicating the number of pixels in a scan line of the image
:SCAN-DIRECTION [Key]
An integer, indicating the direction of the scan. Scan direction 3 is top to bottom, left to right,
and is the only scan direction that this package will deal with at this time.

:SAMPLES-PER-PIXEL [Key]
An integer, indicating the number of samples per pixel. This package will only deal with files
having one sample per pixel at this time.

:CODING-TYPE [Key]
An unsigned integer indicating the coding type of the raster image. A value of 1 indicates
uncompressed array format, and is the only type recognized by this package at this time. For
convenience, the constant

AIS-RASTER-CODING-UCA [Constant]

is bound to the value 1. If the raster coding types are extended, more constants will be
defined.

The rest of the properties are coding type dependent. For the AIS-RASTER-CODING-UCA
file, the following properties are present:

:BITS-PER-SAMPLE [Key]
An unsigned integer, indicating number of bits per sample

:WORDS-PER-SCAN-LINE [Key]
An unsigned integer, indicating how many 16 bit words form a single scan line of the image.

:SCAN-LINES-PER-BLOCK [Key]
A signed integer, indicating how many scan lines are present before there is block padding. A
value of -1 indicates no blocking.

:padding-per-block [Key]
A signed integer, indicating how many padding words per block. A value of -1 indicates no
blocking.

:placement [Key]
The placement property is optional. The value is a property list with keys :LEFT, :BOTTOM, :WIDTH,
and :HEIGHT. The values are unsigned integers.

:photometry [Key]
The photometry property is optional. The value is a property list with keys :SIGNAL (integer), :SENSE
(integer), :SCALE (integer), :SCALE-A (pair of integers), :SCALE-B (pair of integers), :SCALE-C (pair
of integers), :SPOT-TYPE (integer), :SPOT-WIDTH (integer), :SPOT-LENGTH (integer), :SAMPLE-
MIN (integer), and :SAMPLE-MAX (integer).

A complete description of the meaning of the photometry parameters can be found on page 38 of the
AIS format description, filed on (indigo)<altodocs>aismanual.press.
INTRODUCTION
The Analyzer package is used by the Proofreader (see PROOFREADER). It defines a class of analyzers, of which the proofreader is but one. Later, analyzers will be developed for languages other than English.
INTRODUCTION

This package is an extension to the SAMEDIR Library package so that if AUTOSAMEDIRFLG is non-NIL, MAKEFILE will automatically switch to the directory its file argument was originally made to instead of invoking the SAMEDIR dialogue. (It uses the FILEDATES property of the file.)

Notice and Acknowledgement: This package was developed while the author was an employee of Applied Expert Systems, Inc. (Apex), Cambridge, MA. The author thanks the company for its support and assumes full responsibility for the contents and maintenance of this package.

SOFTWARE REQUIRED

AUTOSAMEDIR.LCOM
SAMEDIR.LCOM

FIXES

Extension to SAMEDIR package so that if AUTOSAMEDIRFLG is non-NIL, MAKEFILE will automatically switch to the directory its file argument was originally made to instead of invoking the SAMEDIR dialogue. (It uses the FILEDATES property of the file.)
AUXMENU is a Lispers package that creates a middle-button background menu. This menu acts like the right-button background menu that exists in any Interlisp sysout in most respects. The menu includes commonly used Interlisp functions that require no arguments to be useful.

Global Variables

MiddleButtonBackgroundMenuCommands [Variable]

DefaultMiddleButtonBackgroundMenuCommands [Variable]

MiddleButtonBackgroundMenu [Variable]

MiddleButtonBackgroundMenuCommands is a list of MENU items (in the same format described in the Interlisp Reference Manual) which is used to create the middle button background menu. DefaultMiddleButtonBackgroundMenuCommands is the default value of MiddleButtonBackgroundMenuCommands. Individual users may reset MiddleButtonBackgroundMenuCommands, or they may add to or change it. If the user changes this variable, MiddleButtonBackgroundMenu should be set to NIL. All variables are initialized by the package as it is loaded. All necessary interaction is performed in the promptwindow, and the result of any menu item is printed to the promptwindow if it is non-nil.

Default Menu Items

Login - This item performs a (LOGIN) via the promptwindow.

Greet - This item performs a (GREET).

Logout - This item does a (LOGOUT).

Cleanup - This item performs a (CLEANUP) via the promptwindow.

Reclaim - This item executes (RPT 5 (QUOTE (RECLAIM))).

Closeall - This item closes all currently open files by performing (CLOSEALL).

Open Files - This item lists the currently open files to the promptwindow using (OPENP).
Connect - This item prints the currently connected directory to the promptwindow. The subitems of this item make the connected directory the one shown as the item. The 'Default' subitem connects the system to the value of the variable LOGINHOST/DIR. The 'Other' subitem prompts the user for a directory name, makes that the connected directory, and adds it to the menu.

VMem Size - This item prints the current size of the virtual memory file (in pages) to the promptwindow. It uses (VMEMSIZE).

Free Pages - The number of free pages in device DSK are printed to the promptwindow. (DISKFREEPAGES) is the function that provides this information.

Disk Partition - This item prints the name of the current partition to the promptwindow. The printed value is the result of calling (DISKPARTITION).

Volume Display - Turns the volume display window on via (VOLUMEDISPLAY 'ON).

Default Printers - Types the value of DEFAULTPRINTINGHOST to the promptwindow.

File Changes - Lists the result of (FILEPKGCHANGES) to the promptwindow.
INTRODUCTION

BackgroundImages is a module which makes it easy to apply graphically interesting static images to the background of one’s Lisp screen. To use the package in the simplest way, load it and call

\[ \text{Function} \]

This will put an entry called “Background” on your background menu (in a manner compatible with the module BACKGROUNDMENU), so that it will look something like this:

If (as shown) you select one of the subitems of “Background>Change,” your background will be painted with the image whose name you selected. The background images currently available are

- **DurerCats**: a reflected picture of a cat from an engraving by Albrecht Durer
- **Parc**: a picture of the Xerox Palo Alto Research Center
Rhine:  a picture of a village on the Rhine river
Steinheim:  a picture of a relatively unfortified castle
TwoDollar:  a picture of part of a two dollar bill

If the image you select is a different size than your screen, you may want to control how the image is applied.  There are three different image painting modes: "Center," which centers the image on the screen and paints gray in the remaining space; "Tile," which tiles the screen with the image; and "Reflect," which tiles the screen with edge-matched reflections of the image.  (This last mode is particularly effective with the DurerCats image.)  To change the mode, select one of the subitems of "Background>Mode."  To the currently set mode, just select "Background>Mode" itself.  Note that once you have changed the mode, to see its effect, you must reapply the background image (by selecting "Background>Change>ImageName").

If you want a less busy background, you can use a plain gray.  To apply it, just select "Background."  To change the shade of gray, select "Background>Shade."  Again, to see the effect of the shade change, you must reapply the background shade (by selecting "Background").

DETAILS

Background images to be used with this module must be represented in files that can be read by either HREAD or READPRESS.  For convenience, they should be named according to the conventions mentioned below under BACKGROUND.FILES.

BackgroundImages does take some pains to reduce user wait time.  First, it is very lazy about file interactions, and defers them until it is quite clear they cannot be avoided.  And second, when one selects a background, it is cached so that changing back to it will be significantly faster than fetching it the first time.  Since the cached background bitmaps consume quite a bit of space, they can be removed by the GAINSPACE mechanism.

The public interface to this package, more fully described, is as follows:

(BACKGROUND.SETUP  NAMES)  [Function]

Puts an entry on the background menu which enables users to change backgrounds easily.  The entry will be labeled "Backgrounds" and if invoked will turn the screen background gray.  The entry will have several subitems, each labeled with the name of the background image it will, if selected, put on the screen.  The argument NAMES is meant to specify the names of the images; it must be a list either of dotted pairs (whose CAR is the name of an image and whose CDR is the name of the file in which a representation of that image can be found) or of atoms (each of which is the name of an image).  If NAMES is NIL, BACKGROUND.SETUP will call (BACKGROUND.FILES) to generate a set of background image names.

(BACKGROUND.FILES  WHICH)  [Function]

Returns a list of dotted pairs whose CAR is the name of an image and whose CDR is the name of the file in which a representation of that image can be found.  Generates this list by looking on LISPUSERSDIRECTORIES for files of the form "background-*.bitmap" or "background-*.press"; all such files are taken to be representations of background images.  Image representation files that are not named and located according to this convention will have to be specified directly to BACKGROUND.SETUP.  If WHICH is T, it will search all the LISPUSERSDIRECTORIES; otherwise it will search till it finds the first directory with background images in it.
(BACKGROUND.FETCH  NAME FILENAME MODE)  [Function]
Causes the image whose name is NAME, and for which there is a representation in file FILENAME, to
be applied to the screen background. It is this function which the background menu subitems call to
apply new images. If FILENAME is not specified, BACKGROUND.FETCH will attempt to find an image
representation file whose name is either "background-NAME.bitmap" or "background-NAME.press" on
any of the LISPUSERSDIRECTORIES. MODE specifies how the image will be applied to the
background if it is a different size than the screen. MODE should be one of the atoms CENTER, TILE,
or REFLECT; it defaults to CENTER. CENTER causes the image to be centered with a white border
around it; TILE causes the image to tile the screen; and REFLECT causes the image to tile the screen
such that each tile is a reflection of those adjacent to it.

(BACKGROUND.MODE  MODE)  [Function]
Sets and accesses the mode (as described above) which will be passed to BACKGROUND.FETCH
when the latter is invoked from the background menu subitems. MODE, if provided, gives the new
mode setting. Returns the previous mode setting.

(BACKGROUND.SHADE  NEWSHADE)  [Function]
Changes the default background shade.

(BACKGROUND.CENTER  BITMAP)  [Function]
Returns a screen-sized bitmap with BITMAP centered in it with a border colored with the default
background shade.

(BACKGROUND.TILE  BITMAP)  [Function]
Returns a screen-sized bitmap that is tiled with BITMAP with one of the tiles centered.

(BACKGROUND.REFECT  BITMAP)  [Function]
Returns a screen-sized tiled bitmap such that each tile is a reflection of those adjacent to it and such
that the center tile is a copy of BITMAP.
INTRODUCTION

If you love to load all those fun LispUsers packages but can’t deal with background menus that look like this:

\[
\begin{array}{c}
\text{Inspecticide} \\
\text{Sketch} \\
\text{DInfo} \\
\text{VStats} \\
\text{DumpCache} \\
\text{AR Edit} \\
\text{FileBrowser} \\
\text{SaveVM} \\
\text{Hardcopy} \\
\text{SendMail} \\
\text{Idle} \\
\text{Snap} \\
\text{Lisp Listener} \\
\text{Chat} \\
\text{PSW} \\
\text{TEdit} \\
\text{Keyboard}
\end{array}
\]

don’t despair! With just a few quick calls you can have a background menu that looks like this:

\[
\begin{array}{c}
\text{Idle} \\
\text{Snap} \\
\text{Exec} \\
\text{Chat} \\
\text{PSW} \\
\text{TEdit}
\end{array}
\]

(don’t worry, they didn’t disappear, they’re just hiding under “Exec”).

DESCRIPTION

BackgroundMenu defines several functions for rearranging your background menu to suit your taste.
(BkgMenu.rename.item item newname) [Function]
changes the name of a background menu entry

(BkgMenu.move.item item superitem atend) [Function]
makes item a subitem of superitem. If atend it is placed after any subitems of superitem; otherwise it is placed before them. If superitem is NIL item is placed at the top level of the menu.

(BkgMenu.reorder items superitem atend) [Function]
just like BkgMenu.move.item but moves a list of items. Useful for changing the order of the items in a menu.

(BkgMenu.remove.item item) [Function]
throws item out of your background menu.

(BkgMenu.fixup) [Function]
BackgroundMenuTopLevelItems [Variable]
BackgroundMenuFixupMode [Variable]
each top level item which isn't on the global BackgroundMenuTopLevelItems is made a subitem of BackgroundMenuSuperItem. If BackgroundMenuFixupMode is 'top they’re added before any subitems of BackgroundMenuSuperItem, if it’s 'bottom they’re added after, and if it’s NIL items moved from the top are added at the top and items moved from the bottom are added to the bottom.

(BkgMenu.subitems item) [Function]
returns a list of the subitems of item (or the top level items, if item is NIL).

(BkgMenu.add.item item superitem atend) [Function]
adds a new menu item item as a subitem of superitem. If atend it is placed after any subitems of superitem; otherwise it is placed before them. If superitem is NIL item is placed at the top level of the menu

EXAMPLES
As an example of using BackgroundMenu, this is what I’ve got in my init file (which produces the changes shown above) (note that i’ve already loaded LISTEN):

(BkgMenu.rename.item "Lisp Listener" " Exec ")
("Lisp Listener" is just too long. the blanks before and after Exec are just there to improve the spacing)

(SETQ BackgroundMenuTopLevelItems '(Idle Snap " Exec " Chat PSW TEdit))

(SETQ BackgroundMenuSuperItem " Exec ")
(BkgMenu.fixup)
(‘ Push everything i don’t use regularly under the now-renamed Lisp Listener)

(BkgMenu.reorder.items BackgroundMenuTopLevelItems)
(‘ and put the top level items in the order i prefer)

If I later add more packages which add junk to the top level of my background menu, just calling (BkgMenu.fixup) again will hide anything new under " Exec " with the rest of the junk.
When any of the above functions (except BkgMenu.add.item) require you to specify an item, you can usually just give a string with the menu entry (or an atom, which is coerced to a string). The case has to be correct, and blanks have to be in the right place. The function will do a breadth first search of the background menu and all its submenus to find such an entry. If for some reason you have the same entry in more than one menu, you'll have to disambiguate it. To do this, you pass a list for the item, where the first thing in the list is the menu entry, and the rest of the list is a path through the tree to find it. For instance, the item (one two three) means find an entry whose text is "three", then find an entry in the tree underneath it whose text is "two", and the find an entry under that whose text is "one".

The item argument to BkgMenu.add.item is a standard menu item, i.e. a list of (label form help.string).

All of the functions return T if they were able to do as asked and NIL otherwise (you tried to do something with a menu entry which isn't there, or you tried to make a circular menu structure). The only exception to this rule is BkgMenu.subitems, which as previously mentioned returns a list of the subitems, or the atom NotAnItem if it's given a nonitem.
INTRODUCTION

BICLOCK, a realtime screen clock, with hour, minute and second hands. It behaves as a kind of icon, in that it is partly transparent. The snapshot to the right above shows that the greater part of the window’s area is transparent, in this case the gray background and part of the PSW window show through. The clock-image may be either black or white, and the shadow around the image-parts the opposite color: The reason for having a shadow is to make the clock easier to read. Markers and/or digits may be chosen.

Seconds

The seconds hand is optional. When on, the clock process consumes a lot of time, but because (1) it blocks very frequently and (2) shuts itself off temporarily, if the "load" is higher than usual, that does not seem to irritate at all. The "load" is measured by the continuous average of time spent in block, i.e. each round robin. A "usual load" is computed by a second level of average over the "load" value. The "usual load" is limited by upper and lower "reasonable" constants. If "load" is more than 10% above "usual load" then the seconds hand is shut off. This is a rather heuristic method, but works reasonably well. When the seconds hand is shut off, the image is updated approximately once per minute.

WINDOW COMMANDS

Most window commands are applicable. The clock will preserve its "square" form when shaped. More details of the hour/minute markers/digits will appear only when the window is large enough, less if the window is smaller. The digits' fonts are chosen among fonts already "in core".

Left button

Left buttoning the window will print the current date (and alarptime) in the promptwindow. Holding down left shift key while buttoning the window will copyselect current date, by BKSYSBUF.

Middle button, Alarm

There is a simple alarmclock facility built into the clock. That and some other options may be accessed by middlebuttoning the window and selecting the appropriate command from the menu that pops up.
Choosing the command "Set Alarm" will change the clock into showing current alarmtime and attach an adjust menu below the clockwindow. If no alarm time is known, current daytime plus 1 minute is used as default. Any change to the alarmtime is shown both by the clock and printed in the promptwindow. Buttoning "OK!" in the attached menu exits the adjust mode. When the alarmtime is reached, you will be aware of that fact... to shut the alarm off, use the "Alarm Off" in the popup menu.

FUNCTIONALITY

One clockwindow is usually created automatically when the file is loaded. More clockwindows may be created by the following function call:

(BICLOCK props) [Function]

Creates a new window. Value is the new window. The call may be done either with a free property list as first arg or spread. See properties below. The different properties are also controlled by the variables below. It is allowed to have more than one clock running, but see "bugs" below.

When the BICLOCK file is loaded, the following variables are initialized, some through INITVARS, so that you can set them before loading the file:

BICLOCKUSERPROPS [Variable]
Change this to customize the overall behavior of the clock. Value must be a free property list. Defaults to NIL.

BICLOCKDEFAULTPROPS [Variable]
These are the default properties, don’t modify this, modify BICLOCKUSERPROPS above.

Properties are searched for in the following order.

1. those specified in the function call.
2. those specified by the BICLOCKUSERPROPS variable.
3. those specified by the BICLOCKDEFAULTPROPS variable.

BICLOCKINITIALPROPS [Variable]
Modify this if you like some specific property for the initial clock. BICLOCK is called with these properties when the file is loaded, defaults to NIL. If you want no initial clock, set it to (CREATE NIL).

BICLOCKWINDOW [Variable]
The window of the clock that is created when the file is loaded.

BICLOCKIDLEPROPS [Variable]
(IDLE.BICLOCK) [Function]
BICLOCK is called with BICLOCKIDLEPROPS from the Idle function IDLE.BICLOCK, defaults to start bouncing at center of screen.

Properties

Recognized properties and allowed values are:

SECONDS T (default), if seconds hand shall be used, or NIL, if no seconds
COLOR interior color, one of WHITE (default) or BLACK
MARKS NIL (default), if no marks should be used, or one of HOURS, HOUR&MINUTE, 3/6/9/12 or a modulo number
DIGITS \quad \text{NIL, if no digits, or one of HOUR (default), 3/6/9/12 or a modulo number}

DIGITFORMAT \quad \text{one of ARABIC or ROMAN}

CHIME \quad \text{NIL (default), no chime, or one of HOUR, QUARTER or a modulo number}

ALARM \quad \text{NIL (default), no alarm, or a the standard string representation of a date}

SIZE \quad \text{a number describing both width and height of the clock window, defaults to 119}

HORIZONTAL \quad \text{generic place on screen, one of LEFT, CENTER, RIGHT (default), or a number to specify left border of window}

VERTICAL \quad \text{generic place on screen, one of BOTTOM, CENTER, TOP (default), or a number to specify bottom border of window}

REGION \quad \text{if nonNIL, a region, overrides SIZE, HORIZONTAL and VERTICAL for clockwindow}

WINDOW \quad \text{if nonNIL, a window, overrides REGION, SIZE, HORIZONTAL and VERTICAL}

CREATE \quad \text{T (default), create a clock, or NIL, do not create, probably only useful if you want no initial clock...}

The nonformal meaning of the Modulo numbers mentioned above are: "1" means: on each possible place. "2" means: on even places and so on...

**KNOWN BUGS:**

1. If the window is reshaped when in "set alarm" mode, the whole window group will be square.

2. Running more than one clock concurrently with seconds hand on, may behave a bit round robin because the load sensor is local for each clock and "senses" the other clocks.

3. Overlapping two clock windows creates a funny image in the intersecting area.
This document last edited on 4-mar-87

(READBINARYBITMAP WIDTH HEIGHT FILE) [Function]
reads a series of bytes from FILE and creates a WIDTH times HEIGHT bit map with contents. Note that each scanline of the bit map is rounded up to the nearest multiple of 16 bits (two bytes).

(WRITEBINARY BITMAP FILE) [Function]
writes out BITMAP to FILE in format read by READBINARYBITMAP. Please note that READBINARYBITMAP must be supplied with width and height.

(WRITEBM FILE BITMAP) [Function]
writes BITMAP on FILE first preceding with width and height (in binary) such that it can be read in with READBM.

(READBM FILE) [Function]
reads width, height, and then appropriate size bit map.

(WRITEBMLST FILE LST) [Function]
writes a list of bit maps on FILE.

(READBMLST FILE) [Function]
reads a list of bit maps.

The following functions open and close FILE.

(READPRESS PRESSFILE) [Function]
reads press file PRESSFILE and returns a bit map. Can only handle press files generated by PRESSBITMAP and a couple of other utilities. Has no smarts, and is not easily extended.

(WINDOWBM BITMAP POSITION) [Function]
creates and returns a window containing image of BITMAP. Will be at POSITION or (GETPOSITION).
Bitmap-Gallery

Sampler and Documentation for bitmaps, especially those useful as screen background.

Eventually I’ll rationalize the names and packages. Most of these bitmaps have been snapped from the screen and are smaller than they might appear. They usually look better on screen than they do on paper. Please send suggested additions to Foster.PA.

WARNING: This file is only usable in Lyric.

DESCRIPTION

BUTTONS is a facility for creating icons which will trigger actions when they are clicked in. Each button has a label and an action associated with it. There are three different things which one can do with buttons: Trigger the action, move the button, and bring up a button command menu. These are initiated by use of the left, middle, and right mouse buttons within each button. The command menu is also available through the background menu entry “Button Control.” The button world can be tailored (somewhat) using button properties.

Clicking with the Left mouse button on a button and then letting up causes the action associated with the button to be taken. If the action is a list it will be evaluated, otherwise it is stuffed into the system read buffer. The button inverts while the action is being taken.

Clicking with the Middle mouse button allows one to move the button on the screen. The button moves on a grid, unless the left shift key is down.

Clicking with the Right mouse button brings up a menu with the following commands:

- **Redisplay** -- redisplay this button
- **Move** -- same as clicking with the middle button
- **Copy** -- make a copy of this button and move it
- **Edit** -- invoke the structure editor on the label and the action of this button
- **Close** -- close this button (but keep it)
- **Rollout: Close All Buttons** -- close all open buttons
- **Delete** -- delete this button
- **Rollout: Delete All Buttons** -- delete all existing buttons
- **Create Button** -- make a new button and move it
Exposé Buttons -- redisplay all buttons (including previously closed ones)
Align Buttons -- prompts for alignment axis, then for successive buttons to line up
Save Buttons -- save current buttons and button properties in default data file
Rollout: Save Some Buttons -- prompt for file and for which buttons to save
Restore Buttons -- discard current buttons, restore saved buttons and properties
Rollout: Load Some Buttons -- prompt for file to load, keep/discard current buttons

When BUTTONS is loaded, a single "Create Button" button is placed in the lower left corner of the screen. See RESTORE.BUTTONS below for setting up your buttons programmatically.

FUNCTIONAL INTERFACE

(CREATE-BUTTON action label location noopenflg) [Function]

Creates a button with indicated action and label at the given location and displays it unless noopenflg is non-NIL. If action is NIL, label will be used for action. If label is NIL, (CAR action) will be used for label if action is a list, action otherwise. If both action and label are NIL, the values of the button properties DEFAULT-ACTION and DEFAULT-LABEL will be used instead. If location is not a POSITION or a REGION, the user is prompted for a location.

(BUTTONSPROP propname {newvalue}) [Function]

Returns the current value of the button property propname. If newvalue is given, it becomes the new value. The following properties (and their initial values) are currently in use:

- DEFAULT-LABEL "Create Button"
- DEFAULT-ACTION (CREATE-BUTTON)
- MENU-FONT (MODERN 12 BOLD)
- LABEL-FONT (MODERN 10 BOLD)
- GRID-ORIGIN (15 . 15)
- SAVE-DIRECTORY NIL
- EDIT-SHADE 4104
- EXEC-SHADE 65535

The value of SAVE-DIRECTORY must be acceptable to the function DIRECTORYNAME (i.e., either NIL for login host & directory, or T for current directory, or a standard host & directory spec).

(RESTORE-BUTTONS filename keep-current-buttons?) [Function]

Reinstalls the buttons stored on filename, which defaults to SAVED-BUTTONS.DATA on the directory indicated by the button property SAVE-DIRECTORY. Existing buttons are discarded unless keep-current-buttons? is non-NIL.
(SAVE-BUTTONS filename buttons) [Function]

Saves the given buttons in filename, which defaults to SAVED-BUTTONS.DATA on the directory indicated by the button property SAVE-DIRECTORY. If buttons is NIL, all current buttons will be saved.

(SAVE-SOME-BUTTONS filename buttons) [Function]

Saves the given buttons in filename. If buttons is NIL, you are prompted to indicated the buttons to be saved. If filename is NIL, you are prompted to supply a file in which to save the indicated buttons.

(LOAD-SOME-BUTTONS filename) [Function]

Loads the buttons in filename. You are prompted to indicate whether to keep the current buttons or discard them. If filename is NIL, you are prompted to supply a file from which to load the buttons.
INTRODUCTION

CALENDAR is a program which can be used to display a calendar on your screen, and keep track and remind you of events and appointments. Calendar 2.04 (the current distributed version) runs in the Koto or Lyric releases of Lisp. The version number appears in the title bar of each Calendar window. Calendar needs the Lisp Library package TABLEBROWSER, which it loads automatically. It also uses TEdit. Various font sizes (from 8 to 36) in the families TimesRoman and Helvetica may be needed, depending on the size chosen for month windows. Reminder files created by earlier versions of Calendar are incompatible with this version.

I. STARTING CALENDAR

Load CALENDAR.LCOM from your favorite LispUsers directory, eg.

LOAD ({ERIS}<LISPUSERS>CALENDAR.LCOM

and then type (CALENDAR). You will get a menu of years (the menu always shows five years starting with last year). If you select a year with Left, it will create a Year window containing a calendar for that year. Each month in the Year window is also a menu item. If you now select a particular month with Left, CALENDAR will create a Month window showing a calendar for that month. You can now select a particular day within the month to bring up a Day browser (described in the next section). The Month window also shows small calendars of last month and next month. You can bring up those months in the current month window by selecting them with Left. If you select them with Middle, the program will create a new window for that month. The Year menu has an entry labelled “Other”. If you select this, it will prompt you to type in a year, if you want one that isn’t on the menu.

You can have as many year and month windows open at the same time as you like. Month and day windows can also be reshaped to occupy less room on the screen. You can Shrink any of the CALENDAR windows to an appropriate icon, or close them when they are not needed. The reminder facility remains active. If you close your last year window, call (CALENDAR) again to get a new one. CALENDAR uses the Lisp Prompt Window to display informative messages.

Please send your comments, suggestions, and bug reports to me - Denber.WBST (ARPA: Denber.WBST@Xerox.COM). Thanks.

II. REMINDERS

The Day Browser

Clicking Left in any day in a month window will open a browser on that day. The browser displays each reminder for the day, along with its event time if it is a timed reminder. You may have more than one browser open at the same time. When you close a month window, it will automatically close all day browsers for that month. There is a menu across the top of the browser with the following items:
Add: Lets you create a new reminder in this day. If you select Add, the program will bring up a TEdit window containing a template for the new reminder. The template contains several fields you can select and fill in. These are described in Creating Reminders, below.

Display: Brings up the full contents of the reminder in a TEdit window.

Delete: Useful for deleting reminders that you no longer need. By default, timed reminders are deleted automatically after they "fire"; untimed reminders do not fire and are never deleted automatically. Calendar will immediately remove reminders which you delete from the month window (and the reminder’s line in the day browser is crossed out), however it will leave reminders that have fired visible in the month window until you redisplay it (e.g. September is visible, you select Redisplay from the right-button menu in the title bar or select September again in the Year window, and all fired September reminders will be purged from the month window when it redraws).

Update: Saves your reminders to disk (see the section on Saving reminders below).

Send Mail: Prompts you for a name to send to. The selected reminder will be mailed to that person when it activates, rather than displaying on your screen. Note that no validity checking is done when you enter a name, so your message could conceivably not be delivered if you typed the name wrong, for example. The message is mailed when the time arrives. Of course, this assumes that your system is running at that time, that you have Lafite active, and that Lafite is running in the mode (GV or NS) corresponding to your intended recipients.

Period: Brings up a menu with the choices Daily, Weekly, Monthly. The selected reminder will be made periodic and will appear at the selected intervals.

Creating Reminders

You can create a new reminder either by clicking Add in a day browser, or by clicking the middle button in a day box in the month window. This opens a new reminder form with the following fields:

Title: The reminder title should not exceed one line in length. This field will be displayed in the Day browser and the month window. This field may not be omitted; all others are optional.

Event time: The scheduled time for the event. By default, this is also the time at which the reminder will be activated. If this field is omitted, the reminder is "untimed". Untimed reminders do not alert you. When a timed reminder activates, it beeps and brings up a TEdit window containing the full reminder text.

Alert time: The time at which you would like the reminder to activate. You might want to be reminded of a meeting 10 minutes early, for example. The alert time can be set to any time, before or after the event time, as long as it is in the same day. If this field is omitted, it defaults to the value of the event time.

Alert: Edit this field to contain just the word Yes or No. If you choose No, the reminder will not alert you, even if it is a timed reminder. If this field is omitted, it defaults to the value set in the Options menu (see Programming below).

Duration: The expected length of the event. Version 2.04 makes no use of this field.

Message: The actual message you want to save. This may be any TEdit text or omitted entirely.

The new reminder form includes a menu with the choices Save and Abort. After filling in the fields you want, clicking Save will add the reminder to the system and close the form. Clicking Abort at any point cancels the reminder being created.
The time can be entered in almost any reasonable format, eg. 9:00 AM, 9 AM, 9 a.m., 2:30 PM, 2:30 P.M., 1430, or can be left out by skipping over the field. Times are “AM” by default, so if you only type 8:30, it will assume 8:30 AM. A heuristic is included to ask “Are you sure?” if you type a time earlier than 9 without an AM/PM qualifier (this value is controlled by CALDAYSTART, see Programming, below). Times of noon and midnight are special cases. There is no generally accepted meaning for the expressions "12:00 AM" and "12:00 PM". If you want a reminder at noon, enter the time as "12:00" or just "1200". Because reminders are added to a particular day, midnight is ambiguous; there is no provision for entering a time of midnight.

If you add a reminder for a time that is already in the past (for example, to keep a historical record of an event after the fact), the program will save the reminder but will warn you that the reminder time has already passed.

Expired timed reminders are automatically deleted upon expiration by default. Setting the variable CALKEEPEXPIREDREMS (see Programming, below) will cause timed reminders to be retained after firing.

Reminders which are scheduled for a time when your machine is not running will not be activated the next time you login. This avoids having a possibly long sequence of "dead" reminders popping up at login time.

Saving and loading reminders

You can save your reminders in a file at any point. The first time you start Calendar, it will ask you to provide a default host and directory for reminder files. You should enter this in the usual format, for example {DSK}<Lispfiles> or {ERIS}<your-name>LISP>. This will become the new value of CALDEFAULTHOST&DIR (it is initially NIL). To save your reminders, select Update from any day browser. This will open a pop-up menu of currently loaded files, plus an "other" item for giving a new file name. If you enter a new name, all currently unsaved reminders will be stored under that name. If you select an existing file, the contents of that file will be updated and any new reminders created since the last update will be added to it. If you abandon your sysout or if your machine crashes, you can have Calendar automatically reload your reminders file when you restart (see CALDEFAULTHOST&DIR and CALLOADFILE in Programming, below). You can also load a reminder file at any time by holding the middle button down in the title bar of a month window. This will open a pop-up menu of files that have already been loaded, plus an "other" item to specify a new file. In this version of Calendar there is never any need to load a reminder file more than once. The menu is useful, however, to show which files have already been loaded.

An "almanac" reminder file is distributed along with Calendar. It contains a variety of holidays and notable dates for the year. The file is called CALMANACnn, where nn is the last two digits of the year. For example, the file for 1986 is called CALMANAC86. You can load this file by selecting Other from the middle button menu and typing CALMANAC86.

By default, the program will only save your reminders when you select Update. You may control file updating by changing the Auto File Update option available under the Options menu item in the month window. See Programming, below.

III. PROGRAMMING

A programmatic interface is provided to let you create day, month, or year windows from your own programs.

If your reminder text is a Lisp list (anything inside parentheses), when the reminder fires the program will evaluate the list rather than displaying the reminder in a window and beeping.
Functions

(CALENDAR m d yr) [Function]
m, d, and yr are integers specifying a month, day, and year, respectively. Arguments are specified as follows:
If only yr (must be 4 digits) is supplied, brings up a year window for that year and returns yr.
If m and yr are supplied, brings up a month window for that month and returns m.
If m, d, and yr are supplied, brings up a day window for that day and returns d.
For invalid combinations (missing yr, d and yr only), returns NIL. Also returns NIL if yr is out of range (the calendar algorithm is only valid for years between 1700 and 2100).

Examples:

(CALENDAR 10 NIL 1984) shows a calendar for October 1984 and returns 10.
(CALENDAR 10 NIL 84) returns NIL (out of range).
You can also call Calendar with the keywords TODAY, THISMONTH, and THISYEAR.

Examples:

(CALENDAR 'THISYEAR) shows a Year window for 1986, if this year is 1986. This might be used in an init file, to always start a Calendar of “this year”.

(CALENDAR 'TODAY) opens a Day browser for today, containing all of today’s active reminders.

(CALLOADFILE file-name) [Function]
 Loads the file file-name into the reminder system and returns T. Returns NIL if the file is not found or is not a valid reminder file.

Example:

(CALLOADFILE '(DSK)<LISPFILES>CALREMINDERS)

Variables

CALALERTFLG [Variable]
Initially T. This controls whether or not reminders whose Alert field is not specified should alert you when they fire. T means they will. NIL means they won’t.

CALDAYDEFAULTREGION [Variable]
Initially (32 200 350 100). This specifies the default size for day browsers. The location is only used for day browsers opened programatically.
CALDAYSTART [Variable]
Initially 900. This represents the time (in 24 hour format) at which your regular day starts. The system will use it to confirm times you enter without a "PM" indicator if they are less than this value. For example, it is more likely that 4 means 4 PM than 4 AM.

CALDEFAULTALERTDELTAMIN [Variable]
Initially 0. This represents the time (in minutes) before or after the event time you want reminders to be activated, if no explicit alert time was given for them. To be reminded before the event, make this value negative. The resulting time must still be in the same day as the event.

CALDEFAULTHOST&DIR [Variable]
Initially NIL. This is the host and directory on which your reminder files will be saved if you type the file name without a directory specification. The system will prompt you to enter a value for this the first time you start it.

CALFLASHTIMES [Variable]
Initially 0. Specifies the number of times to flash the destination given by CALFLASHTYPE when a reminder is activated.

CALFLASHTYPE [Variable]
Initially 'None. Specifies which window should be flashed when a reminder is activated. Can be set to 'WINDOW, to flash the reminder display window, or 'SCREEN to flash the entire screen. CALFLASHTIMES (above) should be set to the desired number of flashes.

CALFONT [Variable]
Initially 'TimesRoman36. This variable controls the font used to display the Month Window. You can change it for example, by saying (SETQ CALFONT (FONTCREATE 'HELVETICA 18)). The change takes effect the next time you display a month. If you reshape a month window, the program will try to find a smaller font to fit the new window size, but the value of CALFONT will not be changed.

CALHARDCOPYPOMFLG [Variable]
Initially T. This variable controls the printing of the phase-of-the-moon icons when you hardcopy a month window. Setting it to NIL suppresses this printing. Month windows are hardcopied at printer resolution in Koto, screen resolution in Lyric.

CALHILITETODAY [Variable]
Initially 'CIRCLE. This variable determines how today’s date will be highlighted in a month window. The default is to draw a circle around it. If you set this to 'BOX, a light gray grid will be placed over the date. Setting this to NIL suppresses all date highlighting.

CALKEEPEXPIREDREMSFLG [Variable]
Initially NIL. If you set this to T, Calendar will not automatically delete reminders when they fire (they can still be deleted using the Delete menu command, above). The default action is to delete reminders when they fire, although they will remain visible until the window is redisplayed.
CALMONTHDEFAULTREGION [Variable]
Initially (32 32 868 700). This specifies the default position and size for month windows. If you set the size to a value small enough to allow several month windows side by side, the windows will tile left to right, bottom to top.

CALREMDISPLAYREGION [Variable]
Initially (200 400 300 400). This specifies the default position and size for reminder display windows.

CALTUNE [Variable]
When a reminder is activated, it will play the tune stored here (in PLAYTUNE format). This is initially a two-note “ding-dong”. Set this to NIL if you want no audible warning. 1100’s and 1132’s have no hardware for sound.

CALUPDATEONSHRINKFLG [Variable]
Initially ‘Never. This means that Calendar will save your reminders on a file only when you explicitly click Update from a Day Browser. If set to ‘Shrink, it will cause Calendar to save your reminder file automatically only when you shrink the Month window. This is useful when you are entering many reminders at the same time, but it means you must remember to explicitly shrink the month window or your reminders will be lost if your machine dies. If set to ‘Always, causes Calendar to immediately save each reminder as soon as it is created.

You can also set these variables interactively by clicking on the box marked “Options” in any Month window. This brings up a freemenu similar to the TEdit expanded menu.

<table>
<thead>
<tr>
<th>Calendar Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert: Yes No</td>
</tr>
<tr>
<td>Keep expired rem.: Yes No</td>
</tr>
<tr>
<td>Auto. file update: Always Shrink Never</td>
</tr>
<tr>
<td>Alert delta: 0</td>
</tr>
<tr>
<td>Host &amp; dir.: {OSK}&lt;LISPFILES&gt;</td>
</tr>
<tr>
<td>Apply!</td>
</tr>
</tbody>
</table>

Alert: Specifies the default for the Alert field in the new reminder form. Sets the value of CALALERTFLG (described above).

Keep expired rem.: If set to No, the system will automatically delete reminders when they fire (although they remain listed in the month window until the next time you redisplay it). Sets the value of CALKEEPEXPIREDREMSFLG.

Auto. file update: Always means that the system will update the reminder file every time you create a new reminder. Shrink means update only when a month window is shrunken. Never means updates will be done only when you explicitly select Update from a Day browser. Sets the value of CALUPDATEONSHRINKFLG.

Alert delta: Sets the value of CALDEFAULTALERTDELTA.

Host & dir.: Sets the value of CALDEFAULTHOST&DIR.

After you have made the selections you want, click Apply! This sets the selections and closes the menu. If you don’t want to make any changes, just close the menu (like closing any window). This
preserves the previous settings even if you changed them in the menu. Any changes you make to these variables are not saved automatically in reminder files.

IV. LIMITATIONS

Day groups must begin and end in the same month.

The calendar algorithm is valid only for years between 1700 and 2100.

V. KNOWN BUGS

Today-circling function occasionally fails to erase the old day.

VI. FUTURE PLANS

Automatic scheduling.

Automatic communication with other Calendars.
INTRODUCTION

This module enables the transfer of bitmaps between the Envos Lisp and Xerox ViewPoint environments. The medium used for the transfer is an NS file server (i.e. a file drawer which can be accessed by both environments). The possibility of transferring Lisp bitmaps into the ViewPoint environment is particularly useful for documenting Lisp applications.

MODULE EXPLANATIONS

There are essentially two major functions:

(IL:WRITECANVAS BITMAP FILE) \[Function\]
This function writes the BITMAP on to FILE and makes FILE of type ViewPoint Canvas, whereby FILE must be on an NS file server.

(IL:FETCHCANVAS FILE) \[Function\]
This function reads FILE into a Lisp bitmap, whereby FILE must be on an NS file server. Additionally there are two auxiliary functions to aid in the use of the above two functions.

(IL:SNAPBM) \[Function\]
and

(IL:CANVAS-FROM-WINDOW WINDOW FILE) \[Function\]

EXAMPLES

All examples must be typed into an INTERLISP exec.

To write a canvas of a Lisp screen region:

(WRITECANVAS (SNAPBM))
To write a canvas of a Lisp window:

(CANVAS-FROM-WINDOW (WHICHW)

To read a canvas into a Lisp bitmap:

(SETQ X (OPENSTREAM

(CAVEAT

When fetching a canvas, there is a 50-50 chance that the Lisp bitmap will be O.K. It could, however, come out distorted (this is due to the differing ways in which ViewPoint and Lisp handle bitmaps, Lisp uses 16 complement, ViewPoint 32 complement - or something like that). If this should be the case, simply increase the canvas width in ViewPoint by 5 millimeters (approx. 16 pixels) and repeat the fetching process.

Unfortunately in the Lyric version if one repeatedly wrote a canvas with the same name, the file server somehow got mixed up and set the file-info of the folder above the canvas into "type = canvas"! One could put this right with the (SETFILEINFO...) function in Lisp, although under normal circumstances one does not write out a canvas repeatedly with the same name any way. I have been unable to test the behaviour in MEDLEY.

Compatibility has only been tested up to ViewPoint 1.1.
INTRODUCTION

The file CD implements a UNIX*-style facility for manipulating the connected directory. It also insures that the connected directory is always displayed.

CD PATTERN

MODULE EXPLANATIONS

CD is defined as a command which allows low-overhead means of effecting many common changes of connected directory. Its behaviour is partly conditioned by three global variables:

CD.DEFAULT.HOST [Variable]

CD.DEFAULT.PREFIX [Variable]

CD.DEFAULT.USER [Variable]

CD.DEFAULT.HOST defaults to DSK. CD.DEFAULT.PREFIX defaults to the name (e.g. DSK) of the local disk volume on a Dandelion, otherwise NIL. CD.DEFAULT.USER defaults to the value of USERNAME, and is updated automatically after GREETing.

The value of CD is always a CONS-pair of the old and new connected directories.

On hosts which support some form of sub-directory, CD needs to know the character which is used to separate sub-directories. The table CD.OS.SEPRS is an a-list which determines this mapping - it is initialised to map UNIX* and VMS to ”/” and DSK, NS and IFS to “>”. To enter this table it looks up the host first in CD.OS.SEPRS directly, then via NETWORKOSTYPES. In the documentation which follows, “>” means whatever the separator is for the relevant host.

The possibilities for pattern are as follows:

empty

Connects to the directory determined by the conjunction of CD.DEFAULT.HOST, CD.DEFAULT.PREFIX and CD.DEFAULT.USER.

{anything}

Interprets pattern as a complete directory specification, and connects to it.

<anything

Interprets pattern as a directory specification to be qualified by CD.DEFAULT.HOST and CD.DEFAULT.PREFIX, and connects to it. For example if CD.DEFAULT.HOST is (server) and CD.DEFAULT.PREFIX is NIL, then CD <dir>sdir> is equivalent to CD (server)<dir>sdir>, whereas if
CD.DEFAULT.PREFIX was /user and server was known to be running UNIX*, then CD <dir/sdir> would be equivalent to CD {server}</user/dir/sdir>.

>.>rest

Equivalent to CD rest. This is purely for compatibility with UNIX*.

..>.>rest

Equivalent to peeling off one (sub-)directory from the currently connected directory, followed by CD rest. For example, if connected to {server}<dir>sdir>, then CD ..>sdir1 is equivalent to CD {server}<dir>sdir1>. Note that because of common lisp reader peculiarities, you cannot use .. alone under a common lisp read-table. The synonym << can be used instead.

otherwise

Treat pattern as a further specialisation of the current directory, and connect to the resulting subdirectory. For example, if connected to {server}<dir>sdir>, then CD ssdir is equivalent to CD{server}<dir>sdir>ssdir>.

Note that throughout, the closing ">" is optional.

Menu Interface

At any time you can left button in the window displaying the current connected directory, and see a menu of all the directories you have yet been connected to. Selecting one will move you there. You can also shift-select out of this menu into the current input stream. This latter is very useful when typing file names.

Middle buttonning in the directory display window will give you a menu of directories, followed by a menu of Connect/Browse/Delete. Connect does so, Browse brings up a file browser and Delete removes the directory from subsequent menus.

---

*UNIX is a trademark of Bell Laboratories.
INTRODUCTION

ChatEmacs, in conjunction with the chatemacs.elc module for GnuEmacs, enables use of the mouse for scrolling and selection in GnuEmacs. It also allows use of the META key for escape-prefix commands and automatically switches Chat in and out of Emacs mode when entering and leaving the editor.

DETAILS

After loading ChatEmacs, typing META-char will send an ESCAPE character, followed by the vanilla character. CTRL-META-char sends an ESCAPE followed by CTRL-char. Once ChatEmacs is active, most Emacs commands should require only one keystroke. Since Emacs was originally designed for terminals with a META shift key, this makes the Emacs command set somewhat more regular and easier to remember. For example, scrolling forward and backward will be on CTRL-V and META-V, respectively.

In order to enable mouse actions, first load CHATEMACS.LCOM into Interlisp. After opening a Chat connection and running GnuEmacs, either load chatemacs.elc manually (by giving the ^Xload command), or add the following line to your GnuEmacs init file (.emacs):

(lload "chatemacs")

After loading chatemacs.elc, the title bar on your Chat window should say “Emacs ON”. If not, middle-buttoning the “Emacs” menu item in your Chat window will enable mouse events to be sent to Emacs. After ChatEmacs has been activated for the first time, the Chat window’s title bar will always indicate whether Emacs mode is on or off. If your mouse clicks don’t seem to be taking effect, check the title bar first!

Automatic switching frees the user from having to manually turn ChatEmacs on and off when using Emacs. In most circumstances (see exceptions below) automatic switching will not interfere with other Chat operations, and can be left enabled. Auto-switching is controlled by:

CHATEMACS.SWITCH.ENABLED [Variable]

When this variable is non-NIL, Chat will respond to a sequence of two consecutive ESCAPEs by toggling the flag that controls mouse event sending. The state of the flag is noted in the window’s title bar, just as if the menu command had been executed. CHATEMACS.SWITCH.ENABLED is defaulted to NIL.
auto-switch-enabled [GnuEmacs Variable]

This variable controls auto-switching on the GnuEmacs side of the Chat connection. If it is non-nil, GnuEmacs will send a switch command when chatemacs.elc is loaded, and another when exited via a ^X-^C command.

Using Emacs with the mouse

The chatemacs.elc module, at the GnuEmacs end of the connection, determines the interpretation of mouse clicks. The current user interface is more complicated than I would like, and suggestions for improvements are welcome.

The most basic operations are fairly simple: left button in a text buffer moves the Emacs "point" to wherever the cursor is pointing. Right button moves the mark (the typein cursor will move for a couple of seconds just to show you where you've just put the mark), and copies the new region to the kill buffer (for use with "shift-select," see below).

Scrolling with the mouse works more or less as in Interlisp, with the scrollbar being the right-hand part of the screen past column 80. Alternatively, holding down the META key makes the entire text area act as a "scrollbar". As in most Envos environments, left button scrolls the line that the mouse is pointing to to the top of the window, right button moves the top line down to the mouse cursor, and middle button "thumbs", taking the vertical displacement of the mouse cursor as an offset into the file (i.e., top = beginning of file, bottom line = end of file).

Shift- and control- mouse clicks perform editing operations: shift-left copies the contents of the kill buffer to wherever the mouse is pointing (the closest thing to Interlisp shift-select I could come up with). Control-left and control-right kill from point to where the mouse is pointing (sort of like control-select). Control-shift-left moves the mark without copying anything to the kill buffer.

Mouse clicks in the mode line and minibuffer do things that were inherited from il-mouse's ancestor, a package for the BBN Bitgraph terminal. Maybe you will find them useful. They are: The modeline acts like a sideways scrollbar, left=top. In the minibuffer, left button is equivalent to typing META-X, middle button evals an expression you type in, and (beware!) right button suspends Emacs (equivalent to typing ^X^Z).

As mentioned above, the current user interface is sort of, how shall I say, "gnarly." If you have better ideas, please let me (Gobbel.pa) know.
CHATSERVER

By: Larry Masinter (Masinter.PA@Xerox.COM)

This document last edited on September 7, 1988.

REQUIREMENTS

CHATSERVER-NS Requires: CHATSERVER and COURIERSERVE.

CHATSERVER-RS232 requires: CHATSERVER and (DLTTY or DLRS232C). As of this date, CHATSERVER-RS232 hadn’t been tested with Medley.

CHATSERVER-TCP requires: CHATSERVER and TCP. As of this date, CHATSERVER-TCP is unreliable: the chat server sometimes leaves open the connection and will not open another one.

In general, a protocol chatserver requires CHATSERVER and a a protocol converter. Sources for TCP server available.

CHATSERVER also loads LispUsers modules CL-TTYEDIT and SIMPLECHAT.

The module PREEMPTIVE is useful in conjunction with CHATSERVER but not required.

INTRODUCTION

CHATSERVER is a general facility that allows a Lisp workstation to be controlled from a dumb terminal. In addition to CHATSERVER, you will need a protocol driver: something that connects the CHATSERVER to a communication protocol. The various protocol drivers are the mechanism by which CHATSERVER can be controlled; versions include using XNS via CHATSERVER-NS, TCP/IP TELNET protocol via CHATSERVER-TCP, and RS232 via CHATSERVER-RS232. CHATSERVER-NS is the most reliable, although CHATSERVER-RS232 has worked reliably in the Lyric release.

The server implements password protection using the same mechanism as IDLE. There is another variable, CHATSERVER.PROFILE, which gets searched first for ALLOWED.LOGINS so that you can have a different setting.

IL:CHATSERVER.PROFILE [Variable]

The value of the variable CHATSERVER.PROFILE appended to the front of IDLE.PROFILE when determining login options etc for the chatserver. The property IDLE.ONLY is also consulted; if T, chatserver only allows connections when machine is in idle mode.

Example:

```
(SETQ CHATSERVER.PROFILE ‘(ALLOWED.LOGIN (T) IDLE.ONLY T))
```

means to allow only the previously logged in user, and then, only when in IDLE mode.

QUIT [Exec Command]

The QUIT exec command exits a chatserver session. It signals an error if you are not running in a chatserver session.
Documentation for CHATSERVER-NS:

CHATSERVER-NS implements the Xerox Network Systems GAPTTELNET protocol. It allows connection to a machine running Medley from other machines that implement this protocol, including Viewpoint (using ViewpointChat), External Communication Service servers (which allow dial-in from remote terminals into an XNS network), XDE workstations and other Interlisp-D implementations (Koto, Lyric, Medley.)

Gaptelnet is a courier server program, and so requires the COURIERSERVE lispusers module (which it loads automatically). The following function is part of COURIERSERVE

(COURIER.START.SERVER) [Function]

This "starts" the courier server process which listens for connection attempts. It is necessary to call this (once) before you can CHAT to your Lisp workstation. (If the process dies for some reason, you will not be able to CHAT until you restart the process.)

Documentation for CHATSERVER-TCP:

This module was an attempt to implement a TCP/TELNET server. Unfortunately, the mechanism by which it waits for a connection is buggy, and it does not negotiate terminal characteristics properly with the client calling workstation. It is therefore unreliable & may need to be restarted. Using telnet from a Sun to Lisp I've found it was necessary to explicitly tell the Sun not to echo, to send character at a time, etc.

(TCPCHATSERVER) [Function]

It is necessary to call this function to spawn the process that waits for TCP connections.

Documentation for CHATSERVER-RS232:

The CHATSERVER-RS232 module attempts to allow for connections on the RS232 or TTY port on an 1186 or 1108. It uses DLRS232.

(RS232CHATSERVER) [Function]

Spawns a process waiting for a character to be typed on the RS232 port, and then starts a chatserver session.

Other notes:

The server runs a standard (XCL) exec. Note that you can't do graphics; the debugger will not attempt to open a window, only the type-in commands are available, ED will give you the "teletype" editor. Interrupt characters enabled are ^E, ^D, DEL, ^B, ^H and ^T. (Note that currently interrupts are only processed when they are read, and there is no way to interrupt a run-away process.)

Typeout uses a "---more---" style: after (PAGEHEIGHT) lines, the system will prompt you with a "---more---". Type any character, and the more will be erased.

Chatserver assumes you are chatting from a DM2500 emulator, and treats font changes as a switch between bold and regular as appropriate.

The PREEMPTIVE Lispusers module is useful when running chatserver, because it will keep the running process from blocking out the typein process. For some protocol drivers (and the NS server in particular), this is necessary to avoid timeouts.
CHATSERVER advises various facilities in the environment that normally create menus to check to see if the "controlling" keyboard is not the workstation console; these facilities include TTYIN, the editor, the debugger, CHAT. Thus, calls to the editor use the teletype-style editor from Interlisp, while FIX does not generally allow character editing.
This package checks source files against compiled files in a directory and prompts you about whether you want to (RE)COMPILE the files that need it. It compares the FILECREATED expressions, and determines whether a BRECOMPILE with CHANGES will suffice or if it is necessary to BCOMPL the file.

(CHECKSET FILES COMPFLG) [Function]

FILES is a list of files. If FILES is NIL, CHECKSET is driven by the variable FILESETS.

COMPFLG can be:

N don't compile, just return list. List can be passed to COMPFFILES.

Y or NIL compile

ASK ask, for each file, whether to compile it.

FILESETS [Variable]

Used by (CHECKSET NIL): FILESETS is a list of variables, each of which has a value that is a list of files. (CHECKSET NIL) peforms (for X in FILESETS join (CHECKSET (EVALV X))). For example,

if FILESETS = (0LISPSET 1LISPSET) and 0LISPSET = (ATERM LLREAD BREAK), 1LISPSET = (WINDOW EDIT) then (CHECKSET) will check if each of those files in turn need recompiling.

(COMPFFILES LST) [Function]

takes a list of elements of the form (RECOMPILE FILE) (COMPILE FILE) as returned by CHECKSET with COMPFLG=N and performs the corresponding operation.
HPRINT is designed primarily for dumping circular or reentrant list structures (as well as other data structures for which READ is not an inverse of PRINT) so that they can be read back in by Interlisp. The CIRCLPRINT package is designed for printing circular or reentrant structures so that the user can look at them and understand them.

A reentrant list structure is one that contains more than one occurrence of the same EQ structure. For example, TCONC makes use of reentrant list structure so that it does not have to search for the end of the list each time it is called. Thus, if X is a list of three elements, (A B C), being constructed by TCONC, the reentrant list structure used by TCONC for this purpose is:

```
A B C NIL
```

This structure would be printed by PRINT as ((A B C) C). Note that PRINT would produce the same output for the nonreentrant structure:

```
NIL C A B C NIL
```

In other words, PRINT does not indicate the fact that portions of the structure in the first figure are identical. Similarly, if PRINT is applied to a circular list structure (a special type of reentrant structure) it will never terminate.

For example, if PRINT is called on the structure:

```
NIL
```

it will print an endless sequence of left parentheses, and if applied to:

```
A
```
will print a left parenthesis followed by an endless sequence of \textit{A}'s.

The function \texttt{CIRCLPRINT} described below produces output that will exactly describe the structure of any circular or reentrant list structure. This output may be in either single- or double-line format. Below are a few examples of the expressions that \texttt{CIRCLPRINT} would produce to describe the structures discussed above.

First figure, single-line:
\((\texttt{(A B *1* C)1})\)

First figure, double-line:
\(((\texttt{(A B C) 1})
\texttt{ 1})\)

Third figure, single-line:
\((\texttt{*1* 1})\)

Third figure, double-line:
\((\texttt{1})
\texttt{ 1})\)

Fourth figure, single-line:
\((\texttt{*1* A . 1})\)

Fourth figure, double-line:
\((\texttt{A . 1})
\texttt{ 1})\)

The more complex structure:

\begin{center}
\begin{tikzpicture}
\node (A) at (0,0) {A};
\node (B) at (1,0) {B};
\node (C) at (0,-1) {C};
\node (D) at (1,-1) {D};
\draw (A) -- (B);
\draw (B) -- (D);
\draw (D) -- (A);
\end{tikzpicture}
\end{center}

is printed as follows:

Single-line:
\((\texttt{*2* (*1* 1 *3* 2 A *4* B . 3) . 4})\)

Double-line:
\(((\texttt{1 2 A B . 3) . 4})\)
\texttt{21 3 4}\)

In both formats, the reentrant nodes in the list structure are labeled by numbers. (A reentrant node is one that has two or more pointers coming into it.) In the single-line format, the label is printed between asterisks at the beginning of the node (list or tail) that it identifies. In the double-line format, the label is printed below the beginning of the node it identifies. An occurrence of a reentrant node that has already been identified is indicated by printing its label in brackets.

\texttt{(CIRCLPRINT LIST PRINTFLG RLKNT)} [Function]
Prints an expression describing \texttt{LIST}. If \texttt{PRINTFLG}=\texttt{NIL}, double-line format is used, otherwise single-line format. \texttt{CIRCLPRINT} first calls \texttt{CIRCLMARK}, and then calls either \texttt{RLPRIN1} (if \texttt{PRINTFLG}=\texttt{T}) or \texttt{RLPRIN2} (if \texttt{PRINTFLG}=\texttt{NIL}). Finally, \texttt{RLRESTORE} is called to restore \texttt{LIST} to its unmarked state. Returns \texttt{LIST}.

\texttt{(CIRCLMARK \texttt{LIST} \texttt{RLKNT})} \hspace{1cm} \text{[Function]}

Marks each reentrant node in \texttt{LIST} with a unique number, starting at \texttt{RLKNT} plus one (or one, if \texttt{RLKNT} is \texttt{NIL}). Value is \texttt{RLKNT}. Marking \texttt{LIST} physically alters it. However, the marking is performed undoably. In addition, \texttt{LIST} can always be restored by specifically calling \texttt{RLRESTORE}.

\texttt{(RLPRIN1 \texttt{LIST})} \hspace{1cm} \text{[Function]}

Prints an expression describing \texttt{LIST} in the single-line format. Does not restore \texttt{LIST} to its un\texttt{CIRCLMARKed} state. \texttt{LIST} must previously have been \texttt{CIRCLMARKed}, or an error is generated.

\texttt{(RLPRIN2 \texttt{LIST})} \hspace{1cm} \text{[Function]}

Same as RLPRIN1, except that the expression describing \texttt{LIST} is printed in the double-line format.

\texttt{(RLRESTORE \texttt{LIST})} \hspace{1cm} \text{[Function]}

Physically restores list to its original, unmarked state.

Note that the user can mark and print several structures that together share common substructures, e.g., several property lists, by making several calls to \texttt{CIRCLMARK}, followed by calls to RLPRIN1 or RLPRIN2, and finally to RLRESTORE.

\texttt{(CIRCLMAKER \texttt{LIST})} \hspace{1cm} \text{[Function]}

\texttt{LIST} may contain labels and references following the convention used by \texttt{CIRCLPRINT} for printing reentrant structures in single-line format, e.g., (*1* . 1). \texttt{CIRCLMAKER} performs the necessary \texttt{RPLACA}s and \texttt{RPLACD}s to make \texttt{LIST} correspond to the indicated structure. Value is (altered) \texttt{LIST}.

\texttt{(CIRCLMAKER1 \texttt{LIST})} \hspace{1cm} \text{[Function]}

Does the work for \texttt{CIRCLMAKER}. Uses free variables \texttt{LABELST} and \texttt{REFLST}. \texttt{LABELST} is a list of dotted pairs of labels and corresponding nodes. \texttt{REFLST} is a list of nodes containing references to labels not yet seen. \texttt{CIRCLMAKER} operates by initializing \texttt{LABELST} and \texttt{REFLST} to \texttt{NIL}, and then calling \texttt{CIRCLMAKER1}. It generates an error if \texttt{REFLST} is not \texttt{NIL} when \texttt{CIRCLMAKER1} returns. The user can call \texttt{CIRCLMAKER1} directly to “connect up” several structures that share common substructures, e.g., several property lists.
CL-TTYEDIT

By: Larry Masinter (Masinter.PA@Xerox.COM)

This document last edited on November 24, 1987.

INTRODUCTION

This file patches the TTY editor so that it is a little more usable in Lyric/Medley for non-Interlisp sources. In particular, it changes the TTY editor so that EDITRDTBL is no longer used; the read table in effect at the time the ttieditor is invoked is used instead (*READTABLE*).

It patches the main editor loop (EDITCOM) so that the package and case of edit commands are ignored, i.e., if you type in the P command, it doesn't care whether it is XCL-USER:.P or IL:.P or |p|.

It patches EDITFPAT (which takes "find" patterns) so that you can specify patterns with --, &, ==, *ANY* in any package, and use --- instead of .. (since symbols consisting entirely of dots are not allowed in CL readtables.)

This file is especially useful if you are talking to another machine using CHATSERVER and need to edit something on the remote machine; since the CHAT connection is character only, you can't run (and the system doesn't attempt to run) SEDIT.
COLORDEMO

Maintained By: Frank Shih (Shih.envos@Xerox.com)

Uses: Color, Peano, ColorPolygons

This document last edited on 8-Nov-88

Color Demonstration Programs

The following functions are on file on COLORDEMO.LCOM.

(COLORDEMO) [Function]
brings up a menu of color demonstration programs. The system cycles through the entries on the menu automatically, allowing each to run for a small, fixed amount of time (typically 40 seconds). Selecting one of the entries in the menu causes it to start that program.

(COLORKINETIC Wait Window) [Function]
runs a color version of the standard Kinetic demo in Window. The demo works by BLTSHADEing random textures to Window to random regions of Window using random OPERATIONs with a bias towards OPERATION='REPLACE.

(VINEDEMO Wait Window) [Function]
draws a twisting vine that changes in thickness, direction, and color as it grows inside Window.

(RAINING Wait Window) [Function]
drops of rain appear to splash on to Window causing concentric circular ripples of color to spread outward on the surface of Window.

(MODARTDEMO Wait Window) [Function]
some of the art produced by this demo is at least as good as some that you will see in art galleries. The demo actually works by BITBLTing Window on to itself with a displacement with random SOURCETYPE and OPERATION, mixed in with some BITBLTed random textures.

(STARBURSTDEMO Wait Window) [Function]
far far away in a galaxy somewhere in the future, an unexplained physical force sweeps over peaceful stars turning them at once into brilliant exploding novas which are safely viewed at a distance through the rear view porthole of our fleeing spaceship.

(COLORPEANODEMO Wait Window) [Function]
the Peano fractal curve in color.

(BUBBLEDEMO Wait Window) [Function]

the Window fills with brilliantly colored soap bubbles. This demo works by calling FILLCIRCLE.

(OVERPAINTDEMO Wait) [Function]

uses masking techniques to print over the lower right color demo window. Notice that just the pixels of the character images get printed and not the white pixels that normally surround the character images.

(TILEDEMO Wait) [Function]

takes what currently appears in the four color demo windows and adds their images to a growing list called TILEBITMAPS. The demo then tiles the color screen background followed by repeatedly tiling the four color demo windows with randomly chosen tiles.

(TUNNEL Speed) [Function]

draws a series of concentric rectangles of increasing size in increasing color numbers. Speed determines the size of the rectangles. This can then be “run” by calling ROTATEIT, which is described below.

(MINESHAFT N OutFlg) [Function]

draws a series of concentric rectangles of size N in increasing color numbers. OutFlg determines whether the color numbers increase or decrease. This can then be “run” by calling ROTATEIT, which is described below.

(WELLDEMO Wait) [Function]

draws a series of concentric circles on the color demo windows in increasing color numbers. The circles are then “run” by rotating the color map.

(ROTATEIT BeginColor EndColor Wait) [Function]

goes into an infinite loop rotating the screen color map. The colors between BeginColor (default zero) and EndColor (default maximum color) are rotated. If Wait is given, (DISMISS Wait) is called each time the color map is changed. This provides an easy way of “animating” screen images.

(COLORPOLYDEMO ColorStream) [Function]

is on the file COLORPOLYGONS.DCOM. It runs a version of the Polygons program on the color screen.
COLORNNCC

By: >>Your Name<< (>>Your net address<<)

>>Other packages necessary to run this one<<

This document last edited on >>DATE<<

INTRODUCTION

This package is the Xerox Lisp software driver for Number Nine Computer Corporation's Revolution 512 x 8 color card. The IJCAI 1985 show featured an Interlisp-D color window system running on a Xerox 1108 attached to a Busmaster and color display. That color window system was based partly on a version of this package. This advanced high level software has become available with the Lyric release or Xerox Lisp.

NECESSARY HARDWARE

You need a Xerox 1108 with Extended Processor Option (CPE), Xerox Busmaster card, an IBM PC expansion chasis, a Number Nine Computer Corporation Revolution 512 x 8 color card, and a third party color display. Please contact your Xerox representative for details concerning acquiring and setting up all the required hardware.

Assuming you have all the hardware you need, turn it all on. This means

(1) Your 1108 is running Xerox LISP.
(2) Your PC expansion chassis is plugged in and powered on.
(3) A cable connects between your 1108 CPE board and your Busmaster board. (The Busmaster board does not go into the 1108, but should rest outside the 1108.)
(4) Another cable connects between your PC expansion chassis and your Busmaster board.
(5) A pair of purple and orange wires connects your Busmaster board to the +5V/Gnd power supply terminals on the side of your 1108.
(6) Your Number Nine Revolution 512 x 8 board is plugged into the PC expansion chassis.
(7) Your color display is plugged in and powered on.
(8) Three cables for red, green, and blue signal connect your Number Nine card to your color display.

Any reconnections that involve (3), (4), or (5) should be made while your 1108 is off. Until you issue some software commands, a black display is normal.
Check that your hardware is set up correctly by typing

\( \text{\texttt{COLORNNCC.STARTBOARD}} \) \quad \text{[Function]}\]

Taking less than a second to execute, there should be a noticable flicker on your color display, followed by what can be taken to be a stable abstract pattern representing the contents of the Number Nine card’s RAM when the PC chassis was turned on. If \texttt{COLORNNCC.STARTBOARD} doesn’t return and simply waits, there could be something wrong with the BusMaster card. If \texttt{COLORNNCC.STARTBOARD} does return, but the image is noisy instead of stable, it could be that you have to adjust the frequency selector on your color display.

**COLORNNCC SOFTWARE**

The COLORNNCC package provides the machine dependent portion of software that is needed to drive your color display assuming you are using an 1108 with COLORNNCC card and Busmaster. Other than LOADing the COLORNNCC package and turning the COLORNNCC package on using the function \texttt{COLORDISPLAY}, all additional functionality is provided by and documented with the COLOR package. There are no COLORNNCC functions that the user needs to call directly. The user calls functions described in the COLOR documentation.

Once your hardware is on, you can proceed to issue COLOR commands to your hardware. You should have the COLORNNCC package already LOADed from your LIBRARY directory. That is, you’ve already done something like (LOAD ’<LIBRARY>:COLORNNCC.DCOM). At this point it may be convenient to follow this documentation along with the documentation for COLOR in the Lisp Library Packages Manual. If you now type

\( \text{\texttt{(COLORDISPLAY ’ON ’REV512X8)}} \)

your display will now change from total black to a color test pattern with horizontal and vertical stripes. The sequence of events is that there should be a noticable flicker on your color display, followed by what can be taken to be an abstract pattern representing the contents of the Number Nine card’s RAM when the PC chassis was turned on, followed by a white wall covering up this abstract pattern, followed by the painting of this white wall with horizontal and vertical stripes of color woven together. There are now some simple tests you can do to satisfy yourself that your hardware is working. Here is a small list of things to try:

\( \text{(SETQ CSBM (COLORSCREENBITMAP))} \)
\( \text{(BLTSHADE ’WHITE CSBM)} \)
\( \text{(BLTSHADE ’RED CSBM)} \)
\( \text{(BLTSHADE ’GREEN CSBM)} \)
\( \text{(BLTSHADE ’BLUE CSBM)} \)
\( \text{(SETQ DS (DSPCREATE CSBM))} \)
\( \text{(DRAWLINE 0 0 500 500 10 ’REPLACE DS ’YELLOW)} \)
\( \text{(DRAWLINE 500 0 0 500 10 ’REPLACE DS ’CYAN)} \)
Assuming all has gone well to this point, you should now be able to try all the functions described in the COLOR package documentation. The COLORDEMO package is a good source of test programs to try — (IL:LOAD ’COLORDEMO. LCOM) to get this package. Both COLOR and COLORDEMO documentation are in your LispUsers’ Manual.
INTRODUCTION

This is a demonstration of communication capabilities. The COMMWINDOW module implements a "remote window" capability, where one user can watch (with slow update) a region of another users screen.

Both participants need to have COMMWINDOW loaded.

To show someone else a piece of your screen, call

\[ \text{(SEND-BITS partner &OPTIONAL frame)} \]  [Function]

The partner is the name of the machine you want to talk to. (The watcher has to be registered in the clearinghouse database; this is a NS protocol name.)

frame, if supplied, is a screen region to show. If it is omitted, send-bits will prompt the (sender) for a frame of the screen.

The sender has complete control over the frame. The frame appears as a gray frame around the area shown, like this:

(The frame consists really of 4 thin windows, so that you can really type/button inside it.)

The frame can be moved by left buttoning anywhere on it. Right buttoning on it makes it go away temporarily.

(Reshaping the frame can be accomplished by left buttoning the frame while the shift key is depressed. This doesn’t reshape the remote window currently, so this isn’t very useful.)

Since this is an experiment, there are a couple of parameters you can vary. The function (mode-menu) will bring up a window that lets you control any and all of these parameters.
The first is the shape of the areas sent in each packet.

**Currently available shapes are:**

- **square:** a square of bits as big as will fit in a single packet
- **rectangle:** 4 times wider than it is high.
- **horizontal:** as wide as the frame, and then as high can be
- **vertical:** as high as the frame and as wide as can be
- **h3:** this is a funny mode, where the update is in horizontal chunks, but spread out.

**PARAMETERS**

The parameter \ETHERLIGHTNING lets you tell the low-level ethernet code to randomly drop packets. This parameter can be used to study the effects of noisy communication lines on transmission protocol.

Another parameter gives you some local control over the region within the frame that is updated. There are three available values:

- **Sender:** Update near the sender’s cursor, when it has moved, ASAP.
- **Viewer:** Update near the viewer’s cursor, when it has moved, ASAP.
- **NIL:** don’t do anything special.

Another parameter lets you prune out sending packets that update regions of the display that have not changed. The tradeoff here between the cost of sending the packets vs testing a region to see if it has changed.

A recent addition was the following part of the protocol: when the mouse on the sender is moving, it will send a square around the mouse interleaved with any other transmission ongoing. That means you can make sure a remote area is being updated by wiggling the mouse.

The sender’s mouse is also tracked in the remote viewers viewpoint (the cursor shape is currently not tracked, however). The mouse coordinates are sent every packet, so that mouse position always updates.

The viewer has a limited option to place a pointer back on the sender’s screen: if the viewer holds the shift key down while the viewer’s mouse is in the view point window, a little pointer \[^{R}R\] will appear in the senders window and track the viewers cursor. (The pointer is in fact a little icon window.) When the viewer releases the shift key, the pointer icon disappears.

**CAUTIONS:**

- Don’t move the frame off the screen. It will just signal an error.
- The "don't change unsent tiles" parameter doesn't seem to work.
COMPAREDIRECTORIES

This document edited on

December 2, 1987
December 28, 1998 (Ron Kaplan)
April 7, 2018 (Ron Kaplan)
Rewritten December, 2021 (Ron Kaplan)

COMPAREDIRECTORIES compares the contents of two directories, identifying files according to their creation dates and lengths. It is called using the function

```
(COMPAREDIRECTORIES DIR1 DIR2 SELECT INCLUDEDFILES EXCLUDEDFILES USEDIRECTORYDATES OUTPUTFILE ALLVERSIONS)  [Function]
```

Compares the creation dates of files with matching names in the lists that CDFILES returns for DIR1 and DIR2. Collects or prints CDENTRIES for those files that meet the SELECT criteria. May also collect or print entries for relevant files that exist in DIR1 or DIR2 but not both.

SELECT specifies which the match/mismatch criteria for filtering the output. If SELECT is or contains

- **AFTER** or >: select entries where file1 has a later date than file2
- **BEFORE** or <: select entries where file1 has an earlier date than file2
- **SAMEDATE** or =: select entries where file1 and file2 have the same date
- **-**: exclude entries where file1 does not exist
- **-**: exclude entries where file2 does not exist
- **~=:** exclude entries where file1 and file2 are byte-equivalent

SELECT = NIL is equivalent to (< > - - -). Excludes files with matching dates, a useful default for identifying files that may require further attention.

SELECT = T is equivalent to (= < > - - -). Includes all files for processing by other functions or later filtering by CDSUBSET (below).

SELECT may also contain the token AUTHOR to indicate that authors should be provided in the printed output (see CDPRINT below).

Unless USEDIRECTORYDATES, the FILECREATED date is used for the date comparison of Lisp source and compiled files, otherwise the file-system CREATIONDATE is used.

If OUTPUTFILE=NIL, then the value is a CDVALUE structure with fields (CDPARAMETERS . CDENTRIES). CDPARAMETERS records the parameters in the call to COMPAREDIRECTORIES and CDENTRIES is the list of per-file comparison results. CDPARAMETERS has fields.
CDVALUE contains one entry for each of the file-comparisons that meets the SELECT criteria. Each entry is a CDENTRY record with fields

MATCHNAME INFO1 DATERULE INFO2 EQUIV

where MATCHNAME is the name.extension shared by the two files, and each file info is either NIL (for nonexistent files) or a CDINFO record with fields

(FULLNAME DATE LENGTH AUTHOR TYPE EOL)

TYPE is SOURCE for Lisp source (filecreated) files, COMPILED for Lisp compiled files, otherwise the PRINTFILETYPE (TEXT, TEDIT...) or NIL. EOL is CR, LF, CRLF, or NIL.

When both files exist, the date relation is one of <, =, or >. Otherwise, the date relation is * if only one file exists.

EQUIV is T for files that contain the same bytes. In that case, the date of the earlier file is assumed to be more accurate, it replaces the CREATIONDATE of the earlier file, and the date relation is changed to =.

If OUTPUTFILE is not NIL, then it is a filename or open stream on which selected entries will be printed (T for the terminal) by CDPRINT.

COMPAREDIRECTORIES always sets the variable LASTCDVALUE to the CDVALUE data structure. This is used by the functions below if their CDENTRIES is NIL.

(CPRINT CDVALUE FILE COLHEADINGS PRINTAUTHOR ) [Function]

Prints CDVALUE on FILE, with one line for each entry. The line for each entry is of the form

FILE1 (AUTHOR) SIZE DATE DATEREL DATE  FILE2 (AUTHOR) SIZE

For example

ACE.;1 (Joe) 235 2-May-1985 18:03:54 < 30-Sep-1985 11:14:48 ACE.;3 (Sam) 396

The line for byte-equivalent files is prefixed with ==. If the files are equivalent except for a difference in end-of-line conventions, the equivalence prefix will indicate the convention for each file (C for CR, L, for LF, 2 for CRLF). Thus C2 indicates that the files are equivalent except that file1 marks line ends with CR and file2 with CRLF.

COLHEADINGS can be a pair (col1 col2) of strings to be printed as column headings.

Note that because COMPAREDIRECTORIES sets LASTCDVALUE, evaluating (CPRINT) after COMPAREDIRECTORIES prints the results of the last comparison.

For conciseness, authors are included only if PRINTAUTHOR or if AUTHOR is included in the CDSELECT parameter of CDVALUE. Also, redundant file-name hosts/directories are not printed.

(CEDIT CDVALUE TITLE COLHEADINGS PRINTAUTHOR) [Function]

Produces the CPRINT output in a read-only TEDIT window, with TITLE if given.

(CBROWSER CDVALUE TITLE COLHEADINGS BROWSERPROPS SEPARATEDIRECTIONS MENUITEMS PRINTAUTHOR) [Function]
Produce the **CDPRINT** output in a **TABLEBROWSER** window with menu commands for comparing the contents of individual files, viewing files in read-only **TEDIT** windows, copying files from one directory to another, etc. Lisp source files are compared with **COMPARESOURCES**, text files with **COMPARETEXT**. If **SEPARATEDIRECTIONS**, the entry lines are grouped according to whether the date relation is < or >.

(CDFILES DIR INCLUDEDFILES EXCLUDEDFILES ALLVERSIONS DEPTH)  [Function]

Returns a list of full filenames for files in directory **DIR** (NIL=T=the connected directory) that match the other file-name filtering criteria. Files are excluded if:

Their name does not match a pattern in **INCLUDEDFILES** (NIL = *.*). Dotted files are excluded unless **FILEPATTERNS** includes .* and files in subdirectories are excluded if the number of subdirectories exceeds **DEPTH** (below).

They do not match patterns on the list **EXCLUDEDFILES**. *.* excludes all extensions, *.COM or just COM excludes extensions on **COMPILED-EXTENSIONS**. **EXCLUDEDFILES** contains .* to suppress dotted files unless .* also appears in **INCLUDEDFILES**.

They are not the highest version unless **ALLVERSIONS**=T.

**DEPTH** controls the depth of subdirectory exploration. T means all levels, NIL means no subdirectories. Otherwise the maximum number of > or / characters below the starting **DIR** in the full name of files.

(CDFILES) produces all the newest, undotted files in the immediate connected directory.

(CDMERGE CDVALUES)  [Function]

Merges all subsets of **CDVALUES** that have the same **CDSELECT** into a single **CDVALUE** with the union of their **CDENTRIES**. The **CDCOMPARDATE** of the merger will be the latest of the dates, and the directories and match names will be adjusted to reflect the original subdirectory sources.

(CDVALUE FN)  [Function]

(CDSUBSET CDVALUE FN)  [Function]

**CDMAP** and **CDSUBSET** both apply FN to each **CDENTRY** in **CDVALUE**, perhaps modifying the information in the entry. **CDSUBSET** returns a new cdvalue structure whose entries are the subset of the entries (perhaps modified) for which FN is non-NIL. For convenience, at each invocation the variables MATCHNAME INFO1 DATEREL INFO2 and EQUIV are bound to the corresponding fields and can be used freely by **FN**.

**USEFUL UTILITIES**

(FIX-DIRECTORY-DATES FILES)  [Function]

For every file included in or specified by **FILES**, if it is a Lisp source or compiled whose directory creation date is more than 30 seconds later than its internal filecreated date (presumably because of copying), then its directory date is reset to match the internal date. **FILES** can be a list of file names or a pattern interpretable by **FILDIR**. Returns a list of files whose dates have been changed.

(FIX-EQUIV-DATES CDVALUE)  [Function]

If there is an entry in **CDVALUE** whose files are EQUIVALENT but with different directory creation dates, the directory date of the file with the later date (presumably a copy) is reset to match the date of the earlier
file. In the end all equivalent files will have the same (earliest) date. Returns a list of files whose dates have been changed.

(COPY-MISSING-FILES CDVALUE TARGET MATCHNAMES) [Function]
Target is 1 or 2, indicating the direction of potential copies. If an entry with a source file but no target file has a matchname in MATCHNAMES, the source file is copied to the target directory. All target-absent files are copied if MATCHNAMES is NIL. Source properties (including version number) are preserved in the target.

(COPY-COMPARED-FILES CDVALUE TARGET MATCHNAMES) [Function]
TARGET is 1 or 2, indicating the direction of potential copies. If an entry with both source and target files has a matchname in MATCHNAMES, the source file is copied to a new version of the target file. All files are copied if MATCHNAMES is NIL.

(COMPiled-ON-SAME-SOURCE CDVALUE) [Function]
Returns the subset of entries with Lisp compiled files (dfasl or lcom) that are compiled on the same source, according to SOURCE-FOR-COMPILED-P below. Presumably one should be removed to avoid confusion.

(FIND-SOURCE-FILES CFILES SDIRS DFASLMARGIN) [Function]
Returns (CFILE . SFILES) pairs where CFILE is a Lisp compiled file in CFILES and SFILES is list of files in SDIRS that CFILE was compiled on according to SOURCE-FOR-COMPILED-P. This suggests that at least one of SFILES should be copied to CFILE’s location (or vice versa).

(FIND-COMPILED-FILES SFILES CDIRS DFASLMARGIN) [Function]
Returns (CFILE . SFILES) pairs where SFILE is a Lisp source file in SFILES and CFILES are files in CDIRS that are compiled on SFILE according to SOURCE-FOR-COMPILED-P. This suggests that at least one of CFILES should be copied to SFILE’s location.

(FIND-UNCOMPILED-FILES FILES DFASLMARGIN COMPILEXTS) [Function]
Returns a list of elements each of which corresponds to a source file in FILES for which no appropriate compiled file can be found. An appropriate compiled file is a file in the same location with extension in COMPILEXTS (defaulting to *COMPILED-EXTENSIONS*) that satisfies SOURCE-FOR-COMPILED-P. Each element is a list of the form

(sourcefile . cfiles)
cfiles contains compiled files that were compiled on a different version of sourcefile, NIL if no such files exist. Each cfile item is a pair (cfile timediff) where timediff is the time difference (in minutes) between the creation date of the compiled-file’s source and the creation date of sourcefile (positive if the cfile was compiled later, as should be the case). FILES can be an explicit list of files, or a file specification interpretable by FILDIR; in that case only the newest source-file versions are processed.
(FIND-UNSOURCED-FILES CFILES DFASLMARGIN COMPILEXTS)  [Function]

Returns the subset of the compiled files specified by CFILES for which a corresponding source file according to SOURCE-FOR-COMPILED-P cannot be found in the same directory. CFILES can be a list of files or a pattern that FILDIR can interpret. COMPILEXTS can be one or more explicit compile-file extensions, defaulting to *COMPILED-EXTENSIONS*.

(SOURCE-FOR-COMPILED-P SOURCE COMPiled DFASLMARGIN)  [Function]

Returns T if it can confirm that Lisp compiled file was compiled on Lisp source file. SOURCE and COMPiled can be provided as CREATED-AS values, to avoid repetitive computation. This compares the information in the filecreated expressions, original file names and original dates, and not the current directory names and dates.

It appears that the times in DFASL files may differ from the filecreated source dates by a few minutes. The DFASLMARGIN can be provided to loosen up the date matching criterion. DFASLMARGIN is a pair (max min) and a DFASL compiled is deemed to be compiled on SOURCE if the compiled’s source date is no more than max and no less than min minutes after the source date. A negative min allows for the possibility that the compiled-source date is earlier than the candidate source date. DFASLMARGIN defaults to (20 0). A single positive number x is coerced to (x 0). A single negative number is coerced to (-x x) (compiled file is no more than x minutes later or earlier). T is infinity in either direction. Examples:

(T 0): compiled compiled on source later than source
(0 T): compiled compiled on source earlier than source (odd)
12: compiled compiled on source later than source by no more than 12 minutes  -12: compiled compiled on source 12 minutes before or after source

(FIND-MULTICOMPILED-FILES FILES SHOWINFO)  [Function]

Returns a list of files in FILES that have more than one type of compiled file (e.g. LCOM and DFASL). FILES is interpretable by FILDIR. If SHOWINFO, then the value contains a list for each file of the form

(rootname loaded-version . CREATED-AS information for each compile-type)

Otherwise just the rootname of the source is returns.

(CREATED-AS FILE)  [Function]

If FILE is a Lisp source or compiled file, returns a record of its original filename and filecreated dates, and for compiled files, also the original compiled-on name and date. The return for a source file is a pair

(sfullname sfilecreateddate)

The return for a compiled file is a quadruple

(cffullname cfilecreated sfullname sfilecreateddate)

where sfullname and sourcefilecreated are extracted from the file’s compiled-on information. The return is (fullname NIL) for a non-Lisp file.

(EOLTYPE FILE SHOWCONTEXT)  [Function]
Returns the EOLTYPE of FILE (CR, LF, CRLF) if the type is unmistakable: contains at least one instance of one type and no instances of any others. Returns NIL if there is evidence of inconsistent types. If SHOWCONTEXT is an integer, it is the number of bytes for EOLTYPE to display before and after an instance of an inconsistent type. At each instance, the user is asked whether to continue scanning for other instances. SHOWCONTEXT = T is interpreted as 100.

(BINCOMP FILE1 FILE2 EOLDIFFOK) [Function]

Returns T if FILE1 and FILE2 are byte-identical. If EOLDIFFOK and FILE1 and FILE2 differ only in their eol conventions, the value is a list of the form (EOL1 EOL2), e.g. (CR CRLF). Otherwise the value is NIL.
INTRODUCTION

COMPARESOURCES is a program for comparing two versions of a Lisp source file for differences. The comparison is completely brute-force: COMPARESOURCES reads the complete contents of both files, and compares all the expressions for differences. The files need not be ones produced by MAKEFILE, as COMPARESOURCES reads the contents with READFILE; however, the program is tuned for files of the type produced by MAKEFILE.

HOW TO USE IT

The interface consists of a two functions, COMPARESOURCES and CSBROWSER.

(COMPARSESOURCES FILEX FILEY EXAMINE DW? LISTSTREAM) [Function]

Compares the files named FILEX and FILEY for differences. For each type of file object (function, variable, record, etc), COMPARESOURCES identifies which objects of that type differ, and for each such object prints on LISTSTREAM a comparison using the function COMPARELISTS. If an object exists on only one of the two files, this fact is noted instead by the message "name is not on file".

If DW? is true, COMPARESOURCES calls DWIMIFY on each function body before performing the comparison. This is useful for comparing a file made with CLISP prettyprinted with one made without.

If EXAMINE is true, COMPARESOURCES calls the editor to allow you to more closely examine expressions that differ. Its value is either T, meaning call the editor in all cases, or an atom or a list of atoms chosen from among the following:

OLD Call the editor for changed objects that are on both files.
NEW Call the editor for objects that are on only one file.
MISC Call the editor for changed but otherwise unclassified expressions.
2WINDOWS Call the editor separately for each pair of changed objects.

In the OLD and MISC cases, the editor is called on a list of two elements, the two expressions. In the NEW case, the editor is called on just the single new expression.

The value returned by COMPARESOURCES is a list whose elements are of the form (type . names), listing the names by type of all objects found to be different. Expressions of no particular type are identified collectively as "(Other --)".

(CSBROWSER FILEX FILEY DW? LABEL1 LABEL2) [Function]

This directs the output of a call to COMPARESOURCES to a scrollable window. Clicking on the output for each identified difference brings up for further examination side-by-side SEDIT windows on the
different objects. LABEL1 and LABEL2 are optional strings that override the default way of constructing the title for the browser window.

FORM OF THE OUTPUT

The output of COMPARESOURCES is in several sections. First, all functions are compared. Then expressions of other types (variables, macros, etc) are compared. When a difference is found, COMPARESOURCES prints the name of the object and calls COMPARELISTS, the same Interlisp function called by COMPARE and COMPAREDEFS. Finally, expressions inside of DECLARE: forms are recursively analyzed in a separate section in the same fashion. All DECLARE: forms of the same applicability (e.g., EVAL@COMPILE DONTCOPY) are handled in the same subsection.

The output of COMPARELISTS takes one of three forms. The usual form is an abbreviated printing of the two expressions with equal elements in the two structures denoted by "&" or "-n-" for a subsequence of \( n \) identical expressions. Identical elements are printed only for purposes of establishing the context of differences. For example,

\[
\text{COMPARESOURCES:}
\begin{align*}
\text{(LAMBDA -3- (PROG -16- (for -10- (COND (& (printout & T -4-) -2-)))}
\text{(TERPRI --) &))}
\end{align*}
\begin{align*}
\text{(LAMBDA -3- (PROG -16- (for -10- (COND (& (printout & T -4-) -2-)))}
\text{(TERPRI --) &))}
\end{align*}
\]

indicates that in the function COMPARESOURCES, an extra argument was added to a printout form, and a (TERPRI --) expression was added before the final element of the PROG. The first 17 elements of the PROG form were unchanged, as were the first 11 and last 2 of the for.

A more abbreviated form of output occurs when the expressions differ only in a global substitution. In this case, COMPARELISTS prints "(x -> y)" to denote that all occurrences of \( x \) in the first expression were replaced by \( y \) in the second expression, and there were no other changes.

Finally, COMPARELISTS prints "SAME" if the expressions are "the same". Since COMPARESOURCES only calls COMPARELISTS when the two expressions are not EQUAL, the output SAME specifically means that the expressions differ only in the bodies of comments (which COMPARELISTS ignores).

USER EXTENSIONS

COMPARESOURCES already "knows" about several kinds of file package objects, including FNS, VARS, MACROS, RECORDS, and PROPS. Any expression not identifiable as some particular type is compared as a vanilla expression. You can extend the set of types it knows about by adding to the following list:

COMPARESOURCETYPES [Variable]

The elements of this list are lists of the form

\[
\text{(TYPE PREDICATEFN COMPAREFN IDFN DESCRIPTION)}
\]

as follows:

\[
\begin{align*}
\text{TYPE} & \quad \text{The file package type of the object (or whatever name you wish to give it in the case of fictitious object types).}
\end{align*}
\]
PREDICATEFN A function of one argument, a single top-level expression as read from the file, that returns true if the expression is of the desired type.

COMPAREFN A function of three arguments, one expression from each file (both guaranteed to have satisfied the PREDICATEFN), and the listing stream. COMPAREFN should compare the two expressions in some appropriate way, printing its results to the listing stream. A typical COMPAREFN calls the function COMPARELISTS on some subform of the expressions. If COMPAREFN is NIL, COMPARELISTS is used.

IDFN A function of one argument, an expression, that returns the "name" of the object described by the expression. Two expressions are assumed to define the same object if their names are EQUAL. The name corresponds roughly to a file package name. For example, for type VARS it is the variable name; for type PROPS it is a pair (atom proppname). If IDFN is NIL, CADR is used.

DESCRIPTION A string identifying the kind of object, for use in the comparison printout. If DESCRIPTION is NIL, (L-CASE TYPE T) is used.
INTRODUCTION

COMPARETEXT is a rather non-standard text file comparison program which tries to address two problems: (1) the problem of detecting certain types of changes, such as detecting when a paragraph is moved to a different part of a document; and (2) the problem of showing the user what changes have been made in a document.

The text comparison algorithm is an adaptation of the one described in the article "A Technique for Isolating Differences Between Files" by Paul Heckel, in CACM, V21, #4, April 1978. The main idea is to break each of the two text files into "chunks" (words, lines, paragraphs, ...), hash each chunk into a hash value, and match up chunks with the same hash value in the two files. This method detects switching two chunks, or moving a chunk anywhere else in the document.

COMPARING TEXT FILES

Two text files can be compared with the following function:

(COMpareTEXT FILE1 FILE2 HASH.TYPE CHUNKREGION FILELABELS TITLE TEXTWIDTH TEXTHEIGHT) [Function]

FILE1 and FILE2 are the names of the two files to compare. The order is not important, except that in the resulting graph the FILE1 information will appear on the left, and the FILE2 info on the right. The files may also be provide as input streams.

HASH.TYPE determines how "chunks" of text are defined; how fine-grained the comparison will be. This can be PARA to hash by paragraphs (delimited by two consecutive CRs), LINE to hash by lines (delimited by one CR), or WORD to hash words (delimited by any white space). HASH.TYPE=NIL defaults to PARA.

CHUNKREGION is the region on the display screen used for the file comparison graph, the chunk window. If CHUNKREGION=NIL, the system asks the user to specify a region, prompting with a region that is just wide enough for the graph. If CHUNKREGION=T, a region in the lower left corner is used. If CHUNKREGION is a position, the chunkwindow will be located relative to that position, with its horizontal midpoint at the specified XCOORD and its top at the YCOORD.

FILELABELS is an optional pair of labels that will appear over the columns of the difference graph instead of the (often overly long) full names of the files.

TITLE is an optional title to be used for the comparison window.

TEXTWIDTH and TEXTHEIGHT are optional parameters that control the size of each of the two text-display windows.
COMPARETEXT creates a graph with two columns. Each column contains the label for one of the files, and lists the chunks from that file. Each chunk is represented by an atom NNN:MMM, where NNN is the file pointer of the beginning of the chunk within the file, and MMM is the length of the chunk. Lines are drawn from one column to the other to show which chunks in one file are the same as those in the other file. Chunks with no lines going to them do not exist in the other file. [Note: a series of chunks in one file which are the same as a series of chunks in the other file are merged into one big chunk. A series of unconnected chunks is also merged.]

Pressing the LEFT mouse button over one of the chunk nodes causes the node and its counterpart in the other column to be inverted, and read-only Tedit windows are open on the files with the appropriate text selected. If a Tedit window to a file is already active, the selection is simply moved. If COMPARETEXT.AUTOTEDIT is true (initially), then regions are selected automatically for the Tedit windows, otherwise the mouse must be used to specify ghost regions.

Pressing the MIDDLE mouse button over a chunk node raises a pop-up menu with the items: PARA, LINE, and WORD. If one of these is selected, COMPARETEXT is called to compare the selected chunk with the last selected chunks (the ones that are boxed), using the hash type selected, and create a new graph window.

White space (space, tab, CR, LF) is used to delimit chunks, but is ignored when computing the hash value of a chunk. Therefore, if two paragraphs are identical except that one has a few extra CRs after it, they will be considered identical by COMPARETEXT.

If the variable COMPARETEXT.ALLCHUNKS is NIL (initially T), then the graph is abbreviated so that nodes for identical chunks in the same position are not shown.
This provides an interface to the compiler that avoids the interview for the common cases of in-core compilation. It contains a single function COMPILE!, and the Lispx and edit macros C:

(COMPILE! X NOSAVE NOREDEFINE PRINTLAP) [Function]

Calls the compiler to compile X. If X is a litatom, its definition is compiled and stored in the function cell unless NOREDEFINE, and the old definition if any is saved on the property list unless NOSAVE. No printing of lap or machine code is done unless PRINTLAP.

Thus, to simply compile the function BAR, do COMPILE!(BAR).

X may also be a list form. In this case, COMPILE! assumes that the user is interested just in seeing how that form would compile. The form is embedded in a Lambda expression and compiled. Of course, there is no function-cell to be stored into or saved.

C [Lispx Macro]

The LISPXMACRO C calls COMPILE!, with PRINTLAP on, on the next element of the input line. Thus, C BAR will compile, redefine, and save the old definition for BAR.

C (CONS) will show how a call to CONS would compile.

The edittmacro C calls COMPILE! on the current expression if it is a list, or on the form of which the current expression is an element.
COURIERDEFS contains a procedure-less Courier program, called INTERLISP, which defines several Envos Lisp types as Courier constructed types or as new Courier primitive types (via a COURIERDEF property) for use with Courier server and client programs. The defined Envos Lisp types include:

- **ATOM**: Converts to a string on writing and converts to an atom on reading.
- **FONT**: Converts a FONTDESCRIPTOR to a record describing the font on writing and converts the record back to a FONTDESCRIPTOR on reading.
- **REGION**: A sequence of INTEGER.
- **POSITION**: Converts a POSITION record to two integers on writing and converts back to a POSITION record on reading.
- **NUMBER**: Like INTEGER but can also be NIL.
- **BRUSH**: Converts the various possibilities for a brush (NIL, INTEGER, BRUSH RECORD etc.) to a CHOICE record on writing, converts back to original specification on reading.
- **OPERATION**: An ENUMERATION of NIL, REPLACE, PAINT, INVERT or ERASE.
- **TEXTURE**: Converts a TEXTURE, NIL or T to a CARDINAL on writing, returns a CARDINAL on reading.

This file is loaded by several other modules that define Courier servers and clients. A Courier program can use the types defined in the INTERLISP program by using the INHERITS slot in the Courier program definition.
COURIEREVALSERVE

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

Uses: COURIERSERVE

COURIEREVALSERVE implements both the client and server routines for the simple remote evaluation server described in the COURIERSERVE documentation.

The module defines two user functions:

(REMOTE-EVAL FORM COURIERSTREAM [NOERRORFLG]) [Function]
(REMOTE-APPLY FN ARGS COURIERSTREAM [NOERRORFLG]) [Function]

COURIERSTREAM is obtained by calling COURIER.OPEN to connect with a host that is running the Courier server and has COURIEREVALSERVE loaded. If the NOERRORFLG is non-NIL, it is returned if an error is signaled by the remote host, otherwise the functions generate an error.

Due to the removal of ERRORN as of the Lyric release, the error handling is not as informative as in earlier versions. If you are connected to a pre-Lyric host, errors will work as before, otherwise instead of signaling the actual remote error (eg. "Undefined car of form") the generic "Remote evaluation error!" error is raised. This is to maintain backward compatibility in the EVAL Courier program. Hopefully, this will be replaced by a new version of the EVAL program designed to correctly remote the new condition-based error handler.
COURIERIMAGESTREAM

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

Uses: COURIERSERVE, COURIERDEFS and BITMAPFNS

COURIERIMAGESTREAM implements a Courier client and server program which allows remote hosts to do image stream manipulations on other workstations via the network. To do this, it defines the COURIER virtual image stream type which allows the user to manipulate remote image streams through local image streams.

THE IMAGESTREAM COURIER PROGRAM

The module defines a Courier program called IMAGESTREAM (which inherits from the INTERLISP Courier program defined in COURIERDEFS). For each IMAGEOP in the IMAGEOPs definition, there is an equivalent Courier procedure in the IMAGESTREAM program. The module contains the code for both the Courier client and server.

OPENING AND CLOSING REMOTE IMAGE STREAMS

Remote image streams can be opened using either the COURIER image stream type or using direct Courier calls.

The COURIER Image Stream Interface

Remote Courier image streams can be opened using:

```lisp
(setq COURIERSTREAM (COURIER.OPEN HOST)
(openimagestream COURIERSTREAM 'COURIER OPTIONS))
```

which returns an image stream. The OPTIONS can include FILE and IMAGETYPE which are passed to OPENIMAGESTREAM on the remote host and if not supplied, a nameless DISPLAY image stream is opened. All other options are passed to the remote image stream. The image stream can be closed using CLOSEF.

The Courier Procedure Call Interface

Courier image streams can also be opened using Courier procedure calls from any Courier client with the Courier procedure:

```lisp
(open 0 (file imagetype) returns (handle) reports nil)
```

which is invoked from Lisp by doing:

```lisp
(courier.call COURIERSTREAM 'IMAGESTREAM 'OPEN FILE IMAGETYPE OPTIONS)
```

where FILE, IMAGETYPE and OPTIONS are similar to the arguments to OPENIMAGESTREAM.

This call will return a handle to be used with the remainder of the IMAGESTREAM procedures. To close an image stream from a Courier client use the Courier procedure:
(CLOSE 1 (HANDLE) RETURNS NIL REPORTS NIL)

which is invoked from Lisp by doing:

(COURIER.CALL COURIERSTREAM 'IMAGESTREAM 'CLOSE HANDLE)

DIFFERENCES BETWEEN IMAGEOPS AND IMAGESTREAM COURIER PROCEDURES

All of the IMAGEOPs are implemented in the COURIER image stream type as it merely passes the call to the IMAGEOPs of another image stream type on the remote host. No error checking is done, so invoking an illegal IMAGEOP will cause a Courier rejection of the call.

The arguments to the IMAGESTREAM Courier procedures are generally in the same order as the arguments to the various IM* functions which implement an image stream (stream argument first). An exception is BITBLT (and ScaledBITBLT) which is defined as follows:

(BITBLT 32 (HANDLE BULK.DATA.SOURCE LEFT BOTTOM WIDTH HEIGHT
SOURCETYPE OPERATION TEXTURE CLIPPINGREGION)

The BULK.DATA.SOURCE argument is used to transfer the bitmap using WRITEBINARYBITMAP. This is only relevant to direct Courier calls, the COURIER image stream BITBLT operation hides the differences.

When using the COURIER image stream type, the STRINGWIDTH, CHARWIDTH etc. IMAGEOPs are handled locally, not via Courier calls, to improve efficiency.

IMAGESTREAM PROGRAM VERSIONS

The current implementation of the IMAGESTREAM Courier program is version 1. This module also has the previous version of the program (0) defined as OLDIMAGESTREAM (just the procedure definitions that differ, it inherits from IMAGESTREAM). This allows the current version of the program to accept calls from older versions, but not vice-versa. However, the new version of the IMAGESTREAM Courier program can be loaded and used with the old (pre-Lyric) functions.
COURIERSERVE

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

COURIERSERVE implements a Courier server process for Envos Lisp allowing other hosts to make Courier calls into the workstation. The server supports both multiple Courier stream connections as well as expedited (single packet) and broadcast calls.

STARTING A COURIER SERVER

The Courier server can be started by evaluating:

(COURIER.START.SERVER [RESTART]) [Function]

Once the server is running, it can be invoked by a remote host client using COURIER.OPEN for a Courier stream connection or by using COURIER.EXPEDITED.CALL or COURIER.BROADCAST.CALL for expedited calls. The functions for making Courier client calls from Lisp are documented in the Interlisp-D Reference Manual (pages 31.15–31.26).

(COURIER.RESET.SOCKET) [Function]

(Re)Opens and closes the Courier socket. Not normally a user routine, this function is called by COURIER.START.SERVER but it can be called directly if “socket already open!” errors persist on the Courier socket (5).

DEFINING A COURIER SERVER FUNCTION

Defining a Courier server program is identical to defining a client program except for the additional field IMPLEMENTEDBY in each procedure in the PROCEDURES section of the Courier program definition:

PROCEDURES

((LAYOUT 0 (GRAPHNODES ROOTIDS FORMAT FONT MOTHERD PERSONALD FAMILYD)

RETURNS (GRAPH)

REPORTS (LAYOUT.ERROR)

IMPLEMENTEDBY GRAPH.REMOTELAYOUT))

The order of the RETURNS, REPORTS and IMPLEMENTEDBY fields is significant and should be maintained.

The server function, named in the IMPLEMENTEDBY field, is invoked when a Courier call to the procedure is made. The server function is applied to the Courier stream, the Courier program and the Courier procedure followed by the arguments named in the Courier definition. The arguments for GRAPH.REMOTELAYOUT would be (COURIERSTREAM PROGRAM PROCEDURE GRAPHNODES ROOTIDS FORMAT ...).

Note that the COURIERSTREAM, PROGRAM and PROCEDURE arguments are not necessarily used, they are made available for implementing special servers.
RETURING VALUES FROM A COURIER PROGRAM

Results or errors can be returned by a Courier server function by one of two different methods. In the usual, simple case, the server function can return as its result a list starting with one of RETURN, ABORT or REJECT followed by the appropriate values.

For the RETURN result, the tail of the list should be the results as defined in the Courier procedure definition, eg. (RETURN 23 "John").

For the ABORT result, the tail of the list should contain the reason for the abnormal termination (as defined in the Courier program), followed by any error arguments, eg. (ABORT NAME.NOT.FOUND "John").

For the REJECT result, the tail of the list should contain the rejection error as defined in the Courier standard. The only rejection that should occur inside a server function should be UNSPECIFIED if the program needs to reject for any reason. The other rejection types are handled by the Courier server.

Alternatively, the server function can return results directly to the Courier stream and return NIL as its result. To return results directly to the Courier stream use:

(COURIER.RETURN COURIERSTREAM PROGRAM PROCEDURE RESULTLST) [Function]
(COURIER.ABORT COURIERSTREAM PROGRAM ERROR RESULTLST) [Function]
(COURIER.REJECT COURIERSTREAM ERROR RESULTLST) [Function]

EXPEDITED AND BROADCAST COURIER CALLS

The Courier server allows expedited and broadcast Courier calls. The only difference the server function would see if invoked due to an expedited call is that the Courier stream it is handed is actually a record containing an XIP packet and a socket. If the server function does not use the Courier stream directly, then this difference is invisible.

If the server function actually needs a Courier stream to operate (eg. an NS CHAT server), then it should probably include an USE.COURIER abort error in its definition. If the server function needs a Courier stream due to bulk data arguments, this will be trapped in the Courier server itself, which will reject appropriately and not invoke the server function.

USING BULK DATA IN A SERVER FUNCTION

If a server function takes a bulk data argument (either BULK.DATA.SINK or BULK.DATA.SOURCE), it is handed an open bulk data stream for that argument when invoked. If the server function returns a result by returning one of the RETURN or ABORT forms as its result, the bulk data stream will be closed automatically. If the server function returns results directly to the Courier stream using COURIER.RETURN or COURIER.ABORT, then the server function must first close the bulk data stream using:

(CLOSE.BULK.DATA STREAM [ABORTFLG]) [Function]

The CLOSEF function does not work on the bulk data stream argument and using it will hang the Courier connection. Only the immediate bulk data transfer type is handled. NULL, ACTIVE or PASSIVE bulk data transfer types will cause a Courier rejection of type UNSPECIFIED.

SIMPLE SERVER DEFINITION

Below is the Courier definition for a simple evaluation server. The two functions EVAL.REMOTE and APPLY.REMOTE are all that would need to be defined to make the server run:
((1105 0)

TYPES ((SEXP STRING)
  (FN STRING)
  (ARGS (SEQUENCE SEXPR))
  (ERRORN (RECORD (ERROR.NUMBER CARDINAL)
    (ERROR.MESSAGE SEXPR))))

PROCEDURES ((EVAL 0 (SEXP)
    RETURNS (SEXP)
    REPORTS (REMOTE.EVAL.ERROR REMOTE.READ.ERROR)
    IMPLEMENTEDBY EVAL.REMOTE)
  (APPLY 1 (FN ARGS)
    RETURNS (SEXP)
    REPORTS (REMOTE.APPLY.ERROR REMOTE.READ.ERROR)
    IMPLEMENTEDBY APPLY.REMOTE))

ERRORS ((REMOTE.EVAL.ERROR 0 (ERRORN))
  (REMOTE.APPLY.ERROR 1 (ERRORN))
  (REMOTE.READ.ERROR 2 (ERRORN))
)

RELATED FILES
The modules CHATSERVER-NS, COURIERDEFS, COURIEREVALSERVE, COURIERIMAGESTREAM, MONITOR, REMOTEPSW and NSTALK all define Courier servers and/or Courier type definitions.
CROCK

By: Kelly Roach

New Owner: Herb Jellinek (Jellinek.pa@Xerox.com)

CROCK sets up an analog face clock in the user’s environment. To use, LOAD CROCK.LCOM and call (CROCK). CROCK requires that PROCESSWORLD be running (automatic in Fugue or later).

CROCK

Function CROCK has the form

(CROCK REGION) [Function]

The first invocation creates a clock window, CROCKWINDOW, occupying REGION with style CROCK.DEFAULT.STYLE. If REGION is left NIL, a region will be prompted for. Subsequent invocations use CROCKWINDOW. Only one clock window may exist at any given time. The clock is updated once a minute.

STYLE

The clock’s style is maintained as a property list and can be found by (WINDOWPROP CROCKWINDOW ’STYLE). There are four independent boolean properties which the user may control: HANDS (the hands of the clock), TIMES (time digits printed where the hands end), RINGS (rings on the clock face), and NUMBERS (12 numbers around the outside of the clock face). The style first used will be CROCK.DEFAULT.STYLE (bound to ‘(HANDS T TIMES NIL RINGS NIL NUMBERS T) when CROCK is first loaded).

CROCK.DATEFORMAT

The user can control how the date will be printed in CROCKWINDOW. CROCK.DATEFORMAT should have the form (DATEFORMAT . <tokens>) where each <token> is one of NO.DATE, NO.TIME, NUMBER.OF.MONTH, YEAR.LONG, SLASHES, SPACES, NO.LEADING.SPACES, TIME.ZONE, or NO.SECONDS. These are all listed on pp23.57-58 of the IRM. Unfortunately, some other possibilities, such as DAY.OF.WEEK have not been implemented by Interlisp-D yet and are therefore not available to CROCK yet. The default value for CROCK.DATEFORMAT is (DATEFORMAT NO.SECONDS). For example,

(SETQ CROCK.DATEFORMAT ’(DATEFORMAT SLASHES NUMBER.OF.MONTH NO.SECONDS))

would make CROCK print a date string like

28/09/84 14:53

instead of a date string like

28-Sep-84 14:53
Since CROCK updates itself only once a minute, it is probably a good idea to always include NO.SECONDS in your CROCK.DATEFORMAT.

**CROCK.ALARM AND CROCK.TUNE**

The user can set CROCK’s alarm via

(CROCK.ALARM DATESTRING)  [Function]

where DATESTRING is any arg acceptable to Interlisp’s IDATE (such as the date CROCK prints in CROCKWINDOW). CROCK will act appropriately when time reaches DATESTRING. Dandelion users can set global CROCK.TUNE to a tune to be played by Interlisp’s PLAYTUNE when CROCK’s alarm acts.

**RECOMMENDED USAGE**

The simplest way to call CROCK from your init file or other function is to set your CROCK globals, then call CROCK:

(SETQ CROCK.DEFAULT.STYLE STYLE)  [Variable]
(SETQ CROCK.DATEFORMAT DATEFORMAT)  [Variable]
(SETQ CROCK.TUNE TUNE)  [Variable]
(CROCK REGION)  [Function]

You supply <style>, <dateformat>, <tune>, and <region>. You only need the SETQs if you want non-default values. If no <region> is supplied, CROCK will prompt for one.

**LEFT MOUSE BUTTON**

Buttoning CROCKWINDOW with the left mouse button requests immediate update of the clock. (Of course, it may take a while for the process scheduler to get to it.)

**MIDDLE MOUSE BUTTON**

Buttoning CROCKWINDOW with the middle mouse button presents a menu of commands for modifying the clock’s style. Menu item SHOW.STYLE prints the clock’s style.

**RIGHT MOUSE BUTTON**

Buttoning CROCKWINDOW with the left mouse button presents the usual window menu. RESHAPEing the CROCKWINDOW causes the clock to change its size to fit the new window region. CLOSEing the CROCKWINDOW deletes the clock process.
DATEFORMAT-EDITOR

By: Johannes A. G. M. Koomen
(Koomen.wbst@Xerox.com or Koomen@CS.Rochester.edu)

This document last edited on May 19, 1989 by Bill van Melle.

DESCRIPTION

DATEFORMAT-EDITOR provides a menu-based interface for creating and editing date formatting lists (see IRM, Section 12.5). The menu is a Free Menu (see FREEMENU in Medley Release Notes), and looks like:

```
DATEFORMAT-EDITOR-ITEMS

DATEFORMAT is either NIL or the value returned from a call to the function DATEFORMAT (see IRM, Section 12.5). EDIT-DATEFORMAT starts by pre-selecting date formatting keys according to DATEFORMAT, or default ones if DATEFORMAT is NIL. It then enters a busy-wait loop, blocking until the DateFormat Editor window is closed, or Quit or Abort is selected. EDIT-DATEFORMAT returns a new value obtained from the function DATEFORMAT given the selected date formatting keys if Quit was selected, otherwise NIL.

DATEFORMAT-EDITOR-ITEMS

A list of items acceptable to the function FM.FORMATMENU (see FREEMENU in the Release Notes). Unfortunately, some of the date format details are embedded in the DateFormat Editor, rather than in these items, so leave ID’s and LABEL’s alone, otherwise mung around to your heart’s content if you desire a different layout for the DateFormat Editor. Initial value is reflected by the screen snap above.
(GET-DATEFORMAT-EDITOR RECOMPUTE?) [Document Object]

Returns the FreeMenu window of the DateFormat Editor. If RECOMPUTE? is non-NIL, recomputes the FreeMenu. Use this function with argument T if you change the variable DATEFORMAT-EDITOR-ITEMS.

EXTENDED DATEFORMAT OPTIONS

DATEFORMAT-EDITOR supports the following additional DATEFORMAT options by virtue of loading the module DATEPATCH:

MONTH.LONG [DateFormat Option]

Provides for full names of months rather than the first three characters. For instance, “20 February 1987” is produced by (GDATE NIL (DATEFORMAT MONTH.LONG YEAR.LONG SPACES NO.TIME)).

MONTH.LEADING [DateFormat Option]

Causes the month to appear before the day. For instance, “February 20, 1987” is produced by (GDATE NIL (DATEFORMAT MONTH.LEADING MONTH.LONG YEAR.LONG NO.TIME)). MONTH.LEADING implies SPACES and disables NUMBER.OF.MONTH.
DATESORT
[Internal Lafite Utility]

Datesort places an item on the background menu. When selected you will be
prompted for the name of a Lafite Mail folder to be sorted, and the name of a
new resulting sorted folder. The folder messages will then be sorted in
ascending order on their "Date:" fields (this takes some time).
Introduction

When debugging Common Lisp programs, have you ever wished that the Xerox Lisp debugger let you do things in the right lexical context? Ever wish you could access locally-defined functions, return from blocks, or evaluate variables in the debugger without resorting to the inspector? Ever wish you could tell the "big boys" in Washington a thing or two? Well, two out of three ain’t bad. DEBUGGER-CONTEXT gives you the ability to access and modify the lexical context of code you are debugging in a straightforward way.

User Interface

DEBUGGER-CONTEXT defines two debugger commands that affect the debugger’s lexical context.

**lex**

Sets the lexical context of the debugger window to that of the stack frame selected in the backtrace window (il:lastpos). Henceforth, all evaluation done in this debugger window will be with respect to that lexical environment. The lexical environment of a frame is taken to be the first one encountered as an argument in that frame. Once the `lex` command is given, selecting other stack frames in the backtrace window will not change the lexical environment; you must issue another `lex` command to do so.

The lexical environment of a frame is taken to be the first one encountered as an argument in that frame.

**unlex**

Removes the current lexical context; all evaluation will subsequently be done with respect to the current dynamic environment.
NOTE TO LYRIC/MEDLEY USERS

The DECL module is not supported in Lyric/Medley since it uses the DWIM facilities heavily, and DWIM is not supported in Lyric/Medley. It is being released as a LispUsers module only for backward compatibility. The DECL module only runs under the OLD-INTERLISP-T executive, and all the code that uses it will also have to run under this executive. Therefore, you may wish to convert code that uses DECL to something else.

INTRODUCTION

The Decl LispUsers package is contained on the file DECL.LCOM. The Decl package requires the LambdaTran package. LAMBDATRAN.LCOM will automatically be loaded with Decl if it is not already present.

The Decl package extends Interlisp to allow the user to declare the types of variables and expressions appearing in functions. It provides a convenient way of constraining the behavior of programs when the generality and flexibility of ordinary Interlisp is either unnecessary, confusing, or inefficient.

Decl provides a simple language for declarations, and augments the interpreter and the compiler to guarantee that these declarations are always satisfied. The declarations make programs more readable by indicating the type, and therefore something about the intended usage, of variables and expressions in the code. They facilitate debugging by localizing errors that manifest themselves as type incompatibilities. Finally, the declaration information is available for other purposes: compiler macros can consult the declarations to produce more efficient code; coercions for arguments at user interfaces can be automatically generated; and the declarations will be noticed by the Masterscope function analyzer.

The declarations interpreted by the Decl package are in terms of a set of declaration types called decltypes, each of which specifies a set of acceptable values and also (optionally) other type-specific behavior. The Decl package provides a set of facilities for defining decltypes and their relations to each other, including type-valued expressions and a comprehensive treatment of union types.

The following description of the Decl package is divided into three parts. First, the syntactic extensions that permit the concise attachment of declarations to program elements are discussed. Second, the mechanisms by which new decltypes can be defined and manipulated are covered. Finally, some additional capabilities based on the availability of declarations are outlined.

USING DECLARATIONS IN PROGRAMS
Declarations may be attached to the values of arbitrary expressions and to LAMBDA and PROG variables throughout (or for part of) their lexical scope. The declarations are attached using constructs that resemble the ordinary Interlisp LAMBDA, PROG, and PROGN, but which also permit the expression of declarations. The following examples illustrate the use of declarations in programs.

Consider the following definition for the factorial function \( \text{FACT} \) (\( N \)):

\[
\text{[LAMBDA} \ (N) \ \\
\quad \text{(COND} \ \\
\quad \quad \text{((EQ N 0) 1)} \ \\
\quad \quad \text{(T (ITIMES N (FACT (SUB1 N))})
\]

Obviously, this function presupposes that \( N \) is a number, and the run-time checks in ITIMES and SUB1 will cause an error if this is not so. For instance, \((\text{FACT} \ T)\) will cause an error and print the message NON-NUMERIC ARG T. By defining FACT as a DLAMBDA, the Decl package analog of LAMBDA, this presupposition can be stated directly in the code:

\[
\text{[DLAMBDA} \ ((N \ \text{NUMBERP})} \ \\
\quad \text{(COND} \ \\
\quad \quad \text{((EQ N 0) 1)} \ \\
\quad \quad \text{(T (ITIMES N (FACT (SUB1 N))}
\]

With this definition, \((\text{FACT} \ T)\) will result in a NON-NUMERIC ARG T error when the body of the code is executed. Instead, the NUMBERP declaration will be checked when the function is first entered, and a declaration fault will occur. Thus, the message that the user will see will not dwell on the offending value T, but instead give a symbolic indication of what variable and declaration were violated, as follows:

DECLARATION NOT SATISFIED

((N NUMBERP) BROKEN):

The user is left in a break from which the values of variables, e.g., \( N \), can be examined to determine what the problem is.

The function FACT also makes other presuppositions concerning its argument, \( N \). For example, FACT will go into an infinite recursive loop if \( N \) is a number less than zero. Although the user could program an explicit check for this unexpected situation, such coding is tedious and tends to obscure the underlying algorithm. Instead, the requirement that \( N \) not be negative can be succinctly stated by declaring it to be a subtype of NUMBERP that is restricted to non-negative numbers. This can be done by adding a SATISFIES clause to \( N \)'s type specification:

\[
\text{[DLAMBDA} \ ((N \ \text{NUMBERP} \ (\text{SATISFIES} \ (\text{NOT} \ (\text{MINUSP} \ N))} \ \\
\quad \text{(COND} \ \\
\quad \quad \text{((EQ N 0) 1)} \ \\
\quad \quad \text{(T (ITIMES N (FACT (SUB1 N))}
\]

The predicate in the SATISFIES clause will be evaluated after \( N \) is bound and found to satisfy NUMBERP, but before the function body is executed. In the event of a declaration fault, the SATISFIES condition will be included in the error message. For example, \((\text{FACT} -1)\) would result in:

DECLARATION NOT SATISFIED
The DLAMBDA construct also permits the type of the value that is returned by the function to be declared by means of the pseudo-variable RETURNS. For example, the following definition specifies that FACT is to return a positive integer:

\[
\text{DLAMBDA ([N NUMBERP (SATISFIES (NOT (MINUSP N)]
\quad [RETURNS FIXP (SATISFIES (IGREATERP VALUE 0)]
\quad (COND
\quad \quad \quad ((EQ N 0) 1)
\quad \quad \quad (T (ITIMES N (FACT (SUB1 N)

After the function body is evaluated, its value is bound to the variable VALUE and the RETURNS declaration is checked. A declaration fault will occur if the value is not satisfactory. This prevents a bad value from propagating to the caller of FACT, perhaps causing an error far away from the source of the difficulty.

Declaring a variable causes its value to be checked not only when it is first bound, but also whenever that variable is reset by SETQ within the DLAMBDA. In other words, the type-checking machinery will not allow a declared variable to take on an improper value. An iterative version of the factorial function illustrates this feature in the context of a DPROG, the analog of PROG:

\[
\text{DLAMBDA ([N NUMBERP (SATISFIES (NOT (MINUSP N]
\quad [RETURNS FIXP (SATISFIES (IGREATERP VALUE 0)]
\quad [DPROG ([TEMP 1 FIXP (SATISFIES (IGREATERP TEMP 0]
\quad [RETURNS FIXP (SATISFIES (IGREATERP VALUE 0)]
\quad \quad LP (COND ((EQ N 0) (RETURN TEMP)))
\quad \quad (SETQ TEMP (ITIMES N TEMP))
\quad \quad (SETQ N (SUB1 N))
\quad \quad (GO LP)

DPROG declarations are much like DLAMBDA declarations, except that they also allow an initial value for the variable to be specified. In the above example, TEMP is declared to be a positive integer throughout the computation and N is declared to be non-negative. Thus, a bug which caused an incorrect value to be assigned by one of the SETQ expressions would cause a declaration failure. Note that the RETURNS declaration for a DPROG is also useful in detecting the common bug of omitting an explicit RETURN.

**DLAMBDA**

The Decl package version of a LAMBDA expression is an expression beginning with the atom DLAMBDA. Such an expression is a function object that may be used in any context where a LAMBDA expression may be used. It resembles a LAMBDA expression except that it permits declaration expressions in its argument list, as illustrated in the examples given earlier. Each element of the argument list of a DLAMBDA may be a literal atom (as in a conventional LAMBDA) or a list of the form (NAME TYPE .EXTRAS). Strictly, this would require a declaration with a SATISFIES clause to take the form (N (NUMBERP (SATISFIES --)) --). However, due to the frequency with which this construction is used, it may be written without the inner set of parentheses, e.g., (N NUMBERP (SATISFIES --) --).
**NAME** fulfills the standard function of a parameter, i.e., providing a name to which the value of the corresponding argument will be bound.

**TYPE** is either a Decl package type name or type expression. When the DLAMBDA is entered, its arguments will be evaluated and bound to the corresponding argument names, and then, after all the argument names have been bound, the declarations will be checked. The type checking is delayed so that Satisfies predicates can include references to other variables bound by the same DLAMBDA. For example, one might wish to define a function whose two arguments are not only both required to be of some given type, but are also required to satisfy some relationship (e.g., that one is less than the other).

**EXTRAS** allows some additional properties to be attached to a variable. One such property is the accessibility of **NAME** outside the current lexical scope. Accessibility specifications include the atoms LOCAL or SPECIAL, which indicate that this variable is to be compiled so that it is either a LOCALVAR or a SPECVAR, respectively. This is illustrated by the following example:

```lisp
(DLAMBDA ((A LISTP SPECIAL)
             (B FIXP LOCAL))
  ...
)
```

A more informative equivalent to the SPECIAL key word is the USEDIN form, the tail of which can be a list of the other functions that are expected to have access to the variable.¹

```lisp
(DLAMBDA ((A LISTP (USEDIN FOO FIE))
             (B FIXP LOCAL))
  ...
)
```

**EXTRAS** may also include a comment in standard format, so that descriptive information may be given where a variable is bound:

```lisp
(DLAMBDA ((A LISTP (USEDIN FOO FIE)   (* This is an important variable))
             (B FIXP LOCAL))
  ...
)
```

As mentioned earlier, the value returned by a DLAMBDA can also be declared, by means of the pseudo-variable RETURNS. The RETURNS declaration is just like other DLAMBDA declarations, except (1) in any Satisfies predicate, the value of the function is referred to by the distinguished name VALUE; and (2) it makes no sense to declare the return value to be LOCAL or SPECIAL.

**DPROG**

Just as DLAMBDA resembles LAMBDA, DPROG is analogous to PROG. As for an ordinary PROG, a variable binding may be specified as an atom or a list including an initial value form. However, a DPROG binding also allows **TYPE** and **EXTRAS** information to appear following the initial value form. The format for these augmented variable bindings is (**NAME** **INITIALVALUE** **TYPE** .**EXTRAS**).

The only difference between a DPROG binding and a DLAMBDA binding is that the second position is interpreted as the initial value for the variable. Note that if the user wishes to supply a type declaration for a variable, an initial value **must** be specified. The same rules apply for the interpretation of the type information for DPROGs as for DLAMBDA, and the same set of optional **EXTRAS** can be used. DPROGs may also declare the type of the value they return, by specifying the pseudo-variable RETURNS.
Just as for a DLAMBDA, type tests in a DPROG are not asserted until after all the variables have been bound, thus permitting predicates to refer to other variables being bound by this DPROG. If NIL appears as the initial value for a binding (i.e., the atom NIL actually appears in the code, not simply an expression that evaluates to NIL) the initial type test will be suppressed, but subsequent type tests, e.g., following a SETQ, will still be performed.

A common construct in Lisp is to bind and initialize a PROG variable to the value of a complicated expression in order to avoid recomputing it, and then to use this value in initializing other PROG variables, e.g.

```lisp
(PRQ (A EXPRESSION))
  (RETURN (PRQ ((B... ( A...))
               (C... ( A...))))
    ...]
```

The ugliness of such constructions in conventional Lisp often tempts the programmer to loosen the scoping relationships of the variables by binding them all at a single level and using SETQ’s in the body of the PROG to establish the initial values for variables that depend on the initial values of other variables, e.g.,

```lisp
(PRQ ((A EXPRESSION) B C)
  (SETQ B (...A...))
  (SETQ C ( ...A...))
    ...]
```

In the Decl package environment, this procedure undermines the protection offered by the type mechanism by encouraging the use of uninitialized variables. Therefore, the DPROG offers a syntactic form to encourage more virtuous initialization of its variables. A DPROG variable list may be segmented by occurrences of the special atom THEN, which causes the binding of its variables in stages, so that the bindings made in earlier stages can be used in later ones, e.g.,

```lisp
(DPROG ((A (LENGTH FOO) FIXP LOCAL)
    THEN (B (SQRT A) FLOATP)
    THEN (C (CONS A B) LISTP))
      ...]
```

Each stage is carried out as a conventional set of DPROG bindings (i.e., simultaneously, followed by the appropriate type testing). This layering of the bindings permits one to gradually descend into a inner scope, binding the local names in a very structured and clean fashion, with initial values type-checked as soon as possible.

**DECLARATIONS IN ITERATIVE STATEMENTS**

The CLISP iterative statement provides a very useful facility for specifying a variety of PROGs that follow certain widely used formats. The Decl package allows declarations to be made for the scope of an iterative statement via the DECLARE CLISP (I.S. operator). DECLARE can appear as an operator anywhere in an iterative statement, followed by a list of declarations, for example:

(for J from 1 to 10 declare (J FIXP) do...
Note that DECLARE declarations do not create bindings, but merely provide declarations for existing bindings. For this reason, an initial value cannot be specified and the form of the declaration is the same as that of DLAMBDA, namely create (NAME TYPE . EXTRAS).

Note that variables bound outside of the scope of the iterative statement, i.e., a variable used freely in the I.S., can also be declared using this construction. Such a declaration will only be in effect for the scope of the iterative statement.

DECLARING A VARIABLE FOR A RESTRICTED LEXICAL SCOPE

The Decl package also permits declaring the type of a variable over some restricted portion of its existence. For example, suppose the variable X is either a fixed or floating number, and a program branches to treat the two cases separately. On one path X is known to be fixed, whereas on the other it is known to be floating. The Decl package DPROGN construct can be used in such cases to state the type of the variable along each path. DPROGN is exactly like PROGN, except that the second element of the form is interpreted as a list of DLAMBDA format declarations. These declarations are added to any existing declarations in the containing scope, and the composite declaration (created using the ALLOF type expression), is considered to hold throughout the lexical scope created by the DPROGN. Thus, our example becomes:

```
(if (FIXP X)
  then (DPROGN ((X FIXP))...else (DPROGN ((X FLOATP)) ...))
```

Like DPROG and DLAMBDA, the value of a DPROGN may also be declared, using the pseudo-variable RETURNS.

DPROGN may be used not only to restrict the declarations of local variables, but also to declare variables that are being used freely. For example, if the variable A is used freely inside a function but is known to be FIXP, this fact could be noted by enclosing the body of the function in (DPROGN ((A FIXP FREE)) BODY). Instead of FREE, the more specific construction (BOUNDIN FUNCTION1 FUNCTION 2 . . .) can be used. This not only states that the variable is used freely but also gives the names of the functions that might have provided this binding.

Since the DPROGN form introduces another level of parenthesization, which results in the enclosed forms being prettyprinted indented, the Decl package also permits such declarations to be attached to their enclosing DLAMBDA or DPROG scopes by placing a DEC expression, e.g., (DECL (A FIXP (BOUNDIN FUM)), before the first executable form in that scope. Like DPROGN’s, DECL declarations use DLAMBDA format.

DECLARING THE VALUES OF EXPRESSIONS

The Decl package allows the value of an arbitrary form to be declared with the Decl construct THE. A THE expression is of the form (THE TYPE . FORMS), e.g., (THE FIXP (FOO X)). FORMS are evaluated in order, and the value of the last one is checked to see if it satisfies TYPE, a type name or type expression. If so, its value is returned, otherwise a declaration fault occurs.

ASSERTIONS

The Decl package also allows for checking that an arbitrary predicate holds at a particular point in a program’s execution, e.g., a condition that must hold at function entry but not throughout its execution. Such predicates can be checked using an expression of the form (ASSERT FORM1 FORM2), in which each FORM1 is either a list (which will be evaluated) or a variable (whose declaration will be checked). Unless all elements of the ASSERT form are satisfied, a declaration fault will take place.

ASSERTing a variable provides a convenient way of verifying that the value of the variable has not been improperly changed by a lower function. Although a similar effect could be achieved for predicates by explicit checks of the form (OR PREDICATE (SHOULDNT)), ASSERT also provides the
ability both to check that a variable’s declaration is currently satisfied and to remove its checks at compile time without source code modification (see COMPILIGNOREDECL).

**USING TYPE EXPRESSIONS AS PREDICATES**

The Decl package extends the Record package TYPE? construct so that it accepts decltypes, as well as record names, e.g., (TYPE? (FIXP (SATISFIES (ILESSP VALUE 0))) EXPR). Thus, a TYPE? expression is exactly the same as a THE expression except that, rather than causing a declaration fault, TYPE? is a predicate that determines whether or not the value satisfies the given type.

**ENFORCEMENT**

The Decl package is a “soft” typing system—that is, the data objects themselves are not inherently typed. Consequently, declarations can only be enforced within the lexical scope in which the declaration takes place, and then only in certain contexts. In general, changes to a variable’s value such as those resulting from side effects to embedded structure (e.g., RPLACA, SETN, etc.) or free variable references from outside the scope of the declaration cannot be, and therefore are not, enforced.

declarations are enforced, i.e., checked, in three different situations: when a declared variable is bound to some value or rebound with SETQ or SETQQ, when a declared expression is evaluated, and when an ASSERT expression is evaluated. In a binding context, the type check takes place after the binding, including any user-defined behavior specified by the type’s binding function. Any failure of the declarations causes a break to occur and an informative message to be printed. In that break, the name to which the declaration is attached (or VALUE if no name is available) will be bound to the offending value. Thus, in the FACT T example above, N would be bound to T. The problem can be repaired either by returning an acceptable value from the break via the RETURN command, or by assigning an acceptable value to the offending name and returning from the break via an OK or GO command. The unsatisfied declaration will be reasserted when the computation is continued, so an unacceptable value will be detected.3

The automatic enforcement of type declarations is a very flexible and powerful aid to program development. It does, however, exact a considerable run-time cost because of all the checking involved. Factors of two to ten in running speed are not uncommon, especially where low-level, frequently used functions employ type declarations. As a result, it is usually desirable to remove the declaration enforcement code when the system is believed to be bug-free and performance becomes more central. This can be done with the variable COMPILIGNOREDECL.

**COMPILIGNOREDECL**

Setting the value of the variable COMPILIGNOREDECL to T (initially NIL) instructs the compiler not to insert declaration enforcement tests in the compiled code. More selective removal can be achieved by setting COMPILIGNOREDECL to a list of function names. Any function whose name is found on this list is compiled without declaration enforcement.

**IGNOREDECL. VAL**

Declaration enforcement may be suppressed selectively by a file using the IGNOREDECL file package command. If this appears in a file’s file commands, it redefines the value of COMPILIGNOREDECL to VAL for the compilation of this file only.

Note: The period in theIGNOREDECL file package command is significant. To set COMPILIGNOREDECL to T, use (IGNOREDECL . T), not (IGNOREDECL T).

**DECLTYPES**

A Decl package type, or decltype, specifies a subset of data values to which values of this type are restricted. For example, a “positive number” type might be defined to include only those values that
are numbers and greater than zero. A type may also specify how certain operations, such as assignment or binding (see BINDFN), are to be performed on variables declared to be of this type.

The inclusion relations among the sets of values that satisfy the different types define a natural partial ordering on types, bound by the universal type ANY (which all values satisfy) and the empty type NONE (which no value satisfies). Each type has one or more supertypes (each type has at least ANY as a supertype) and one or more subtypes (each type has at least NONE as a subtype). This structure is important to the user of Decl as it provides the framework in which new types are defined. Typically, much of the definition of a new type is defaulted, rather than specified explicitly. The definition will be completed by inheriting attributes which are shared by all its immediate supertypes.

An initial set of decltypes that defines the Interlisp built-in data types and a few other commonly used types is provided. Thereafter, new decltypes are created in terms of existing ones using the type expressions described below. For conciseness, such new types can be associated with literal atoms using the function DECLTYPE.

**PREDEFINED TYPES**

Some commonly used types, such as the Interlisp built-in data types, are already defined when the Decl package is loaded. These types, indented to show subtype-supertype relations, are:4

```
ANY
ATOM            LST
ARRAYP      STRINGP    FUNCTION    STACKP
LITATOM         ALIST    HARRAYP
NIL           LISTP       READTABLEP
NUMBERP
FIXP
LARGE
SMALLP
FLOAT

NONE
```

Note that the definition of LST causes NIL to have multiple supertypes, i.e., LITATOM and LST, reflecting the duality of NIL as an atom and a (degenerate) list.

In addition, declarations made using the Record package also define types that are attached as subtypes to an appropriate existing type (e.g., a TYPEDECLARATION declaration defines a subtype of LISTP, a DATATYPE declaration a subtype of ANY, etc.) and may be used directly in declaration contexts.

**TYPE EXPRESSIONS**

Type expressions provide convenient ways for defining new types in terms of modifications to, or compositions of one or more existing types.

```
(MEMQ VALUE1 . . . VALUE N) [Type Expression]
```

Specifies a type whose values can be any one of the fixed set of elements VALUE 1 . . . VALUE N. For example, the status of a device might be represented by a datum restricted to the values BUSY and
FREE. Such a “device status” type could be defined via (MEMQ BUSY FREE). The new type will be a subtype of the narrowest type that all of the alternatives satisfy (e.g., the “device status” type would be a subtype of LITATOM). The membership test uses EQ if this supertype is a LITATOM; EQUAL otherwise. Thus, lists, floating point numbers, etc., can be included in the set of alternatives.

(ONEOF TYPE 1. . .TYPE N) [Type Expression]

Specifies a type that is the union of two or more other types. For example, the notion of a possibly degenerate list is something that is either LISTP or NIL. Such a type can be (and the built-in type LST in fact is) defined simply as (ONEOF NIL LISTP). A union data type becomes a supertype of all of the alternative types specified in the ONEOF expression, and a subtype of their lowest common supertype. The type properties of a union type are taken from its alternative types if they all agree, otherwise from the supertype.

(ALLOF TYPE 1. . .TYPE N) [Type Expression]

Specifies a type that is the intersection of two or more other types. For example, a variable may be required to satisfy both FIXP and also some type that is defined as (NUMBERP (SATISFIES PREDICATE)). The latter type will admit numbers that are not FIXP, i.e., floating point numbers; the former does not include PREDICATE. Both restrictions can be obtained by using the type (ALLOF (NUMBERP (SATISFIES PREDICATE)) FIXP).

(OF AGGREGATE OF ELEMENT) [Type Expression]

Specifies DECLaggregate, a type that is an aggregate of values of some other type (e.g., list of numbers, array of strings, etc.). AGGREGATE must be a type that provides an EVERYFN property. The EVERYFN is used to apply an arbitrary function to each of the elements of a datum of the aggregate type, and check whether the result is non-NIL for each element. ELEMENT may be any type expression. For example, the type “list of either strings or atoms” can be defined as (LISTP OF (ONEOF STRINGP ATOM)). The type test for the new type will consist of applying the type test for ELEMENT to each element of the aggregate type using the EVERYFN property. The new type will be a subtype of its aggregate type.

(SATISFIES TYPE (SATISFIES FORM 1. . .FORM N)) [Type Expression]

Specifies a type whose values are a subset of the values of an existing type. The type test for the new type will first check that the base type is satisfied, i.e., that the object is a member of TYPE, and then evaluate FORM 1. . .FORM N. If each form returns a non-NIL value, the type is satisfied. The value that is being tested may be referred to in FORM 1. . .FORM N by either (a) the variable name if the type expression appears in a binding context such as DLAMBDA or DPROG, (b) the distinguished atom ELT for a SATISFIES clause on the elements of an aggregate type, or (c) the distinguished atom VALUE, when the type expression is used in a context where no name is available (e.g., a RETURNS declaration). For example, one might declare the program variable A to be a negative integer via (FIXP (SATISFIES (MINUSP A))) or declare the value of a DLAMBDA to be of type ((ONEOF FIXP FLOATP) (SATISFIES (GREATERP VALUE 25))).

Note that more than one SATISFIES clause may appear in a single type expression attached to different alternatives in a ONEOF type expression, or attached to both the elements and the overall structure of an aggregate. For example,

[LISTP OF [FIXP (SATISFIES (ILEQ ELT (CAR VALUE)
                      (SATISFIES (ILESSP (LENGTH VALUE) 7))]]

specifies a list of less than seven integers each of which is no greater than the first element of the list.

(SHARED TYPE) [Type Expression]
Specifies DECLshared, a subtype of TYPE, with default binding behavior, i.e., the binding function (see BINDFN), if any, will be suppressed. For example, if the type FLOATP were redefined so that DLAMBDA and DPROG bindings of variables that were declared to be FLOATP copied their initial values (e.g., to allow SETNs to be free of side effects), then variables declared (SHARED FLOATP) would be initialized in the normal fashion, without copying their initial values.

**NAMED TYPES**

Although type expressions can be used in any declaration context, it is often desirable to save the definition of a new type if it is to be used frequently, or if a more complex specification of its behavior is to be given than is convenient in an expression. The ability to define a named type is provided by the function DECLTYPE.

\[(DECLTYPE \ TYPENAME \ TYPE \ PROP1 \ VAL1 \ \ldots \ PROPN \ VALN)\]  

[NLlambda, nospread function.  TYPENAME is a literal atom, TYPE is either the name of an existing type or a type expression, and PROP 1, VAL 1...PROP N, VAL N is a specification (in property list format) of other attributes of the type. DECLTYPE derives a type from TYPE, associates it with TYPENAME, and then defines any properties specified with the values given.

The following properties are interpreted by the Decl package. Each of these properties can have as its value either a function name or a LAMBDA expression.

**TESTFN**  

will be used by the Decl package to test whether a given value satisfies this type. The type is considered satisfied if FN applied to the item is non-NIL. For example, one might define the type INTEGER with TESTFN FIXP.

**EVERYFN**  

EVERYFN specifies a mapping function that can apply a functional argument to each “element” of an instance of this type, and which will return NIL unless the result of every such application was non-NIL. FN must be a function of two arguments: the aggregate and the function to be applied. For example, the EVERYFN for the built-in type LISTP is EVERY. The Decl package uses the EVERYFN property of the aggregate type to construct a type test for aggregate type expressions. In fact, it is the presence of an EVERYFN property that allows a type to be used as an aggregate type.

**BINDFN**  

BINDFN is used to compute from the initial value supplied for a DLAMBDA or DPROG variable of this type, the value to which the variable will actually be initialized. FN must be a function of one argument that will be applied to the initial value, and which should produce another value which is to be used to make the binding. For example, a BINDFN could be used to bind variables of some type so that new bindings are copies of the initial value. Thus, if FLOATP were given the BINDFN FPLUS, any variable declared FLOATP would be initialized with a new floating box, rather than sharing with that of the original initial value.

**SETFN**  

is used for performing a SETQ or SETQQ of variables of this type. FN is a function of two arguments, the name of the variable and its new value. A SETFN is typically used to avoid the allocation of storage for intermediate results. Note that the SETFN is not the mechanism for the enforcement of type compatibility, which is checked after the assignment has taken place. Also note that not all functions that can change values are affected: in particular, SET and SETN are not.

**MANIPULATING NAMED TYPES**
DECLTYPES is a file package type. Thus all of the operations relating to file package types, e.g., GETDEF, PUTDEF, EDITDEF, DELDEF, SHOWDEF, etc., can be performed on decltypes.13

The file package command, DECLTYPES, is provided to dump named decltypes symbolically. They will be written as a series of DECTYPE forms that will specify only those fields that differ from the corresponding field of their supertype(s). If the type depends on any unnamed types, those types will be dumped (as a compound type expression), continuing up the supertype chain until a named type is found. Care should be exercised to ensure that enough of the named type context is dumped to allow the type definition to remain meaningful.

The functions GETDECLTYPEPROP and SETDECLTYPEPROP, defined analogously to the property list functions for atoms, allow the manipulation of the properties of named types. Setting a property to NIL with SETDECLTYPEPROP removes it from the type.

RELATIONS BETWEEN TYPES

The notion of equivalence of two types is not well defined. However, type equivalence is rarely of interest. What is of interest is type inclusion, i.e., whether one type is a supertype or subtype of another. The predicate COVERS can be used to determine whether the values of one type include those of another.

(COVERS HI LO) [Function]

COVERS is T if HI can be found on some (possibly empty) supertype chain of LO; else NIL. Thus, (COVERS ‘FIXP (DECLOF 4))= T, even though the DECTYPE of four is SMALLP, not FIXP. The extremal cases are the obvious identities:

(COVERS ‘ANY ANYTYPE) = (COVERS ANYTYPE ‘NONE) = (COVERS X ) for any type X = T.

COVERS allows declaration-based transformations of a form that depend on elements of the form being of a certain type to express their applicability conditions in terms of the weakest type to which they apply, without explicit concern for other types that may be subtypes of it. For example, if a particular transformation is to be applied whenever an element is of type NUMBERP, the program that applies that transformation does not have to check whether the element is of type SMALLP, LARGEP, FIXP, FLOATP, etc., but can simply ask whether NUMBERP COVERS the type of that element.

The elementary relations among the types, out of which arbitrary traversals of the type space can be constructed, are made available via:

(SUBTYPE TYPE) [Function]

Returns the list of types that are immediate subtypes of TYPE.

(SUPERTYPES TYPE) [Function]

Returns the list of types that are immediate supertypes of TYPE.

THE DECLARATION DATA BASE

One of the primary uses of type declarations is to provide information that other systems can use to interpret or optimize code. For example, one might choose to write all arithmetic operations in terms of general functions like PLUS and TIMES and then use variable declarations to substitute more efficient, special-purpose code at compile time based on the types of the operands. To this end, a data base of declarations is made available by the Decl package to support these operations.

(DECLOF FORM) [Function]

Returns the type of FORM in the current declaration context. If FORM is an atom, DECLOF will look up that atom directly in its data base of current declarations. Otherwise, DECLOF will look on the
property list of (CAR FORM) for a DECLOF property, as described below. If there is no DECLOF property, DECLOF will check if (CAR FORM) is one of a large set of functions of known result type (e.g., the arithmetic functions). Failing that, if (CAR FORM) has a MACRO property, DECLOF will apply itself to the result of expanding (with EXPANDMACRO), the macro definition. Finally, if FORM is a Lisp program element that DECLOF “understands” (e.g., a COND, PROG, SELECTQ, etc.), DECLOF applies itself recursively to the part(s) of the contained form which will be returned as value.14

DECLOF [Property]

Allows the specification of the type of the values returned by a particular function. The value of the DECLOF property can be either a type, i.e., a type name or a type expression, or a list of the form (FUNCTION FN), where FN is a function object. FN will be applied (by DECLOF) to the form whose CAR has this DECLOF property on its property list. The value of this function application will then be considered to be the type of the form.

As an example of how declarations can be used to automatically generate more efficient code, consider an arithmetic package. Declarations of numeric variables could be used to guide code generation to avoid the inefficiencies of Interlisp's handling of arithmetic values. Not only could the generic arithmetic functions be automatically specialized, as suggested above, but by redefining the BINDFN and the SETFN properties for the types FLOATP and LARGEP to reuse storage in the appropriate contexts (i.e., when the new value can be determined to be of the appropriate type), tremendous economies could be realized by not allocating storage to intermediate results that must later be reclaimed by the garbage collector. The Decl package has been used as the basis for several such code optimizing systems.

DECLARATIONS AND MASTERSCOPE

The Decl package notifies MASTERSCOPE about type declarations and defines a new MASTERSCOPE relation, TYPE, which depends on declarations. Thus, the user can ask questions such as “WHO USES MUMBLE AS A TYPE?,” “DOES FOO USE FIXP AS A TYPE?,” and so on.

END NOTES

1. USEDIN is mainly for documentation purposes, since there is no way for such a restriction to be enforced.
2. Like USEDIN declarations, FREE and BOUNDIN declarations cannot be checked, and are for documentation purposes only.
3. With this exception, assignments to variables from within the break are not considered to be in the scope of the declarations that were in effect when the break took place and so are not checked.
4. LST is defined as either LISTP or NIL, i.e., a list or NIL. The name LST is used because the name LIST is treated specially by CLISP. A LIST is defined as either NIL or a list of elements each of which is of type LISTP.
5. When a value is tested, the component type tests are applied from left to right.
6. The built-in aggregate types are ARRAP, LISTP, LST, and STRINGP (and their subtypes).
7. As no predefined type has a binding function, this is of no concern until the user defines or redefines a type to have a binding function.
8. Actually, any property can be attached to a type, and will be available for use by user functions via the function GETDECLTYPEPROP.
9. Typically, the TESTFN for a type is derived from its type expression, rather than specified explicitly. The ability to specify the TESTFN is provided for those cases where a predicate is available that is much more efficient than that which would be derived from the type expression. For example, the type
SMALLP is defined to have the function SMALLP as its TESTFN, rather than (LAMBDA(DATUM) 
(AND(NUMBERP DATUM)(FIXP DATUM) (SMALLP DATUM))) as would be derived from the subtype 
structure.

10. Note that a type’s EVERYFN is not used in type tests for that type, but only in type tests for types 
defined by OF expressions that used this type as the aggregate type. For example, EVERY is not 
used in defining whether some value satisfies the type LISTP. The Decl package never applies the 
EVERYFN of a type to a value without first verifying that the value satisfies that type.

11. For a PPROG binding, FN will be applied to no arguments if the initial value is lexically NIL.

12. The BINDFN, if any, associated with a type may be suppressed in a declaration context by 
creating a subtype with the type-expressing operator SHARED.

13. Deleting a named type could possibly invalidate other type definitions that have the named type as 
a subtype or supertype. Consequently, the deleted type is simply unnamed and left in the type space 
as long as it is needed.

14. “The current declaration context” is defined by the environment at the time that DECLOF is called. 
Code-reading systems, such as the compiler and the interpreter, keep track of the lexical scope within 
which they are currently operating, in particular, which declarations are in effect. Note that (currently) 
DECLOF does not have access to any global data base of declarations. For example, DECLOF does 
not have information available about the types of arguments of, or the value returned by, a particular 
function, unless it is currently “inside” that function. However, the DECLOF property can be used to 
inform DECLOF of the type of the value returned by a particular function.
The DEFAULTSUBITEMFN module redefines the DEFAULTSUBITEMFN to permit an extended specification of menu subitems. If the CAR of the 4th element of a menu item is the keyword EVAL, the CADR of that 4th element is evaluated and the results used as the subitem specifications. During the evaluation the variables MENU and ITEM are bound respectively to the menu and item of which the EVAL subitem spec is a part. This module is only a stopgap measure until it is possible to easily redefine the BackgroundMenu subitem function, but it will provide this facility on all menus that do not explicitely specify a subitem function.

example menu item entries:

(foo foo.selected "No help for you!" (EVAL dynamic.foo.subitems))

using a variable containing subitems, or

(foo foo.selected "No help for you!" (EVAL (compute.foo.subitems))

using a function to recompute the subitems.

It is prudent to make the expressions used in the EVAL subitems quite efficient, since they will be called many times.
INTRODUCTION

DIALPHONE is a simple computer-controlled telephone dialer. It requires a modem connected to the RS-232 port. It should work with a wide variety of modems since it makes no assumption about any return codes from the modem. It lets you dial your phone by typing (or selecting) a number from the computer’s keyboard. A history list of recently dialed numbers is maintained. It knows how to deal with differences between dialing local extensions, outside calls, and long distance. It also translates phone numbers containing letters back into numbers.

OPERATION

Load DIALPHONE.LCOM from your local LispUsers directory and call (DIALPHONE). The program will ask you for your own phone number. This is used within Xerox for billing long distance calls. If you just enter a CR, the program will not append any number at the “quick-quick-quick-slow” tone when dialing long distance. Next, it will try to attach a menu with a telephone icon to an AddressBook window (if you have the LispUsers package AddressBook loaded), since it makes a useful complement to AddressBook. If you do not have AddressBook loaded, it will prompt you to click in some window where you would like the Dial icon attached. If you click in an area of background, a stand-alone menu will be created. Before dialing a number, check the various parameters described below.

To dial a number, click on the phone icon with the left mouse button. You will see the prompt ”Number please:” in the prompt window. You may now either type in a number or shift-select it out of another window. To abort the operation, type a CR without a number. If you select the icon with the middle button, you will get a menu of the last 10 numbers dialed. Listen to the number being dialed over the modem’s speaker, then pick up the receiver. The program will make the modem hang up automatically shortly after the number is dialed.

The program converts any letters in the number you give it into numbers. The program is designed for use on a PBX-style system (although it is easy to modify if desired). Numbers less than six digits long are assumed to be internal extensions and are dialed exactly as given. Numbers or 7 or 8 digits are assumed to be local outside calls; the program prefixes a ”9” to them. Numbers longer than 8 digits are assumed to be long distance; the program appends your extension to them for billing. Xerox Intelligent numbers should be typed in their usual form, starting with ”8*”. Area codes and exchanges should be separated with dashes, e.g. ”716-555-1212”.

You can also call the program directly, e.g. (DIALPHONE “555-1212”). It will return the number dialed. If you try to dial a number while the modem port is already in use, the program will print an error message in the Prompt Window and return without dialing.

DIALHISTSIZE [Variable]
This controls how many numbers will appear in the menu you get when you select the phone icon with the middle button. Default = 10.

**DIALPREFIX**  
[Variable]

The modem command your modem needs to initiate dialing. Default = "ATDT". Change this to "ATDP" if you do not have touch-tone service.

**DIALSUFFIX**  
[Variable]

The modem command your modem needs to terminate a command. Default = <CR> (ASCII 13).

**LASTNUMBERDIALED**  
[Variable]

The last number you dialed. Initially NIL.

**PHONEBILLNUMBER**  
[Variable]

The number the program should use to append to long-distance numbers. Initially "" (null string).
**INTRODUCTION**

DICTTOOL is the user’s interface to the Dictionary Server. The Dictionary Server is a prototype of a shared network resource for providing a suite of dictionary-based capabilities to programs running on client workstations. It has on it the American Heritage dictionary, the Word Finder synonym package by Microlytics, a Proofreader, and the WordNerd, a package for searching for words based on their meaning.

(Note: The American Heritage dictionary has been licensed to us by Houghton-Mifflin for research purposes only, and so we have not made the Dictionary Server generally available. The Dictionary Server should only be used by people within PARC.)

**HOW TO USE DICTTOOL**

When you load the DICTTOOL, it automatically adds a new menu item named "Dictionary" to the TEdit menu and the Background menu. The "Dictionary" menu item has three sub-items: "Get Definition", "Get Synonyms", and "Search For Word". Here is how each one works:

**Get Definition**

If you make a selection in a TEdit document, and then invoke the "Get Definition" command in that document, then DictTool will ask for a confirmation and then fetch the definition for that word from the Dictionary Server, printing it in a separate window. If there is more than one entry in the American Heritage Dictionary for that word, then it will print the definitions one after another. The Dictionary Server knows how to find the root forms of words, and so "breathing" "breathes" and "breathe" will all give you the same entry.

If there is no selection in the TEdit document, or if you deny the confirmation, or if instead of using the TEdit menu you use the Background menu, then DictTool will first prompt you for a word to look up and then fetch its definition. (Since it is very hard to make a null selection with TEdit, DictTool treats a one character selection as meaning "no selection". If you really want to look up a single letter in the dictionary, you can type it in when prompted for a word.)
If you want to look up several definitions at once, separate the entries with semi-colons followed by spaces. (i.e. "camera; photography; motion picture"). Semi-colons are used as delimiters because some of the entries in the American Heritage Dictionary have spaces and commas in them (as in "motion picture"). It also makes it easier to look up words in the output of the WordNerd (see "Search For Word" below).

Get Synonyms

The interface for getting synonyms is exactly the same as the interface for getting definitions. If you make a selection, then DictTool will first confirm the selection and then print out the synonyms in the same window that the definitions are printed in. If you don't make a selection, then DictTool will first prompt you for a word. The format of the information printed out is a series of synonym classes separated by carriage returns. Each synonym class begins with the part of speech that its elements belong to. The elements themselves are separated by commas.

Search For Word

The interface to the WordNerd is a little different from the other interfaces. Instead of typing just one word in, you want to type a list of keywords separated by spaces. For instance, if you were looking for the word for a mechanical model of the solar system, you might type:

Type keywords to search on: mechanical model solar system

The WordNerd then searches for words that have at least two of these keywords in their definitions. The results would be sorted according to the number of keywords found, with the words having the most keywords printed first:

mechanical model solar system: orrery
mechanical solar system: mechanism
model solar system: planetarium
mechanical system: automation; bar1; component; degree of freedom; energy level; hookup; ignition; instrument; key1; linkwork; load; machine; neutral; perpetual motion; quantize; resonance; schematic; servomechanism; shafting; stress; suspension; unit
solar system: Copernican; cosmic; Earth; Ganymede3; Jupiter2; Mars2; mercury; Milky Way; nebular hypothesis; Neptune3; Pallas; planet; planetesimal hypothesis; Pluto2; Saturn2; solar battery; space; sun; Uranus2; Venus2; Vesta2

(The numbers after some of the words mean that this is the nth entry of this word in the American Heritage Dictionary.) If there is a word in the list that you want to see the definition for, you can merely select it and get its definition with "Get Definition". In this case you would probably want to know what "orrery" means:
**or|re|ry n., pl. -ries.** A mechanical model of the solar system. [After Charles Boyle (1676–1731), fourth Earl of Orrery, for whom one was made.]

There is also a mechanism for indicating that two words are synonyms of one another, and hence should not be counted as separate keywords for the purpose of deciding whether a word has the minimum two keywords. All you need to do is put parentheses around the words in question. For instance if you were looking for the word for the little plastic thing on the end of a shoe lace, you might try:

*Type keywords to search on:* (shoe lace shoelace) (end tip)

And get in return:

**shoe+ end+:** aglet; fall; heel1; lift; point; quarter; spike1; toe

(A plus at the end of a word indicates a synonym class.)

If you only give the DictTool one word, then it will print out all of the words in the dictionary that have that word in its definition.

**Max Words**

There are two sub-items in the "Search For Word" sub-menu: "Max Words" and "Min Keywords". The first sub-item, "Max Words", allows the user to specify the maximum number of words that should be returned on each search. DictTool is set up to only return 100 words at a time. If WordNerd finds more than a hundred words, then it truncates the list and indicates how many words it eliminated. If you want to see the words that were eliminated, just make the same request with the same keywords in the same order and the WordNerd will return the next 100 words. (If there is no selection in the document, then DictTool will prompt you with the last set of keywords so that this is easier.) However, if 100 words is too many or too few, you can change it with this menu item or by setting the global variable DictTool.MaxWords.

**Min Keywords**

DictTool is set up to only return a word if it has at least two of the user’s keywords in its definition. If the user wants, he can raise or lower the minimum as he sees fit. The minimum only comes into play whenever the user gives more keywords than the minimum, otherwise the WordNerd looks for words that have at least one of the keywords in their definition. A minimum of 1 means that only one word has to match. A negative minimum means that the WordNerd will set the minimum relative to the number of keywords given. For instance, a minimum of -1 says that all but one of the keywords have to match for the word to be returned. A minimum of zero means that all of the words have to match.

**Search For Phrase**
The Search For Phrase command returns all of the entries in the American Heritage Dictionary that have a particular phrase in them. It does this with the help of the Search For Word command, which is why it is a sub-command of that command. Whenever you search for a phrase, the dictionary server first uses the Search For Word command to get the list of words in the dictionary that have all of the words of the phrase in it. It then looks up the definition of each of these words, and returns the words that have the phrase in their definition. This can be a very time-consuming operation, so you should use this command sparingly. But if you are concerned about locality and word order, then this command can save you a lot of time.

PROOFREADING

The Dictionary Server also provides proofreading facilities similar to the PROOFREADER package. The interface is exactly the same: there is a "Proofread" menu item on the TEdit menu which produces a special fixed menu for proofreading. The only difference is that all of the proofreading is done remotely on the server. You should only use the Dictionary Server for proofreading small documents; if you are going to do a lot of proofreading, it is better to use the PROOFREADER. (For more documentation on how to proofread, see PROOFREADER.)
INTRODUCTION
DIGI-CLOCK is a digital clock which allows you to keep track of the time in multiple time zones.

STARTING DIGI-CLOCK
Loading DIGI-CLOCK will kill any existing DIGI-CLOCK process and restart the clock. Once the clock is loaded it can be restarted by typing (DIGI-CLOCK) or (DIGI-CLOCK T). The second of these restarts the clock from scratch, rebuilding everything; the first, simply restarts the process and does not undo any changes made to the clock. Left buttoning in the window causes the clock to update itself. The clock updates itself approximately once a minute.

CHANGING DIGI-CLOCK
The clock font, the time, the local time zone, the alarm, the alarm mode (loud or quite), the clock mode (12 or 24 hour) are all settable from the middle button menu. This menu also allows you to add clocks for other time zones. The auxiliary clocks also have middle button menus which allow you to set the time zone for that window and edit the time zone heading. The default is for all of the auxiliary clocks have the same font and changing the font in one changes the font in all of them unless the submenu item "Set Aux Clock Font In Just This Window" is selected. Selecting "Shape to Fit" will reshape the clock windows to their minimum size.

If the menu font options are not sufficient you can set the global variables *DC-FONT* and *DC-AUXW-FONT*. The date format is bound to the variable *DC-DATETIMEFORMAT* and can be changed by editing or setting this variable. The clock does not deal with seconds gracefully in 12-hour mode and it will not allow NUMBER.OF.MONTH in 12-hour mode. The regional time zones are stored on the global list *DC-TIME-ZONE-LIST*.

SETTING DIGI-CLOCK
Choosing "Set Time" from the middle button menu, brings up a menu which allows you to set the time.

SETTING THE DIGI-CLOCK ALARM
DIGI-CLOCK includes an alarm clock which can be set to any number of dates in any order. The alarm stores a brief message to remind you why the alarm was set. To set the alarm choose the "Set Alarm" middle button option. Once you have set the time, the clock will prompt you for a message. This message can be longer than the window, but only one line long. When the alarm rings, the window will shape to fit the message.

The alarm calls the function RINGBELLS once a minute until the alarm is turned off, which can be annoying. To run the alarm in quiet mode, select Quiet Alarm from the middle button menu. Selecting Quiet Alarm changes this menu option to Loud Alarm and sets the alarm to run in quiet mode. Selecting Loud Alarm will toggle the alarm back to its original noisy setting.

To unset the alarm, select "Delete Alarm Setting" from the middle-button menu and then select the time you want deleted from the pop-up menu.
To turn the alarm off, select “Turn Alarm Off” from the middle-button menu.
INTRODUCTION

DInfo is a system for browsing graph structured documentation. Graphs for the Interlisp-D Reference Manual and the Xerox Quintus Prolog Manual are available, as are tools for creating and editing new graphs.

USER INTERFACE

Selecting DInfo from the background menu will pop up a menu listing the available graphs (see DINFO.GRAPHS below). Selecting one of these items will bring up a browser on that graph. Most interaction with DInfo is done through menus at the top of each graph browser which look like this:

```
Node: Level Zero Protocols
      Top!  IRM Top
      Parent! Ethernet Protocols
      Previous! Protocol Layering
      Next!  Level One Protocols
        Display: Graph Menu Text History
        Find!  Lookup!
          IRM DInfo
```

The Expanded Menu may be closed independently of the graph browser, and re-opened by selecting Expanded Menu from the title bar menu. Except for this command, the commands in the title bar menu are identical to their counterparts in the Expanded Menu, so only the latter commands are documented.

Next to Node:, Top!, Parent!, Previous!, and Next! are printed the names of the node currently being visited, the name of the top node in the graph, the name of the node previous to the current node, and the name of the node next to the previous node, respectively. Top!, Parent!, Previous!, and Next! are also commands as follows:

- **Top!**
  
  Visits the top node in the graph.

- **Parent!**
  
  Visits the parent of the current node.
**Previous!** [DInfo Menu Command]
Visits the node previous to the current node.

**Next!** [DInfo Menu Command]
Visits the node following the current node.

**Previous!** and **Next!** thus provide sequential access to the graph.

The Display: toggles control what will be displayed when a node is visited:

**Graph** [DInfo Menu Toggle]
toggles display of a Grapher display of the graph local to the current node. Selecting a node in this display will visit the corresponding node in the graph.

**Menu** [DInfo Menu Toggle]
Toggles display of a menu of subnodes of the current node. If the current node has no subnodes no menu will be displayed. Selecting an item in the subnode Menu will visit that node in the graph.

**Text** [DInfo Menu Toggle]
Toggles display of the text of the current node. Turning this off will speed up the visiting of nodes considerably, useful when searching for a particular node.

**History** [DInfo Menu Toggle]
Toggles display of a menu containing the history of nodes visited. Selecting an item from this menu will revisit that node.

**Lookup!** [DInfo Menu Command]
If selected with the left mouse button prompts for a term and then calls the LOOKUPFN of the graph with it. Using the middle button will re-call the LOOKUPFN with whatever was used previously. This is intended for the lookup of terms in a graph-dependent index. In the case of the *Interlisp-D Reference Manual* DInfo Graph, Lookup! will lookup a term in the index of the IRM, and then visit the node containing the reference to this term.

**(DINFO GRAPH.OR.FILE WINDOW.OR.REGION — —)** [Function]
Starts a DInfo browser on GRAPH.OR.FILE in WINDOW.OR.REGION. If GRAPH.OR.FILE is NIL, an empty graph will be created. If WINDOW.OR.REGION is NIL, the user will be prompted for a window or region.

**GLOBAL VARIABLES**

**DINFOMODES** [Variable]
Determines which of the toggles will be selected when DInfo is initially started; it should be a list with recognized members being GRAPH, MENU, TEXT, and HISTORY. Default is (GRAPH TEXT).

**DINFO.HISTORY.LENGTH** [Variable]
Determines the maximum length of DInfo’s history. Default is 20.

**DINFO.GRAPHS** [Variable]
Determines the contents of the menu raised by selecting DInfo from the background menu. Should be a menu-items style list where when the CADR of an item is evaluated it returns either a DInfo Graph (a DINFOGRAPH record) or the name of a file containing a DInfo Graph (i.e, something suitable for passing to DInfo as the GRAPH.OR.FILE argument).
The following information is included for the programmer interested in adding alternate graphs to DInfo.

**DINFONODE**

[Record]

Contains the following fields:

- **ID**  Unique identifier for node in graph, a la GRAPHHNODE field NODEID. Note that EQ is used for checking identity of nodes.
- **LABEL**  The print name of a node. Analagous to the GRAPHHNODE field NODELABEL.
- **FILE**  The file containing the documentation for this node. Should not generally include HOST and DIRECTORY fields as DInfo will default these (assuming all documentation files are on one directory, see below).
- **FROMBYTE**  Byte number in FILE where the documentation for this node begins.
- **TOBYTE**  Byte number in FILE where the documentation for this node ends.

DInfo uses OPENTEXTSTREAM to display its files, and thus any TEdit file can be included. Note that if a file has any formatting (image objects in particular), the byte number of a character in a file is not necessarily the same as the TEdit character number of that character.

- **PARENT**  The ID field of the node parent to this node.
- **CHILDREN**  A list of the ID's of the subnodes of this node.
- **NEXTNODE**  The ID of the next node in the graph.
- **PREVIOUSNODE**  The ID of the node previous to this node in the graph.
- **USERDATA**  Unused. Note that there is no special access function for this field as, for example, WINDOWPROP is for the USERDATA field of a WINDOW. This field is left open for use by implementors for whatever they see fit.

**DINFOGRAPH**

[Data Type]

Contains the following fields of interest to the implementor:

- **NAME**  The name of the graph. Note that when DInfo reads a graph from a file (with DINFO.READ.GRAPH) this field is set to the NAME field of the file name the graph is read from.
- **NODELST**  The list of nodes in the graph. Each node should be a DINFONODE record.
- **TOPNODEID**  The ID field of the root, or top node of the graph.
- **WINDOW**  The main window of the graph browser.
- **CURRENTNODE**  Used by DInfo to keep track of where in the graph it is.
- **DEFAULTHOST**  Used if no host is specified in the FILE field of a node.
- **DEFAULTDEVICE**  Used if no device is specified in the FILE field of a node.
- **DEFAULTDIR**  Used if no directory is specified in the FILE field of a node.

Note that DEFAULTHOST, DEFAULTDEVICE and DEFAULTDIR are set when a DINFOGRAPH is read from a file (by DINFO.READ.GRAPH) to the host, device and directory of that file.

- **TEXTPROPS**  Will be passed as the PROPS argument to OPENTEXTSTREAM when the file for a node in the graph is displayed. This feature can be to used to fake some formatting.
LOOKUPFN  Will be called when the user selects Lookup! from DInfo’s Expanded Menu with two arguments: The string to look up, and the current DInfo graph.

MENUFN  Called when the middle mouse is depressed in the title bar of a graph’s window. If not specified, DINFO.DEFAULT.MENU will be used. Passed one argument of the current DInfo graph. DINFO.EDIT.MENU is a MENUFN that allows editing of DInfo graphs. Selecting >>Empty Graph<< from the menu raised by selecting DInfo from the Background Menu will start DInfo on an empty graph with this MENUFN.

FREEMENUITEMS  DInfo’s Expanded Menu is implemented as a FreeMenu. This property holds a list of FreeMenu item descriptions suitable for passing to FREEMENU (see FreeMenu documentation). This list will be appended onto the bottom row of buttons (Find! and Lookup!) whenever a FreeMenu is created for this graph.

USERDATA  Accessed by the macro DINFOGRAPHPROP. See below.

(DINFOGRAPHPROP GRAPH PROP VALUE)  [Macro]
If VALUE is not specified, will return the PROP of GRAPH. PROP can be either a real DINFOGRAPH field or something in the USERDATA field. If VALUE is specified it will be put in GRAPH at PROP. Note that in this case it will return the new value stored in, not the previous value, as many other Interlisp-D access functions do.

(DINFO.UPDATE GRAPH NODE SEL)  [Function]
Will visit NODE in GRAPH. NODE, if specified, should be a DINFONODE record which is in the NODELIST of GRAPH. SEL is used by DInfo’s Interlisp-D Reference Manual lookup facility, and should be useful in implementing other lookup facilities. SEL determines what in the TEXT of this node will be selected. SEL should be a string or a list of the format (NAME X) where NAME is the name of the selection, X is the character number in the text of NODE to be scrolled to. If SEL is a string, the string will be searched for in the text of NODE and selected. This is useful for the lookup of terms.

(DINFOGRAPH WINDOW)  [Function]
Return the DINFOGRAPH associated with window. Note that the pointer from the window to the graph is destroyed when the window is closed to remove circularity. For this reason it is better to keep a handle on the DINFOGRAPH and use (DINFOGRAPHPROP <DInfoGraph> ‘WINDOW) when you need the WINDOW.

(DINFO.READ.GRAPH FILE QUIETFLG)  [Function]
Reads a file written by DINFO.WRITE.GRAPH, and returns the DINFOGRAPH contained therein. If QUIETFLG is non-NIL, nothing will be printed out while reading.

(DINFO.WRITE.GRAPH GRAPH FILE)  [Function]
Writes GRAPH to FILE such that it can be read by DINFO.READ.GRAPH.

(DINFO.READ.KOTO.GRAPH GRAPH FILE)  [Function]
Reads a file written by Koto DINFO.WRITE.GRAPH and returns a Lyric DINFOGRAPH. Thus:

(DINFO.WRITE.GRAPH
   (DINFO.READ.KOTO.GRAPH <file1> T)
   <file2>)

will convert the Koto format DINFOGRAPH in <file1> to a Lyric format DINFOGRAPH in <file2>.
DIR-TREE

Dir-Tree builds directory trees using the grapher package.
It works on IFS, XNS, and NFS devices from Medley.
Loading Dir-Tree puts a menu option on your background menu.
Dir-Tree can take awhile to compute a large directory. Do not give it a /users directory to graph.

From the directory window you can left button on a node and bring up a menu to Connect to the directory or call FileBrowser on the directory.

At the moment shift-select from the graph does not work but you can achieve the same effect by clicking the middle mouse button on a node.

Holding the left mouse button down in the title bar brings up the recompute option. On NS servers it also allows you to set the Enumeration Depth.

I make no pretenses that Dir-Tree is anything like a finished product. However, it has been satisfactorily working for me in its present state for over a month now (Jan ’89).

I have been asked when it will be available. Since I will not have any time to work on it until the NoteCards doc is done, those who are interested are welcome to use it in its present state.

KNOWN PROBLEMS:

When using it from a Sun DO NOT use the {UNIX} device. This hopelessly confuses Dir-Tree.

When specifying the root directory on a Sun, you must get the case right. Dir-Tree will still generate a graph but it will only go down one level, and it will not correctly truncate the root directory name in the graph window.

Keith Mountford.
DESCRIPTION

DOC-OBJECTS is a generic, extensible interface for including image objects in TEdit documents. It hooks into TEdit by an extra entry on TEdit’s middle button menu, as well as by redefining what happens on typing CTRL-O. Clicking the menu entry or typing CTRL-O brings up an Objects menu. Selecting an object causes an instance of the designated object to be inserted in the document at the position of the caret. Clicking outside the Objects menu has no effect. DOC-OBJECTS comes with a set of predefined Document Objects, which are described below. Additional Objects can easily be added to the Objects menu.

Predefined Objects

TimeStamp [Document Object]

A TimeStamp reflects the date the document containing it was last PUT into a file. Each PUT causes a TimeStamp to be updated. Clicking the mIddle button over a TimeStamp brings up a DateFormat editor. The TimeStamp can be given any appearance consistent with the function DATEFORMAT (see IRM, Section 12.5). The object following the next colon is a TimeStamp object for this file: 15 Sep 1988 18:11 PDT (Thursday). Individual characters of a TimeStamp cannot be altered by TEdit, but a TimeStamp can be given arbitrary TEdit Looks. The DATEFORMAT-EDITOR package is automatically loaded by the DOC-OBJECTS package.

FileStamp [Document Object]

A FileStamp reflects the name of the file into which the document containing it was last PUT. Each PUT causes a FileStamp to be updated. It cannot be edited. A FileStamp is initially displayed as ‘-- not yet filed --’.

Include [Document Object]

This document object is a dynamic version of the static TEdit Include command, and is intended to facilitate the unbundling of document chapters and sections, while maintaining the ability to print the entire document or any portion of it. When an Include object is created, the user is prompted for a file name. An Include object can be enabled or disabled. If it is enabled, the object shows in the TEdit window as ‘@Include[MySubFile.TEdit]’, and the indicated file will be included during a hardcopy operation. If it is disabled, then the object shows (both in the TEdit window and on hardcopy) as ‘@DoNotInclude[MySubFile.TEdit]’.
Middle-clicking on an Include object pops up a menu with the following fields: "New File" (prompt for a new file name), "Edit File" (TEdit the Include file, or bring it to the top if it is already being edited), "Enable" (include the file during hardcopy), and "Disable" (do not include the file during hardcopy).

Two caveats:

1) For best results, make an Include object the last thing in a paragraph, or put it in a paragraph of its own, and set the line and paragraph leadings to 0. The Include object forces a paragraph break right after the Include object during hardcopy, to prevent the looks of the paragraph containing the Include object to mask the looks of the first paragraph in the file being included.

2) A document containing Include objects is best hardcopied from a FileBrowser window, rather than through the hardcopy command on the TEdit window menu. It will work properly either way, but it's a bit unnerving to watch TEdit trying to reflect on the display the inclusion of one or more files before hardcopy and the removal of the included files after hardcopy.

Horizontal Rule

This provides a more user-friendly interface to the HRULE package (which is automatically loaded by the DOC-OBJECTS package). Upon selecting it a numberpad is brought up repeatedly, with which the user can indicate the thickness of alternating black and white lines. The resulting HRule object is inserted in the document whenever the numberpad is aborted or returns 0. The DOC-OBJECTS package also modifies the HRule object such that it can be edited: clicking the middle button over an HRule object brings up a structure editor (such as SEdit) on a list containing the thicknesses of the lines composing the HRule. This list can be altered in any way, as long as the editor returns another list of numbers (presumably of odd length).

Eval'd Form

Selecting this object causes a type-in window to pop up. The value of the form typed in is assumed to be an image object. This is what TEdit used to do on typing CTRL-O. For TEdit's purpose, an image object is a Lisp value of type IMAGEOBJ, BITMAP, STRINGP, LITATOM, or REGION. The latter is assumed to refer to a region of the screen.

Screen Snap

Selecting this object prompts for a region of the screen. A bitmap containing a copy of the given region of the screen is inserted in the document. This is equivalent to clicking the right button in the display's background while holding the SHIFT key down.

Extending the Document Objects interface

DocObjectsMenuCommands

This variable contains a list of menu items which are displayed in the Document Objects pop-up menu. It is analogous to the variable BackgroundMenuCommands (cf. IRM, Section 28.8). The Lisp form in each item is assumed to evaluate to an image object (as defined under Eval'd Form described above).

DocObjectsMenu

This variable caches the Document Objects menu. Set it to NIL whenever you alter the variable DocObjectsMenuCommands.
DocObjectsMenuFont [Variable]

This variable contains a font descriptor which is used for displaying the items in the Document Objects menu. The initial value is (FONTCREATE '(MODERN 12 BOLD)). Set the variable DocObjectsMenu to NIL whenever you alter DocObjectsMenuFont.

(DOCOBJ-STRING-IMAGEBOX STRING IMAGESTREAM) [Function]

A useful function for Document Objects that wish to display as a string of characters (such as a TimeStamp). The Document Object’s IMAGEBOXFN can call this function to obtain an image box with the TEdit Looks that apply to the Document Object taken into account.

(DOCOBJ-WAIT-MOUSE WINDOWSTREAM) [Function]

A useful function for Document Objects that wish to assure that their buttoneventfn takes action only if the mouse buttons were let up within the Object’s region (i.e., the clipping region of the Object’s window stream). It returns T when the mouse buttons go up within the region, or NIL when the mouse moves out of the region while a button is still down.

The Excruciatingly User Friendly Environment

By: Jeff Shrager et al.

Checked out for Medley by Larry Masinter (Masinter.PA@Xerox.COM)

Files: DONZ. DONZ.dfasl DONZ.TEDIT

Description:
Loading DONZ starts a background process (DONZ.RUN) which causes your ICONS to become “user friendly”. Telling you what this means would spoil all the fun of discovery.

Customizing DONZ:
The delay between activations of DONZ is done by (DISMISS DONZ.DELAY). Its value defaults to 5000 (5 seconds). When DONZ wakes up, it tries out one window, selected at random, from all the windows in (OPENWINDOWS). If the selected window is not an ICON, nothing happens and DONZ wakes up again in 5 more seconds. If that window is an ICON, then DONZ tries to find a message for it as described below. This method results in DONZ’s “friendliness rate” running approximately in proportion to the ratio of icons to opened windows on your screen. Thus, if you are doing real work, DONZ won’t bug you, but if you just have a screen full of icons, DONZ will be exceedingly friendly.

The list DONZ.TEST.MESSAGE.ALIST has the form:

(frob1 frob2 frob3...)

where each frob is of the form:

(testfn msg1 msg2 msg3...)

TESTFN will be called with one argument: the *MAIN* window with which this icon is associated. That is, for instance, the TEDIT window that the icon will expand to...NOT the icon window. TESTFN should decide whether or not this window is of a type that it will handle, and return T or NIL as appropriate. When one of the TESTFNs returns T, one of the messages in the tail of the associated frob list will be selected at random and displayed...in the way that they are displayed...you’ll see! If none of the frobs accepts responsibility for the present icon, there are a few default messages built into DONZ.

The msgs should be lists containing individual words (appropriately capitalized) so that .PARA in the PRINTOUT can do the appropriate word division.

Notes:
DONZ has to be killed via the PSW. Be gentle.

DONZ continues to run during screen idle. This results in fairly funny theatrics on the part of your icons.
The display is done with PRINOUT which does some bogusness to indent, erasing some of the good parts of the window. This is slightly messy, but otherwise innocuous.

Anyone who can guess the origin of the name of this package belongs on the East Coast.

Acknowledgements:

Thanks to Ros Chast for originating the idea, Mike Kazar and Dave Nichols for their original implementation of DONZ at CMU.
INTRODUCTION

This package is the Xerox Lisp software driver for the Dorado (Xerox 1132) color display.

NECESSARY HARDWARE

You need a Xerox 1132 with color card and a third party color display. Please contact your Xerox representative for details concerning acquiring and setting up all the required hardware. Some notes on configuring the Conrac color monitor are given at the end of this document.

Assuming you have all the hardware you need, turn it all on. This means

1. Your 1132 is running Xerox LISP.
2. Your 1132 has an 1132 color card installed.
3. Your color display is plugged in and powered on.
4. Three cables for red, green, and blue signal connect the 1132 color card to the color display.

Any reconnections should be made while your 1132 is off. Until you issue some software commands, a black color display is normal.

DORADOCOLOR SOFTWARE

The DORADOCOLOR package provides the machine dependent portion of software that is needed to drive your color display assuming you are using an 1132 with 1132 color card. Other than LOADing the DORADOCOLOR package and turning the DORADOCOLOR package on using the function COLORDISPLAY, all additional functionality is provided by and documented with the COLOR package. There are no DORADOCOLOR functions that the user needs to call directly. The user calls functions described in the COLOR documentation. A single exception to these comments is a global variable \DORADOCOLOR.LEFTMARGIN which controls the period of time the display controller should wait before turning on the color guns. \DORADOCOLOR.LEFTMARGIN is normally set to 56; if this value causes odd results with your monitor, try setting \DORADOCOLOR.LEFTMARGIN a little higher or
lower and reinitializing the display. (You can reinitialize the display by calling COLORDISPLAY twice in succession).

Once your hardware is on, you can proceed to issue COLOR commands to your hardware. You should have the DORADOCOLOR package already LOADed from your LIBRARY directory. That is, you’ve already done something like (FILESLOAD DORADOCOLOR). At this point it may be convenient to follow this documentation along with the documentation for COLOR in the Lisp Library Packages Manual. If you now type

(COLORDISPLAY 'ON 'DORADOCOLOR)

your display will now change from total black to a color test pattern with horizontal and vertical stripes. The sequence of events is that there should be a noticable flicker on your color display, followed by a white wall covering the color display, followed by the painting of this white wall with horizontal and vertical stripes of color woven together. There are now some simple tests you can do to satisfy yourself that your hardware is working. Here is a small list of things to try:

(SETQ CSBM (COLORSCREENBITMAP))
(BLT SHADE 'WHITE CSBM)
(BLT SHADE 'RED CSBM)
(BLT SHADE 'GREEN CSBM)
(BLT SHADE 'BLUE CSBM)
(SETQ DS (DSPCREATE CSBM))
(DRAWLINE 0 0 500 500 10 'REPLACE DS 'YELLOW)
(DRAWLINE 500 0 0 500 10 'REPLACE DS 'CYAN)

Assuming all has gone well to this point, you should now be able to try all the functions described in the COLOR package documentation. The COLORDEMO package is a good source of test programs to try — (IL:LOAD 'COLORDEMO.LCOM) to get this package. Both COLOR and COLORDEMO documentation are in your LispUsers’ Manual.

KNOWN BUGS

As of 11/88, there are several known bugs with the color code. Dragging the mouse off the right hand edge of the display appears to hang the Dorado. Also, color fonts do not seem to work (probably because in Medley AC fonts are unrotated using pilotbbt).

APPENDIX - THE CONRAC COLOR MONITOR

This section describes configuring the Conrac color monitor (model 7211C19) for use with the Dorado.
**Back Panel** - Connections need to be made as follows: each color cable (red, green, blue) should be connected to the color-corresponding IN terminal. The black cable should be connected to the SYNC/HDRIVE IN terminal. The rocker switches next to the connectors should be set to 75 ohms.

**Front Panel** - The BRIGHT and CONTRast knobs push in to configure to their preset settings, pull out for adjustment. The SCREEN buttons should be toggled out, the CHANNEL button should be toggled out.

**Internal Switches** - If after connecting the monitor and starting up the color software, the display does not appear to be in sync, you may need to check the internal settings inside the monitor. To do so, you will need to remove the cover and several internal metal panels (which may be screwed to the bottom of the monitor as well). Viewed from the front of the monitor, on the left hand side is the Scan Board, on the right hand side is the Video Board. Adjustments should be made with the power off, exercise caution!

On the Scan Board, there is a Scan Rate Jumper (pins 52-61) which controls the scan rate (different resolutions). This jumper should be in the bottom position (pins 52-59), specifying low resolution (525 lines).

Below it to the left are three potentiometers, the lower one (R126) controls the horizontal hold for low resolution. Other "pots" of interest control pincushion (R65), width (R78), height (R4), v-hold (R2), v-center (R24), h-center (R90).

On the Video Board, there is a Sync Jumper (pins 35-37) which controls the sync rate. This jumper should be in the upper position (pins 35-36).

Further details can be found in the Conrac 7211 Manual.
DSPSCALE

By: Christopher Lane  (Lane@Sumex-Aim.Stanford.Edu)

DSPSCALE allows a program to output to different types of streams (display, Interpress, etc.) without corrections for scaling. This module provides self-scaling graphics through two different methods: a virtual self-scaling image stream that overlays a regular image stream and/or new versions of the various image stream graphic manipulation functions (DRAWLINE, DSPTOPMARGIN, etc.). The goal of both methods is to make it possible to modify the normal scaling factor of an image stream without modification to the program generating the output.

VIRTUAL SELF-SCALING IMAGE STREAM

This module implements a virtual image stream type, called SCALED, which is used to overlay any other image stream and provide automatic scaling to the natural scale of the image stream or any user selected scaling factor. The function OPENIMAGESTREAM is used to overlay a scaled image stream over a regular one. For example, the following will open a scaled image stream on top of an Interpress image stream:

(OPENIMAGESTREAM (OPENIMAGESTREAM ’TEST.IP ’INTERPRESS) ’SCALED)

The only difference between the virtual stream and a normal image stream is that the SCALE argument to the DSPSCALE function is active and can be used to change the scale of the stream (multiplying the scale specified by the standard scaling factor of the stream).

SELF-SCALING GRAPHICS FUNCTIONS

As an alternative to the self-scaling image stream, self scaling versions of the various graphics functions are provided. For most of the graphic functions, self-scaling versions have been defined which have an ! (exclamation point) at the end of their name (eg. DRAWLINE vs. DRAWLINE!):

CENTERPRINTINREGION!  DRAWELLIPSE!  DSPSCALE!
CHARWIDTH!  DRAWLINE!  RELDRAWTO!
CHARWIDTHY!  DRAWPOINT!  RELMOVETO!
CURSORPOSITION!  DRAWPOLYGON!  SCALDBITBLT!
BITBLT!  DRAWTO!  STRINGREGION!
BITMAPSIZ!  FILLCIRCLE!  STRINGWIDTH!
BLTSHADE!  FILLPOLYGON!  DSPSPACEFACTOR!
BITBLT!  FONTPROP!  DSPTOPMARGIN!
DSPBACKUP!  GETPOSITION!  DSPXOFFSET!
DSPCLIPPINGREGION!  DSPLEFTMARGIN!  DSPRIGHTMARGIN!
DRAWARC!  DSPLNEFEED!  DSPXPOSITION!
DRAWBETWEEN!  MOVETO!  DSPYOFFSET!
DRAWCURCLE!  MOVETOUPPERLEFT!
DRAWCURVE!  DSPRIGHTMARGIN!

The set includes both output and input functions since it is necessary when getting, for example, a mouse position, to unscale the position to put it back into the program’s virtual coordinate system. By default, these functions can be used directly in place of their non-! counterparts and they will automatically scale their arguments to the DSPSCALE of the output stream. Some of the above functions are not identical with their non-! counterparts, as explained below:
In this version of DSPSCALE, the SCALE argument is active and will multiply STREAM's normal scaling factor. If you have a program that draws a circle, for example, to a window using the appropriate ! functions, you can cause it to draw a different size circle (larger or smaller) by using DSPSCALE! to change the scaling factor of the window without touching the source program.

All of the above functions have one extra argument (as compared to their non-! equivalents) which is the STREAM in question. This is necessary to do the scaling calculations.

The module also defines a couple of new stream manipulation functions:

Defines the amount of X and Y translation that should be added to graphic operations to STREAM. Similar to DSPTRANSLATE but works even if the image stream does not have an IMTRANSLATE method. The second form of the arguments is for backward (Koto) compatibility.

Essentially the inverse of DSPSCALE!, this function lets you set how many UNITS (pixels or whatever) the source program generates for each unit pixel on the output stream (multiplied by the output stream's default scaling).

It is possible to use both the virtual image stream and the self-scaling graphics functions together as long as the self-scaling graphics functions are applied to the real stream, not the virtual one.

**Lisp Data Type Scaling Functions**

The routines below are used by the ! functions and the virtual image stream for scaling numbers, positions, regions and other data types and are useful for defining other self-scaling functions:

(DSPSCALE.BRUSH BRUSH STREAM) [Function]
(DSPSCALE.DASHING DASHING STREAM) [Function]
(DSPSCALE.POINTS KNOTS STREAM) [Function]
(DSPSCALE REGION REGION STREAM) [Function]
(DSPSCALE.NUMBER NUMBER STREAM) [Function]
(DSPSCALE.POSITION POSITION STREAM) [Function]
(DSPSCALE.XPOSITION NUMBER STREAM) [Function]
(DSPSCALE.YPOSITION NUMBER STREAM) [Function]
(DSPSCALE.WIDTH WIDTH STREAM) [Function]
(DSPUNSCALE.REGION REGION STREAM) [Function]
(DSPUNSCALE.POSITION POSITION STREAM) [Function]
(DSPUNSCALE.NUMBER NUMBER STREAM) [OFFSET] [Function]
(DSPUNSCALE.XPOSITION NUMBER STREAM) [Macro]
(DSPUNSCALE.YPOSITION NUMBER STREAM) [Macro]
EDITBG is a tool for editing both the background and background border shades. The functions CHANGEBACKGROUND and CHANGEBACKGROUND_BORDER both take a shade argument but the shade is interpreted differently. A normal black & white shade consists of 16 pixels (see EDITSHADE in the Interlisp Reference Manual) as does the border shade, which covers twice the area. The normal shade has 4 x 4 pixels but the border shade has 2 x 8 pixels where the pixels are twice as tall. WHITESHADE and BLACKSHADE appear the same for both, as does the standard background shade (shown below) but arbitrary shades do not appear the same.

\[ 34850 = 2^{15} + 2^{11} + 2^{5} + 2^{1} \]

(EDITBACKGROUND) [Function]

Brings up an edit tool (also available from the background menu) which lets you edit both a normal shade and a border shade and see how they combine:

The bottom half of the window has a background texture editor on the left and a border texture editor on the right. The top half of the window shows the background texture within the border texture as it would appear on the screen. Buttoning the small box in the center of the window will change the background and border textures on the screen to those displayed.
EDITKEYS provides a set of "logical" keys corresponding to the Dandelion (1108) function keys. This allows 1132 users to take advantage of interfaces designed for the 1108 keyboard. Calling (BUILDFNKEYS) builds a window with 8 keys like the one below:

These keys can be "pressed" by bugging the mouse (left or middle mouse button) inside the key's image. The effect of pressing one of these keys is to generate the same character code as the key generates on the 1108. The state of the shift keys (at the time the mouse is let up) are taken into consideration, but interfaces that use KEYDOWNP are not affected.
DESCRIPTION

This document describes how to define new kinds of equations to be used with the equation editor in TEdit, and how to construct equation image objects by function calls.

User Switches:

The global variable `EquationDefaultSelectionFn` specifies the default function to be called when an equation is selected with the middle mouse button. The initial value, EQIO.DefaultSelectFn, allows the user to select a piece of the equation by selecting from a menu.

The global variable `UnknownEquationData` is a formatted string to use for displaying equations whose types are not defined.

The global variable `EquationInfo` is used to record all currently defined equation types. The specification information can be obtained by calling

(EQIO.GetInfo `type info`) [Function]

which returns the specified info for equations of the given type. Any of the PROPS mentioned below for EQIO.AddType, or `formFn` or `numPieces`, can be used as a value for `info` to get the corresponding data for this type of equation. Example: (EQIO.GetInfo 'fraction 'numPieces) returns the number of pieces in a fraction.

Individual specification items of an existing equation type can be modified using

(EQIO.SetInfo `type info newValue`) [Function]

although the caller must be sure that any new information is consistent with the remaining properties. For example, (EQIO.SetInfo 'fraction `menuLabel myLabel) will make the value of myLabel be used for fractions in the equation type menu.

Defining new kinds of equations:

This module allows new types of equations to be defined. An equation consists of some number of pieces of text and, perhaps, some extra symbols or lines. A method for computing the relative position of the various pieces must be specified when new equation types are used. The pieces of equations consist of "formatted strings" which allow font information to be associated with strings and can also include image objects (which thus allows equations to contain other equations). Formatted strings are described below. Additional properties can be specified to determine the particular behavior of the new equation.

Additionally, a function can be provided to allow equations of the new type to be created under program control. Typically these are named EQ.Make.xxx where xxx = atom specifying the equation type.
Specifically, a new equation type (or a new definition for an existing type) is created by calling

\[(\text{EQIO.AddType type formFn numPieces PROPS})\]  

where

- *type* is an atom identifying the equation type (e.g. fraction)
- *formFn* is the name of a function, described in detail below, which specifies the relative location of the equation pieces and, if requested, draws any extra lines or symbols required by the equation that are not included in any of its pieces. The formFn can also specify the selection region to be used for each piece of the equation, i.e. that region of the equation within which the left mouse button can be used to select the piece.
- *numPieces* is the number of parts the equation has (e.g. a fraction has two parts: numerator and denominator). If the equation has a variable number of pieces, then numPieces is the default initial value.
- *PROPS* is a prop list of optional properties for the equation which are described below.

The equation form function:

The form function is called with arguments (eqnObj imageStream draw?) and specifies the size of the entire equation and the location of each piece with respect to the lower left corner of the box. Furthermore, if *draw?* is non-NIL, it draws any extra lines or symbols required by the equation that are not included in any of its pieces. (If *draw?* is NIL, nothing should be drawn -- the function is being called only to determine how big the equation is and the relative location of its parts.) The formFn can also specify the selection region to be used for each part of the equation.

For example, a fraction has two parts (numerator and denominator) and a single extra line between them. In this case the formFn draws the line and specifies the location of the numerator and denominator.

Specifically, the formFn should return an equation specification created by a call to

\[(\text{EQIO.MakeSpec box dataSpecList})\]  

where *box* is an IMAGEBOX which specifies the size of the equation; and *dataSpecList* is a list containing a piece specification for each piece of the equation. A piece specification is created by a call to

\[(\text{EQIO.MakeDataSpec pos selectRegion})\]  

where *pos* is the position, relative to the lower left corner of the box, where this piece is to be displayed and *selectRegion* gives the selection region to use for this piece (relative to the I.L. corner of the equation box). If *selectRegion* is NIL, then the region within which the piece is displayed will be used as the selection region. Normally the selectRegion should include the display region inside it, and is intended to allow selection regions to be larger than just the display region. Note that *pos* specifies where the stream should be positioned before displaying the formatted string defining the contents of the piece.

The ATTACHEDBOX routines, described below, may be useful for constructing the form functions of new equations since it provides functions to position various regions so that they do not overlap.

Equation type properties:
The following properties can be specified for any equation type when it is defined with EQIO.AddType. Note that all equations of a given type have the same values for these properties.

- **changeFn**  A function with argument (eqnObj) called when the number of pieces in a variable piece equation is changed. It is meant to allow any specific properties such as saved menus to be adjusted to reflect the change.

- **initialData**  A way to specify the text to be used when equations of this type are created. It can be either the name of a function or a list. If it is a list, then it should contain a single integer for each piece of the equation. This number specifies how the font size for that piece should be changed relative to the initial font size set in TEdit. For example, 0 means use the default font, +1 means use the next bigger font, -2 means use a font two sizes smaller, etc. Missing values default to zero, i.e. the pieces are initially set in the normal size font. The actual fonts used are specified by the array EquationFontSpecs and any request for a font larger (smaller) than the largest (smallest) available in the array defaults to using the largest (smallest). In this case, the initial text will be a single blank.

If initialData is a function, it is called with arguments (initialFontSpec type numPieces dataList) when a new equation of this type is created. It should return a list of formatted strings, with each item in the list to be used for the corresponding piece of the equation. The argument initialFontSpec will specify the current font when the equation is added; and numPieces will be the number of pieces in the equation. dataList, if non-NIL, is a list of items to use for each of the pieces of the equation. The items can be either format strings, or just a string in which case the initialData function should attach an appropriate font.

- **initialPropFn**  A function with argument (type) called when a new equation of this type is created. It returns a prop list to be used as properties for this equation. These values are added to (and override) any props given in objectProps. For example, this allows the user to specify the number of rows and columns in a new matrix. If the number of pieces is to be specified, it should be returned as the value of the numPieces prop, and the equation type should allow a variable number of pieces.

- **makeFn**  A function which constructs an image obj for this type of equation from its arguments. Generally this will just provide a convenient way of calling EQN.Make.

- **menuLabel**  A label to use for this type in the equation type menu displayed after selecting Equation in the main TEdit menu. If not given, the type atom is used as the label.

- **objectProps**  A prop list of properties and their initial values that are needed for this equation. These properties can be used by the formFn to lay out the equation and will typically be modified by the wholeEditFn.

- **pieceNames**  A list of names of the pieces of the equation. This is used by the default middle button selection function to provide a menu of choices. E.g. ("numerator" "denominator") for a fraction. If this property is not specified, then the default menu will just contain the numbers of the pieces. This is generally meant for equations with a fixed number of pieces.

- **specialSelectFn**  A function with argument (eqnObj) to be called when the equation is selected with the middle button instead of the default action. It should return the number of the piece selected, or NIL if no piece of the equation is selected. The selected piece, if any, will then be edited.

- **wholeEditFn**  A function with arguments (eqnObj window button) called when the entire equation, rather than a single piece, is selected. This can be used to change global properties of
the equation and should return non-NIL if the object is modified, NIL otherwise. window is the
window which contains the equation and button is the mouse button used to select it.

- variable? Non-NIL to indicate this equation type allows a variable number of pieces.

**Equation data functions:**

The functions used with new equation types should make use of the routines provided for formatted
strings as well as the following functions when using the various equation data:

- (EQIO.EqnType eqnObj) returns the atom specifying the kind of equation eqnObj is.
- (EQIO.EqnDataList eqnObj) returns the list of formatted strings which specify the pieces of the
equation.
- (EQIO.SetDataList eqnObj newDataList) replaces the data list (i.e. the list of formatted strings
corresponding to each piece of the equation) with newDataList. The caller must update the
number of pieces in the equation appropriately. This is useful, for instance, when the wholeEditFn
has made major changes in the equation.
- (EQIO.EqnData eqnObj piece#) returns the formatted string corresponding the the piece of
eqnObj specified by piece#.
- (EQIO.EqnProperty eqnObj prop {newValue}) returns the current value of the specified property
of eqnObj if newValue is not present, otherwise sets the specified property to the value of
newValue even if it is NIL. This can be used to associate arbitrary properties with individual
equations. Currently, the following properties are used by the equation editor and should not be
used for other purposes:
  - fontSpec a specification of the current font at the time the equation was created
  - numPieces the current number of pieces in a variable-piece equation
  - selectionMenu the current default middle-button selection menu for a variable-piece
equation

When equations are copied, any data items that are not atoms, strings or lists are set to NIL. These
items are also PRIN2'ed on files. Thus other data types should only be used to cache values (e.g.
menus) that can be recomputed if necessary from the other properties.

- (EQIO.NumPieces eqnObj {newValue}) returns the current number of pieces in eqnObj if
  newValue is not present. Otherwise if eqnObj is a variable-piece equation, it sets the number of
  pieces to newValue and adjusts any necessary properties by calling the equation’s changeFn.

Additionally, properties can be associated with the equation type itself by use of

- (EQIO.TypeProp type prop {newValue}) which gets or sets the property prop for equation type.
  This can be used to save properties that are the same for all equations of a given type (e.g.
  selection menus for equations with a fixed number of pieces).

**Equation image objects** can be created by a program (and then, for example, inserted into TEdit) by
use of

- (EQN.Make type dataList fontSpec PROPS) which makes a type equation whose arguments are
  format strings contained in dataList. fontSpec is an initial font specification and PROPS is a prop
  list of equation properties which should include numPieces for equations with a variable number
  of pieces.
FORMATSTRINGS

The basic components of equations are represented as formatstrings which allow fonts and super/subscripting to be associated with strings and can also include image objects. A format string is a list of items, each of which is either an imageobject or a list giving a font specification, a string and an optional shift specifying the number of points to move up when displaying the string. The following functions can be used to create and display format strings as well as insert and extract them from TEXTSTREAMs. All formatstrings must be on a single line.

Functions:

For creating and accessing format strings:

(FS.MakeItem fontSpec string shift) [Function]
creates a formatstring item from fontSpec, a font specification such as (Gacha 10), string and shift. The string can be null.

(FS.ItemFont item) [Function]
returns the font associated with item, or NIL if item is an imageobject.

(FS.ItemValue item) [Function]
returns item if it is an imageobject, otherwise its associated string.

(FS.ItemShift item) [Function]
returns the shift associated with item.

For inserting and extracting from TEXTSTREAMs:

(FS.Extract stream) [Function]
returns a format string created from the text in the TEXTSTREAM stream. Any unallowed characters (as determined by FS.AllowedChar) in the stream are ignored. Note that any format information other than character fonts, super/subscripting and image objects is discarded. The file pointer associated with the stream is modified.

(FS.Insert data stream) [Function]
inserts the format string data at the current location in TEXTSTREAM stream.

For displaying and manipulating the format strings:

(FS.Box data imageStream) [Function]
returns an IMAGEBOX specifying the size of the format string data on imageStream.

(FS.Copy data) [Function]
returns a copy of the format string data.

(FS.Display data imageStream invert?) [Function]
displays the format string data on imageStream. If invert? is non-NIL, the display is inverted.

(FS.Get fileStream) [Function]
reads a formatstring, or list of formatstrings, from the current location on fileStream.
(FS.Put data fileStream)  [Function]

prints the formatstring (or list of formatstrings) data to fileStream.

Additional functions:

(FS.AllowedChar charcode)  [Function]

returns non-NIL if charcode is allowed in formatstrings.

(FS.RealStringP item nullOK)  [Function]

returns non-NIL if item's value is a string (rather than an imageobject) and either nullOK is non-NIL or the string is not the nul string.

ATTACHED BOXES

The following functions place image boxes in specific locations with respect to a main box so that the added boxes won't overlap. The desired position of a new box is specified by the side of the main box to place it next to and the position of a point on the side of the new box with respect to a point on the side of the main box. The placed regions are specified with respect to the lower left corner of the main box. Sides are specified by one of the atoms top, bottom, left or right and are with respect to the main box.

The position of the added box is specified relative to some side of the main box. Specifically, the location of a reference point on the near side of the added box, the addPt, is given with respect to a reference point on the side of the main box, the mainPt. The possible points along the side are specified by one of the atoms low, high, center or display corresponding to the corner nearest the lower left corner of the box, the corner farthest from the l.l. corner of the box, the center of the side, and the display point of the image box respectively. The location of the addPt with respect to the mainPt is specified by a distance along the side, the shift, and a distance perpendicular to the side, the gap. These distances can be positive or negative. A negative value for the gap will cause the added box to overlap the main box. All boxes are assumed to have no kerning (i.e. XKERN field is zero).
Functions:

For creating and accessing format strings:

(AB.PositionRegion mainBox addedRegions side mainPt addBox addPt gap shift clear) [Function]

Positions addBox with respect to mainBox avoiding overlap with previously added regions. The parameters are: mainBox is an image box specifying the main box; addedRegions is a list of regions (measured with respect to the lower left corner of mainBox) that have already been placed next to the main box; side is the side (one of top, bottom, left or right) of the main box next to which the new box should be placed; mainPt is the reference point along the side of the main box (one of low, high, center or display); addBox is an image box specifying the box to be placed; addPt is the reference point along the side of the added box; gap and shift specify the relative positions of the reference points; and clear is the minimum (nonnegative) distance that the new box is allowed to be from any of the previously added regions (NIL defaults to zero which prevents any overlap of the added regions).

The function returns a list of the form (region newAddedRegions) where region is the region, w.r.t. the lower left corner of mainBox, where addBox was placed and newAddedRegions is the list of added regions updated to include this newly placed region. If the specified location of addBox causes it to be within a distance clear of any of the regions in addedRegions, the box is moved away from the main box in a direction perpendicular to the side (i.e. the gap is increased) until it is far enough from the previous regions.

(AB.Position2Regions mainBox addedRegions side highBox highPt lowBox lowPt highGap lowGap highShift lowShift clear) [Function]

This function places two boxes next to the same side of mainBox. If the two new boxes are within a distance clear of each other, they are moved apart in a direction parallel to the side next to which they are placed so that the distance each box moves is proportional to its size. Then these regions are individually checked for being too close to previously added regions and, if necessary, are moved away from the main box (i.e. perpendicular to the side). The function returns a list of the form (highRegion lowRegion newAddedRegions).
Example:
To place box B to the right of box A such that the low point of the near side of box B is a distance gap from the center of the right side of A, i.e.

\[
\text{main box A}\quad \text{gap}\quad \text{added box B}
\]

use (AB.PositionRegion A addedRegions 'right 'center B 'low gap 0) where addedRegions is a list of previously added regions which should not overlap B.
DESCRIPTION
This module provides interactive editing of mathematical equations within TEdit. An equation consists of a number of pieces of text and possibly one or more special symbols. For many purposes, such as deletion and copy selection, equations behave as a single (large) character in TEdit. Operations on their pieces are described below.

To load:
The equation editor and a standard set of equation types is obtained by loading EQUATIONS.LCOM.

To use:
This section describes the procedures by which equations can be inserted into documents and their pieces modified.

Adding an equation to a TEdit document:
To add an equation, first move the caret to the desired insertion point and then select “Equation” from the main TEdit menu (obtained by holding down the middle button in the window’s title bar). This will display a menu of known equation types. Selecting one of these will insert the corresponding equation into the document at the current location of the caret. To abort the insertion, click outside the menu. Once the equation is inserted, a subeditor will be created for each of the equation pieces, one at a time. This can be used to fill in the various pieces of the equation and its use is described below.

Some equation types will prompt for additional information before inserting the new equation (e.g. inserting a matrix will prompt for the desired number of rows and columns).

Editing a currently existing equation:
In order to modify a piece of an existing equation (e.g. the numerator of a fraction), the piece must be selected with the mouse in one of two ways. First, you can point at the piece in the displayed equation and press the left mouse button. Alternatively, pointing at the equation and pressing the middle button will display a menu from which the desired piece can be selected. This is useful for selecting pieces that are too small to conveniently point at with the mouse. In either case, if a piece is selected, a subeditor will start on that piece. In addition, some equation types may also allow changes to global properties when no specific piece is selected (e.g. changing the number of rows in a matrix).

Using the equation piece subeditor:
The subeditor is attached to the bottom of the main edit window and allows individual pieces of the equation to be modified with normal TEdit operations. While a subeditor is active, the corresponding piece of the equation in the main window is inverted. Since the text in equation pieces must be on a single line, the subeditor will not accept control characters such as carriage returns. Instead the edit window will flash when such characters are typed.
In the subeditor, the TEdit menu is modified to provide a limited set of TEdit commands as well as additional commands relevant to equations. The menu appears as

```
Find
Looks
Substitute
Character Looks
Equation
Exit
```

Selecting Find, Looks, Substitute or Character Looks invokes the corresponding TEdit action. Selecting Equation acts as described above and allows equations to be embedded inside other equations. Exit ends the subedit of the equation piece, updates the equation in the main editor and, if this is a newly inserted equation, automatically starts editing the next piece.

The Exit item also has three possible subitems which are used to exit from the equation editor and specify a desired follow up action. Specifically, Next Piece ends the edit of the current equation piece and creates a new editor on the next piece. In this context, the pieces of the equation are considered to form a circular list so that successive uses of the Next Piece option will edit each piece of the equation in turn. The second subitem, Finish Eqn, ends the current equation edit and does not continue with any other pieces of the equation. Finally, Abort ends the current edit without changing the equation.

When a subeditor is terminated, any TEdit looks or formatting other than character fonts and sub/superscripting are ignored.

The subeditor can also be terminated by the key normally used to advance to the next fill-in slot in TEdit (i.e. text of the form ">>...<<"). Specifically, if there are no remaining slots in the subeditor, using this key is equivalent to selecting Exit from the command menu described above. By default, this key is the middle-blank key on Dolphins and Dorados and the OPEN key on DLions.

**User Switches:**

The global variable EquationFontSpecs is an array of font specifications in order of increasing size which is used to determine initial fonts for the equation pieces. This can be modified if additional or different default fonts are desired.

The global variable EQ.UseNSChars determines the kind of characters to use when displaying equations that use special symbols (e.g. sum or product) on the screen. Specifically, if non-NIL then symbols from the NS character set are used, otherwise the Sigma 20 font is used. It is initially set to NIL.

When NS characters are used (on the screen when EQ.UseNSChars is non-NIL, or for Interpress), the global variable EQ.NSChars determines the particular NS characters to use. It is a property list of the form (TYPE1 ITEM1 ...) where TYPE is the kind of equation (e.g. SUM, PRODUCT, etc) and ITEM gives the font and character number to use, e.g. ((MODERN 30) 61301) for an INTEGRAL. This variable compensates for the lack of large symbols in various Interpress fonts.

The file EQUATIONPROGRAM.TEDIT describes how to define new kinds of equations, as well as how to create equations in a program with function calls.

**Examples:**

Examples of equations are given in the file EQUATIONEXAMPLES.TEDIT. The equation module must be loaded before reading this file.
Limitations:

- Equations that are larger than the available room in the current TEdit window will not be displayed.
- The text of each piece of an equation must be on a single line.
- All image objects inserted into equations, as well as the equations themselves, must not have any kerning, i.e. the XKERN field of all imagebox records must be zero.

Koto Incompatibility:

Due to a change in image object I/O, files containing equations written in Lyric/Medley may not be readable in Koto.
ETHERBOOT

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

Uses: Various microcode, germ and boot files.

ETHERBOOT is a Envos Lisp background network server process which allows Dandelions and/or Doves (other than the one the server is running on) to boot utility programs from the Ethernet (as an alternative to floppies). On a Dandelion, a 3, 4 or 6 boot from the maintenance panel initiates an Etherboot; on a Dove the boot icons are used (sometimes in combination with a number key):

<table>
<thead>
<tr>
<th>Dandelion</th>
<th>Dove</th>
<th>Boot Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0003</td>
<td>F3</td>
<td>Ethernet non-diagnostic boot of the Installer</td>
</tr>
<tr>
<td>0004</td>
<td>F7</td>
<td>Ethernet diagnostic boot of the Installer</td>
</tr>
<tr>
<td>0006</td>
<td>F3-1</td>
<td>Ethernet boot of experimental software</td>
</tr>
</tbody>
</table>

(ETHERBOOT [LOGFILE])

To start the server, (ADD.PROCESS ‘(ETHERBOOT)). LOGFILE is an optional argument which should be an open stream to log transactions in.

BOOTFILEDIRECTORIES

The boot files are searched for on the directories in this list which should point to the (possibly remote) directory where the boot files are kept, initially `{CORE} {DSK}`. The server will not respond to requests for boot files that are not available.

(CACHE.BOOT.FILES [TYPES])

Since Lisp can take longer to open a remote file than the timeout on some (simple) requests, this function can be used to copy some of the boot files listed in ETHERBOOTFILES to the BOOTFILECACHEDIRECTORY. TYPES defaults to those listed in BOOTFILECACHETYPES.

BOOTFILECACHEDIRECTORY

The directory into which CACHE.BOOT.FILES copies boot files, initially {CORE}.

BOOTFILECACHETYPES

The default types of files that CACHE.BOOT.FILES copies to the BOOTFILECACHEDIRECTORY, initially `{DB GERM}`.

BOOTFILERQUESTTYPES

An association list which contains the type numbers of the requests that the boot server handles along with a description of the request type and the function which handles it. Currently, the request types are Simple and SPP.
## ETHERBOOTFILES

The table of boot file numbers and names. Each entry consists of a description of the boot file, the name of the file and the file number (48 bit) by which the file is requested. Since the boot server is table driven, different boot files can be substituted. Initially, ETHERBOOTFILES contains:

```plaintext

</tr>
</tbody>
</table>
```

The boot file numbers overlay the host number space so Dandelion/Dove boot file numbers begin at 25200000000 octal.

### KNOWN PROBLEMS

- The server can only handle one connection at a time.
- Due to as yet unknown reasons, a Dandelion running the server is not able to service simple Dove requests; all other combinations should work.
EXAMINEDEFS brings up side-by-side windows for comparison of the definitions of NAME as TYPE from sources SOURCE1 and SOURCE2.

(EXAMINEDEFS NAME TYPE SOURCE1 SOURCE2 TITLE1 TITLE2 REGION)  [Function]

The kind of comparison is determined by the value of the variable EXAMINEWITH. If EXAMINEWITH is SEDIT, the different definitions are shown in sided-by-side SEDIT windows. This allows for examination--but not editing--of the definitions: The structures shown in SEDIT are copies of the definitions that GETDEF obtains from the sources and so any changes in either SEDIT will have no lasting effect. A separate SEDIT session with a particular definition (maybe different from either of the sources) can be used in parallel for edits guided by the separate examination. Also, currently, the particular locations of differences in the two definitions are not highlighted by SEDIT selections.

If EXAMINEWITH is COMPARETEXT (the initial value), then the definitions are printed in read-only TEDIT windows (as per PF-TEDIT) and compared with COMPARETEXT. The COMPARETEXT browser makes it easy to iterate from difference to difference.

If SOURCE1 or SOURCE2 is a list and not a GETDEF source specification, then a copy of that structure will be taken as the definition to be shown.

If REGION is a region, it is used as the initial suggestion for the constellation region that side-by-side SEDIT windows will share. (COMPARETEXT windows are determined by the COMPARETEXT protocols.)

TITLE1 and TITLE2 if provided are used to override the default titles of the examination windows. The windows are attached, in that they move, reshape, and close together, but scroll independently.

A second function is provided to bring up side-by-side TEDIT-SEE windows as an aid in examining the differences between files. The optional REGION again specifies a constellation region that the TEDIT’s for the two files will share.

(EXAMINEFILES FILE1 FILE2 TITLE1 TITLE2 REGION)  [Function]
EYECON

By: Bob Bane (Bane.envos@Xerox.com)

DESCRIPTION

EYECON creates a window with two eyes in it that follow your cursor around. The eyes also wink when you click your mouse buttons: left and right buttons close the corresponding eye, middle button closes both. Here’s what it looks like:

![EYECON Window](image)

The EYECON window can be shrunk into an icon that looks like this:

![EYECON Icon](image)

doing this kills the process which tracks the cursor. Opening the icon restarts the tracking process.

To start it, load EYECON and call (EYECON.OPEN left bottom) to create an EYECON window at (left bottom).

INSPIRATION

I hacked this up after hearing about something similar that runs under Suntools. The bitmap for the eyes was borrowed from Spy and slightly modified (thanks, Larry!). Julian Orr suggested that the eyes should wink.
FILEWATCH

INTRODUCTION

FILEWATCH is a facility for keeping an eye on open files. It periodically updates a display showing each open file stream, its current file pointer location, the total file size, a percentage bar, and a read/write/both indicator.

DESCRIPTION

Invoking the function FILEWATCH (or selecting the "FileWatch" entry on the BackgroundMenu) starts up the FileWatch process if not already running, or brings up a FileWatch control menu allowing you to forget a currently displayed file (i.e., stop displaying the file), recall a previously forgotten file, close an open file (after mouse confirmation), change some or all FileWatch display properties, or quit the FileWatch process. The Forget, Recall and Close entries on the FileWatch control menu have roll-outs to let you perform the operation on several files at once.

FileWatch can be customized by setting the FileWatch properties (see below) using the function FILEWATCHPROP. Right buttoning any FileWatch window brings up the FileWatch control menu, with the provision that the Forget and Close commands apply to the file displayed in that FileWatch window. Middle buttoning any FileWatch window allows you to move the entire FileWatch display, and left buttoning cause the window to be redisplayed.

DETAILS

(FILEWATCH Command) [Function]
If Command is 'ON and no FileWatch process is already running, starts a process to watch open files. If Status is 'OFF or 'QUIT and there is a FileWatch process running, kills the process. If Command is neither one of the above nor one of the FileWatch commands listed below, starts a process to watch open files if not already running, otherwise brings up the FileWatch control menu. Returns the process if running, otherwise NIL.

FORGET [FileWatch command]
Brings up a menu of files currently being watched. Select the one you no longer want to have watched.

FORGET-MANY [FileWatch command]
Repeatedly performs the FORGET command until no other files are being watched or you make a null selection.

RECALL [FileWatch command]
Brings up a menu of forgotten files. Select the one you want to have watched again.
RECALL-MANY
[FileWatch command]
Repeatedly performs the RECALL command until all forgotten files are being watched again or you make a null selection.

CLOSE
[FileWatch command]
Brings up a menu of open files. Select the one you want to have closed.

CLOSE-MANY
[FileWatch command]
Repeatedly performs the CLOSE command until all open files have been closed or you make a null selection.

MOVE
[FileWatch command]
Performs the SET-ANCHOR, SET-POSITION, and SET-JUSTIFICATION commands.

SET-ANCHOR
[FileWatch command]
Brings up a menu of four corner names. Select the one on you wish to anchor the FileWatch display. For instance, selecting Top-Right causes FileWatch windows to be stacked downwards with the top right corner of the first FileWatch window at the FileWatch display position.

SET-POSITION
[FileWatch command]
Indicate where the FileWatch display should be positioned by moving the region of the combined FileWatch windows.

SET-JUSTIFICATION
[FileWatch command]
Requests confirmation to turn FileWatch window justification on, i.e., make all FileWatch windows the same width as the largest one.

(FILEWATCHPROP PropName [PropValue])
[Function]
If PropValue is given, sets the property value accordingly. Always returns the current (old) value of the property. This is a general facility which you can use for whatever purpose you deem appropriate. However, there are some properties that have a predefined meaning to FileWatch:

ALL-FILES?
[FileWatch property]
If NIL, FileWatch displays only user visible open files; otherwise all open files (including, for example, dribble and file cacher files) are displayed. Initially set to NIL. Caveat: setting this property to T will give you access to things that might be dangerous to play with. In particular, closing certain system files on the Dorado may cause your machine to crash, and may leave the local file system in an unhealthy state.

ANCHOR
[FileWatch property]
Each open file that is being watched gets its own FileWatch window. Multiple windows are stacked automatically. The total region occupied by this stack is anchored at the corner indicated by this property. The only legal values are TOP-LEFT, TOP-RIGHT, BOTTOM-LEFT, BOTTOM-RIGHT. Initially set to BOTTOM-RIGHT. If the anchor is at one of the bottom corners the stack grows upward, otherwise downward. If the anchor is at one of the left corners the stack is aligned by left edge, otherwise by right edge (see also the JUSTIFIED? property).
FILTERS [FileWatch property]

A list of file patterns, for example '("{CORE}.*;.*")'. An open file that matches any of the patterns will not be watched. Initially set to NIL. Note that each pattern is expanded to include the HOST and DIRECTORY equal to that of (DIRECTORYNAME), EXTENSION and VERSION equal to "***", unless already specified. For example, in my case, the filter ""JUNK"" expands to "{Ice}<Koomen>Lisp>*JUNK*.*;*". If you really wanted to filter all junk files, use the filter "(*);JUNK".

FONT [FileWatch property]

The font used for the FileWatch displays, specified in a form suitable to give to the function FONTCREATE. Initially set to '(GACHA 8).

INTERVAL [FileWatch property]

The value given to the function BLOCK. This should be either NIL or an integer indicating the number of milliseconds to wait between FileWatch display updates. Initially set to 1000. Note that FileWatch generates several FIXP's for large files every time through the loop, so setting this to NIL may cause excessive storage allocation and reclamation.

JUSTIFIED? [FileWatch property]

If T all FileWatch windows are aligned along both left and right edges, and are grown or shrunk as needed to accommodate the maximum filename length currently in use. This is aesthetically more pleasing but incurs increased overhead due to frequent reshaping of the windows. Initially set to NIL.

POSITION [FileWatch property]

The location of the anchored corner of the FileWatch display. Initially set to the bottom right corner of the screen: (CONS SCREENWIDTH 0).

SHADE [FileWatch property]

The shade used for the FileWatch thermometers. Initially set to GRAYSHADE.

SORTFN [FileWatch property]

Either NIL or the name of a function taking two filenames as arguments (such as ALPHORDER), which is used to sort the list of open files being watched. Initially set to NIL (i.e., no sorting).
INTRODUCTION

The Fillregion package provides a function which will allow the user to "fill in" arbitrary regions of a bitmap or window with a shade or bitmap (or any valid shade argument to BITBLT). The regions must be defined by a black or white outline. There are two functions provided to the user: FILL_REGION and AUTO_FILL.

(FILL_REGION  window.or.bm  interior.pos  shade)  [Function]

- window.or.bm: Must be either a window or bitmap otherwise an error occurs.
- interior.pos: Must be a position within window.or.bm that is within the interior of the region to be filled.
- shade: Shade can be any valid shade argument that BITBLT will accept.

This will return the window.or.bm with the specified region filled in. The region to be filled is determined by the pixel specified at interior.pos. If the pixel is black, all the connected black regions will be shaded, otherwise, if the pixel is white, all the connected white region will be filled. If the user aborts the function before completion, the original window.or.bm will be restored.

(AUTO_FILL  shade)  [Function]

- shade: Shade can be any valid shade argument that BITBLT will accept.

With your mouse pointing inside the appropriate region in a window, this function will fill in the region with the shade specified. This package only works for one bit per pixel bitmaps, color is not supported.

Example:

(AUTO_FILL 1234)
results in:

Comments and suggestions are welcome.
INTRODUCTION

Finger is a facility for determining and displaying information about other users running Xerox LISP. It displays the user's name, the Etherhostname (or the octal net address when no nameserver is available) and the user's idle time (time since last keystroke or mouseaction). Only other users who have the finger server loaded will be displayed. Users can specify the net radius to query, a list specifying only which users they want displayed, or similarly, only which hosts are to be displayed.

Loading Finger begins the finger server (which responds to queries). To display finger information, the following top-level function is provided:

(FINGER WHO HOST HOPS ICON?) [Function]

WHO is an optional list of usernames specifying which people are to be displayed if a response is received. who defaults to FINGER.CROWD, initially NIL meaning display all responses.

HOST is an optional list of etherhostnames analogous to WHO. Specifying both WHO and HOST denotes union. HOST defaults to NIL, denoting all hosts.

HOPS specifies the net radius to query. 0 specifies only nets to which you are directly connected. hops defaults to FINGER.NET.HOPS, initially 2.

ICON? specifies whether initial display should be the finger icon or a display window. ICON? defaults to NIL meaning display. {typically, in an init file the call would be (FINGER NIL NIL NIL T)}.

The display window is updated each time the users bugs the display window with left or middle mouse button, and when most window operations are performed on the display window (shape, repaint, expand from icon, etc.). Right button retains the standard window menu.

Options:

the following are user specifiable variables affecting the operation of Finger.

FINGER.ICON.POSITION a position indicating the original position for the icon. Initially (900,500).

FINGER.DISPLAY.POSITION a position indicating the original position for the display window. Initially (650,325).

FINGER.DISPLAY.HEIGHT height of the display window. Initially 140. The display width is correct for the display format and need not be changed.

FINGER.TIMEOUT milliseconds to wait for the last response packet. Initially 1500.
FINGER.NET.HOPS net radius to be queried.
FINGER.CROWD list of potential users to be displayed (discussed above).
FINGER.INFINITY.MINUTES number of minutes to be considered infinite idle time. Initially 90.

Additional functions of interest to the user are:

(END.FINGER) which kills the finger server process, closes the sockets, closes the windows, etc.
(FINGER.SERVER) will start a finger server process.
The Free Menu Creator application is designed to create interactively Free Menu description lists. It is a full graphical tool with which you can move, shape, box, group the Free Menu Items and attach properties to them. At any time you can make the application compute the description list and then test the Free Menu that you have just created.

OPENING A FREE MENU CREATOR (FMC) WINDOW

Once you have loaded the application the ‘FMCreator’ option is added to the background menu. By selecting it you will create a FMC window of the form:

The bottom window is the main window: you will add, move ... items to it.

Two menu windows (Free Menus in fact) are attached on top of the main window: the Item Properties menu (IP menu) and the Group Properties menu (GP menu). They are provided for setting and changing item or group properties.

Between the menus and the main window is the Prompt window. Its purpose is mainly to display various information such as messages, prompts ...
THE RIGHT BUTTON MENU

Pressing the right button inside the main window will pop up the following menu:

![Menu Diagram]

You can fix this menu on the right edge of the main window by selecting the 'Fixed Menu' option.

A SAMPLE SESSION

Suppose you want to create the following Free Menu (this example is taken from the FREE MENU Lyric Release Notes):

![Example Menu Diagram]

First create the 'Example' item:
- select TYPE in the IP menu: the following pop-up menu appears:
- choose the type of item you want to create, e.g. DISPLAY
- select LABEL in the IP menu and type 'Example'
- choose the font by clicking in the FAMILY, SIZE and FACE items, which will cause the following menus to pop up:

<table>
<thead>
<tr>
<th>FAMILY</th>
<th>SIZE</th>
<th>FACE</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASSIC</td>
<td>6</td>
<td>REGULAR</td>
</tr>
<tr>

</tbody>
</table>

- now, the properties you wanted for that new item are set. So click in the NEW field and then move the mouse to the place where you want to put the item.

When you release the mouse button the item is fixed in the window. It is surrounded by a gray rectangle which means that it is selected:

![Example]

If you move the mouse inside the selection rectangle the cursor will change to:

![Cursor]

By pressing the left button while the cursor is inside a selection, you can move that selection.

Repeat the same operation for the 'NORTH', 'SOUTH', 'EAST', 'WEST', 'ONE', 'TWO' and 'THREE' items.

To place the items exactly where you want you can use (and combine) the following facilities:
- use the GRID (from the right menu):
Select multiple items by pressing the left button and the META key, while the cursor is above them. You can also extend a multiple selection by pressing Left-Meta outside any item and shaping a ghost region:

```
NORTH  SOUTH  EAST  WEST
```

Each item of a multiple selection is surrounded by a dotted rectangle. You can move a multiple selection in the same way you move a unique selection.

The Align and Center functions all refer to the first selected item. For example, if you choose 'Align Tops' then all the items except for the first one will be moved so that their top is at the same Y coordinate as that of the first item:

```
SOUTH
NORTH  SOUTH  EAST
```

Now, let's box the 'Example' item:
- select the item
- select **SHOW** in the IP menu: this updates the menu according to the item
- set the **BOX** and **BOXSHADE** properties:

<table>
<thead>
<tr>
<th>BOX</th>
<th>SHADE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>OTHER</td>
</tr>
<tr>
<td>9</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td></td>
</tr>
</tbody>
</table>

- select **APPLY**: the item is redisplayed surrounded by a box
- press the middle button inside the item: you can now shape the box (the shaping is controlled so that the space between the item and its box is the same horizontally and vertically):

Whenever you need to change some items’ property (ies), select the item and then select **SHOW** in the IP menu: this updates the menu according to the item. Then, you can change any property, and update the item according to the IP menu by selecting **APPLY**.

You can also change properties of multiple items: make a multiple selection, set the property (ies) you want to change, then select **APPLY**: the following menu pops up:

```
Apply which Property?
TYPE
LABEL
BOX
BOXSHADE
BACKGROUND
FONT
CHANGESTATE
SELECTEDFN
DOWNFN
HELDFN
MOVEDFN
```

Only the selected property will be applied to the items.

When setting a box property on multiple items, a box is created around each item, not around the whole selection. To wrap a set of items by a box you must first **GROUP** the items. That’s what we want to do for the ‘ONE’, ‘TWO’, ‘THREE’ items:

- select the items
- choose **GROUP** from the right menu
Groups are automatically boxed at creation. You can modify groups in the same way as you modify simple items, using the GP menu. Groups can be moved and shaped like simple items.

Now, create the ‘A’, ’B’, ’C’ items, setting their TYPE to NWAY. Group the items, select SHOW in the GP menu, set COLLECTION to ‘COL1’, set DESELECT to T - then select APPLY : you have created the collection.

Create the ‘DELTA’ item and then the ‘Choose Me’ STATE item. For this last item specify a MENU property, selecting MENU in the IP menu. This opens the following SEdit window :

```
(SEdit Package: INTERLISP
  (("ITEMS") "[FONT]" "[TITLE]"

The first element of the list should be an item list, as suitable for standard menus. The second and third elements are optional : FONT should be a list of the form (FAMILY SIZE FACE), TITLE should be a litatom or a string.

Edit the list ((BRAVO DELTA) (MODERN 12 ITALIC)) and close the SEdit window. Now, select INITSTATE : this will pop up the following menu :

NIL
T
BRAVO
DELTA
OTHER

As you can see the items you just edited are part of this menu. Select DELTA.

One more property is required : the LINKS property. Select LINKS : the following menu appears :

Add Link
Remove Link

Choose ‘Add Link’ and click on the DELTA item : the link is created.

At any time you can create the actual Free Menu out of your FMC window by selecting the COMPUTE option from the right menu. This creates the description list, which is stored in the FM-DESCRIPTION global variable. A call to the FREEMENU function is done automatically with FM-DESCRIPTION as an argument, and the Free Menu window is opened.

REFERENCE GUIDE

General window behavior

The main window, the prompt window and the properties windows behave as a whole. Moving, shaping, shrinking and closing can be directed from anyone of them. Shaping affects only the main
The main window is not scrollable.
The right menu, when fixed, can be closed solely.
Hardcopying the main window does not use the standard hardcopy functions. Instead, the contents is 'pretty-hardcopied', but the current version can't print large windows on multiple pages.

**The right menu**

*Redraw*: use Redraw to redisplay the contents of the window. This can be useful when items overlap.

*Grid*: selecting the Grid option displays the grid state in the prompt window.
  - *No Grid*: removes the grid.
  - *Size* suboptions: specifies a grid size (in pixels). Grid alignment refers to the lower left corner of items.
    - *Display Grid*: displays the grid in the window.
    - *Remove Grid Display*: removes the grid display, but the grid remains active.

*Delete*: deletes the selected item(s). Items deleted are saved in a list so they can be undeleted. The number of deleted items is displayed in the prompt window.
  - *Forget save list*: deleted items are destroyed and can't be undeleted.

*Undelete*: undeletes last deleted item.
  - *Last*: same effect
  - *All*: undeletes all deleted items
  - *List*: pops up a menu of all the deleted items. The selected item gets undeleted.

*Group*: groups a multiple selection. A group can include groups. The components of a group are not individually accesible.

*Ungroup*: unpacks a group. The ungrouping operation works only at the first level, i.e. included groups are not unpacked.

*Align*: the Align suboptions all work on a multiple selection (items and/or groups). The alignment operation refers to the first selected item.
  - *Left sides*: align left sides of selected items
  - *Right sides*: align right sides of selected items
  - *Tops*: align tops of selected items
  - *Bottoms*: align bottoms of selected items

*Center*: the Center suboptions all work on a multiple selection (items and/or groups). The centering operation refers to the first selected item.
  - *Horizontally*: center items so their center is on the same X coordinate as that of the first selected item
  - *Vertically*: center items so their center is on the same Y coordinate as that of the first selected item

*Select All*: selects all the window contents

*Background*: pops up a shade menu for setting the window background shade

*Summary*: creates a TEdit window listing a summary of the window contents. Only interesting properties are described, depending on the item type. Groups contents are indented hierarchically.

*Import*: allows items importation from a Free Menu. This function works but is currently bugged: importing items with a MENU property is not supported; when importing groups only their contents are imported.
**Compute**: generates a description list of the items suitable for the FREEMENU function. The list is stored in the FMC-DESCRIPTION global variable. Opens a Free Menu built out from FMC.

**Get**: loads the contents of a FMC window, previously stored on disk by a Put operation. The loaded items (groups) are added to the current contents of the window.

**Put**: saves the contents of a FMC window on disk.

**Fixed Menu**: when the right menu is popped up by the right mouse button, attaches the menu to the main window. Once the menu is fixed, has no effect.

The Item Properties menu

**APPLY**: if the selection is unique sets the selected item properties to the properties described in the menu. If the selection is multiple, pops up a menu of properties and sets the selected property of all the selected items according to the menu.

**SHOW**: updates the menu according to the selected item, thus allowing editing its properties.

**NEW**: creates a new item which properties are described in the menu.

**TYPE**: lets the user specify the TYPE property from a pop-up menu.

**LABEL**: lets the user edit the LABEL property. If no label is edited the item will be displayed in FMC with the pseudo-label "NOLABEL".
Right-buttoning in this field will start label edition, clearing the field first.
Middle-buttoning puts the cursor in the GETREGION state, and sets the label to the bitmap specified by the user.

**ID**: lets the user edit the ID property. The edited string is always MKATOMed in the description list.

**FONT**: FAMILY, SIZE and FACE allow font descriptions from pop-up menus.

**BOX**: BOX=0 means no box.

**BOXSHADE, BACKGROUND**: pop up a shade menu, including an 'OTHER' option for shade editing.

**MENU**: opens a SEdit window where the user specifies the MENUITEMS, MENUFONT and MENUTITLE properties. The list must be of the form (MENUITEMS [MENUFONT] [MENUTITLE]).

**INITSTATE**: pops up a menu of possible INITSTATE values, depending on the item TYPE and possible MENUITEMS.

**CHANGESTATE, SELECTEDFN, DOWNFN, HELDFN, MOVEDFN**: open a SEdit window for the corresponding property. The edited list can be of the form (FUNCTION function-name) or a LAMBDA-expression.

**LINKS**: pops up a menu with 2 items: 'Add Link' and 'Remove Link'. 'Add Link' prompts the user to click on the item that is to get linked (this item must have an ID). 'Remove Link' removes the link.

**INFINITENEXT**: this toggle item is suitable for EDIT or NUMBER items only.

**MESSAGE**: starts editing the MESSAGE property (right buttoning clears the field first).

The Group Properties menu

**APPLY, SHOW, ID, BOX, BOXSHADE, BACKGROUND** behave in the same way as in the IP window.
**COLLECTION** : starts editing a COLLECTION name. Specifying a COLLECTION property is suitable only for groups which items are NWAY.

**DESELECT** : a toggle item whose value is relevant only for COLLECTIONs.

**About item shaping**

The effects of middle buttoning inside an item is different whether the item is boxed or not. If the item is boxed, shaping will be constrained as described in the sample session, i.e. BOXSPACE must be the same horizontally and vertically. If the item is not boxed, shaping is constrained so that only the item’s width can be changed, in fact modifying the MAXWIDTH property.

**Copy functions**

The effects of pressing the COPY key and left buttoning when a FMC window has the TTY depend on what is to be copied:

- when clicking in a SKETCH window, the selected objects are made a graphic LABEL
- when clicking in a FMC window, the selected items are copied in the target window (the source and the target can be the same).
INTRODUCTION

The FONTSAMPLE package provides a function which will easily generate sample sheets of your favourite fonts on your favourite printer.

FUNCTIONS

(FontSample Fonts CharacterSets Printer StreamType) [Function]

Creates a sample sheet for the font described by the font descriptor(s) Fonts on the image stream generated by passing Printer and StreamType to OPENIMAGESTREAM. Fonts may be either a single font descriptor (the result of a call to FONTCREATE) or a list of font descriptors. CharacterSets may be either a single number, or a list of numbers representing character sets. The default value of CharacterSets (if NIL is passed) is 0 (the Roman Alphabet and Punctuation). FontSample will create a page for each font and character set combination specified, consisting of all the characters of the font/character set combination, arranged on a 16 by 16 grid, and labelled in the default 12pt font for the stream.

For example, to create a sample sheet for the Modern 12pt regular font, character sets 0 and 239 (general and technical symbols 2) on the Interpress printer Fountain one might do:

(FontSample (FONTCREATE 'MODERN 12 'MRR 0 'INTERPRESS) '(0 239) '{LPT}Fountain:)

(FontSampleFaked FontAsList Printer StreamType) [Function]

There are very often fonts on printers that Interlisp-D cannot speak about, because it is lacking a font width file. FontSampleFaked can produce sample sheets for many of these fonts. FontAsList should be a font expressed in the raw form that FONTCREATE takes, Printer and StreamType are as for FontSample, however passing DISPLAY for StreamType will not produce meaningful results.

To produce a sample sheet for the Vintage 10pt bold font on the Interpress printer Fountain one might incant:

(FontSampleFaked '(Vintage-Printwheel 10 BRR) '{LPT}Fountain:)

NOTES

Be careful if you create sample sheets for many fonts at once – especially the larger type sizes (24pt and up) – you may cause an Interpress printer to hang and require rebooting to recover.
FORMACRO and FORMACRO.DFASL -- Still another portable iteration macro for commonlisp. Its main claims are almost 100% compatibility with the semantics of the Interlisp-Clisp FOR (especially when used the the XFORMS which fix a few incompatibilities); and user extensibility (unfortunately not compatible with IL:I.S.OPR). Embedded keywords (e.g. IN, COLLECT) may be in any package.
INTRODUCTION

This package (actually a complimentary pair of files) extends the capabilities of the Lisp Library FTPSERVER package to support multiple simultaneous connections between Xerox 11xx series AI workstations.

INSTALLATION

To install this package, load the FTPSERVERPATCH.LCOM file on the 11xx machine(s) that are to be servers (this will load FTPSERVER if it is not already loaded). Then load the DPUPFTPPATCH.LCOM file on any of the 11xx machines that are to be clients of these servers. You must set the value of IL:*FTP.NEGOTIATED.CONNECTION.HOSTS* on each of the client machines to specify the server machines that support the FTPSERVERPATCH system of multiple simultaneous connections (below).

VARIABLES

IL:*FTP.NEGOTIATED.CONNECTION.HOSTS* [Global Variable]

This variable must be set to specify the server machines that support the FTPSERVERPATCH system of multiple simultaneous connections. Its value is a list of PUP host numbers. (Specifically, it is a list of the values of (CAR (BESTPUPADDRESS <SERVER–HOST–NAME>)) for each of the server machines.)

HOW IT WORKS

This package modifies the DPUPFTP code of the client machines, so that when it is trying to open an FTP connection BSP stream, it first checks to see if the server host is one of the IL:*FTP.NEGOTIATED.CONNECTION.HOSTS*, and if so, it sends a message to the modified FTPSERVER on that system (using PUP type \PT.NEGOTIATED.CONNECTION (= 128) on PUP socket \PUPSOCKET.NEGOTIATED.CONNECTION (=63)). The server machine creates a socket for this connection and starts a standard FTPSERVER listener process on this socket, and returns the socket number to the client. (The process is modified so it will go away when the connection is closed instead of lingering forever.) The client uses the returned socket number for the connection instead of \PUPSOCKET.FTP. If the server is NOT on IL:*FTP.NEGOTIATED.CONNECTION.HOSTS*, or fails to respond within 10 seconds with the new socket number, then \PUPSOCKET.FTP is used. When the negotiated connection server is started on the server machine (with the incantation (FTPSERVER) which is the original FTPSERVER start up), it also will start up a permanent FTPSERVER listener on \PUPSOCKET.FTP so regular connection requests can be handled.

ACKNOWLEDGEMENTS

Thanks to Tom Lipkis of Savoir for suggesting this sort of scheme.
GITFNS provides a Medley-oriented interface for comparing the files in two different branches of a git repository. This makes it easier to understand what functions or other definitions have changed in a Lisp source file, or what text has changed in a Tedit file. This may be particularly helpful in evaluating the changes in a pull request.

Separately, GITFNS also provides tools and conventions for bridging between git’s file-oriented style of development and version control and Medley’s residential development style with its own version control conventions. GITFNS allows for intelligent comparisons between Lisp source files, Tedit files, and text files in a local git clone and a local Medley-style working directory, and for migrating files to and from the git clone and the working directory.

Git projects: Connecting git clones to GITFNS capabilities

The GITFNS capabilities operate on pre-existing clones of remote git repositories that have been installed at the end of some path on the local disk. The path to a clone can be used to create a “git project” for that clone:

```lisp
(GIT-MAKE-PROJECT PROJECTNAME PROJECTPATH WORKINGPATH EXCLUSIONS
  DEFAULTSUBDIRS) [function]
```

where

- `PROJECTNAME` is the name of the project (e.g. MEDLEY, NOTECARDS, LOOPS...)
- `PROJECTPATH` is the local path to the clone (e.g. `{dsk}<users>...>git-medley`)
- `WORKINGPATH` is optionally the local path to a corresponding Medley-residential working directory (e.g. `{dsk}<users>...>working-medley`)

When the project has a `WORKINGPATH`:

- `EXCLUSIONS` is a list of files and directories to be excluded from comparisons (beyond what its .GITIGNORE specifies)
- `DEFAULTSUBDIRS` is a list of subdirectories to be use in working-path comparisons when directories are not otherwise specified.

For convenience, if `PROJECTPATH` is NIL or T (and not a path), then a sequence of probes based on `PROJECTNAME` attempts to find a clone directory (with a .git subdirectory):

```lisp
(UNIX-GETENV PROJECTNAME)
(UNIX-GETENV (CONCAT PROJECTNAME 'DIR))
(CONCAT MEDLEYDIR "../git-" PROJECTNAME)
```

(a sister of MEDLEYDIR named git-PROJECTNAME, e.g. `git-notecards`)

Thus:
If MEDLEYDIR is defined,
 (GIT-MAKE-PROJECT 'MEDLEY) will make the MEDLEY project
If NOTECARDS is defined
 (GIT-MAKE-PROJECT 'NOTECARDS) will make the NOTECARDS project
If NOTECARDS is not defined but the clone >git-notecards> is a sister of MEDLEYDIR, then the
NOTECARDS project will still be created.

If a clone is discovered and a project is created, the value of GIT-MAKE-PROJECT is
PROJECTNAME. Otherwise, NIL will be returned if PROJECTPATH is T (= no-error), and
PROJECTPATH=NIL will result in an error.

When GITFNS is loaded, GIT-MAKE-PROJECT is called for MEDLEY, NOTECARDS, and LOOPS, with
PROJECTPATH=T. Thus, those projects will be created automatically, if MEDLEYDIR is defined and
the relevant directories exist in their expected relative positions.

When they are created, GIT-PROJECTS are registered by name on the a-list GIT-PROJECTS, and they
can otherwise be referenced by their names.

The variable GIT-DEFAULT-PROJECT, initially MEDLEY, contains the project name used by the
commands below when the optional projectname argument is not provided.

GIT-MAKE-PROJECT also creates a pseudohost {Gprojectname} whose path prefix is the prefix for
the project’s clone. If WORKINGPATH is provided, then a second pseudohost {Wprojectname}
points to the working files for the project.

GITFNS also defines two directory-connecting commands for conveniently connecting to the git
and working pseudohosts of a project:

cdg (projectname) (subdir)    [command]
cdw (projectname) (subdir)    [command]

For example, cdg notecards library connects to {GNOTECARDS}/library/.

Comparing directories and files in different git branches

In its simplest application, GITFNS is just an off-to-the-side add-on to whatever work practices the
user has developed with respect to a locally installed git project. Its only advantage is to allow for more
interpretable git-branch comparisons, especially for pull-request approval. These comparisons are
provided by the prc (“pull request compare”) Medley executive command:

prc (branch) (DRAFT) (projectname)    [command]

This compares the files in branch against the files in the main branch of the project
(origin/master or origin/main). Thus, suppose that a pull request has been issued on github for a particular
branch, say branch rmk15 of the default project. Then

prc rmk15

brings up a lispusers/COMPAREDIRECTORIES browser for the files that currently differ between
origin/rmk15 and origin/master. If the selected files are Lisp source files, the Compare item on
the file browser menu will show the differences in a lispusers/COMPARESOURCES browser. The
differences for other file types will be shown in a lispusers/COMPARETEXT browser.

If branch is not specified and the shell command gh is available, then a menu of open pull-request
branches will be provided. If gh is not available, the menu will offer all known branches. If the optional
DRAFT is provided, then the menu will include draft PR’s as well as open ones.

If one PR, say rmk15, contains all the commits of another (rmk14), then the menu will indicate this by
rmk15 > rmk14
Note that the prc comparison is read-only: any comments, approvals, or merges of the branch must be specified using the normal Medley-external git interfaces and commands.

prc is the special case of the more general bbc command ("branch-branch compare") for comparing the files in any two branches:

```
bbc branch1 branch2 (project) [command]
```

This compares the files in branch1 and branch2, for example:

```
bbc rmk15 lmm12 (local)
```

This will compare the files in origin/rmk15 and origin/lmm12 in the GIT-DEFAULT project. branch1 defaults to the origin files of the currently checked out branch, the second defaults to origin/master. If local is non-NIL, then a branch that has neither local/ or origin/ prepended will default to local (e.g. local/rmk15) instead of origin/. Local refers to the files that are currently in the clone directory, which may not be the same as the origin files, depending on the push/pull status.

Either of the branches can be specified with an atom local, remote, or origin, in which case bbc will offer menus listing the currently existing branches of that type.

NOTE: Branch comparison makes use of a git command that has a limit (diff.renameLimit) on the number of files that it can successfully compare. A message will be printed if that limit is exceeded, asking whether a larger value for that limit should be applied globally.

The command cob ("check out branch") checks out a specified branch:

```
cob branch (nexttitlestring) (project) [Command]
```

This checks out branch of project and then executes git pull. The branch parameter may also be a local branch, T (= the current working branch), or NEW/NEXT (= the next working branch). The current working branch is the branch named <initials>nnn, e.g. rmk15. The initials are the value of INITIALS as used for SEDIT time stamps, and nnn is the largest of the integers of all of the branches beginning with those initials.

If branch is NEW or NEXT, then a new initialed branch is created and becomes the user’s current branch. Its number is one greater than the largest number of previous initialed branches. If nexttitlestring is provided, then that string will be appended to the name of the branch, after the initials and next number, and two hyphens. Spaces in nexttitlestring will also be replaced by hyphens, according to git conventions.

If branch is not provided, a menu of locally available branches pops up.

The currently checked out branch is obtained by the b? command:

```
b? (project) [command]
```

**Correlating git source control with separate Medley development**

It is generally unsafe to do Medley development by operating with files in a local clone repository. Medley provides a residential development environment that integrates tightly with the local file system. It is important to have consistent access to the source files of the currently running system, especially for files whose contents have been only partially loaded. A git pull or a branch switch that introduces new versions of some files or removes old files altogether can lead to unpredictable disconnects that are hard to recover from. This is true also because development can go on in the same Medley memory image for days if not weeks, so it is important to have explicit control of any file version changes.
GITFNS mitigates the danger by conventions that separate the files in the git clone from the files in the working Medley development directory. The location of the Medley development source tree for a project is given by the WORKINGPATH argument to GIT-MAKE-PROJECT. If WORKINGPATH is T or NIL and there exists a directory >working-projectname> as a sister to the clone, then that is taken to be the WORKINGPATH and thus the prefix for a pseudohost (Wprojectname).

When Medley development is carried out in the WORKINGPATH, the variable MEDLEYDIR should point initially to the working directory, and the directory search paths (DIRECTORIES, LISPUSERSDIRECTORIES, FONTDIRECTORIES, etc.) all have MEDLEYDIR (or {WMEDLEY}) as a prefix. In that case, the clone for the project, if PROJECTPATH doesn’t specify it explicitly, should be located at the >git-medley> sister directory of MEDLEYDIR.

Any back and forth transfer of information between the git clone and Medley development must be done by explicit synchronization actions. Crucially, Medley-updated files do not appear in the clone directories and new clone files do not move to the Medley directories without user intervention.

The files in Medley working tree and the git clone of a project can be compared with the gwc ("git-working-compare") command:

```
gwc subdirectories (project) [command]
```

This produces a browser for all the files in the corresponding WORKINGPATH subdirectories that differ from the files in the currently checked out branch of the git clone. If subdirectories is omitted, it defaults to the DEFAULTSUBDIRS of the project. If it is ALL, then files in all subdirectories that are not found in the project’s EXCLUSIONS are compared.

In addition to the commands for comparing and viewing files, the menu for this browser also has commands for copying files from the git clone {Gprojectname} to {Wprojectname} and deleting files from {Wprojectname}.

If the master/main branch is the current branch then the menu has no commands to change the clone directory. The browser will show those files that have been updated from a recent merge, and they can individually be copied from the git branch to realign the two source trees with incremented Medley version numbers. If the comparison is with a different branch, say the user’s current staging branch, copying files from the working Medley to the git clone or deleting git files will set git up for future commits.

Note that the menu item for deleting Medley files will cause all version to be removed, not just the latest one, to avoid the possibility that an earlier one is revealed. Deletion for Medley files is also accomplished by renaming to a (Wprojectname)<deletion> subdirectory so that they can be recovered if a deletion is in error. Files in the git-clone are removed from the file system immediately, since git provides its own recovery mechanism for those files.

GITFNS does not (yet?) include functions for commits, pushes, or merges for updating the remote repository. Those have to be done outside of Medley through the usual github interfaces, as guided by the information provided by the comparisons.
GRAPHCALLS

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

Uses: GRAPHER, MSANALYZE (WHERE-IS & HELPSYS optional)

GRAPHCALLS is an extended graphical interface to the Envos Lisp CALLS function. It is to CALLS what BROWSER is to SHOW PATHS in MASTERSCOPE. It allows fast graphing of the calling hierarchy of both interpreted and compiled code, whether or not the source is available (see the CALLS function in the MASTERSCOPE section of the Lisp Library Modules manual), allowing examination of both user and system functions. The sources of the functions do not have to be analyzed by MASTERSCOPE first.

Additionally, buttoning a function on the graph brings up a menu of operations that can be done with the function, such as editing, inspecting, further graphing etc.

(GRAPHCALLS FUNCTION &REST OPTIONS) [Function]

Graphs the calling hierarchy of FUNCTION. Terminal nodes on the graph (those which call no other functions or are undefined) are printed in a bold version of the graph’s font indicating that they cannot be graphed further:

```
\UNPACKDATE
\DATE
\OUTDATE
\LISPERROR
\NTH
\SUBSTRING
\NCHARS
\ALLOCSTRING
\RPLRIGHT
\RPLSTRING
```

The remainder of the arguments, in keyword format, make up OPTIONS eg.

```
(GRAPHCALLS 'DATE :FONT '(GACHA 10) :DEPTH 4 :FILTER 'FGETD)
```

Options include:

- **:STREAM** An image stream to display the graph on. The options list is saved on the stream.
- **:FILTER** A predicate to apply to the functions when building the graph to test their eligibility to appear on the graph. The filter can be any defined function; the default is not to filter. Interesting filters include:
  - **WHEREIS** Limits the tree to only functions the user as has loaded and prunes out system functions and SYSLOADed files. Quite useful.
FGETD Limits the tree to only functions that are actually defined. Thus if you are perusing the tree for BITBLT and do not have and are not interested in the color code, FGETD will remove all of the undefined color bitmap functions.

EXPRP Limits the tree to interpreted functions. Useful for graphing functions in the development stage.

CCODEP Limits the tree to compiled functions.

NO\ Keeps low level functions starting with \ (i.e. \OUTDATE) off of the graph. Useful for getting an overview of system functions and when advising system functions (as \ed functions should probably not be advised).

:DEPTH The calling hierarchy is graphed to depth levels (defaults to 2).

:FORMAT Passed to LAYOUTGRAPH and can be any format specification (LATTICE, VERTICAL, REVERSE etc.); defaults to (HORIZONTAL COMPACT REVERSE/DAUGHTERS). In the forest format multiple instances of a function appear on the graph after every calling function and a boxed node indicates the function appears elsewhere on the graph, possibly graphed further. In the lattice format each function gets placed on the graph only once (particularly useful for dynamic graphing, described below), and boxed nodes indicate recursive functions calls.

:SEARCHFN A function to use to generate the children of a given node. It should return a list whose first item is a list of the children, the other items in the list are ignore. Using this feature, it is possible to graph things other than functions. To graph what files load other files, supply a search function of (LAMBDA (FILE) (LIST (FILECOMSLST FILE 'FILES))) and a file name for the function argument.

:ADVISE Advises the functions after they are graphed (see Dynamic Graphing below); recognized values are one or both of the following:

INVERT Visually tracks a running program.

COUNT Counts function calls in a running program.

:DELAY The delay to use in advised graphs; defaults to 500 milliseconds.

:NAMEFN A function to use to generate the node labels on the graph.

:FONT The font to use to display the graph; defaults to (GACHA 8).

:SHAPE A boolean that indicates if the window should be shaped to fit the graph; defaults to NIL.

:PRIN2FLG A boolean that indicates to use PRIN2 when printing node labels, defaults to NIL.

:SUBFNDEFFLG A boolean that enables graphing of compiler generated functions; defaults to T.

:TOPJUSTIFYFLG Passed to SHOWGRAPH; defaults to NIL.

:ALLOWEDITFLG Passed to SHOWGRAPH; defaults to NIL.
The menu that pops up when you left button a function on the graph contains the following items:

- **?** = Print the arguments to the function, if available.

- **HELP** Calls HELPsys on the function.

- **FNTYP** Print the function’s FNTYP.

- **WHERE** Do a WHEREis (with FILES = T) on the function.

- **EDIT** Calls the editor on the function if available for editing.

- **TYPEIN** BKSYSBUFs the name of the function into the typein buffer.

- **BREAK** Applies BREAK to the function. Its subitems are:
  - **BREAKIN** Breaks the function only in the context of a particular calling function. In lattice format, if the function has more than one function calling it on the graph, the user is prompted to indicate the caller in which to break the function.
  - **UNBREAKIN** Undoes BREAKIN.
  - **UNBREAK** Applies UNBREAK to the function.
  - **TRACE** Applies TRACE to the function.
  - **TRACEIN** Traces the function only when called from inside a particular function, like BREAKIN above. Use UNBREAKIN to remove the trace, or else UNBREAK on the window menu.

- **CCODE** Calls INSPECTCODE on the function if it is compiled code.

- **GRAPH** Calls GRAPHCALLS to make a new graph starting with function, inherits the original graph’s options.

- **FRAME** Inspect the local, free and global variables of the function. These are the last three lists of the CALLS function placed into INSPECT windows. Its subitems are:
  - **>FRAME** Like FRAME but for all of the functions on the sub-tree starting at the selected node and only for FREEVARS and GLOBALVARS.
  - **<FRAME** Like >FRAME but for all of the functions above the function in the graph, i.e. the FREEVARS and GLOBALVARS in the function’s scope.

Buttoning the graph outside a node give you a menu with these options:

- **UNBREAK** Does an (UNBREAK), unbreaking all broken functions.

- **RESET** Resets the counters for the COUNT option and redisplayes the graph.

**DYNAMIC GRAPHING**

When the ADVISE option is specified with the value(s) of INVERT and/or COUNT, GRAPHCALLS will advise all of the functions on the graph (in the context of their parent) to invert their corresponding node on the graph (as well as delay some to allow it to be seen) and/or follow each function name by a count of the number of times it has been executed. In invert mode, a node remains inverted as long as control is inside its corresponding function and it returns to normal when the function is exited. The
lattice format is best when using the invert feature. Closing the graph window UNADVISEs the functions on the graph.

An example of this is (GRAPHCALLS 'DATE :ADVISE 'INVERT) and then evaluate (DATE).

GRAPHCALLS will not graph or advise any function in the system list UNSAFE.TO.MODIFY.FNS when the advise option is used. Functions which are unsafe to advise should be added to this list.

CAVEAT PROGRAMMER! This feature must be used with caution. As a rule, one should not do this to system functions, but only one’s own, use WHEREIS as a filter for this. Advising system code indiscriminately will probably crash the machine unrecoverably.

You can, at some risk, interactively break and edit functions on the graph while the code is executing. Also, creating subgraphs of advised graphs will show the generated advice functions not the original functions called, as will creating new graphs of functions in advised graphs. You can create advised graphs of functions already graphed normally on the screen.

(GRAPHCALLSW (REBUILD?))

Puts up a command window with menus that will interactively set up calls to GRAPHCALLS. The menus let you set the Invert, Count and Edit flags, select from common filters and formats and set the depth of the graph. You can also change the amount of delay used in the advised functions when doing dynamic graphing. If you specify an advised graph (Invert or Count) and do not specify a WHEREIS filter, you will be asked to confirm with the mouse for your own protection.

More than one item on the filter and flags menus can be selected at a time. Buttoning a selected item on these menus unselects it. The command menu contains the following:

Function Prompts for the name of a function to graph when the Graph item is selected.

Include Adds files or functions to the list of items to allow on the graph, see the Include/Exclude algorithm below.

Exclude Adds files of functions to the list of items disallowed on the graph, see the Include/Exclude algorithm below.
Clear  Clears all of the settings on the command window to their defaults. Also clears the Include/Exclude lists.

Graph  Graphs the function by calling GRAPHCALLS with the selected options.

Include and Exclude allow fine tuning of the filter function. If the function passes the filter, then the following are tried until one determines whether or not the function will be on the graph:

- If a set of functions has been explicitly excluded, and the function is a member of this set, it will NOT appear on the graph.
- If a set of functions has been explicitly included, and the function is a member of this set, it WILL appear on the graph.
- If a set of files has been explicitly excluded, and the function is in one of those files, it will NOT appear on the graph.
- If a set of files has been explicitly included, and the function is not in one of those files, it will NOT appear on the graph.

The function WILL appear on the graph.

The format menu contains two items that are not passed on to GRAPER but are used to select alternate NAMEFN options:

- **ArgList** Supplies a NAMEFN that will print the function and its arguments (using SMARTARGLIST) as the node label.
- **WhereIs** Supplies a NAMEFN that will print the function followed by the file(s) found by doing WHEREIS (with FILES = T) if any.

When the command window is open, middle buttoning a node on a GRAPHCALLS graph will bring up a menu of commands relating to command window and graphs. The menu contains:

- **EXCLUDE** Adds the function to the exclude functions list of the command window. This is the only way to exclude system functions which get added to the SYSTEM file exclusion list.

The command window can also be obtained via the background menu. Subsequent calls to GRAPHCALLSW (either directly or via the background menu) will reuse the old command window if there is one. If this window is damaged, and redisplay does not help, then setting REBUILD? to T will build a new command window from scratch.

**NOTES**

- Function call graphs are constructed using breadth first search but GRAPER lays out graphs depth first so functions may be expanded in different places on the graph than expected.
- GRAPHCALLS sysloads GRAPER and MSANALYZE if they are not already loaded.
- In dynamic graphs, variables caused by advising show up in the frame inspections.
- The global variable GRAPHCALLS.DEFAULT.OPTIONS contains all of the defaults for GRAPHCALLS keywords, in property list format.
GraphGroup

By: Nick Briggs (Briggs.pa@Xerox.com)

For internal use only.

The GraphGroup package contains functions for generating a graph showing the structure of a Grapevine distribution list.

DESCRIPTION

There is a single user-callable function:

(GraphGroup GroupName InfoStream LayoutOptions ExpandNSGroups) [Function]

GroupName is the group to be graphed.

Because it is rather slow tracking down the whole structure of a group, if InfoStream is non-nil GraphGroup will print on InfoStream a trace consisting of: a "[" followed by the number of entries in the group each time it starts a (sub-) group, a "." or "?" each time it identifies an individual, and a "]" at the end of a group. T is a good choice for this parameter.

LayoutOptions is a list of options, in property list format, to be passed to the Grapher function LAYOUTSEXPR. Properties recognized are: FORMAT, BOXING, FONT, MOTHERD, PERSONALD, and FAMILYD. See the Grapher documentation for a description of how to use these options. In most cases you will get a satisfactory graph by leaving this parameter NIL. Should you be planning to hardcopy the resulting graph on an NS printer it is recommended that if you specify a font you use an NS font (such as Classic or Modern) so that the layout spacing is done correctly.

If ExpandNSGroups is T, then GraphGroup will attempt to trace into the NSworld when it finds Grapevine RNNames that it recognizes as having pseudo-registries that are really NS domain/organizations.
INTRODUCTION

like FGREP of Unix: searches for strings in files.

(GREP STRS FILES)  [Function]

STRS is a string or a list of strings. FILES is a file or a list of files. Searches for the given string(s) in
the given file(s), showing each line.

(PHONE name)  [Function]

Calls (GREP name PHONELISTFILES). PHONELISTFILES is initialized to NIL. (The PARC init file
resets it to point to the PARC phone list.)

For example,

(GREP (QUOTE ED) (QUOTE {INDIGO}<REGISTRAR>PARCPHONELIST.TXT))

will print:

(from {INDIGO}<REGISTRAR>PARCPHONELIST.TXT:3)
4183 <Endicott>, Fred  35-1354
4435 <Piala>, Ed  35-2166
4598 <RKennedy>, Ray  34-78
4839 <McCreight>, Ed  35-2146
5759 Pedersen, Jan  32-202
4818 Satterthwaite, Ed  *  35-2174
MES Solcz, Edward J.  8* 348-1214
ATA Wahlenmeier, Fred  887-4018
GRID-ICONS

By: sML (Lanning.pa@Xerox.com)

Last edited: September 14, 1987

INTRODUCTION

Grid-Icons provides the Lisp user with a set of default window icons that resemble those found in the Viewpoint system. There is an option that the user can set to force these icons to be positioned on a grid, instead of the unrestricted positioning allowed by Lisp.

USING GRID-ICONS

All that is required is loading the file GRID-ICONS. When the file is loaded, it redefines a number of standard window icons in the system.

REDEFINED ICONS

Note that GRID-ICONS not only redefines TEdit and Sketch icons, it also changes the way that the icon title is computed: the host and directory information is removed, so that only the name and extension remain.
In Lyric, it is possible to redefine the standard icon used by the system. GRID-ICONS uses this, and redefines the standard system icon in LYRIC.

NEW ICONS

GRID-ICONS defines a handy icon for accessing the list of files that have been loaded into your system.

Buttoning on this icon will pop up a menu of all loaded files (as determined by the value of the variable FILELST). Selecting a file from this menu will open up an editor on the COMS of that file. There is an additional item on the menu, "* New file *", that can be used to create a new file, and then edit its COMS. This icon window is stored in the variable LOADED-FILES-ICON-WINDOW.

USER FUNCTIONS

The user can declare that any given window stick to grid positions.

(GRID-WINDOW window)  [Function]

Causes window to pay attention to ENFORCE.ICON.GRID; if the value of ENFORCE.ICON.GRID is true, the window will make sure that it is centered on a grid location. By default the spy button and icons produced by the ICONW and TITLEICONW functions pay attention to ENFORCE.ICON.GRID.
VARIABLES THAT CONTROL GRID-ICONS

There are a few variables that control how GRID-ICONS works.

ENFORCE.ICON.GRID  [Variable]

If ENFORCE.ICON.GRID is true, window icons (and any window declared "gridded" by the GRID-WINDOW function) will be restricted to be positioned on a grid. The default value of ENFORCE.ICON.GRID is NIL.

IGNORE.ICON.GRID  [Window property]

The IGNORE.ICON.GRID window property provides a way to control icon gridding on an icon-by-icon basis. If the IGNORE.ICON.GRID window property of an icon is true, the icon will not be restricted to grid positions. This window property is checked only if ENFORCE.ICON.GRID is true.

ENFORCE.ICON.REGIONS  [Variable]

You can enforce icon gridding in individual regions of the screen by using the variable ENFORCE.ICON.REGIONS. If the value of ENFORCE.ICON.GRID is true, and the icon does not have a IGNORE.ICON.GRID window property, the proposed new position for the icon is tested against the value of ENFORCE.ICON.REGIONS. If ENFORCE.ICON.REGION is NIL, gridding is enforced as described above. Otherwise, ENFORCE.ICON.REGION should be a list of regions; gridding will be enforced only if the proposed position is within one of these regions. The default value of ENFORCE.ICON.REGIONS is NIL. [Thanks/blame to Ramana Rao for this.]

ICON.SIZE  [Variable]

ICON.SIZE specifies the maximum size of the icons, for use in computing the grid positions of icons. It is a cons of the maximum width and the maximum height. The default value is (85 . 85), which is the "correct" value for the icons defined in this utility.

ICON.SPACING  [Variable]

ICON.SPACING specifies the gap between icons, for use in computing the grid positions of icons. It is a cons of the horizontal gap and the vertical gap. The default value is (5 . 5).

GRID.OFFSET  [Variable]

GRID.OFFSET specifies origin of the icon grid. The default value is (0 . 0).

DEFAULTICONFONT  [Variable]

The value of DEFAULTICONFONT is the default font used by the system when printing titles in icons. Since the icons defined in GRID-ICONS tend to be smaller then the original icons, you might want to use a slightly smaller font then the default. Personally, I recommend setting DEFAULTICONFONT to (FONTCREATE '(HELVETICA 8)).
Hanoi

By: Larry Masinter (Masinter.pa@Xerox.com)

INTRODUCTION
Ancient graphics demo, upgraded to be idle hack. Adds Hanoi to list of idle displays.

OPERATION
(HANOI NRINGS WINDOW FONT ONCE) [Function]
Will display in WINDOW (or HANOIWINDOW, created first time) a towers-of-hanoi problem and solve it. It periodically blocks so you can run it as a background process. NRINGS is the number of rings. If NRINGS is a list it is the labels printed on the rings in font FONT. It conforms to the window shape if you reshape it. It will run indefinitely unless ONCE is non-NIL.
This document was last edited on December 29, 1987.

**Introduction**

This module adds a "To a file and a printer" option to the Hardcopy item on the system window and background menus. This option sends the contents of a window or screen region to a printer, and simultaneously creates a file containing a printer-ready copy of it (e.g., an Interpress master); this makes it easy to run off multiple copies later.

**Using it**

When loaded, HARDCOPY-RETAIN calls the function xcl-user::install-option to side effect il:|WindowMenuItems| and il:|BackgroundMenuItems| and to set il:|WindowMenu| and il:|BackgroundMenu| to nil, thus forcing them to be recalculated.
HASHBUFFER combines hash files with hash arrays in order to improve hash file performance when keys are accessed multiple times. This module also defines two functions for moving data between hash files and hash arrays.

The functions below are used in place of the hash file routines. When a hash file is opened, a hash array is created, of a complimentary size. When requests for keys are made, the array is searched, and if a value is found, it is returned. If a value is not found, the file is searched and if a value is found there, it is stored in the array and returned. If a value is not found, a marker is put in the array so that the file is not searched again.

(OPENHASHBUFFER FILE [ACCESS MINKEYS OVERFLOW HASHBITSFN EQUIVFN]) [Function]

Opens an existing hash file and returns a hash buffer datum which must be given to the other hash buffer functions. Only the FILE argument is required; the MINKEYS argument is used for the size of the hash array and if not supplied the size of the hash file is used. Setting MINKEYS smaller than the size of the hash file allows a fast, small hash array window onto a larger, slower hash file. The OVERFLOW, HASHBITSFN and EQUIVFN arguments are passed to HASHARRAY.

(CREATEHASHBUFFER FILE [VALUETYPE ITEMLENGTH #ENTRIES OVERFLOW HASHBITSFN EQUIVFN]) [Function]

Like OPENHASHBUFFER but creates a new hash file. The FILE, VALUETYPE and ITEMLENGTH arguments are passed to CREATEHASHFILE; the OVERFLOW, HASHBITSFN and EQUIVFN arguments are passed to HASHARRAY. The #ENTRIES argument is used for both the file and array.

(CLOSEHASHBUFFER HASHBUFFER [FILEONLY?]) [Function]

Closes the hash file and sets the hash array to NIL so that it can be reclaimed. If FILEONLY? is non-NIL then only the hash file is closed, the hash array will be left alone.

(GETHASHBUFFER KEY HASHBUFFER) [Function]

(PUTHASHBUFFER KEY VALUE HASHBUFFER) [Function]

Retrieve and store VALUE for KEY in the hash buffer. If the hash file is only open for input, then storing a key will only affect the hash array. If the hash file is open for output, then storing a key will put it in both the hash array and hash file. If VALUE is NIL, then a delete is performed.

(HASHARRAY.TO.HASHFILE HASHARRAY HASHFILE [TESTFN]) [Function]

Uses MAPHASH to move the contents of HASHARRAY into a hash file. If HASHFILE is a file name, CREATEHASHFILE is called; if HASHFILE is an open hash file datum, it is used and left open. TESTFN, if supplied, is called before each PUTHASHFILE on (KEY VALUE HASHARRAY HASHFILE) and if it returns non-NIL, the key and value are copied to the file.
(HASHFILE.TO.HASHARRAY HASHFILE [HASHARRAY TESTFN])  [Function]
Uses MAPHASHFILE to move the contents of HASHFILE into a hash array. If HASHARRAY is not supplied a new hash array is created. TESTFN is called before each PUTHASH on (KEY VALUE HASHFILE HASHARRAY) and if it returns non-NIL, the key and value are copied to the array.
HASHDATUM

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

Uses: HASH

HASHDATUM facilitates storing random Envos Lisp datatypes on hash files using the hashed text feature of the HASH Lisp Library module. The module defines functions which access an item on a hash file as a stream of bytes using user supplied input and output functions. Since the items are stored using text hashing, when rehashing or copying of the file occurs, the data portion of the file is copied correctly.

(GETHASHDATUM KEY HASHFILE READFN) [Function]
(PUTHASHDATUM KEY DATUM HASHFILE PRINTFN) [Function]

Use READFN and PRINTFN to store and retrieve DATUM on HASHFILE. The READFN takes a stream as its argument, the PRINTFN takes the DATUM and a stream. The put function returns the hash file text pointer record which contains two byte pointers that indicate where the datum begins and ends on the file. The get function returns the result of the READFN.

The following macros and functions are also defined using the above functions:

(GETHASHGRAPH KEY HASHFILE) [Macro]
(PUTHASHGRAPH KEY GRAPH HASHFILE) [Macro]

Use GRAPHER functions READGRAPH and DUMPGRAPH to store GRAPH on HASHFILE under KEY.

(GETHASHBITMAP KEY HASHFILE) [Macro]
(PUTHASHBITMAP KEY BITMAP HASHFILE) [Macro]

Use READBITMAP and PRINTBITMAP to store BITMAP on HASHFILE in a text format.

(GETHASHBINARYBITMAP KEY HASHFILE) [Macro]
(PUTHASHBINARYBITMAP KEY BITMAP HASHFILE) [Macro]

Use READBM and WRITEBM from BITMAPFNS to store BITMAP on HASHFILE in a binary format.

(GETHASHTEXTEDIT KEY HASHFILE [WINDOW PROPS]) [Function]
(PUTHASHTEXTEDIT KEY TEXTOBJ HASHFILE) [Macro]

Use OPENTEXTSTREAM and TEDIT.PUT.PCTB from TEDIT to store TEXTOBJ on HASHFILE, preserving both the text and formatting information. WINDOW and PROPS are optional and are passed to OPENTEXTSTREAM. If the WINDOW argument is not supplied, the result of the get function can be passed to OPENTEXTSTREAM along with a window to display the text.

(GETHASHUGLY KEY HASHFILE) [Macro]
(PUTHASHUGLY KEY UGLYVAR HASHFILE) [Macro]
Use HREAD and HPRINT to store random data, like menus, on \textit{HASHFILE}.
HEADLINE contains functions for creating and closing windows which contain headlines ("headline windows").

**(HEADLINE PHRASE FONT POSITION ALIGNMENT)**  [Function]

Creates a headline window with PHRASE printed in font FONT at position POSITION aligned as per ALIGNMENT; the window is just large enough to hold the headline. PHRASE is any Lisp object. FONT defines a font as per FONTCREATE (eg. (TIMESROMAN 18 BOLD) ); if NIL, TimesromanD 36 is used. POSITION is a position giving the reference point for placing the window; if NIL, the user is given a chance to position the window with MOVEW. If POSITION is given, ALIGNMENT gives the alignment of the window with respect to POSITION as (xalignment . yalignment) where xalignment is one of LEFT, CENTER, or RIGHT and yalignment is one of BOTTOM, CENTER, or TOP; for convenience, if Position is CENTER then it is taken to mean (CENTER . CENTER), etc.

**(HEADLINE.ARRAY TITLES ALIGNMENT SEPARATION POSITION)**  [Function]

Creates a set of vertically arranged headline windows. TITLES is a list of (phrase font) sublists where phrase and font are as in Headline. ALIGNMENT is one of LEFT, CENTER, or RIGHT, indicating how the windows are aligned with each other; defaults to CENTER. SEPARATION indicates the spacing between the bottoms of the windows; defaults to 70. POSITION indicates where the top (first) of the windows is to appear; defaults to somewhere near the top center of the screen.

**(BILLBOARD)**  [Function]

Identical to HEADLINE.ARRAY, left in for backward compatibility.

**(BANNER PHRASE FONT POSITION ALIGNMENT)**  [Function]

Same as HEADLINE except it prints the phrase vertically.

**(BANNER.ARRAY TITLES ALIGNMENT SEPARATION POSITION)**  [Function]

Same as HEADLINE.ARRAY except it prints the phrases vertically, left to right.

**(CLOSE.HEADLINES)**  [Function]

Closes all the active headline windows.
INTRODUCTION

HelpSys is the interface to the online version of the Interlisp-D Reference Manual. It provides both sequential perusal of the manual and random access lookup and display of index entries.

Interlisp-D Reference Manual DInfo Graph

Helpsys uses the DInfo library package as a means of accessing the Interlisp-D Reference Manual. Once you have loaded Helpsys, selecting DInfo from the Background Menu will raise a menu which will contain an item named Interlisp-D Reference Manual. Selecting this item will start DInfo on the DInfo graph for the manual. (Note: IRM.HOST&DIR must be set correctly before HelpSys will work; see Installing HelpSys, below). See the documentation for DInfo for more information on this package.

?<cr> [EXEC macro]

Helpsys enables the EXEC and TEXEC macro ?<cr>. Typing this (a question-mark followed by a carriage-return) will cause the CAR of the form currently being typed to be looked up. This works much like the more familiar ?=<cr> macro which displays argument lists.

Lookup! [DInfo Command]

Selecting Lookup! from DInfo’s menu in the IRM DInfo Graph will prompt for and look up a term.

INSTALLING HELPSYS

Helpsys requires a number of files which should be provided with the LispUsers release. These are the 31 chapter files (CHAP*.TEDIT) the top node file (IRMTOP.TEDIT), the file containing the DINFOGRAPH (IRM.DINFOGRAPH) and the index hash file (IRM.HASHFILE).

To install HELPSYS you must copy all these files to one directory, and set the variable IRM.HOST&DIR to the name of this directory.

IRM.HOST&DIR [Variable]

This determines where HelpSys will look for the manual files and hash file. This should be set in your site init file. As file servers can often be quite loaded down, HelpSys will work much faster if you cache these files on the local disk.

IRM.HASHFILE.NAME [Variable]

If this is NIL, HelpSys will look for the hash file as IRM.HASHFILE on IRM.HOST&DIR, otherwise it uses the value of this variable. Note that the hash file must be on a random access filing device (eg. the local disk).

PROGRAMMERS’ INTERFACE
(IRM.LOOKUP KEYWORD TYPE GRAPH SMARTFLG) [Function]

This is the primary function of HelpSys. If TYPE is specified, then the primary manual entry for KEYWORD of TYPE, or the first if there is no primary, will be displayed in WINDOW. If TYPE is not specified, then a pop-up menu will be raised containing all the manual entries for KEYWORD. Primary entries are marked with stars (*’s) on either end of the item. GRAPH should be the IRM Dinfo graph, and defaults to IRM.DINFOGRAPH.

(IRM.SMART.LOOKUP KEYWORD GRAPH) [Function]

Uses wild card matching if *’s are in KEYWORD (* matches any substring) or tries spelling correction. A pop-up menu is raised if more than one wild card match is found. Note that the first time a * appears in a KEYWORD, HelpSys will need to load the list of possible keywords for matching against, and only after this list has been loaded will spelling correction be enabled. This is the function called by the Lookup! button in DInfo’s FreeMenu. GRAPH again defaults to IRM.DINFOGRAPH.

(IRM.RESET) [Function]

Will reset HelpSys so that everything will be reinitialized.
INTRODUCTION

The package H allows the user to augment the Interlisp–D environment with an Horn Clauses Theorem prover: in it it's possible to call semantic attachments (SAs) to Lisp (i.e. lisp functions) as FOL does.

A BRIEF HISTORY

The original idea comes from Chester (Chester, 1980), (Chester, 1980): it was revised by Simmons (Simmons, 1984). A prototype of this program was developed at the University of Milan by Vieri Samek Ludovici, Giorgio Tornielli and Roberto Ghislanzoni using VLisp. Currently it is offered on Interlisp–D environment.

USE OF PACKAGE

Load the file H-LOAD.DCOM. This loads all necessary files. On your machine, you have now two environments: the H developer and the H deliver. In H developer you can plan, construct and edit your HKBs (H Knowledge Bases), and use it from Lisp executive window, simply by H:loading the HKBs created. H is a very good logic paradigm for LOOPS: from executive window, it is possible to have as many calls to the prover as you need.

THE H DEVELOPER

From the background menu chose H: this offer you a window in which is active a read-prove-print loop. Open as many windows as you want: all HKBs are local to the windows. The H Control Window has the following entries:

— Show Profile : This shows in the Prompt Window the current settings for environment bound to the window; the MODE of demonstration (FIRST: stop to the first goal proved; ALL: reach all goals: T: interactive mode); the LIMIT of the search tree; the TRACING of prover: the PMTRACING, that shows the pattern matching at work.

— Show(Axiom) : shows the clauses that define a predicate; the submenu allows to see the lambda-definition of a semantic attachment. The choice is made from a pop-up menu.

— Delete(Axiom) : this erases from database the clauses choosen by the user. Erases also the SA from the submenu.

— Edit(Axiom) : it allows to create and edit both predicates and SA, using the standard DEdit facilities.

— SetLimit : sets the limit of the search tree.

— Mode : chose the mode of demonstration.

— Shortform : it enables or disabled the control for occurrence, so it is not possible to unify the variables already bound in that piece of unification to themselves.

— Trace : it enables in a separate window the tracing of demonstration.

— Trace PM : it enables the tracing of the unifier.

— LoadHKB : loads a H Knowledge base in the environment: the name of KB is shown beside the window; do not provide the .HKB extension to the name: the system does it.

— SaveHKB : saves the current environment in a KB: don't provide extension.

— EraseEnv : erases the entire environment.
— **Exit**: exits and closes window.

All the windows that H uses ("Show window", "Trace window", "PM Trace window") has the middle button capability in order to allow to dribble into a file everything that is printed in the window; it is very similar to CHAT’s dribble option.

**THE H DELIVER**

There are a lot of functions available from Lisp Executive that allow the programmer to use the HKBs previously created:

- **(H.erase)**
  Erases all environment (i.e., predicates and SAs) previously loaded.

- **(H.load database)**
  Loads H database into environment.

- **(H.save database)**
  Saves all current environment into a file

- **(H.? pred1 ... predN)**
  Start the demonstration of the predicates specified. Return the list of predicates proved with the variables of the call set.

- **(H.all variables conj)**
  Returns the list of all specified variables that satisfy the predicate(s). Remember that variables must begin with a ‘:’ (semicolon).

- **(H.any howmany variables conj)**
  Returns `howmany` instantiation values of variables that make true the predicate(s).

- **(H.attach foo lambda–expression)**
  Defines a SA named `foo` to be the value of the LAMBDA-expression written as the second argument.

- **(H.addaxiom axioms–list)**
  Adds new axioms to the existing one for that predicate.

- **(H.axiom axioms–list)**
  Defines new axioms for the predicate. Deletes the previous ones.

- **(H.del axiom)**
  Deletes a single axiom from the database; the other axioms for that predicates are not touched.

- **(H.show)**
  Shows the definition of the given predicates.

- **(H.the variable conj)**
  Returns only one value for the variable that satisfies the goal.

- **(SET.H.MODE mode num)**
  Set the mode of demonstration: mode may be one of atoms ‘first, ‘all, ‘interactive. If atom ‘limit, then you must provide the number of depth (default 200).

**H PRIMITIVES**

Both environments have three important primitives SA:
(set var expr)
Sets in the current level of unification the variable to the value of the expression expr.

(assert axiom)
Assert in the database the given axiom. without erasing the old ones.

(delete axiom)
Delete in the database the given axiom.

In the system also is present the cut facility ('/'), that has similar behaviour as PROLOG cut ('!').

H DEMOS
An example of axioms may be this:

\(((\text{append \() :a :a))\)
\(((\text{append (:a . :b) :c (:a . :d)) \text{< (append :b :c :d))})\)

You can call from H-executive:

\(<\text{append (1 2 3) (4 5 6) :d})\)

that returns

\(((\text{append (1 2 3) (4 5 6) (1 2 3 4 5 6)})\)

Also, if you have in your database:

\(((\text{A 1}))\)
\(((\text{A 2}))\)

and

\(((\text{B 3}))\)
\(((\text{B 4}))\)

you can call from TTY exec:

\((H.? (A :1)) \text{-} \rightarrow (((A 1)))\)

or

\((H.? (A :k) (B :o)) \text{-} \rightarrow (((A 1) (B 3)))\)

Moreover:

\((H.\text{all } ':k '((A :k))) \text{-} \rightarrow (2 1))\)
\((H.\text{all } '((:a :b) '((A :a) (B :b))) \text{-} \rightarrow ((2 4) (2 3) (1 4) (1 3)))\)
\((H.\text{any } 2 ':j '((A :j))) \text{-} \rightarrow (2 1))\)

For demo. load the HKBs H-MAZE,H- BLOCKS and try the following:

(showworld)

that shows you the block world situation: try then

\((\text{please (put the red cube on the blue one)})\)
\((\text{please (pick up cube2)})\)

and so on
The other examples solve for you the maze problem and other interesting things: discover by yourself how they work ...

INTRODUCTION

HISTMENU is a Xerox Lisp (Medley, Lyric or Koto) program that provides quick access to commands recently typed in the Exec window. The original HISTMENU was written by Danny Bobrow but seems to have been lost over time. This version was reverse engineered from a running instance in an old sysout.

OPERATION

Load HISTMENU.LCOM from your local Lispusers directory. Then call

(HistoryMenu [histMenuLength] [histMenuPosition])

where

histMenuLength optionally specifies the number of commands you want displayed. Default is 30.

histMenuPosition optionally specifies a position on the display to place the menu. Default is to place it using the mouse.

Clicking Left on any menu item will redo that command.

Clicking Middle brings up a pop-up menu that lets you issue one of the four Programmer's Assistant commands REDO, FIX, UNDO, ?? plus an option Delete which removes that item from the History Menu.

Clicking Right bring up a pop-up menu with the three standard options Bury, Move, and Shrink plus an option Update which updates the entries in the History Menu to again show the last n commands from the Exec window.

I have made one change to the original HISTMENU. In the original, it would send the command to whatever window had the keyboard focus. So if you were in a TEdit window, clicking a HISTMENU item would place “REDO 354” in the TEdit window. This version only allows commands to go into a selected Exec window.

OPTIONS
HPGL defines a Lisp image stream type that generates output for plotters (and other devices) which use the *Hewlett-Packard Graphics Language*. The module does not define any user functions, the HPGL streams are accessed via OPENIMAGESTREAM and the hardcopy functions.

**PLOTTERS**

Some plotters which use HPGL either as their primary language or as an optional extra:

- Hewlett-Packard (most)
- Facit 4551
- Gould Color-writer 6120 and 6320
- Taxan 710
- IBM 7371
- Roland DYX-880 and 980

The file extensions HPGL and PLOT are recognized by the system as plotter output file types.

**OPTIONS**

The driver accepts the following in the OPTIONS argument to OPENIMAGESTREAM:

- **SCALE**: Image scaling; value should be a POSITION record which indicates where the second scaling point should be placed (the initial scaling point is at 0,0). By default, uses `(SCREENWIDTH . SCREENHEIGHT)`.
- **ROTATE**: Paper rotation; value should be 0 or 90, defaults to landscape plotting (0).
- **PAPER**: Paper size; value is a small integer, the HP 7475A accepts 3 (A3) or 4 (A4).
- **TERMINATOR**: Label terminator character; value should be a character, the default is ‘^A’.
- **VELOCITY**: Pen velocity; plotter specific.

**IMPLEMENTATION**

The driver was implemented using an HP 7475A plotter but the plotter output conforms to the more restrictive HP 9872 syntax to be more widely applicable. The driver uses the following variables which may need adjustment for other types of plotters:

- **HPGL.FONTS**: An ALST of font names and (small integer) plotter font numbers.
- **HPGL.OPTIONS**: An ALST of plotter specific options that can be passed to OPENIMAGESTREAM and the corresponding HPGL command to print.
- **HPGL.DASHING**: An ALST of HPGL line types (small integers) and dashing lists.
- **HPGL.FONT.EXPANSIONS**: An ALST of font face expansions (REGULAR, COMPRESSED and EXPANDED) and the relative scale of each.
- **HPGL.TERMINATOR**: The default end of instruction terminator character, initially ‘;’. 
HPGL.SEPARATOR  The default parameter separator character, initially ','.
HPGL.TEXT.TERMINATOR  The default end of label terminator character, initially '^A'.
HPGL.CHORD.ANGLE  The chord angle used by the circle and arc instructions. Defaults to NIL which causes the plotter’s default to be used.
HPGL.PATTERN.LENGTH  The default pattern length for the hardware dashing. Defaults to NIL which causes the plotter’s default to be used.
COLORNAMES  System variable used to convert between RGB triples and pen numbers. The order of entries affects the pen number to color correspondences.

DASHING
To minimize the complexity of the driver and maximize the speed of plotting, for operations other than DRAWLINE, the driver only uses the built-in dashing types of the plotter. The correspondences between the dashing style and HPGL line type number are kept in the HPGL.DASHING variable which can be modified or extended for plotters with different dashing styles than those displayed below:

1 . . . . . . . . . . (1 49)
2 _____ _____ _____ _____ _____ (25)
3 _____ _____ _____ _____ _____ (35 15)
4 _____ . _____ . _____ . _____ . _____ . (39 5 1 5)
5 _____ . _____ . _____ . _____ . _____ . (35 5 5 5)
6 _____ . _____ . _____ . _____ . _____ . (25 5 5 5 5 5)
_______________________________________ NIL

If the driver is loaded after SKETCH, the dashing types are added to SKETCH’s dashing menu.
IDEASKETCH

By: Richard Burton (Burton.Pa@Xerox.com)

Uses: Sketch

This document last edited on 26-Jan-89 19:09:56.

INTRODUCTION

Idea Sketch is an adaptation of Sketch that is designed to allow easy jotting down and laying out of ideas. An idea sketch window is actually a sketch window with a command menu tuned for manipulating text and defaults set up for connecting text (i.e. arrowheads are added.)

Selecting the "More Menu" items gets the standard sketch menu.
INTRODUCTION

This module contains a couple of random demonstration programs, useful as "Idle programs", callable from the background menu. The Idle display options includes Lines Warp-Out Radar Triangles RandAngles Polygons Bubbles and Kaleidoscope.

These are implemented by the following functions:

(POLYGONS W NOBLOCK TIMER) [Function]

Calls (POLYGONS) or (POLYGONS window) to perpetually draw polygons in the given window (it (re)uses POLYGONSWINDOW if argument is NIL). To run in the background, you can ADD.PROCESS((POLYGONS (CREATEW]). Controlled somewhat by the global parameters POLYGONMINPTS (minimum number of vertices), POLYGONMAXPTS (maximum number of vertices), POLYGONSTEPS (number of steps between min and max), and delays POLYGONWAIT (time between different polygons) and POLYGONWAIT2 (delay between initial display of beginning and end and the movement phase.)

If NOBLOCK is T, it doesn’t block at all (runs after but can’t run in background.) If TIMER is given, then POLYGONS will stop after TIMER is expired. (Used by the demo system.)

(LINES W N LCNT STEPS ODDSTEP) [Function]

Similar to POLYGONS in controls, but draws perpetually changing form using line draw. W defaults a “demo window”, but is the window on which the display is drawn, N is the number of endpoints (e.g., 2 draws lines, 3 draws triangles, 7 draws 7-segment figures), LCNT is the "number of lines on the screen at any one time", STEPS is the number of lines to draw between start and end (the higher this number, the closer together the lines are), and ODDSTEP is a flag: if T, then the odd endpoints remain the same every other iteration (try (LINES NIL 3 1 40 T).) The background RandAngles means: (LINES W (RAND 3 7) (RAND 1 16) (RAND 25 100)), while Triangles is (LAMBDA (W) (LINES W 3 1 40)), etc.

(BUBBLES WINDOW) [Function]

Perpetually draws circles. Controlled by BUBBLECNT, which is read at startup as the number of circles visible at any one time.

(KAL W PERIOD PERSISTENCE) [Function]

Borrowed from the KAL LispUsers package: draws a random symmetric pattern of dots. Pretty. Period affects the style of display, while PERSISTENCE affects how many dots are on the screen at once.

(WARP W) [Function]

Draws a sequence of circular patterns that resemble piles of sand. Or not; you decide.

POLYGONS, LINES and BUBBLES adjust themselves to the size of the window, so you can reshape the window in the middle of the demo.
The **INSPECTCODE-TEDIT** package advises the INSPECTCODE facility to have some extended capabilities when the TEDIT and GRAPHCALLS packages are loaded (i.e. it uses TEDIT and GRAPHCALLS).

If TEDIT is not defined, then the standard INSPECTCODE will be used. If TEDIT is loaded, then a read-only TEDIT/INSPECTCODE window will be opened, and will have a special INSPECTCODE menu for **LEFT** or **MIDDLE** buttoning in the titlebar. All of the options, except for **Quit**, in this menu use the current selection in the window. You make selections with the mouse buttons in the standard TEDIT ways. The options in the INSPECTCODE titlebar menu are:

- **GraphCalls**
  - If the GRAPHCALLS package is loaded, then calls **GRAPHCALLS** on the current selection.

- **InspectCode**
  - Opens a new **INSPECTCODE** window on the current selection.

- **Inspect**
  - Does an **INSPECT** on the value of the current selection. This item has SUBITEMS (see below).

- **Pretty Print Value**
  - Prompts for region to open a window, and prettyprints the value of the current selection in it. This item has SUBITEMS (see below).

- **Quit**
  - Closes this window and kills the associated TEDIT process. (Closing the window with the WindowMenu, or by calling **CLOSEW** on it does the same thing.)

The **Inspect** and **Pretty Print Value** menu options have the following SUBITEMS which affect how the value of the current selection is determined:

- **Freely**
  - The value of the current selection is determined by any binding that a free-reference from the INSPECTCODE window menu handling code (i.e by
(EVALV selection)). This is the default behavior when a menu selection is made directly from the titlebar menu without using the SUBITEMS menu.

Globally

The value of the current selection is determined by its top level (Global) binding.

In Process Context

The value of the current selection is determined by its binding in the context of a specified process. A menu of all current processes will be brought up to allow you to specify a process.

INSPECTCODE-TEDIT also defines the LISPXMACRO IC which INSPECTCODE's its argument.
KEYOBJ

By: Greg Nuyens

Supported by Jan Pedersen (Pedersen.pa@Xerox.com)

KEYOBJ provides a LISP imageobject which mimics a key. The default image looks like this:

![Center](image)

These keys are pressed by clicking the mouse inside the key’s image. The result of pressing a key is determined (just like the physical key) by the Interlisp-D system function KEYACTION. To enter a KEYOBJ into TEdit type ^o. Inside the window that pops up, call the following function:

(KEYOBJ.CREATE KeyName KeyLabel Abortable) [Function]

KeyName is the key that you want the object to behave like. (CENTER in the example above). KeyLabel is an optional label other than the key whose action it mimics. If KeyLabel is a list of two elements, the first is displayed above the second. Abortable is a flag which indicates that no transitions should be generated if the mouse button is released outside the key image.

KEYOBJ.FONT [Variable]

Determines the font in which the label is created inside the keyobj. Default is Helvetica 10.
KINETIC

By: Anon.

Recompiled for Medley by Larry Masinter (Masinter.PA@Xerox.COM)

INTRODUCTION
An ancient graphics hack, converted to work with idle.

OPERATION
(KINETIC WINDOW) [Function]
to randomly invert rectangles on WINDOW, or on KINETICWINDOW (set up first time). Choosing the Kinetic on the Idle Choose Display menu will select the KINETIC function as the Idle display.

CHECKSHADE [Variable]
If non-nil, CHECKSHADE is a texture which is used for some of the rectangles sometimes. Defaults to 63903.
The purpose of this package is to facilitate defining new LAMBDA words in such a way that a variety of other system packages will respond to them appropriately. A LAMBDA word is a word that can appear as the CAR of a function definition, like LAMBDA and NLAMBDA. New LAMBDA words are useful because they enable the user to define his or her own conventions about such things as the interpretation of arguments, and to build in certain defaults about how values are returned. For example, the DECL package defines DLAMBDA as a new LAMBDA word with unconventional arguments such as the following:

(DLAMBDA ((A FLOATP) (B FIXP) (RETURNS SMALLP))

(FOO A B))

In order for such an expression to be executable and compilable, a mechanism must be provided for translating this expression to an ordinary LAMBDA or NLAMBDA, with the special behavior associated with the arguments built into the function body. The LambdaTran package accomplishes this via an appropriate entry on DWIMUSERFORMS that computes the translation.

Besides executing and compiling, Interlisp applies a number of other operations to function definitions (e.g., breaking, advising), many of which depend on the system being able to determine certain properties of the function, such as the names of its arguments, their number, and the type of the function (EXPR, FEXPR, etc.). The LambdaTran package also provides new definitions for the functions FNTYP, ARGLST, NARGS, and ARGTYPE which can be told how to compute properties for the user’s LAMBDA-words.

A new LAMBDA-word is defined in the following way:

1. Add the LAMBDA-word itself (e.g., the atom DLAMBDA) to the list LAMBDASPLST. This suppresses attempts to correct the spelling of the LAMBDA-word.

2. Add an entry for the LAMBDA-word to the association list LAMBDATRANFNS, which is a list of elements of the form: (LAMBDA-WORD TRANFN FNTYP ARGLIST), where (LAMBDA-WORD) is the name of the LAMBDA-word (e.g., DLAMBDA).

TRANFN is a function of one argument that will be called whenever a real definition is needed for the LAMBDA-word definition. Its argument is the LAMBDA-word definition, and its value should be a
conventional LAMBDA or NLAMBDA expression which will become the translation of the Lisp LAMBDA-word form. The free variable FAULTFN is bound to the name of the function in which the LAMBDA-word form appeared (or TYPE-IN if the form was typed in).

FNTYP determines the function type of a definition beginning with LAMBDA-WORD. It is consulted if the definition does not already have a translation from which the function type may be deduced. If FNTYP is one of the atoms EXPR, FEXPR, EXPR*, or FEXPR*, then all definitions beginning with LAMBDA-word are assumed to have that type. Otherwise, FNTYP is a function of one argument that will be applied to the LAMBDA-word definition. Its value should be one of the above four function types.

ARGLIST determines the argument list of the definition if it has not already been translated (if it has, the ARGLIST is simply the ARGLIST of the translation). It is also a function of one argument, the LAMBDA-word definition, and its value should be the list of arguments for the function (e.g., (A B) in the DLAMBDA example above). If the LAMBDA-word definition is ill formed and the argument list cannot be computed, the function should return T. If an ARGLIST entry is not provided in the LAMBDATRANFNS element, then the argument list defaults to the second element of the definition.

As an example, the LAMBDATRANFNS entry for DLAMBDA is (DLAMBDA DECL EXPR DLAMARGLIST), where DECL and DLAMARGLIST are functions of one argument.

Note: if the LAMBDA-word definition has an argument list with argument names appearing either as literal atoms or as the first element of a list, the user should also put the property INFO with value BINDS on the property list of the LAMBDA-word in order to inform DWIMIFY to take notice of the names of the arguments when DWIMIFYing.
By various folks, including help from Mike Dixon (MikeDixon.PA@Xerox.COM) and Larry Masinter (Masinter.pa@Xerox.com)

This Life program is a translation of the Smalltalk-80 version in the book *Smalltalk-80: The Language and its Implementation*, by Goldberg and Robson.

Input is a window where the "on" pixels are interpreted as living cells. The window is continually updated as life goes on.

Now an "idle" hack: LIFEDEMO as a display function plays life with the bits of the screen (in a copy of them in a window, e.g., it doesn’t smash your screen.)

(Lifeldle W N) [Function]

Run Life in window W, using the bits behind W as a starting point. N is optional, and can either be 1, 2,4 or 8. Its the magnification of the life window.

(Life W N) [Function]

Like Lifeldle but uses the current contents of the window.
INTRODUCTION

Some utility files are so useful that users will always want them in their system: these files are typically loaded from the users INIT file. A (rather large) number of other utilities are only sometimes useful. Users are faced with the choice of either loading these files from their INIT files (slowing down the initialization process and consuming space, whether the utility is needed or not) or having to remember how to load and initialize these files.

LOADMENUITEMS addresses this problem: it defines a new filepackage command that can be used to add entries onto the background menu for easy loading of utility files.

[NOTE: All (advertised) symbols in this utility are in the INTERLISP package.]

EXAMPLE

The filepackage command

(COMS
    ;; Make it easy to load some oft-used utilities
    (FILES LoadMenuItems)
    (LOADMENUITEMS WritingAids Sketch VirtualKeyboards ProofReader)
    (LOADMENUITEMS ProgrammingAids (Spy (SPY.BUTTON)))
    (LOADMENUITEMS NIL VStats Calendar))

will add an entry "Load utility" to the background menu. "Load utility" will have three subitems: Misc, ProgrammingAids, and WritingAids:

WritingAids will in turn have three subitems: ProofReader, Sketch, and VirtualKeyboards; Misc will have the subitems Calendar and VStats; ProgrammingAids will have the single subitem Spy.
Selecting any of these final menu items will load the corresponding file. In addition, the Spy menu item will evaluate the form (SPY.BUTTON) after loading the file Spy.

INTERFACE

(LOADMENUIITEMS group utilDescr1 utilDescr2 ...) [FilePackageCommand]

Dumps out to the file a form that will add items to the background menu for loading utilDescr1, utilDescr2, ... Each item will be added to the group subitem of the "Load utility" item on the background menu; if group is NIL it defaults to "Misc".

In the simplest case, utilDescr is a LITATOM. This is used when you want to load a file without any extra initialization, and the file is on one of the directories in DIRECTORIES. Selecting the resulting item will evaluate (DOFILESLOAD 'utilDescr) and print an informative message in the prompt window when the DOFILESLOAD is finished. The added item will have the label utilDescr.

In the general case, utilDescr is a list. This is used when you want to specify an initialization form to be evaluated when the utility is loaded, or when the file description is not a LITATOM. In this case, selecting the menu item will evaluate (DOFILESLOAD (CAR 'utilDescr)). If utilDescr is a list of two elements, the CADR of utilDescr will be evaluated after the utility is loaded; otherwise an informative message will be printed in the prompt window. The added item will have as a label the first LITATOM in the CAR of utilDescr; this is the first file that will be loaded when the item is selected.

In each of the above cases, the item is removed from the background menu after the utility is loaded and initialized.

When a utility is loaded from the "Load utility" menu, the event is added to the history list. This way you can UNDO loading a utility.

Some illustrative examples:

;; This adds the item "VStats" to the "Misc" subitem
(LOADMENUIITEMS NIL VStats)

;; Selecting the "Spy" item will load SPY and call SPY.BUTTON to bring up the spy button icon
(LOADMENUIITEMS ProgrammingAids (Spy (SPY.BUTTON)))

;; This will add the item "GO" to the "Games" group
(LOADMENUIITEMS Games (((SYSLOAD FROM {PHYLUM}<Foster>Lisp>) GO)))

;; These items are useful for Lafite users, but aren't always needed
(LOADMENUIITEMS MailTools LafiteFind Undigestify MailScavenge)

FUNCTIONS
(AddLoadMenuItem group fileDescr startUpForm)  [Function]
Add a menu item to the background menu that will load the files. The item will be added under the top level item "Load utility". group is the submenu name for this file; the default is Misc. fileDescr is a list that can be passed to DOFILESLOAD to load the files. startUpForm is an optional form that will be evaluated after the DOFILESLOAD; the default will print a nice message in the prompt window. The LOADMENUITEMS filepackage command described above expands to calls to AddLoadMenuItem.

AddLoadMenuItem is UNDOable.

(PickLoadUtilityItem utility-name &OPTIONAL group-name no-errors-p)  [Function]
This is the programmatic equivalent of selecting the item named utility-name from the "Load utility" item on the background menu. If group-name is given, only that group under the "Load utility" item is searched for the utility; otherwise the entire menu item is searched. If multiple matching items are found, a continuable error is signaled. Proceeding from this error will let you pick one of the items to execute. If no matching items are found, a continuable error is signaled. The no-errors-p flag controls whether or not these errors are actually signaled: if no-errors-p is true, PickLoadUtilityItem ignores the errors. PickLoadUtilityItem return T if the utility was loaded, NIL otherwise.
NOTES ABOUT LOGIC MEDLEY RELEASE

This LOGIC release (1.3) is more robust than previous on top of Lyric; there are some bugs fixed. The major enhancement is the possibility of handle multiple SEDIT sessions: there is a global variable, *LOGIC-CLOSE-ON-COMPLETION-FLG* (defaulting to T), that controls the behaviour of the editing: NIL means not to close the editing window and not to perform a check on the correctness of the axiom just typed in, T means to check definitions and to close the editing window.

INTRODUCTION

This package is devoted to people who want to use a logic paradigm in their programming environment. LOGIC was initially developed in Franz Lisp at the Computer Science Department of the University of Milan: now a modified part of its kernel is running in Common Lisp, so it is possible to use it under every machine running CL: within the Xerox environment, some features are available in order to ease the construction of the programs.

All of the source codes are available: sorry if they are awful! But it’s better to have efficiency than syntactic sugar ...

LOGIC MANUAL

LOGIC is essentially a theorem prover based on Horn clauses: the user is allowed to create many theories and within these theories to specify some predicates (clauses); as FOL does, it is also possible to specify some semantic attachements (SA), in order to use all the capabilities of the environment: in our implementation, these SAs are expressed in Lisp. A goal proof is performed within specified theory(es); the user is allowed to dynamically change the theories involved.

These are the elements of the language:

- a variable is an atom beginning with ‘?’
- an atomic formula is a list beginning with the name of the predicate and followed by the terms: (on table book) (mother ?x ?y)
- a clause is a list beginning with the consequent, followed by the special symbol ‘:-’, and by the sequence of the antecedents:

• a set of clauses is the definition of a predicate

• a theory is a set of the definitions of some predicates

HOW TO LOAD AND INIT LOGIC

In order to use LOGIC, load the files LOGIC and LOGIC-UNIFIER. From within the Xerox Lisp Environment, you can also load the development environment LOGIC-DEVEL.DFASL. After loading the files, call the functions:

• (CREATE-BACKGROUND-THEORY): this function creates the main theory reading the data it needs from the file LOGIC.LGC.

• (CREATE-VARIABLES): this functions creates and initializes the variables used by the unifier; it takes a few time to perform its job. This call is due to a lack of the Xerox garbage collector: since the unifier uses techniques of redenomination, a great number of symbols is generated; the 1186 does not release the space used by these symbols, and so they fill up the GC table. The workaround is to re-use all the symbols generated.

If you want to port this code on another machine running CL, it is a matter of taste to eliminate this piece of code, with a little hacking on the source codes.

These are the functions available from the top-level executive of Lisp:

(ALL VARS CONJ THS) [Function]

Returns the vars that satisfies the goal (conj) in the list of theories (ths): the background theory is always used. For example you can ask the system to prove:
(ALL '(?a ?b) '((append ?a ?b (1 2 3))) '(append-theory))
--> ((NIL (1 2 3)) ((1) (2 3)) ((1 2) (3)) ((1 2 3) NIL))

(ANY HOW-MANY VARS CONJ THS) [Function]

Returns how-many vars that satisfies the goal:
(any 2 '?a '((append ?a ?b (1 2 3))) '(append-theory))
--> (NIL (1))

(ATTACH SA-NAME DEFINITION THEORY-NAME) [Function]

Allows to create semantic attachments:
(ATTACH 'createw '(lambda (name) (IL:CREATEW () name)) 'my-theory)
and now:
(ANY 1 () '(createw "Kiss me on my lips") 'my-theory)
--> ;; creates a window on the screen
(CREATE-THEORY  THEORY-NAME) [Function]

Creates a brand-new theory with that name: return the name of the theory created, not the theory itself.

(LIST-ALL-THEORIES) [Function]

Return a list of the defined theories, currently available.

(LOAD-THEORY THEORY-NAME) [Function]

Loads from the current directory the specified theory-name; the name of the theory file has the extension .LGC, and it must be previously created by the corresponding function SAVE-THEORY

(LOGIC-ADDA PRED CLAUSES THEORY-NAME) [Function]

Adds to the definitions of the predicate pred the specified clauses, that holds in the theory theory-name: the clauses are put in front of the already existing clauses:

(LOGIC-ADDA 'C' '(((C 1) ((C ?x) :- (A ?x))) 'my-theory)

(LOGIC-ADDZ PRED CLAUSES THEORY-NAME) [Function]

Adds to the definitions of the predicate pred the specified clauses, that holds in the theory theory-name: the clauses are put at the end of the already existing clauses:

(LOGIC-ADDZ 'C' '(((C 2) ((C ?x) :- (A ?x) (B :y))) 'my-theory)

(LOGIC-ASSERT PRED CLAUSES THEORY-NAME) [Function]

Replaces all previous definitions of the predicate pred with clauses.

(LOGIC-DELETE PRED-OR-SA THEORY-NAME) [Function]

Erases from the theory theory-name the definition of pred-or-sa, that may be either a predicate or a semantic attachment

(LOGIC-DELETE-FACT FACT-NMAME FACT-CLAUSE THEORY-NAME) [Function]

Erases from the definition of the clauses on the predicate FACT-NAME the specified clause FACT-CLAUSE, within the theory THEORY-NAME.

(MERGE-THEORIES NEW-THEORY-NAME &REST LIST-OF-THEORIES) [Function]

Creates the new theory NEW-THEORY-NAME made up by all the predicates and sas that hold in all the theories LIST-OF-THEORIES: now no control is performed on the consistency in the merging of the theories

(PROVE CONJ THS ) [Function]
Calls the prover on the specified goals conj. THIS is a list of the theory(es) used. PROVE returns only T or NIL.

(SAVE-THEORY THEORY-NAME) [Function]

Writes on the local directory the contents of the theory theory-name. You will find later a file whose name is composed by the theory name and the extension LGC. The format of the contents of the file is the following:

theory-name
number of semantic attachments
<sa name1> <sa definition>
.. 
<sa nameN> <sa definition>
number of predicates
<predicate name 1> <clauses for predicate 1>
.. 
<predicate name N> <clauses for predicate N>

A theory file (with .LGC extension) may be created by the user employing a text editor like Emacs or VI (on Symbolics, SUNs etc.), avoiding the saving of the theory every change he performs.

(SHOW-DEFINITION ELEMENT THEORY-NAME) [Function]

Shows the definition of element, either a predicate or a semantic attachment.

(SHOW-THEORY THEORY-NAME &OPTIONAL VERBOSE) [Function]

Shows the contents (name of predicates and sas) of the theory theory-name; if verbose is T, all the definitions are shown.

THE BACKGROUND THEORY

In the background theory, many interesting primitive predicates are available:

/ [Predicate]

The cut predicate, well-known to the PROLOG programmers: a typical example of its use can be the definition of the predicate NOT:

(((not ?formula) :- (wff ?formula) ! (fail))
((not ?formula)))

(TRUE) [Predicate]
This predicate always succeeds

(FAIL) [Predicate]
The predicate that never succeeds
(PRINT ?arg) [Predicate]
Prints the argument ?arg passed by

(EVAL&PRINT ?arg) [Predicate]
This predicate evaluates and print the result of evaluation of the form ?arg:
(prove '((eval&print (+ 3 4))) '(my-theory))
7
T

(LOGIC-ADDA ?PREDICATE-NAME ?CLAUSES ?THEORY-NAME) [Predicate]
Adds in front of the clauses that define the predicate ?PREDICATE-NAME in the theory ?THEORY-NAME the other clauses ?CLAUSES

(LOGIC-ADDZ ?PREDICATE-NAME ?CLAUSES ?THEORY-NAME) [Predicate]
Adds to the end of the clauses that define the predicate ?PREDICATE-NAME in the theory ?THEORY-NAME the other clauses ?CLAUSES

(LOGIC-ASSERT ?PREDICATE-NAME ?CLAUSES ?THEORY-NAME) [Predicate]
Replaces all definition for the predicate ?PREDICATE-NAME in the theory ?THEORY-NAME with the new clauses ?CLAUSES

(LOGIC-DELETE ?PREDICATE-OR-SA-NAME ?THEORY-NAME) [Predicate]
Deletes all definition for predicate (or sa) ?PREDICATE-OR-SA-NAME in the theory ?THEORY-NAME

(LOGIC-DELETE-FACT ?FACT-NAME ?FACT-CLAUSE ?THEORY-NAME) [Function]
Erases from the definition of the clauses on the predicate ?FACT-NAME the specified clause ?FACT-CLAUSE, within the theory ?THEORY-NAME.

(SET ?var value) [Predicate]
With this predicate it is possible to set a variable within the demonstration (remind that a variable always starts with a '?'):
(prove `((set ?x (list 'a 'b 3))(print ?x)) '(my-theory))
--> (a b 3)
T

(RETRACT ?theory-name) [Predicate]
Tells the interpreter that it must use no more the theory ?theory-name during the ongoing demonstration; this elision is made only on the current active node of the demonstration tree

(USE-THEORY ?theory-name) [Predicate]
Tells to the interpreter that it must use the theory ?theory-name for the ongoing demonstration.
(\textsc{WFF} \textit{?formula}) \quad \textbf{[Predicate]}

This is a second order predicate that allows you to prove the truth value of the well formed formula \textit{?formula}.

If you load only the LOGIC files, this is the environment you have. On Xerox machines, you can also load the file LOGIC-DEVEL, that allows you to have the development environment: a new entry in your background menu is created, and so you are able to open a logic demonstration window.

This is the control menu:

\begin{itemize}
  \item \textbf{SHOW-PROFILE}: shows the current profile: the MODE of demonstration (FIRST, ALL, INTERACTIVE), and the tracing flags on unifier and solver
  \item \textbf{TRUTH VALUE ONLY}: this flag controls if the prover returns all the goals with the variables instantiated or only the values T or NIL
  \item \textbf{SHOW AXIOM}: shows the definition of an axiom or of a semantic attachment
  \item \textbf{EDIT AXIOM}: edits the definition of an axiom or of a semantic attachment
  \item \textbf{DELETE AXIOM}: deletes the definition of an axiom or of a semantic attachment
  \item \textbf{SET MODE}: sets the mode of the demonstration: this may be ALL, FIRST or INTERACTIVE
  \item \textbf{TRACE SOLVER}: the solver is the procedure of the interpreter that takes as arguments a tree, a formula and the clauses for that formula, and gives back the new tree obtained by the resolution
\end{itemize}
operation; its behaviour is traced on a debugging window which has the middle menu capability of dribbling; the output file has the extension TRC.

TRACE UNIFIER: traces the going on of the unifier on a debugger window; this window too has the middle menu capability of dribbling its output. The pattern, the datum and the unification environment will be shown to the user.

CREATE THEORY: creates a new theory

DELETE THEORY: all the theories loaded are showed in a tablebrowser at the left of the main window; when you select one or more theories, this means that you want to use them for your demonstration; this command deletes the selected theories; you can however undelete or expunge them with the subitems of this entry. Remember that, for undeleting the selected theories with the tablebrowser mark( ), you must click middle button on it and press CTRL (PROP) key

MERGE THEORIES: merges the selected theories in a new theory; the user is prompted for the name of the new theory

LOAD THEORY: loads a theory from a file in the current directory

SAVE THEORY: save the selected theory(ies) on the corresponding files

ERASE ENV: erases all the environment of the window

EXIT: exits from the environment

Remember that, for every demonstration requested, there must be at least one theory selected in the tablebrowser at the left of the main window

I hope these notes help you to use LOGIC.

You can find some examples in the theory file LOGIC- EXAMPLES.LGC.

Any suggestion is welcome: since it is not fully tested, please notify every kind of error or bug you will find.

EXAMPLES

Choose LOGIC from the background menu: a new window will appear: choose LOAD THEORY from the control menu and type in LOGIC-EXAMPLES at the request in the prompt window: mark the theory loaded in the theories window and try:

((APPEND ?A ?B (1 2 3)))

the system will respond you
((APPEND NIL (1 2 3) (1 2 3)))

Click now on SHOW PROFILE: you will see

MODE: FIRST /Unifier: NOTRACE /Solver: NOTRACE /Values: NIL

Choose SET MODE ALL (submenu) and retry the same goal as before: you get the answer:

((APPEND NIL (1 2 3) (1 2 3)))

((APPEND (1) (2 3) (1 2 3)))

((APPEND (1 2) (3) (1 2 3)))

((APPEND (1 2 3) NIL (1 2 3)))

NIL

In the theory LOGIC- EXAMPLES a simple little maze is described: type in the goal:

((search a g))

that will find a path from the room ‘a’ to the room ‘g’.

Here are other examples of goals you can try:

((sa-member 3 (1 2 3 4 5)))

((logic-member 3 (1 2 3 4 5)))

The first one is a SA, the latter is a predicate.

((NOT (A 1))) -- T

((NOTNUMBER 2 (1 3 4))) -- T

and so on.

Try now all the other features of the language.

You can ask the system for the same goals from the lisp listener:

(load-theory ‘logic-examples)

(prove '((APPEND ?X ?Y (1 2 3 4)) '(logic-examples)) -- T
(all '(?X ?Y) '((APPEND ?X ?Y (1 2 3 4)) '(logic-examples))
--> ((NIL (1 2 3 4)) ((1) (2 3 4)) ((1 2) (3 4)) ((1 2 3) (4)) ((1 2 3 4) NIL))

Have fun!
SUMMARY

LOGTIME is a facility for keeping track of how you spend your time. Clicking on the background menu entry "Log Time" loads a data file and starts up a process. The process wakes at regular intervals and prompts the user for the activity engaged in during the latest interval. The default response is the previous activity. Clicking the right mouse button on the prompt window brings up a menu of known activities. Control-E in the prompt window causes the latest interval to be ignored. Clicking on the background menu entry "Log Time" when a LOGTIME process is already active causes the process to be awoken immediately. Rollout menu entries provide a way to edit the current data, to report on the data accumulated for the current day, and to stop keeping track of time (either "Quit" which updates the datafile, or "Abort" which throws away current data).

DESCRIPTION

(LOGTIME.START  datafile)  [Function]

Starts and returns a new LOGTIME process to keep track of time, using datafile as the file to load and store data, unless a LogTime process is already running, in which case NIL is returned. If datafile is NIL, it defaults to LOGTIME.DATAFILE (see below).

(LOGTIME.UPDATE)  [Function]

Wakes up the LOGTIME process, if any, causing an immediate prompt for an activity.

(LOGTIME.STOP  abortflg)  [Function]

Stops and returns the LOGTIME process currently running, if any. If abortflg is NIL, the datafile indicated in the preceeding call to LOGTIME.START is updated. The "Quit" roll-out entry on the background menu invokes (LOGTIME.STOP).
The "Abort" roll-out entry on the background menu invokes (LOGTIME.STOP  T).
(LOGTIME.EDIT olddatafile newdatafile) [Function]

Loads olddatafile if necessary. Invokes the Lisp editor on a list of entries, where each entry is a list of starting date, ending date and activity, e.g. ("10-Oct-89 13:07" "10-Oct-89 13:12" "Mail"). If all entries can be reparsed upon return from the editor the dataset is modified accordingly. If the data did not come from the LOGTIME process currently running (if any) the data are written back to newdatafile if given, otherwise to olddatafile.
The "Edit" entry on the background menu invokes (LOGTIME.EDIT).

(LOGTIME.REPORT bydateflg verboseflg fromdate todate datafile reportfile) [Function]

Generates a report of the data in datafile (defaults to LOGTIME.DATAFILE). If bydateflg is non-NIL the report is sorted by date, otherwise by activity. If verboseflg is non-NIL, the report lists each single entry in the dataset, otherwise only cumulative time (per date or per activity) is given. If fromdate is given (a string acceptable to IDATE) all entries prior to this date are skipped. If the time is omitted from fromdate it is assumed to be 0:00. If todate is given (a string acceptable to IDATE) all entries past this date are skipped. If the time is omitted from todate it is assumed to be 23:59. The report will be generated on reportfile (which defaults to LOGTIME.REPORTFILE).
The "Report" entry on the background menu invokes (LOGTIME.REPORT T T <today>).

LOGTIME.INTERVAL [Variable]

The number of minutes the LOGTIME process will sleep in between prompts. Initial value is 15.

LOGTIME.DATAFILE [Variable]

The name of the default datafile. Initial value is (CONCAT (DIRECTORYNAME) "LogTime.Data").

LOGTIME.REPORTFILE [Variable]

The name of the default reportfile. Initial value is T.

LOGTIME.PROMPT.URGENCY [Variable]

The value used for the PROMPTFORWORD argument urgency.option. Initial value is 'TTY.
INTRODUCTION

The LOOKUPINFILES package is a facility for building quick and easy access to on–line files. It allows search for a target string though all files in a specified list. It finds the target, and brings up the file in a window, with the target selected in inverse video. The file can then be used as the source for text for other documents. It is the basis for the user facilities of ADDRESSBOOK and FIND-CITATION. Its interface is defined by the function:

(MakeLookupWindow fileList processName mainWindowRegion iconBM iconMask iconPosition iconTitle)

These arguments are used as follows:

- fileList: List of file names. Search goes through these files in order
- processName: Name appearing in PSW for this lookup process
- mainWindowRegion: Region for window showing text found
- iconBM: Bit map for icon when mainWindow is shrunk
- iconMask: Mask for icon
- iconPosition: Position for icon
- iconTitle: Title put under icon to distinguish lookup operation

Arguments other than fileList are optional. Calling MakeLookupWindow will construct a Lookup window, and shrinks it to the icon provided. Opening this icon shows the
window interface to the search process. To find any string in one of the files, type the string followed by a return. The program will quickly search through the files and show you an occurrence of the string typed. The located string is shown in inverse video. The title of the window will contain the name of the file in which the entry was found. The search ignores case; e.g. "bobrow" matches "Bobrow". The text of the document is scrollable, and any portion can be shift selected into another document.

Type carriage return, ^X, or click on Next Occurrence to search further in the files for the same string. If no (further) occurrences are found, the text window will display a message indicating the failure. Searching again after failure will start the search from the beginning of all the files, using the same lookup string. Typing a new string can be repeated as many times as you like. When you are done, just SHRINK the window back to its icon by using the Shrink selection in the title bar.

The window below is taken from the use of this package as an online address book.

---

**Example LOOKUPINFILES window**

---

**Notes**

**Caching Files**

When you first create the window, the program will copy the files to {CORE}, significantly speeding up queries. Bugging in the title of the main window with the left or middle mouse button will produce a menu with an option to recache all these files.
Editing Your Files

To edit the file in which a string is found, click middle button in the title of the main window, and select the option "Edit file named in window title". A TEDIT process editing the file will be set up. This process is independent of the lookup process. To select the file to be edited, rolloff the above item, and select "Select file to edit". A menu of files used by the Lookup process will be presented to you. Selecting one will cause that file to be edited.

To make editing changes visible to the lookup process, PUT the file in TEDIT; when it is done, recache the file in core. To recache just the file edited, (the one specified in the title bar of the window), select the option "Recache file named in window title" in the middle button title bar menu. You can recache all files by selecting the option "Recache all files" in the title menu (a subselection of the item "Recache file named in window title").

Adding to the List of Files

To add to the list of files being used for lookup, select the option "Add new file" in the title bar menu. This file will be added to the beginning of the list of files to be searched, and cached in core.

Deleting a file from the List of Files

To delete from the list of files being used for lookup, select the option "Delete file from list" in the title bar menu. This file will be deleted from the list of files to be searched.
MACWINDOWS

Changes shrinking and expanding icons with a zoom.
INTRODUCTION

File: MAGNIFIER.LCOM

Tired of giving demos in which only the two people sitting next to you can see the screen? This small package implements magnifying windows, windows that show an enlarged copy of that portion of the screen that is around the cursor. A magnifying window can be created either by calling the function MAGNIFYW or by selecting the item "Magnifier" from the background menu. A magnifying window can be made to any size and is distinguished by its large border. Once a magnifying window has been created, it can be activated by clicking the left button in it. While activated, the cursor will be replaced by a black rectangle and the contents of the rectangle will be displayed in the magnifying window enlarged by a factor of 4. The contents will continue to track the location of the cursor until the left button is clicked a second time. The magnifier can be reshaped.

Suggested use: When six people drop into your office unannounced for a demo, create a magnifying window across the top or bottom of your screen (so the people in the back can see it easily). When it is important for people to read what you are talking about, move the cursor into the magnifier, click the left button, move the cursor over the area of interest and, when the image in the magnifier has what you want, click the left button again. This will leave an enlarged part of the screen in the magnifier and free the mouse of other things. You can leave magnifier active but it will not block (so no other processes get to run) and if you move the cursor, the image in the magnifier will move too.
**INTRODUCTION**

MakeGraph is a module which sits on top of Grapher and helps one create graphs depicting a data structure by walking through it. The central idea is that each point in the walk (and node in the graph) is characterized by a datum/state pair and motion is defined by a graph specification in the form of state transition function. This function is specified by a collection of state specifications, each of which indicates how to display (label and font) the datum when one is in that state and how to find the datum/state pairs which are the sons of that node. Also the state specification may specify additional roots for the walk. The generation of a branch of the graph ceases when either there are no sons of a node, or an already encountered node is revisited (identical datum and identical state). The module contains a function for creating such graphs and an example of its use: a function which graphs the graph specifications themselves. Comments are welcomed.

**FUNCTIONS**

The main functions are:

```lisp
(MAKE.GRAPH WINDOW TITLE GRAPH.SPECIFICATION ROOTS CONTEXT
  LEFTBUTTONFN MIDDLEBUTTONFN TOPJUSTIFYFLG DEPTH)  [Function]
```

Creates a MAKEGRAPH window. If `WINDOW` is NIL, then a new one will be created and the user will be prompted to position it. Otherwise, the graph will be shown in `WINDOW`. The window will be titled with `TITLE`, will call `LEFTBUTTONFN` and `MIDDLEBUTTONFN` on nodes selected (or NIL if selection is made where no node is positioned), and will be justified as indicated by `TOPJUSTIFYFLG` (a la Grapher). The button functions are defaulted to MAKE.GRAPH.LEFTBUTTONFN (which scrolls the window so that the selected node is in the middle of the window, or if the left shift key is depressed, prints out information about it) and MAKE.GRAPH.MIDDLEBUTTONFN (which provides a menu of two choices: INSPECT - inspects the datum of the node selected, or if the left shift key is depressed, inspects the node itself; and SUB.GRAPH - which opens another MAKEGRAPH window with the same parameters as this one, but with graph starting at the selected node). The arguments to MAKE.GRAPH are added as properties to the window under their argument names. Selecting in the title invokes the functions which are the values of the window properties `TITLE.LEFTBUTTONFN` and `TITLE.MIDDLEBUTTONFN` (not in the calling sequence; set by the user if desired; called with a single argument - `WINDOW`; defaulted to a function which provides a menu of UPDATE and SHOW.GRAPH.SPEC (see functionality below)). The graph is created according to the `GRAPH.SPECIFICATION` (see below) to depth `DEPTH`, starting from `ROOTS` which are (DATUM . STATE) pairs. `CONTEXT` is an extra argument which is a passed along to all accessing expressions.

**GRAPH.SPECIFICATION**  [Parameter]

A GRAPH.SPECIFICATION is a property list of STATE.SPECIFICATIONs where the properties are the state names.
STATESPECIFICATION

A STATESPECIFICATION is a property list whose properties and values are as follows (in this, EXPR
means a LISP form which will be evaluated in an environment in which DATUM is bound to the node’s
datum, STATE to the node’s state, and CONTEXT to context):

LABEL

an expression returning something which will be printed as the label of the node; if no LABEL property
is provided, the string "???") will be used.

FONT

an expression returning the font to be used for this node; if no FONT property is provided, the default
font for the grapher will be used.

SONS

a form indicating a list of (DATUM . STATE) pairs to be used in generating the sons of this node; the
acceptable forms are any of the following:

(data-expression state-expression)

where data-expression returns a list of datum’s for the son nodes, and state-expression is evaluated in
the context of each of these in turn to produce the corresponding state of each.

(LIST (data-expression state-expression) ...)

a template of expressions which are evaluated individually to produce a list of sons of the same form,
viz. (DATUM . STATE) pairs.

(EVAL expression)

the expression returns a list of (DATUM . STATE) pairs of the sons.

(UNION sons-spec ...) 

where each sons-spec is any of these forms (recursively).

(TRACE sons-spec)

a device for helping debug graph specifications; the value is the value of sons-specs; the user is given
the chance to INSPECT them after they have been generated.

ROOTS

like SONS, except the resulting (DATUM . STATE) pairs are used as possibly additional roots of the
graph.

(MAKE.GRAPH.CONSTRUCT GRAPHSPECIFICATION INITIAL.ROOTS CONTEXT DEPTH)

This is the functional heart of MAKE.GRAPH broken out for those who wish to handle their own
interactions with grapher and the window package. It produces a list of graphnodes with labels and
sons as specified by GRAPHSPECIFICATION (see MAKEGRAPH), starting from INITIAL.ROOTS
which are (DATUM . STATE) pairs. CONTEXT is an extra argument which is a passed along to all
accessing expressions. Returns the list of graphnodes.
(MAKE.GRAPH.FIND.ROOTS GRAPH.SPECIFICATION INITIAL.ROOTS CONTEXT DEPTH)  
[Function]

Finds the real roots from a set of initial roots, using the same processing as MAKEGRAPH uses. This is helpful when you want to hand a "correct" set of roots of a structure to MAKEGRAPH without having to explore the dependencies within that structure. As with MAKEGRAPH, the data structure is processed according to the GRAPH.SPECIFICATION (see MAKEGRAPH), starting from INITIAL.ROOTS which are (DATUM . STATE) pairs. CONTEXT is an extra argument which is passed along to all accessing expressions. Returns the real roots as a list of (DATUM . STATE) pairs.

Supporting Functions

(MAKE.GRAPH.UPDATE.WINDOW WINDOW)  
[Function]

Uses the window properties (which may have been changed) to reinvoke MAKE.GRAPH on the window.

(MAKE.GRAPH.SHOW.SPEC GRAPH.SPECIFICATION)  
[Function]

Uses MAKE.GRAPH to produced a graph of a GRAPH.SPECIFICATION. It uses as the graph.specification for this layout the value of the variable MAKE.GRAPH.SPEC.SPEC which presents GRAPH.SPECIFICATION (reflectively) as a graph.specification. (MAKE.GRAPH.SPEC.SPEC can serve as a template for other graph.specifications. It is a fairly complex 9-state specification. For a simpler example see below under MAKE.GRAPH.SHOW.LIST.)

(MAKE.GRAPH.EXAMPLE.1)  
[Function]

Calls MAKE.GRAPH.SHOW.SPEC on MAKE.GRAPH.SPEC.SPEC.

(MAKE.GRAPH.SHOW.LIST OBJECT)  
[Function]

Uses MAKE.GRAPH to produced a graph of an arbitrary Lisp object. It uses as the graph.specification for this layout the value of the variable MAKE.GRAPH.LIST.SPEC which presents OBJECT as a tree whose nodes are LISTPs and whose leaves are non-LISTPs.

MAKE.GRAPH.LIST.SPEC  
[Variable]

MAKE.GRAPH.LIST.SPEC is the simple 1-state specification below, included here as an example of a graph.specification

(OBJECT ( DOC (ANY LISP OBJECT)             - some documentation
            LABEL (COND ((LISTP DATUM) "( )")
                    (T DATUM))
            SONS ((COND ((LISTP DATUM) DATUM)
                    (T NIL))
                   (QUOTE OBJECT))
        )
)

For a more complex example see above under MAKE.GRAPH.SHOW.SPEC.

(MAKE.GRAPH.EXAMPLE.2)  
[Function]

Calls MAKE.GRAPH.SHOW.LIST on MAKE.GRAPH.LIST.SPEC; that is, produces a graph of this simple graph.specification as a list. Notice that selecting the title command UPDATE in this window will yield a different graph of the same structure, viz. as a GRAPH.SPECIFICATION.
Other useful functions

(MAKE.GRAPH.DATUM NODE) [Function]
Returns the DATUM associated with the graph node NODE.

(MAKE.GRAPH.STATE NODE) [Function]
Returns the STATE associated with the graph node NODE.

(MAKE.GRAPH.FATHER NODE) [Function]
Returns the graph node which is the father of the graph node NODE.
INTRODUCTION
In its latest incarnation Manager supports MasterScope and improves its performance.

USING MANAGER:
Manager provides a way to perform most common File Manager operations onscreen using menus, both pop-up and permanent. Activity centers around the filelst, or main, menu, and menus of items of a type in the file (like all FNS, or all VARS).

Printing and interaction is done through the Manager Command Activity Window. The first time it is needed you’ll be prompted to size it onto the display. Thereafter, it will be used as needed. If shrunken before use it will wait 10 seconds after an operation and then shrink down again.

The FILELST menu
The manager provides a menu of the FILELST:
The names in the FILELST menu can be copy selected.

Middle buttoning on the title bar of the FILELST menu pops up a menu of operations which are applied to all loaded files:

These operations are the same as the similarly named functions in the File Manager interface, except for the following slide off options:

CleanUp:
- Set default: TCOMPL, the default compiler will be TCOMPL.
- Set default: CL:COMPILE-FILE, the default compiler will be CL:COMPILE-FILE.

MS DataBase FNS:
- various MasterScope database flags can be set

Add, notice a file via:
- LOADFNS
- LOADFROM
- LOAD
- ADDFILE*
  Edit FILELST, edit the FILELST directly in a lisp editor window.

Quit:
- Quit*, shut down the Manager, all menu caches cleared, windows closed.
- Reset, shut down and turn on the Manager again.

Left buttoning on a file in the FILELST menu (without sliding off) pops up a menu of operations on that file:
See:

- fast*, prints the source of the file.
- scrollable, displayed in a scrollable TEdit window.

(Re)Load:

- Load*, use current DFNFLG settings.
- Sysload, load with File Manager turned off.

MakeFile, dump the file

- MakeFile*, dump the source of the file by remaking it.
- New, dump the source without copying unchanged defs from existing file.
- Fast, dump source without prettyprinting (fast).
- CommonLisp, dump source in commonlisp format (loads common-makefile if needed).

List, list the source file on the default printer.

CleanUp:

- CleanUp*, dump the file according to CLEANUPOPTIONS.
- Set default compiler: TCOMPL.
- Set default compiler: CL:COMPILE-FILE.

MasterScope:

- Analyze*, analyze the fns on the file.
- Check, check the file for problems.
- Show Paths, show paths of function calls on this file.
- DatabaseFNS, display the database property for this file (loads databasefns if needed):
  - Set to ASK, ask about saving MS DB information.
  - Set to ON, automatically maintain MS DB information.
  - Set to OFF, do not save MS DB information.
- Load DB, load an existing MS DB for this file.
- Dump DB, dump the current MS DB for this file.

Compile:

- Compile*, compile the file based on the current settings.
- CL:COMPILE-FILE, compile the file with CL:COMPILE-FILE.

Changes:

- Brief*, prints the changes that have been made to this file.
- Everything, prints the complete list of files changes.
- Edit PL, brings up a lisp editor on the file's property list.

Middle buttoning on a file in the filelst menu (without sliding off) pops up a menu of generic operations on that file:

- Delete, removes the file object from the system.
- Rename, prompts for a new name and renames the file.
- Copy, prompts for a new name and copies the file under that name.
- Mark, mark the contents of the file as changed.
- Unmark, unmark the contents of the file as changed.
Left buttoning on a file and sliding off to the right pops up a menu of types in the file:

![Menu of types]

Releasing on one of these places a menu of items of that type on the file:

![Menu of items]

This menu is not pop-up and remains on the display.

**The items of a type menu:**

These menus contain the names of all instances of a particular type on a file. Names of items in these menus can be copy selected.

Left buttoning on an item name pops up a menu of operations on that type:

![Menu of operations]

- **Edit**, brings up the source text of the item in a lisp editor.
- **PrettyPrint**: prints the source text of the item quickly.
- **Value**, prints the global value of the item's name (assumed a symbol).
- **Function Def**, prints the global function definition of the item's name (assumed a symbol).
- **Property List**, prints the global property list of the item's name (assumed a symbol).
- **Documentation**: prints the item's documentation string.
- **Describe**, calls describe on the item's name (assumed a symbol).
The menu of item operations shown above is the general one. There are special menus for the following types:

FNS, FUNCTIONS, RECORDS, VARS

Middle buttoning on an item name pops up a menu of generic operations on that type:

Delete, removes this item from its file.
EditAll, edits all occurrences of this item's name in the latest source file (uses EDITCALLERS).
Rename:
  Rename*, rename this item in its file and update all uses of the name.
  CopyDef, copy this item under a new name.
  Rename All, rename this item in *ALL* loaded files.
Move, move this item into another file.
Copy, copy this item into another file.
Mark:
  Changed*, mark this item as changed by being edited.
  Defined, mark this item as changed by being defined.
  Deleted, mark this item as changed by being deleted.
Unmark, unmarks the source of this item as being changed (marks it "unchanged).

The file's makefile-environment has its readable argument used to bring up the lisp structure editor properly on objects in the file. When SEdit is the lisp editor, the package used depends on SEdit's "correct package" heuristic (usually that of the symbol naming what is being edited).

Loading and controlling Manager:

Just load the file. Manager can be started either from the background menu or by calling the FNS MANAGER (see below).

Programmer's interface to Manager:

(MANAGER POSITION) [FNS]
Starts up the manager. If POSITION is given, the fileist menu will be appear there.

(MANAGER.RESET RESTARTFLG) [FNS]
Shuts down the manager. If RESTARTFLG is true, manager will be immediately restarted after the shutdown.
Manager.SORTFILELSTFLG [INITVAR]
If true, the FILELST will be sorted, without side effecting the actual FILELST variable. If unset, defaults to T.

Manager.MENUROWS [INITVAR]
Maximum number of rows in a manager menu. If unset, defaults to 20.

manager-marked-shade [INITVAR]
The shade used to indicate that an item has been marked as changed. If unset, defaults to MENUBOLDFONT.

Change History

This is a history of edits made to the Manager. Please add your initials and a short description of what you changed to the END of the file. Be sure to include the name of the definition you modified.

andyiii - All menus are sorted now.
andyiii - Appropriate sub-menu update when something is changed that they contain.
andyiii - Un-marking a file in the main menu now works and updates all the sub-menus of that file.
andyiii - Added option to MAKEFILE menu item for files to write CommonLisp source using common-makefile.
andyiii - Added commonlisp DESCRIBE for items
andyiii - Added a way to add files to the file managers main menu
andyiii - Can edit files property list from CHANGES menu
andyiii - Can now mark a whole file from main menu
andyiii - Can chose between TCOMPL (.LCOM files) and compile-file (.dfasl files) This is awkard since is uses the global variable *default-cleanup-compiler*
andyiii - Can get CommonLisp documentation string and descriptons
andyiii - Can now PrettyPrint a value, function def, or prop list and also show how the item would be written to a file
andyiii - Cleaned up specialized menus for FNS, FUNCTIONS, VARS and PROPS
andyiii - All dialog now goes through the MANAGER ACTIVITY WINDOW
RAF 7/31/87 - Fixed the rename option to not specify a source file, uses the ? search (core then file).
RAF 7/31/87 - Added an "edit all occurrences of item's name" option to file relations menu.
RAF 7/31/87 - Manager.ACTIVEFLG is now a special that is bound by all advice to avoid redundant updates inside of themselves. This is a big speed improvement!
RAF 7/31/87 - Fixed Manager.HASITEM and Manager.HIGHLIGHT to use SASSOC, so that list items in menus get highlighted properly.

RAF 7/31/87 - Middle button on Manager file menu now brings up rename, etc. Used to bring up coms to edit (inconsistent).

RAF 7/31/87 - Main menu flashes if bad button/command is given.

RAF 8/4/87 - MANAGER-ADDTOFILES? now initialized to NIL, reducing redundant updates.

RAF 8/14/87 - In Manager.ALTERMARKING: removed extra code which tracked the files containing updated menus. Removed call to Manager.CHECKFILE. Made call to Manager.MAINUPDATE pass T if the reason for marking was DEFINED or DELETED; these cases also call Manager.COMSOPEN.

RAF 8/15/87 - In Manager.DO.COMMAND: moved binding of ACTIVITY-WINDOW-WAS-SHRUNK into the form eval'ed in the process where references are made. Moved setting of ACTIVITY-WINDOW-WAS-SHRUNK after the spot where its referent ACTIVITY-WINDOW is initialized.

RAF 8/16/87 - Advice for LOAD and LOADFNS now call Manager.CHECKFILE instead of Manager.MAINUPDATE (latter only does highlight updating, former can rebuild main menu). Advice for ADDTOFILES? now doesn't disable manager inside of its advised form, so that the ADDTOCOMS and DELFROMCOMS advice will work.

RAF 8/17/87 - Added Manager.FILELSTCHANGED? (which is tricky, since sorting in the main menu changes its order). Manager.CHECKFILE now tests whether the file being checked is in the main menu. If not the main menu is rebuilt. MANAGER fns disables manager around its call to UPDATEFILES. Manager.GETFILE takes a prompt argument (which is now passed in by Manager.DO.COMMAND).

RAF 8/18/87 - Manager.REMOVE.DUPLICATE.ADVICE now disables the manager when it manipulates the advice (to avoid animating the changes in the menus). The advice on LOAD and LOADFNS now call Manager.REMOVE.DUPLICATE.ADVICE.

RAF 8/20/87 - Fixed Manager.MAKEFILE.ADv to handle atomic cleanup options. Also made the top level Manager.RESET call take Manager.ACTIVEFLG, so that manager stays on when reloaded if it was on already. Manager.REMOVE.DUPLICATE.ADVICE now removes *all* duplicates of the first piece of advice (rather than only the second).

RAF 8/21/87 - Made MANAGER-WINDOWS be an initvar so that Manager.RESET from top level sees the right thing on first startup.

RAF 8/22/87 - Changed the manager shrunken bitmap to something more respectable. Added ADVISE and UNADVISE menu options for the ADVISE definer. Added a "Show all advice in effect" option to the manager main window middle button menu. Changed the messages printed out by Manager.DO.COMMAND to all use printout and lambdafont for highlighting.

RAF 9/3/87 - Added a clause in the startup fns MANAGER which reports when FILELST is empty and manager can't start. Also fixed a bug in where marking a file didn't bold the main menu entry (added an updatefiles in Manager.ALTERMARKING). Also caused the advice on the "redundant" call to (MARKASCHANGED :IN DEFAULT.EDITDEFA0001) to fire when FILELST is being edited (seems it was the only way to call markaschanged in that one case).

RAF 11/18/87 - Changed the call to EDITDEF in Manager.DO.COMMAND to include a :DONTWAIT option. The tracks a change in SEdit for the Mototwn release.

RAF 11/18/87 - Added some type checking to the sort testing function Manager.SORT.COMS so that it doesn't convert its arguments to strings unless they're not LITATOMS. This should make menu generation alot faster.
MATHTONS

INTRODUCTION

This file defines the translation array needed to convert from the Press MATH font to corresponding NS characters. This allows documents containing the MATH font to be printed on Interpress printers.

The array \MATHTONSARRAY contains the translations for most of the characters. Some may not be available on particular printers, causing them to appear as black boxes.
Contains a tool for translating File Manager format Interlisp source files from Medley into Common Lisp text files. The software runs in the Medley system.
MISSILE

By: Anonymous
Maintained by: Frank Shih (Shih.envos@Xerox.com)

INTRODUCTION
MISSILE is a Lisp version of the video game, Missile Command. It was discovered on a file server after a Lisp class.

STARTING MISSILE
Load MISSILE.LCOM, and then call (IL:INIT-MISSILE). Try to destroy incoming missiles by clicking the mouse button in the sky. The rest should be obvious. Warning: the game makes lots of noise.

RESTARTING MISSILE
After a game of MISSILE, it can be restarted from the background menu.
MODERNIZE

By Ron Kaplan

This document was last edited in May 2022

MODERNIZE is a simple Lispusers package that changes the mouse actions on Medley windows so that moving and shaping can be done in a way that approximates the behavior of windows on modern platforms, Mac, Windows, etc. It also adds some meta keys to emulate more conventional behavior.

Thus, for a window that has been created or transformed in this way, you can move the window by left-clicking in the title bar and dragging the window's ghost region. Or you can reshape by clicking in a corner of the title bar or near the bottom of the window to drag out the ghost region by that corner.

The menu behavior for other buttons or buttons clicked in other positions is unchanged.

For bottom corners, "near" means inside the window within MODERN-WINDOW-MARGIN (initially 25) pixels above or to the left/right of the corner.

For top corners, "near" means within the title bar and within the margin from the left/right edges. (Windows that don't have a title-bar, like Snap windows, can be set up so that moving can happen by clicking anywhere, and shaping at the top is determined by the margin inside the window region.

The function MODERNWINDOW.SETUP establishes the new behavior for classes of windows:

(MODERNWINDOW.SETUP ORIGFN MODERNWINDOWFN ANYWHERE TITLEPROPORTION)

ORIGFN is either the name of the BUTTONEVENTFN for a class of windows (e.g. \TEDIT.BUTTONEVENTFN for Tedit windows) or it is a function that creates windows of a particulate kind (e.g. SNAPW or ADD-EXEC).

MODERNWINDOW.SETUP moves the definition of ORIGFN to the name (PACK* MODERN-ORIG-ORIGFN). It then provides a new definition for ORIGFN that does the window moving or reshaping for clicks in the triggering locations, and otherwise passes control through to the original definition.

If ORIGFN is a button event function, then MODERNWINDOWFN should not be specified. In that case a new definition for ORIGFN is constructed to provide the desired windowing behavior.

Otherwise, if ORIGFN is the function that creates windows of a class (e.g. SNAPW), then a MODERNWINDOWFN should be provided to create such windows (by calling (PACK* MODERN-ORIG-ORIGFN)). The definition of MODERNWINDOWFN replaces the original definition of ORIGFN.

TITLEPROPORTION may be a number between 0 and .5. It specifies the proportion from either edge of the title bar where clicks will be interpreted as window operations. For example, if TITLEPROPORTION is .25, then a title click that is up to a quarter of the way from the left or right edge of the window will trigger the moving operation. Clicks in the middle 50% of the title bar will always pass through.

If the flag ANYWHERE is non-NIL, especially for windows without a title bar, then the moving behavior is triggered by a click anywhere in the window (except the corners).
Because this works by redefining existing functions, it is important that the MODERNIZE package be loaded AFTER Tedit and Sedit, if those are not already in the sysout. And it should be called to upgrade the proper functions for other window classes that might later be added.

Provided these capabilities are already loaded, the following window classes are "modernized" when MODERNIZE is loaded:

TEDIT
SEDIT
INSPECTOR
SNAP
DEBUGGER
EXEC
TABLEBROWSER
FILEBROWSER
FREEMENU
GRAPHER
PROMPTWINDOW
SPY
TOTOPW

If it is not known or it is inconvenient to systematically upgrade a button function or a window-creation function, the new behavior can be provided after a particular window has been created, by invoking

(MODERNWINDOW WINDOW ANYWHERE TITLEPROPORTION)

This saves the windows existing BUTTONEVENTFN as a window property PREMODERN-BUTTONEVENTFN, and installs a simple stub function in its place.

If things go awry:

(UNMODERN.SETUP ORIGFN

is provided to restore the original behavior for windows whose buttonevent function is ORIGFN.

(UNMODERNWINDOW WINDOW)

restores a modernized window to its original state.

MODERNIZE also augments the Tedit keyboard commands, to increase compatibility with modern interfaces:

Meta,q is a synonym for Quit
Meta,a is a synonym for Select All

Known issues:

Clicking at the bottom of an EXEC window running TTYIN is effective only when the input line is empty.
MONITOR

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

Uses: COURIERSERVE, BITMAPFNS

MONITOR is a remote screen monitor which shows a scaled down version of the entire remote screen and a small section at full size which can be moved around.

The module contains the code for the client and the server and must be loaded on both. The program supports multiple instances of the tool, even at different scale factors, and works correctly between machines with different size displays.

The lower, full screen window is mouse sensitive. Pressing the left button in the window updates the upper, closeup window to contain the portion of the remote screen indicated by the cursor. Pressing the middle button in the full screen window causes the compressed image of the remote screen in the lower window to be updated.

(MONITOR HOST [SCALE]) [Function]

Opens a remote screen monitor onto HOST, where HOST is any specification that COURIER.OPEN accepts. SCALE is optional and determines the amount of compression of the remote screen bitmap as well as the amount of area covered by the closeup.

The useful range of scale factors is from 2 to about 8; a scale factor of N will compress the remote screen by 1/N in width and height and the closeup will cover 1/N^2 of the area of the remote screen.

MONITOR.SCALE = 3 [Variable]

If not specified, the SCALE argument to MONITOR defaults to the value of MONITOR.SCALE.

KNOWN PROBLEMS

• The Courier program number that the MONITOR Courier program uses is unregistered.
• The monitor does not yet correct for VIDEOCOLOR (which affects both the client and server).
INTRODUCTION

If you like to keep your icons neatly arranged on your screen, NEATICONS is for you. After this package is loaded, whenever an icon is created by shrinking a window, that icon will be “neat.” But what is a neat icon? A neat icon is one that is lined up with another icon or window, or the edge of the screen. The easiest way to see this is to load the package, shrink a few windows (creating a snapshot and shrinking it is easy), and move them around. When a neat icon is moved near another icon or window or the edge of the screen, it is “grabbed” and moved neatly near it.

Neat icons line themselves up in a variety of ways. They will flush themselves with the edge of the screen. They will move themselves a fixed number of pixels from the edge of another window. Or they will align one of their edges with the corresponding edge of another window. When you move a neat icon, it will try to find a “neat” position near where you placed it, and place the window there instead. It may find a nearby position that is horizontally neat but not vertically, or vice versa. In any case, it will move the window into the nearest neat position it can find, or leave it where you put it if it can’t find any nearby neat places.

EXAMPLES

Here are a few examples of how your icons will be arranged. A typical cluster of neat icons:
Neat icons can align themselves with the side of a window:

But more typically, they will align themselves with the corner of a window:
And they occasionally align themselves near the corner where two windows overlap:

```
+-------------------------+-------------------------+
| 41 \MOUSE, PROCESS     | 38 WINDOW MOUSE        |
| 18                        | 50                        |
|                          |                          |
|                          |                          |
|                          |                          |
|                          |                          |

+-------------------------+-------------------------+
```

### DETAILS

You can just load this module and forget about it, and it will behave as advertised. It does have two user-settable parameters, and two user-callable functions, however. These are documented below.

Please note that the NEATICONS module is contained entirely in the NEATICONS package. This package exports the following symbols.

**How near is near?**

**NEATICONS:DEFAULT-TOLERANCE** [Variable]

This global parameter determines how many pixels vertically and horizontally an icon will be moved in order to make it neat. This defaults to 100.

**Spacing between icons**

**NEATICONS:DEFAULT-SPACING** [Variable]

This global parameter determines how many pixels apart neat icons will be placed. The default is 5.

**Making a window neat**

Loading the NEATICONS module causes SHRINKW to be advised, so every time a window is shrunk, the icon is made neat. So icons created before you load NEATICONS will not be neat, but they can be made neat by expanding and then re-shrinking them.

But suppose you want to make a regular window neat?

**(NEATICONS:NEATEN &OPTIONAL WINDOW)** [Function]

makes WINDOW neat. WINDOW defaults to (WHICHW), so you can point at a window with the mouse and type (NEATICONS:NEATEN).

**Making a window sloppy**

**(NEATICONS:UNNEATEN &OPTIONAL WINDOW)** [Function]

makes WINDOW no longer neat. It behaves just like a normal, sloppy, vanilla window. WINDOW defaults to (WHICHW).
Other MOVEFNs

The NEATICONS module uses each window’s MOVEFN prop. If you wish to have another MOVEFN on a neat window, you can. If a window has MOVEFN when it is NEATICONS:NEATENed, it will be preserved. If you wish to add a MOVEFN to an existing neat window, you should put it on the window’s

NEATICONS:USERMOVEFN [Window Prop]

prop. This prop should hold a list of functions. When a neat window is moved, first it finds the nearest neat place. Then the first function on the window’s NEATICONS:USERMOVEFN prop is called with the neat position as argument. If this function returns IL:DON’T, the window won’t be moved. If it returns NIL, the position argument it was passed is passed to the second function on the list. If it returns a position, this position is passed to the second function on the list. The result of each function on the list is treated similarly, until all the functions have been called. The latest position is used as the position to move the window to.
NOTEPAD

By: D. Austin Henderson, Jr. (AHenderson.pa@Xerox)

Compiled for Medley by Larry Masinter (Masinter.PA@Xerox.COM)

Auxiliary file: NOTEPAD-CORESTYLES

NOTEPAD is a module for creating NOTEPAD windows - windows in which one can do artwork at the bitmap level. The ideas in this module come pretty directly from other people’s work, both inside and outside Xerox, including Markup, Draw and Smalltalk. Notepad as it stands is the product of about a man-week of work, using standard Interlisp-D as released and the EDITBITMAP module of bitmap manipulation functions. It provides a nearly unusable interface to some distinctly interesting functionality. Comments and suggestions are welcomed.

NOTEPAD (BITMAP COLORFLG)

Creates a NOTEPAD window. If BITMAP is NIL, then you are prompted for region for the window. Otherwise, a region is defined from the size of BITMAP, and you are prompted to move it to a desired position. If COLORFLG is non-NIL, the NOTEPAD window will be used only for control (for menu’s, etc.), and all the painting will take place on the color screen.

There are two menus: one in the title of the window, and one in the window proper. Both are invoked by buttoning with either left or middle buttons.

Title menu

This menu gives access to commands for manipulating the window as a whole:

- New Notepad
- Copy Notepad
- Save as a bitmap.

Window menu

This menu has two columns of commands: those in the left column of the menu are for painting/erasing material into/from the bitmap (if this menu is invoked with the left button, painting is implied; if with the middle button, erasing); those in the right column of the menu are for changing the style in which the operations work.

Painting/Erasing

You can paint/erase using trajectories, or using (or editing) single objects. The commands in the left column of the menu are divided into two sets which reflect this division.
Trajectories

Sketch: follows the mouse to define a trajectory of points at which to sketch.

Line: prompts for endpoints (fix and rubberband) and uses the points on the line as a trajectory.

Circle: prompts for center and a point on the circumference, and uses the points on the line as a trajectory.

Ellipse: prompts for center, end of semi-major axis and end of semi-minor axis, and uses the points on the line as a trajectory.

Open curve: prompts for first point and one or more subsequent points. You indicate that you are finished by depressing the left shift key on the last point defining the curve. A smooth curve is fitted through these points and used as a trajectory.

Closed curve: Like open curve, except that the fitted curve is closed, starting at the last point given, and proceeding to the first and then subsequent points.

Objects/editing

Text: prompts for text, and permits positioning it with the mouse.

Area of the screen: Prompts for a (rectangular) region of the screen and places permits placing them where you want in the window.

Shade rectangle: prompts for a region, and paints/erases it with the current shade (a shade of black does complete paint and erase).

Fill: Prompts for a region within which to fill, and a point within the area to be filled; fills the area (not necessarily a rectangle, but defined by being closed rectilinearly) with the current shade.

Edit area: prompts for a region of the window and invokes the (Trillium) bitmap editor (standard Interlisp-D bitmap editor is the "hand-edit" choice on the submenu; others allow reflecting, rotating, shifting, inverting, putting on borders, etc.) on it. If the bitmap resulting from the edit is the same size as the original, it replaces the original region; if not, you are prompted for a place to put it.

Style

Notepad operations (see above) are carried out in a style. The style at any given moment is given by a collection of characteristics. The current style can be saved (use the command SAVE.STYLE) under a name and restored (RESTORE.STYLE). Styles may be deleted (DELETE.STYLE) from the collection of saved styles. The style collection is currently part of notepad. Consequently, moving styles between loadups is not directly supported. (It is always possible to save it on a separate file. The styles are stored as the value of NOTEPAD.STYLES. It includes bitmaps, and must therefore be added as an UGLYVARS.)

The characteristics in the style are:

Brush: A bitmap which is either painted or erased at each point on or resulting from (see symmetry) a trajectory (see the operations paint, line, circle, ellipse). DEFINE.BRUSH prompts for a region which will then become the brush. EDIT.BRUSH permits editing of the brush bitmap (using the same editor as the operation EDIT.AREA - see above). BRUSH=COOKIE.CUT.WITH.MASK also defines a brush (see mask, below).

Use mask: An indication of whether of not to use the masking function (see mask, below) before painting/erasing. USE.MASK toggles this setting.
Mask: A bitmap which is used to clear out an area before the brush is used. The mask is erased if the brush is painting, and visa-versa. DEFINE.MASK prompts for a region which will then become the mask. EDIT.MASK permits editing of the mask bitmap (using the same editor as the operation EDIT.AREA - see above). MASK=OUTLINE.OF.BRUSH defines the mask to be the same size as the brush, with a pattern (of black) which is the filled-in outline of the brush. BRUSH=COOKIE.CUT.WITH.MASK allows you to move the mask over a section of the window and define the brush as the points so covered.

Use grid: An indication of whether or not to use the gridding function (see grid, below) while painting/erasing. USE.GRID toggles this setting.

Grid: An origin and the point (1, 1) of a grid to be used to "attract" the points used in following a trajectory. DEFINE.GRID prompts for the origin and (1, 1) point of the grid.

Use symmetry: An indication of what sort of symmetry function to use while painting/erasing. USE.SYMMETRY permits setting it as you choose. The choices are none, left/right, up/down, 4-fold (both left/right and up/down) and 8-fold (4-fold plus reflecting about the 45-degree diagonals). The brush/mask used when painting/erasing symmetrically can themselves be either identical to the brush/mask in use or symmetrically reflected. USE.SYMMETRIC.BRUSH/MASK toggles this setting.

Point of symmetry: The point with respect to which the symmetry functions are defined. POINT.OF.SYMMETRY prompts for this point.

Text font: The font in which text is printed. DEFINE.FONT permits choosing one of the fonts already loaded or OTHER (in which case you can type in the font description (family size face)).

Shade: The shade used for the rectangle and fill operations. EDIT.SHADE permits you to edit the shade (using the standard Interlisp-D shade editor).
NOVAFONT

By: Nick Briggs (Briggs.pa@Xerox.com)

INTERNAL

By Nick Briggs
With prodding from Larry Masinter

This utility file allows Lisp to use fonts in the NOVAFONT format, which is used by Viewpoint.

NovaFont files have in them both the display bitmaps for all sizes of the font, and also the printer widths.

NovaFont files need to be explicitly noticed.

(notice-novafont-file filename) [Function]

After calling notice-novafont-file, the fonts in the given file name will be "known" by the environment. For example,

(notice-novafont-file "{eris}<lispcore>xeroxprivate>fonts>optimamedium.novafont")

After this, FONTCREATE will get the bits from the file.

The novafont reader is crafted in such a manner that it only ever reads the file forwards, so you can load fonts from an NS server. For PARC users, note that there are a bunch of NovaFonts (a few malformed...) on

{starfile public;}<vp applications>*.novafont

including all the "printwheel" fonts, all the Japanese and Chinese character sets (60Q thru 140Q approx), the PC fonts, Quartz.

Unfortunately, it currently doesn't die "gracefully" on the malformed files. It can't just call VP-FONT-P on the files and continue on because it would mean backing up the file pointer.

Instead of loading NovaFonts on demand, all of the display fonts in a NovaFont file can be loaded at once by calling

(load-novafont-file filename) [Function]
The NS font families all have screen fonts that display at approximately their nominal point size. This means that there is a closer congruence between their appearance on the display and on hardcopy than there is for, say, the Press fonts. Unfortunately, this means that the NS display fonts are "too small"—a size that is quite readable on hardcopy can be uncomfortably small on the display. The module NSDISPLAYSIZES attempts to ameliorate this problem by fooling FONTCREATE into using bigger fonts for display without changing anyone's belief in the nominal size of the font.

Loading NSDISPLAYSIZES.LCOM modifies FONTCREATE's font file lookup procedure so that a request for NS display font of size \( n \) actually reads the font file for size \( n+2 \). For example, (FONTCREATE 'MODERN 10) will actually read the display font file belonging to Modern 12, but FONTCREATE will still believe the resulting font is Modern 10. Font sizes greater than 12 are not affected, on the grounds that those fonts are already big enough to read, and not all fonts are available in size \( n+2 \) for large \( n \); hence, for example, Classic 12 and Classic 14 will end up using the same actual font for display. Also, since Terminal 14 does not yet (as of this printing) exist, Terminal 12 remains Terminal 12.

A font is considered an NS font if its name is a member of the list NSFONTFAMILIES, whose initial value is (CLASSIC MODERN TERMINAL OPTIMA TITAN).

Loading the module clears the internal font cache of all NS display fonts, so that subsequent calls to FONTCREATE will not erroneously return a font cached earlier under the default lookup procedure. Of course, if someone has already set some font variable to (FONTCREATE 'MODERN 10), that font descriptor will not be affected.

Note that this module has no effect on hardcopy—a font is always printed at the size you named it. And you can still use TEdit's Hardcopy display mode to see how a piece of text will be formatted on the printer.

If the VIRTUALKEYBOARDS module is present, then loading NSDISPLAYSIZES automatically edits its keyboard specifications so that it continues to use Classic 12 in its keyboard displays. Without this fix, the keyboard display routines will try to create Classic 12, which NSDISPLAYSIZES coerces to Classic 14, and as a result the keyboards will be poorly displayed and lack many characters (since Classic 14 is not as complete as 12). If you load VIRTUALKEYBOARDS after NSDISPLAYSIZES, you should call (VKBD.FIX.FONT) yourself to make the change.

Note that other modules can have similar problems if they have hardwired into them a specific size of NS font as being appropriate for their display configuration. For such modules to operate correctly in the presence of NSDISPLAYSIZES, they might want to be aware of the function used to coerce sizes:

\[
\text{NSDISPLAYSIZE FAMILY SIZE FACE EXTENSION} \quad \text{[Function]}
\]

Returns a font size that (FONTCREATE FAMILY SIZE FACE) will use instead of SIZE. EXTENSION must be a member of DISPLAYFONTEXTENSIONS in order that we know we are doing this for the display. Follows the rules described above. For example, (NSDISPLAYSIZE 'MODERN 12 'MRR 'DISPLAYFONT) returns 14. (NSDISPLAYSIZE 'GACHA 12 'MRR 'DISPLAYFONT) returns 12.
In the simplest case a module could just test for the existence of `NSDISPLAYSIZE` and choose one size or another. For example,

```lisp
(setq myfont (fontcreate 'modern (if (getd 'nsdisplaysize)
  then 10
  else 12)))
```
An "object window" is a window that contains a sequence of arbitrary image objects arranged either vertically or horizontally. The OBJECTWINDOW package provides the functions for creating such a window, adding objects and manipulating them in various ways, and invoking their IMAGEFNS functions according to mouse or other signals.

An object window is created by the function OBJ.CREATEN:

```
(OBJ.CREATEN WINDOWTYPE REGION/WINDOW TITLE BORDERSIZE NOOPENFLG SEPDIST BOXFN DISPLAYFN BUTTONINPN )
```

The arrangement of objects is determined by the obligatory WINDOWTYPE, either VERTICAL or HORIZONTAL. The other arguments are optional. REGION/WINDOW, TITLE, BORDERSIZE, and NOOPENFLG are passed to CREATEW to create the window. If REGION/WINDOW is a window, it is converted to an object window with TITLE. Otherwise, a new window with region REGION/WINDOW if non-NIL. The objects in the window will be separated (vertically or horizontally) by SEPDIST points, defaulting to 0. The arguments BOXFN, DISPLAYFN, and BUTTONINFN are provided as default functions if it is convenient to insert objects whose IMAGEFNS are not fully fleshed out. HARDCOPYFN overrides the default hardcopy function for the window, and HCPYHEADING is used instead of TITLE for hardcopy output.

```
(OBJWINDOWP WINDOW)  [Function]
True if WINDOW is an object window.

(OBJ.ADDTOW WINDOW OBJECT)  [Function]
Adds OBJECT at the end of the object sequence in WINDOW.

(OBJ.ADDMANYTOW WINDOW OBJECTS)  [Function]
Equivalent to calling OBJ.ADDTOW for each object in OBJECTS.

(OBJ.INSERTOBJECTS WINDOW NEWOBJECTS OLDOBJECT WHERE)  [Function]
Inserts NEWOBJECTS at position WHERE (BEFORE or AFTER) with respect to OLDOBJECT.

(OBJ.CLEARW WINDOW)  [Function]
Clears the visible objects in WINDOW.

(OBJ.DELFROMW WINDOW OBJECT)  [Function]
OBJECT is removed from WINDOW.

(OBJ.REPLACE WINDOW OLD.OBJECT NEW.OBJECT DONT.REDISPLAY.FLG)  [Function]
Replaces OLD.OBJECT with NEW.OBJECT in WINDOW, redisplaying the visible objects unless DONT.REDISPLAY.FLG.

(OBJ.FIND REGION WINDOW SEARCHOBJECT)  [Function]
Returns the region in WINDOW occupied by SEARCHOBJECT.

(OBJ.MAP.OBJECTS WINDOW MAPFN)  [Function]
Applies MAPFN to each object OBJ in WINDOW. If MAPFN returns an image object, that object replaces OBJ in WINDOW.

(OBJ.OBJECTS WINDOW)  [Function]
Returns the list of objects in WINDOW.
Obviously Synchronizable Series Expressions:  
Part I: User's Manual for the OSS Macro Package

by

Richard C. Waters

Abstract

The benefits of programming in a functional style are well known. In particular, algorithms that are expressed as compositions of functions operating on series/vectors/streams of data elements are much easier to understand and modify than equivalent algorithms expressed as loops. Unfortunately, many programmers hesitate to use series expressions, because they are typically implemented very inefficiently.

A Common Lisp macro package (OSS) has been implemented which supports a restricted class of series expressions, obviously synchronizable series expressions, which can be evaluated very efficiently by automatically converting them into loops. Using this macro package, programmers can obtain the advantages of expressing computations as series expressions without incurring any run-time overhead.

Copyright Massachusetts Institute of Technology, 1988

This report describes research done at the Artificial Intelligence Laboratory of the Massachusetts Institute of Technology. Support for the laboratory's artificial intelligence research has been provided in part by the National Science Foundation under grant IRI-8616644, in part by the IBM Corporation, in part by the NYNEX Corporation, and in part by the Advanced Research Projects Agency of the Department of Defense under Office of Naval Research contract N00014-85-K-0124.

The views and conclusions contained in this document are those of the authors, and should not be interpreted as representing the policies, neither expressed nor implied, of the National Science Foundation, of the IBM Corporation, of the NYNEX Corporation, or of the Department of Defense.

Acknowledgments.
Both the OSS macro package and this report have benefited from the assistance of a number of people. In particular, C. Rich, A. Meyer, Y. Feldman, D. Chapman, and P. Anagnostopoulos made suggestions which led to a number of very significant improvements in the clarity and power of obviously synchronizable series expressions.
1. All You Need To Know to Get Started

This first section describes everything you need to know to start using the OSS macro package. It then presents a detailed example. Section 2 is a comprehensive reference manual. It describes the functions supported by the OSS macro package in detail. Section 3 contains the bibliography. Section 4 explains the warning and error messages that can be produced by the OSS macro package. Section 5 is both an index into Section 2 and an abbreviated description of the OSS functions. [This section is omitted in the on-line version. Use searching to find individual function descriptions.]

A companion paper [6] gives an overview of the theory underlying the OSS macro package. It explains why things are designed the way they are and compares the OSS macro package with other systems that support operations on series. In addition, the companion paper gives a brief description of the algorithms used to implement the OSS macro package. As part of this, it describes a number of subprimitive constructs which are provided for advanced users of the OSS macro package.

The OSS data type.
A series is an ordered linear sequence of elements. Vectors, lists, and streams are examples of series data types. The advantages (with respect to conciseness, understandability, and modifiability) of expressing algorithms as compositions of functions operating on series, rather than as loops, are well known. Unfortunately, as typically implemented, series expressions are very inefficient---so inefficient, that programmers are forced to use loops whenever efficiency matters.

Obviously Synchronizable Series (OSS) is a special series data type that can be implemented extremely efficiently by automatically converting OSS expressions into loops. This allows programmers to gain the benefit of using series expressions without paying any price in efficiency.

The OSS macro package adds support for the OSS data type to Common Lisp [4]. The macro package was originally developed under version 7 of the Symbolics Lisp Machine software [7]. However, it is written in standard Common Lisp and should be able to run in any implementation of Common Lisp. (It has been tested in DEC Common Lisp and Sun Common Lisp as well as Symbolics Common Lisp.)

The basic functionality provided by the OSS macro package is similar to the functionality provided by the Common Lisp sequence functions. However, in addition to being much more efficient, the OSS macro package is more powerful than the sequence functions, because it includes almost all of the operations supported by APL [3] and by the Loop macro [2]. As a result, OSS expressions go much farther than the sequence functions towards the goal of eliminating the need for explicit loops.

Predefined OSS functions.
The heart of the OSS macro package is a set of several dozen functions which operate on OSS series. These functions divide naturally into three classes. Enumerators produce series without consuming any. Transducers compute series from series. Reducers consume series without producing any. As a mnemonic device, the name of each predefined OSS function begins with a letter code that indicates the type of operation. These letters are intended to be pronounced as separate syllables.

Predefined enumerators include Elist which enumerates successive elements of a list, Evector which enumerates the elements of a vector, and Eup which
enumerates the integers in a range. (The notation [...] is used to represent
an OSS series.)

\[
\begin{align*}
\text{(Elist '}(a b c)) & \Rightarrow [a b c] \\
\text{(Evecto}r '#(a b c)) & \Rightarrow [a b c] \\
\text{(Eup 1 :to 3}) & \Rightarrow [1 2 3]
\end{align*}
\]

Predefined transducers include Tpositions which returns the positions of the
non-null elements in a series and Tselect which selects the elements of its
second argument which correspond to non-null elements of its first argument.

\[
\begin{align*}
\text{(Tpositions [a nil b c nil nil])} & \Rightarrow [0 2 3] \\
\text{(Tselect [nil T T nil] [1 2 3 4])} & \Rightarrow [2 3]
\end{align*}
\]

Predefined reducers include Rlist which combines the elements of a series into
a list, Rsum which adds up the elements of a series, Rlength which computes
the length of a series, and Rfirst which returns the first element of a series.

\[
\begin{align*}
\text{(Rlist [a b c])} & \Rightarrow (a b c) \\
\text{(Rsum [1 2 3])} & \Rightarrow 6 \\
\text{(Rlength [a b c])} & \Rightarrow 3 \\
\text{(Rfirst [a b c])} & \Rightarrow a
\end{align*}
\]

As simple illustrations of how OSS functions are used, consider the following.

\[
\begin{align*}
\text{(Rsum (Evecto}r '#(1 2 3))) & \Rightarrow 6 \\
\text{(Rlist (Tpositions (Elist '}(a nil b c nil)))}) & \Rightarrow (0 2 3)
\end{align*}
\]

Higher-Order OSS functions.
The OSS macro package provides a number of higher-order functions which
support general classes of OSS operations. (Each of these functions end
in the suffix "F", which is pronounced separately.)

For example, enumeration is supported by (EnumerateF init step test). This
enumerates an OSS series of elements starting with init by repeatedly applying
step. The OSS series consists of the values up to, but not including, the
first value for which test is true.

Reduction is supported by (ReduceF init function items) which is analogous to
the sequence function reduce. The elements of the OSS series items are
combined together using function. The quantity init is used as an initial
seed value for the accumulation.

Mapping is supported by (TmapF function items) which is analogous to the
sequence function map. A series is computed by applying function to each
element of items.

\[
\begin{align*}
\text{(EnumerateF 3 #'1- #'minusp) } & \Rightarrow [3 2 1 0] \\
\text{(ReduceF 0 #'+ [1 2 3])} & \Rightarrow 6 \\
\text{(TmapF #'sqrt [4 9 16])} & \Rightarrow [2 3 4]
\end{align*}
\]

Implicit mapping.
The OSS macro package contains a special mechanism that makes mapping
particularly easy. Whenever an ordinary Lisp function is applied to
an OSS series, it is automatically mapped over the elements of the OSS
series. For example, in the expression below, the function sqrt
is mapped over the OSS series of numbers created by Evecto.

\[
\begin{align*}
\text{(Rsum (sqrt (Evecto r #(4 16))))} \\
\Rightarrow (\text{Rsum (TmapF #'sqrt (Evecto r #(4 16))}) \Rightarrow 6
\end{align*}
\]

To a considerable extent, implicit mapping is a peripheral part of the OSS
macro package---one can always use TmapF instead. However, due to the ubiquitous nature of mapping, implicit mapping is extremely convenient. As illustrated below, its key virtue is that it reduces the number of literal lambda expressions that have to be written.

\[(R\text{sum} (\text{expt} (\text{abs} (E\text{vector}'\#(2 -2 3))) 3)) == (R\text{sum} (\text{TmapF}'\#'(\lambda (x) (\text{expt} (\text{abs} x) 3)) (E\text{vector}'\#(2 -2 3)))\] => 43

Creating OSS variables.
The OSS macro package provides two forms (letS and letS*) which are analogous to let and let*, except that they make it possible to create variables that can hold OSS series. (The suffix "S", pronounced separately, is used to indicate primitive OSS forms.) As shown in the example below, letS can be used to bind both ordinary variables (e.g., n) and OSS variables (e.g., items).

\[
(\text{defun} \text{average} \ (v) \\
(\text{letS} \ ((\text{items} (E\text{vector} v)) \\
(\text{sum} (R\text{sum} \text{items})) \\
(n (R\text{length} \text{items}))) \\
(/ \text{sum} n)))
\]

(average '#(1 2 3)) => 2

User-defined OSS functions.
New OSS functions can be defined by using the form defunS which is analogous to defun. Explicit declarations are required inside defunS to indicate which arguments receive OSS series. The following example shows the definition of an OSS function which computes the product of the numbers in an OSS series.

\[
(\text{defunS} \text{Rproduct} \ (\text{numbers}) \\
(\text{declare} \ (\text{type} \text{oss} \text{numbers})) \\
(R\text{reduceF} 1 \#'\* \text{numbers}))
\]

(Rproduct [2 4 6]) => 48

Restrictions on OSS expressions.
As illustrated by the examples above, OSS expressions are constructed in the same way as any other Lisp expression---i.e., OSS functions are composed together in any way desired. However, in order to guarantee that OSS expressions can always be converted into highly efficient loops, a few restrictions have to be followed. These restrictions are summarized in the beginning of Section 2 and discussed in detail in [6].

Here, it is sufficient to note that the OSS macro package is designed so that it is impossible to violate most of the restrictions. The remaining restrictions are checked by the macro package and any violations are automatically fixed. However, warning messages are issued whenever a violation is detected, because, as discussed in the beginning of Section 2, it is often possible for the user to fix a violation in a way which is much more efficient than the automatic fix supplied by the macro package.

The best approach for programmers to take is to simply write OSS expressions without worrying about the restrictions. In this regard, it should be noted that simple OSS expressions are very unlikely to violate any of the restrictions. In particular, it is impossible for an OSS expression to violate any of the restrictions unless it contains a variable bound by letS or defunS. When violations do occur, they can either be ignored (since they cannot lead
to incorrect results) or dealt with on an individual basis (which is advisable since violations can lead to significant inefficiencies).

Benefits.
The benefit of OSS expressions is that they retain most of the advantages of functional programming using series, while eliminating the costs. However, given the restrictions alluded to above, the question naturally arises as to whether OSS expressions are applicable in a wide enough range of situations to be of real pragmatic benefit.

An informal study [5] was undertaken of the kinds of loops programmers actually write. This study suggests that approximately 80% of the loops programmers write are constructed by combining a few common kinds of looping algorithms. The OSS macro package is designed so that all of these algorithms can be represented as OSS functions. As a result, it appears that approximately 80% of loops can be trivially rewritten as OSS expressions. Many more can be converted to this form with only minor modification.

Moreover, the benefits of using OSS expressions go beyond replacing individual loops. A major shift toward using OSS expressions would be a significant change in the way programming is done. At the current time, most programs contain one or more loops and most of the interesting computation in these programs occurs in these loops. This is quite unfortunate, since loops are generally acknowledged to be one of the hardest things to understand in any program. If OSS expressions were used whenever possible, most programs would not contain any loops. This would be a major step forward in conciseness, readability, verifiability, and maintainability.

Example

The following example shows what it is like to use OSS expressions in a realistic programming context. The example consists of two parts: a pair of functions which convert between sets represented as lists and sets represented as bits packed into an integer and a graph algorithm which uses the integer representation of sets.

Bit sets.
Small sets can be represented very efficiently as binary integers where each 1 bit in the integer represents an element in the set. Below, sets represented in this fashion are referred to as bit sets.

Common Lisp provides a number of bitwise operations on integers which can be used to manipulate bit sets. In particular, logior computes the union of two bit sets while logand computes their intersection.

The functions in Figure 1.1 convert between sets represented as lists and bit sets. In order to perform this conversion, a mapping has to be established between bit positions and potential set elements. This mapping is specified by a universe. A universe is a list of elements. If a bit set b is associated with a universe u, then the ith element in u is in the set represented by b iff the ith bit in b is 1.

For example, given the universe (a b c d e), the integer #b01011 represents the set {a,b,d}. (By Common Lisp convention, the 0th bit in an integer is the rightmost bit.)

Given a bit set and its associated universe, the function bset->list converts the bit set into a set represented as a list of its elements. It does this by enumerating the elements in the universe along with their positions and
constructing a list of the elements which correspond to 1s in the integer
representing the bit set. (When no :to argument is supplied, Eup counts up
forever.)

The function list->bset converts a set represented as a list of its elements
into a bit set. Its second argument is the universe which is to be associated
with the bit set created. For each element of the list, the function
bit-position is called in order to determine which bit position should be set
to 1. The function ash is used to create an integer with the correct bit set
to 1. The function ReduceF is used to combine the integers corresponding to
the individual elements together into a bit set corresponding to the list.

The function bit-position takes an item and a universe and returns the bit
position corresponding to the item. The function operates in one of two ways
depending on whether or not the item is in the universe. The first line of
the function contains an OSS expression which determines the position of the item
in the universe. If the item is not in the universe, the expression returns
nil. (The function Rfirst returns nil if it is passed a series of length
zero.)

If the item is not in the universe, the second line of the function adds the
item onto the end of the universe and returns its position. The extension of
the universe is done be side-effect so that it will be permanently recorded in
the universe.

(defun bset->list (bset universe)
  (Rlist (Tselect (logbitp (Eup 0) bset) (Elist universe)))))

(defun list->bset (list universe)
  (ReduceF 0 #'logior (ash 1 (bit-position (Elist list) universe)))))

(defun bit-position (item universe)
  (or (Rfirst (Tpositions (eq item (Elist universe))))
      (1- (length (nconc universe (list item))))))

(Figure 1.1: Converting between lists and bit sets.)

Figure 1.2 shows the definition of two OSS reducers which operate on OSS
series
of bit sets. The first function computes the union of a series of bit sets,
while the second computes their intersection.

(defun Rlogior (bsets)
  (declare (type oss bsets))
  (ReduceF 0 #'logior bsets))

(defun Rlogand (bsets)
  (declare (type oss bsets))
  (ReduceF -1 #'logand bsets))

(Figure 1.2: Operations on OSS series of bit sets.)

Live variable analysis.
As an illustration of the way bit sets might be used, consider the following.
Suppose that in a compiler, program code is being represented as blocks of
straight-line code connected by possibly cyclic control flow. The top part of
Figure 1.3 shows the data structure which represents a block of code. Each
block has several pieces of information associated with it. Two of these
pieces of information are the blocks that can branch to the block in question
and the blocks it can branch to. A program is represented as a list of blocks
that point to each other through these fields.

In addition to control flow information, each structure contains information
about the way variables are accessed. In particular, it records the variables
that are written by the block and the variables that are used by the block
(i.e., either read without being written or read before they are written). An
additional field (computed by the function determine-live discussed below)
records the variables which are live at the end of the block. (A variable is
live if it has to be saved, because it can potentially be used by a following
block.) Finally, there is a temporary data field which is used by functions
(such as determine-live) which perform computations involved with the blocks.

The remainder of Figure 1.3 shows the function determine-live which, given a
program represented as a list of blocks, determines the variables which are
live in each block. To perform this computation efficiently, the function
uses
bit sets. The function operates in three steps. The first step
(convert-to-bsets) looks at each block and sets up an auxiliary data structure
containing bit set representations for the written variables, the used
variables, and an initial guess that there are no live variables. This
auxiliary structure is defined by the third form in Figure 1.3 and is stored in
the temp field of the block. The integer 0 represents an empty bit set.

The second step (perform-relaxation) determines which variables are live. This
is done by relaxation. The initial guess that there are no live variables in
any block is successively improved until the correct answer is obtained.

The third step (convert-from-bsets) operates in the reverse of the first step.
Each block is inspected and the bit set representation of the live variables is
converted into a list which is stored in the live field of the block.

(defstruct (block (:conc-name nil))
  predecessors ;Blocks that can branch to this one.
  successors ;Blocks this one can branch to.
  written ;Variables written in the block.
  used ;Variables read before written in the block.
  live ;Variables that must be available at exit.
  temp) ;Temporary storage location.

(defun determine-live (program-graph)
  (let ((universe (list nil)))
    (convert-to-bsets program-graph universe)
    (perform-relaxation program-graph)
    (convert-from-bsets program-graph universe)
    program-graph))

(defun convert-to-bsets (program-graph universe)
  (letS ((block (Elist program-graph)))
    (setf (temp block) (make-temp-bsets
                      :used (list->bset (used block) universe)
                      :written (list->bset (written block) universe)
                      :live 0)))
    program-graph)

(defun perform-relaxation (program-graph)
  (let ((to-do program-graph))
    (loop
      (when (null to-do) (return (values)))
      (let* ((block (pop to-do))
             (estimate (live-estimate block)))
        (when (not (= estimate (bset-live (temp block))))
          (convert-to-bsets program-graph universe)
          (perform-relaxation program-graph)
          (convert-from-bsets program-graph universe)
          program-graph)
        program-graph)))
(setf (bset-live (temp block)) estimate)
(letS ((prev (Elist (predecessors block))))
  (pushnew prev to-do)))

(defun live-estimate (block)
  (letS ((next (temp (Elist (successors block))))
         (Rlogior (logior (bset-used next)
                          (logandc2 (bset-live next)
                                    (bset-written next)))))))

(defun convert-from-bsets (program-graph universe)
  (letS ((block (Elist program-graph)))
    (setf (live block)
          (bset->list (bset-live (temp block)) universe))
    (setf (temp block) nil)))

(Figure 1.3: Live variable analysis.)

On each cycle of the loop in perform-relaxation, a block is
examined to determine whether its live set has to be changed. To do
this (see the function live-estimate), the successors of the
block are inspected. Each successor needs to have available to it the
variables it uses, plus the variables that are supposed to be live
after it, minus the variables it writes. (The function logandc2
takes the difference of two bit sets.) A new estimate of the total
set of variables needed by the successors as a group is computed by
using Rlogior.

If this new estimate is different from the current estimate of what
variables are live, then the estimate is changed. In addition, if the
estimate is changed, perform-relaxation has to make sure that
all of the predecessors of the current block will be examined to see
if the new estimate for the current block requires their live
estimates to be changed. This is done by adding each predecessor onto
the list to-do unless it is already there. As soon as the
estimates of liveness stop changing, the computation can stop.

Summary.
The function determine-live is a particularly good example of the way OSS
expressions are intended to be used in two ways. First, OSS expressions are
used in a number of places to express computations which would otherwise be
expressed less clearly as loops or less efficiently as sequence function
expressions. Second, the main relaxation algorithm is expressed as a loop.
This is done, because neither OSS expressions (nor Common Lisp sequence
function expressions) lend themselves to expressing the relaxation algorithm.
This highlights the fact that OSS expressions are not intended to render loops
entirely obsolete, but rather to provide a greatly improved method for
expressing the vast majority of loops.
2. Reference Manual

This section is organized around descriptions of the various functions and forms supported by the OSS macro package. Each description begins with a header which shows the arguments and results of the function or form being described. For ease of reference, the headers are duplicated in Section 5. In Section 5, the headers are in alphabetical order and show the page where the function or form is described.

In a reference manual like this one, it is advantageous to describe each construct separately and completely. However, this inevitably leads to presentation problems, because everything is related to everything else. Therefore, one cannot avoid referring to things which have not been discussed. The reader is encouraged to skip around in the document and to realize that more than one reading will probably be necessary in order to gain a complete understanding of the OSS macro package.

Although the following list of OSS functions is large, it should not be taken as complete. Every effort has been made to provide a wide range of useful predefined functions. However, except for a few primitive forms, all of these functions could have been defined by the user. It is hoped that users will write many more such functions. A key reason for presenting a wide array of predefined functions is to inspire users with thoughts of the wide variety of functions they can write for themselves.

Restrictions and Definitions of Terms.

As alluded to in Section 1, there are a number of restrictions which OSS expressions have to obey. The OSS macro package is designed so that all but three of these restrictions are impossible to violate with the facilities provided. As a result, the programmer need not think about these restrictions at all.

The OSS macro package checks to see that the remaining three restrictions are obeyed on an expression by expression basis and automatically fixes any violations which are detected. However, the automatic fixes are often not very efficient. As a result, it is advisable for the user to fix such violations explicitly.

Given that simple OSS expressions are very unlikely to violate any of the restrictions, and any violations which do occur are automatically fixed, it is reasonable for the reader to skip this section when first reading this manual. However, it is useful to read this section before trying to write complex OSS expressions.

The discussion below starts by defining two key terms (on-line functions and early termination) which are used to categorize the OSS functions described in the rest of this manual. The discussion then continues by briefly describing the three restrictions which can be violated. (See [6] for a complete discussion of all the restrictions.)

On-line and off-line.
Suppose that $f$ is an OSS function which reads one or more series inputs and writes one or more series outputs. The function $f$ is on-line [1] if it operates in the following fashion. First, $f$ reads in the first element of each input series, then it writes out the first element of each output series, then it reads in the second element of each input series, then it writes out the second element of each output series, and so on. In addition, $f$ must immediately terminate as soon as any input runs out of elements. If an $f$ is
not on-line, then it is off-line.

In the context of OSS expressions, the term on-line is generalized so that it applies to individual OSS input and output ports in addition to whole functions. An OSS port is on-line iff the processing at that port always follows the rigidly synchronized pattern described above. Otherwise, it is off-line. From this point of view, a function is on-line iff all of its OSS ports are on-line.

The prototypical example of an on-line OSS function is TmapF (which maps a function over a series). Each time it reads an input element it applies the mapped function to it and writes an output element. In contrast, the function Tremove-duplicates (which removes the duplicate elements from a series) is not on-line. Since some of the input elements do not become output elements, it is not possible for Tremove-duplicates to write an output element every time it reads an input element.

For every OSS function, the documentation below specifies which ports are on-line and which are off-line. In this regard, it is interesting to note that every function which has only one OSS port (e.g., enumerators with only one output and reducers with only one input) are trivially on-line. The only OSS functions which have off-line ports are transducers.

Early termination.

An important feature of OSS functions is the situations under which they terminate. The definition of on-line above requires that on-line functions must terminate as soon as any series input runs out of elements. If an OSS function can terminate before any of its inputs are exhausted, then it is an early terminator. The degenerate case of functions which do not have any series inputs (i.e., enumerators) is categorized by saying that enumerators are early terminators iff they can terminate.

As an example of an early terminator, consider the function TuntilF (which reads a series and returns all of the elements of that series up to, but not including, the first element which satisfies a given predicate). This function is an early terminator, because it can terminate before the input runs out of elements.

The documentation below specifies which functions are early terminators. Besides enumerators, their are only 7 OSS functions which are early terminators.

Isolation. A data flow arc delta in an OSS expression X is isolated iff it is possible to partition the functions in X into two parts Y and Y’ in such a way that: delta goes from Y to Y’, there is no OSS data flow from Y to Y’, and there is no data flow from Y’ to Y. For example, consider the OSS expression (letS ((x (f y))) (i (h x (g x)))) which corresponds to the graph in Figure 2.1. [Not shown in this textual version of the memo. See the printed version.]

The data flow arc delta4 is isolated. To show this, one merely has to partition the expression so that f, g, and h are on one side and i is on the other. The question of whether or not the other data flow arcs are isolated is more complicated to answer. If delta3 crosses a partition, then delta1 must cross this partition as well. As a result, delta3 is isolated iff delta1 carries a non-OSS value. (This is true no matter what kind of value passes over delta3 itself.) In a related situation, delta2 is isolated iff (it and therefore delta1) carries a non-OSS value. Finally, consider the arc delta1. Here there are two potential
partitions to consider: one which cuts delta2 and one which cuts delta3. The data flow arc delta1 is isolated iff either it (and therefore delta2) or delta3 carries a non-OSS value.

The concept of isolation is extended to inputs and outputs as follows. An output p in an expression X is isolated iff X can be partitioned into two parts Y and Y’ such that: every data flow originating on p goes from Y to Y’, every other data flow from Y to Y’ is a non-OSS data flow, and there is no data flow from Y’ to Yf. An input q in an expression X is isolated iff X can be partitioned into two parts Y and Y’ such that: the data flow terminating on q goes from Y to Y’, every other data flow from Y to Y’ is a non-OSS data flow, and there is no data flow from Y’ to Y.

For example, in Figure 2.1, the outputs of f and h are isolated as is the input of i. The input and output of q are isolated iff f computes a non-OSS value. The inputs of h are isolated iff the data flow arcs terminating on them are isolated.

Non-OSS data flows must be isolated.
In order for an OSS expression to be reliably converted into a highly efficient loop, every non-OSS data flow in it must be isolated. As an example of an expression where this is not true, consider the following. In this expression, the data flow implemented by the variable total is not isolated.

```lisp
(let* ((nums (Evector '#(3 2 8))) ;Signals warning 16
        (total (ReduceF 0 #'+ nums)))
  (Rvector (/ nums total))) => #(3/13 2/13 8/13)
```

(The basic problem here is that while the elements created by Evector are being used to compute total, they all have to be saved so that they can be used again later in order to perform the indicated divisions. Eliminating the need for such storage is the key source of efficiency underlying OSS expressions.)

Off-line OSS ports must be isolated.
In order for an OSS expression to be reliably converted into a highly efficient loop, every off-line port must be isolated. As an example of an expression which has an off-line output which is not isolated, consider the following. In this expression, the data flow implemented by the variable positions is not isolated.

```lisp
(let* ((keys (Elist list)) ;Signals warning 17.1
        (positions (Tpositions keys)))
  (Rlist (list positions keys)))
```

(The basic problem here is that since Tpositions skips null elements of the input, Tpositions sometimes has to read several input elements before it can produce the next output element. This forces an unpredictable number of elements of keys to be saved so that they can be used later when creating lists. As above, eliminating the need for such storage is the main goal of OSS expressions.)

Code copying.
If an OSS expression violates either of the above restrictions, the OSS macro packaged automatically fixes the problem by copying code until the data flow or port in question becomes isolated. For instance, the example above of an OSS expression in which a non-OSS data flow is not isolated is fixed as follows.
\[
\begin{align*}
\text{(letS* (nums (Evector '#(3 2 8)))} \\
\text{(total (ReduceP 0 '#' (Evector '#(3 2 8)))))} \\
\text{(Rvector (/ nums total))) } => \text{#(3/13 2/13 8/13)}
\end{align*}
\]

Even though the problem has been automatically fixed, the OSS macro package issues a warning message. This is done for two reasons. First, if side-effects (e.g., input or output) are involved, the code copying that was performed may not be correctness preserving. Second, large amounts of code sometimes have to be copied and that can introduce large amounts of extra computation.

A major goal of OSS expressions is ensuring that expressions which look simple to compute actually are simple to compute. Automatically introducing large amounts of additional computation without the programmer’s knowledge would violate this goal. At the very least, issuing warning messages makes programmers aware of what is expensive to compute and what is not. Looked at from a more positive perspective, it encourages them to think of ways to compute what they want without code copying being required.

For instance, consider the example above of an OSS expression in which an off-line port is not isolated. It might be the case that the programmer knows that list does not contain any null elements and that Tpositions is therefore merely being used to enumerate what the positions of the elements are. In this situation, the expression can be fixed as follows, which does not require any code copying. (The key insight here is that the positions do not actually depend on the values in the list.)

\[
\begin{align*}
\text{(let ((list '(a b c)))} \\
\text{(letS* ((keys (Elist list))} \\
\text{(positions (Eup 0))))} \\
\text{(Rlist (list positions keys))) } => \text{((0 a) (1 b) (2 c))}
\end{align*}
\]

(It is interesting to note that if an expression is a tree (as opposed to a graph as in Figure 2.1), then every data flow arc and every port is isolated. This is why OSS expressions which do not contain variables bound by letS, lambdaS, or defunS cannot violated either of the isolation restrictions. This is also why code copying can always fix any violation---code copying can convert any graph into a tree.)

On-line subexpressions.
The two isolation restrictions above permit a divide and conquer approach to the processing of OSS expressions. If an OSS expression obeys the isolation restrictions, then it can be repeatedly partitioned until all of the data flow in each subexpression goes from an on-line output to an on-line input. The subexpressions which remain after partitioning are referred to as on-line subexpressions.

Termination points.
The functions in each on-line subexpression can be divided into two classes: those which are termination points and those which are not. A function is a termination point if it can terminate before any other function in the subexpression terminates. There are two reasons for functions being termination points. Functions which are early terminators are always termination points. In addition, any function which reads an OSS series which comes from a different on-line subexpression is a termination point.

Data flow paths between termination points and outputs.
In order for an OSS expression to be reliably converted into a highly
efficient loop, it must be the case that within each on-line subexpression, there is a data flow path from each termination point to each output. As an example of an OSS expression for which this property does not hold, consider the following. Partitioning divides this expression into two on-line subexpressions, one containing list and one containing everything else. In the large on-line subexpression, the two instances of Evector are termination points. The program violates the property above, because there is no data flow path from the termination point (Evector weight-vector) to the output of (Rvector squares).

```
(defun weighted-squares (value-vector weight-vector)
  (let* ((values (Evector value-vector)) ;Signals warning 18
          (weights (Evector weight-vector))
          (squares (* values values))
          (weighted-squares (* squares weights)))
    (list (Rvector squares) (Rvector weighted-squares))))
```

```
(weighted-squares #(1 2 3) #(2 3 4)) => (#(1 4 9) #(2 12 36))
(weighted-squares #(1 2) #(2 3 4)) => (#(1 4) #(2 12))
(weighted-squares #(1 2 3) #(2 3)) => (#(1 4 9) #(2 12))
```

(The basic problem here is that if the number of elements in value-vector is greater than the number of elements in weight-vector, the computation of squares has to continue even after the computation of weighted-squares has been completed. This kind of partial continuing evaluation in a single on-line subexpression is not supported by the OSS macro package, because it was judged that it requires too much overhead in order to control what gets evaluated when.)

When an OSS expression violates the restriction above, the violation is automatically fixed by applying code copying. It is impossible for an on-line subexpression to violate the restriction unless it computes two different outputs. Code copying can always be used to break the subexpression in question into two parts each of which computes one of the outputs. Unfortunately, this can require a great deal of code to be copied. There are two basic approaches which can be used to fix a violation much more efficiently: reducing the number of termination points and increasing the connectivity between termination points and outputs.

The easiest way to decrease the number of termination points is to replace early terminators by equivalent operations which are not early terminators. If an early terminator is not an enumerator, then this can always be done without difficulty. (The documentation below describes a non-early variant for each early terminating transducer and reducer.) If multiple enumerators are the problem (as in the example above) decreasing the number of termination points is usually not practical. However, sometimes an enumerator which terminates can be replaced by an enumerator which never terminates.

The connectivity between termination points and outputs can be increased by using the function Tcotruncate. This is the preferred way to fix the problem in the example above.

**General Information**

Before discussing the individual OSS functions in detail, a few general comments are in order. First, all of the OSS functions and forms are defined in the package OSS. To make these names easily accessible, use the package OSS (i.e., evaluate (use-package "OSS")). If this is not done, the names will have
to be prefixed with "oss:" when they are used.

Naming conventions.  The names of the various OSS functions and forms follow a strict naming convention.  The first letter of an OSS function name indicates the type of function as shown below.  The letter codes are written in upper case in this document (case does not matter to Common Lisp) and each letter is intended to be pronounced as a separate syllable.

- **E** Enumerator.
- **T** Transducer.
- **R** Reducer.

The last letter of each OSS special form is "S".  In general, this indicates that the form is primitive in the sense that it could not be defined by the user.  Some OSS functions end in the letter "F".  This is used to indicate that the function is a higher-order function which takes functions as arguments.

The naming convention has two advantages: one trivial but vital and the other more fundamentally useful.  First, many of the OSS functions are very similar to standard Common Lisp sequence functions.  As a result, it makes sense to give them similar names.  However, it is not possible to give them exactly the same names without redefining the standard functions.  The naming convention allows the names to be closely related in a predictable way without making the names unreasonably long.

Second, the naming convention highlights several properties of OSS functions which make it easier to read and understand OSS expressions.  In particular, the prefixes highlight the places where series are created and consumed.

The names of arguments and results of OSS functions are also chosen following naming conventions.  First, all of the names are chosen in an attempt to indicate type restrictions (e.g., number indicates that an argument must be a number; item indicates that there is no type restriction).  Plural names are used iff the value in question is an OSS series (e.g., numbers indicates an OSS series of numbers; items indicates an OSS series of unrestricted values).  The name of a series input or output begins with "O" iff it is off-line.

OSS series. Two general points about OSS series are worthy of note.  First, like Common Lisp sequences, OSS series use zero-based indexing (i.e., the first element is the 0th element).  Second, unlike Common Lisp sequences, OSS series can be unbounded in length.

Tutorial mode.  A prominent feature of the various descriptions is that they contain many examples.  These examples contain large numbers of OSS series as inputs and outputs.  In the interest of brevity, the notation [...] is used to indicate a literal OSS series.  If the last entry in a literal OSS series is an ellipsis, this indicates that the OSS series is unbounded in length.

```
[1 2 3]
[a b (c d)]
[T nil T nil ...]
```

The notation [...] is not supported by the OSS macro package.  It would be straightforward to do so by using set-macro-character.  Perhaps even better, one could use set-dispatch-macro-character to support a notation #[...]
analogous to #(...). However, although literal series are very useful in the examples below, experience suggests that literal series are seldom useful when writing actual programs. Inasmuch as this is the case, it was decided that it was unwise to use up one of the small set of characters which are available for user-defined reader macros or user-defined # dispatch characters.

Many of the examples show OSS expressions returning OSS series as their values. However, one should not take this literally. If these examples are typed to Common Lisp as isolated expressions, they will not return any values. This is so, because the OSS macro package does not allow complete OSS expressions to return OSS series. The examples are intended to show what would be returned if the example expressions were nested in larger expressions.

oss-tutorial-mode &optional (T-or-nil T) => state-of-tutorial-mode

The above notwithstanding, the OSS macro package provides a special tutorial mode in which the notation [... ] is supported and OSS expressions can return (potentially unbounded) OSS values. However, these values still cannot be stored in ordinary variables. This mode is entered by calling the function oss-tutorial-mode with an argument of T. Calling the function with an argument of nil turns tutorial mode off.

Using tutorial mode, it is possible to directly duplicate the examples shown below. However, tutorial mode is very inefficient. What is worse, tutorial mode introduces non-correctness-preserving changes in OSS expressions. (For example, in order to correctly duplicate the examples that illustrate error messages about non-terminating expressions and the fact that OSS series are not actually returned by complete OSS expressions, tutorial mode must be turned off.) All in all, it is important that tutorial mode not be used as anything other than an educational aid.

OSS functions are actually macros. Every OSS function is actually a macro. As a result, OSS functions cannot be funcall’ed, or apply’ed. When the user defines new OSS functions, they must be defined before the first time they are used. Also, when an OSS function takes keyword arguments, the keywords must be literals. They cannot be expressions which evaluate to keywords at run time.

Finally, the macro expansion processing associated with OSS expressions is relatively time consuming. In order to avoid this overhead during the running of a user program, it is important that programs containing OSS expressions be compiled rather than run interpretively.

A minor advantage of the fact that everything in the OSS macro package is a macro is that once a program which uses the macro package is compiled, the compiled program can subsequently be run without having to load the OSS macro package.

A more important advantage of the fact that everything in the OSS macro package is a macro is that quoted macro names can be used as functional arguments to higher-order OSS functions. (In contrast, quoted macro names cannot be used as functional arguments to higher-order Common Lisp functions such as reduce.) Although this may appear to be a minor benefit, it is actually quite useful.

Enumerators

Enumerators create OSS outputs based on non-OSS inputs. There are two basic kinds of enumerators: ones that create an OSS series based on some formula (e.g., enumerating a sequence of integers) and ones that create
an OSS series containing the elements of an aggregate data structure (e.g., enumerating the elements of a list). All the predefined enumerators are on-line. In general, they are all early terminators. However, as noted below, in some situations, some enumerators produce unbounded outputs and are not early terminators.

Eoss  &rest expr-list => items

The expr-list consists of zero or more expressions. The function Eoss creates an OSS series containing the values of these expressions. Every expression in expr-list is evaluated before the first output element is returned.

(Eoss 1 'a 'b) => [1 a b]
(Eoss) => []

To get the effect of delaying the evaluation of individual elements until they are needed, it is necessary to define a special purpose enumerator which computes the individual items as needed. However, due to the control overhead required, this is seldom worthwhile.

It is possible for the expr-list to contain an instance of :R. (This must be a literal instance of :R, not an expression which evaluates to :R.) If this is the case, then Eoss produces an unbounded OSS series analogous to a repeating decimal number. The output consists of the values of the expressions preceding the :R followed by an unbounded number of repetitions of the values following the :R, if there are any such values. (In this situation, Eoss is not an early terminator.)

(Eoss 1 'a :R 'b 'c) => [1 a b c b c b c ...]
(Eoss T :R nil) => [T nil nil nil ...]
(Eoss 1 :R) => [1]
(Eoss :R 1) => [1 1 1 ...]

Eup  &optional (start 0) &key (:by 1) :to :below :length => numbers

This function is analogous to the Loop macro [2] numeric iteration clause. It creates an OSS series of numbers starting with start and counting up by :by. The argument start is optional and defaults to integer 0. The keyword argument :by must always be a positive number and defaults to integer 1.

There are four kinds of end tests. If :to is specified, stepping stops at this number. The number :to will be included in the OSS series if (- :to start) is a multiple of :by. If :below is specified, things operate exactly as if :to were specified except that the number :below is never included in the OSS series. If :length is specified, the OSS series has length :length. It must be the case that :length is a non-negative integer. If :length is positive, the last element of the OSS series will be (+ start (* :by (1- :length))). If none of the termination arguments are specified, the output has unbounded length. (In this situation, Eup is not an early terminator.) If more than one termination argument is specified, it is an error.

(Eup :to 4) => [0 1 2 3 4]
(Eup :to 4 :by 3) => [0 3]
(Eup 1 :below 4) => [1 2 3]
(Eup 4 :length 3) => [4 5 6]
(Eup) => [0 1 2 3 4 ...]

As shown in the following example, Eup does not assume that the numbers being enumerated are integers.
(Eup 1.5 :by .1 :length 3) => [1.5 1.6 1.7]

Edown &optional (start 0) &key (:by 1) :to :above :length => numbers

The function Edown is analogous to Eup, except that it counts down instead of up and uses the keyword :above instead of :below.

(Edown :to -4) => [0 -1 -2 -3 -4]
(Edown :to -4 :by 3) => [0 -3]
(Edown 1 :above -4) => [1 0 -1 -2 -3]
(Edown 4 :length 3) => [4 3 2]
(Edown) => [0 -1 -2 -3 -4 ...]
(Edown -1.5 :by .1 :length 3) => [-1.5 -1.6 -1.7]

Esublists  list &optional (end-test #'endp) => sublists

This function creates an OSS series containing the successive sublists of list. The end-test must be a function from objects to boolean values (i.e., to null/non-null). It is used to determine when to stop the enumeration. Successive cdrs are returned up to, but not including, the first one for which end-test returns non-null.

(Esublists '(a b c)) => [(a b c) (b c) (c)]
(Esublists '(a . b c) #'atom) => [(a b . c) (b . c)]

The default end-test (#'endp) will cause Esublists to blow up if list contains a non-list cdr. More robust enumeration can be obtained by using the end-test #'atom as in the second example above. The assumption that list will end with nil is used as the default case, because the assumption sometimes allows programming errors to be detected closer to their sources.

Elist  list &optional (end-test #'endp) => elements

This function creates an OSS series containing the successive elements of list. It is closely analogous to Esublists as shown below. In particular, end-test has the same meaning and the same caveats apply.

(Elist '(a b c)) => [a b c]
(Elist '()) => []
(Elist '(a b . c) #'atom) => [a b]
(Elist list) == (car (Esublists list))

The value returned by Elist can be used as a destination for alterS.

(let ((list '(a b c)))
  (alterS (Elist (cdr list)) (Eup))
  list) => (a 0 1)

Ealist  alist &optional (test #'eql) => keys values

This function returns two OSS series containing keys and their associated values. The first element of keys is the key in the first entry in alist, the first element of values is the value in the first entry, and so on. The alist must be a proper list ending in nil and each entry in alist must be a cons cell or nil. Like assoc, Ealist skips entries which are nil and entries which have the same key as an earlier entry. The test argument is used to determine when two keys are the same.
(Ealist '((a . 1) (a . 3) (b . 2))) => [a b] [1 2]
(Ealist nil) => [ ] [ ]

Both of the series returned by Ealist can be used as
destinations for alterS. (In analogy with
multiple-value-bind, letS can be used to bind both values
returned by Ealist.)

(let ((alist '((a . 1) (b . 2))))
  (letS (((key val) (Ealist alist)))
    (alterS key (list key))
    (alterS val (+ val)))
  alist) => '(((a) . 2) ((b) . 3))

The OSS function Ealist is forced to perform a significant amount
of computation in order to check that no duplicate keys or null
entries are being enumerated. In a situation where it is known that
no duplicate keys or null entries exist, it is much more efficient to
use Elist as shown below.

(letS* ((e (Elist '((a . 1) (b . 2))))
         (keys (car e))
         (values (cdr e)))
  (Rlist (list keys values))) => ((a 1) (b 2))

Ealist  plist => indicators values

This function returns two OSS series containing indicators and their
associated values. The first element of indicators is the first
indicator in the plist, the first element of values is the
associated value, and so on. The plist argument must be a
proper list of even length ending in nil. In analogy with the
way get works, if an indicator appears more than once in
plist, it (and its value) will only be enumerated the first time it
appears. (Both of the OSS series returned by Eplist can be used
as destinations for alterS.)

(Eplist '(a 1 a 3 b 2)) => [a b] [1 2]
(Eplist nil) => [ ] [ ]

The OSS function Eplist has to perform a significant amount
of computation in order to check that no duplicate indicators
are being enumerated. In a situation where it is known that
no duplicate indicators exist, it is much more efficient to
use EnumerateF as shown below.

(letS* ((e (EnumerateF '(a 1 b 2) #'cddr #'null))
         (indicators (car e))
         (values (cadr e)))
  (Rlist (list indicators values))) => ((a b) (1 2))

Etree  tree &optional (leaf-test #'atom) => nodes

This function creates an OSS series containing all of the nodes in
tree. The function assumes that tree is a tree built of lists,
where each node is a list and the elements in the list are the
children of the node. The function Etree does not assume that
the node lists end in nil; however, it ignores any non-list
cd.rs. (This behavior increases the utility of Etree when it is
used to scan Lisp code.) The nodes in the tree are enumerated in
preorder (i.e., first the root is output, then the nodes in the tree
which is the first child of the root is enumerated in full, then the
nodes in the tree which is the second child of the root is enumerated
in full, etc.).
The leaf-test is used to decide which elements of the tree are leaves as opposed to internal nodes. Failure of the test should guarantee that the element is a list. By default, leaf-test is #'atom. This choice of test categorizes nil as a leaf rather than as a node with no children.

The function Etree assumes that tree is a tree as opposed to a graph. If tree is a graph instead of a tree (i.e. some node has more than one parent), then this node (and its descendants) will be enumerated more than once. If the tree is a cyclic graph, then the output series will be unbounded in length.

(Etree 'd) => [d]
(Etree '((c) d)) => [((c) d) (c) c d]
(Etree '((c) d)
  #'(lambda (e)
      (or (atom e) (atom (car e))))) => [((c) d) (c) d]

Efringe tree &optional (leaf-test #'atom) => leaves

This enumerator is the same as Etree except that it only enumerates the leaves of the tree, skipping all internal nodes. The logical relationship between Efringe and Etree is shown in the first example below. However, Efringe is implemented more efficiently than this example would indicate.

(Efringe tree) == (TselectF #'atom (Etree tree))
(Efringe 'd) => [d]
(Efringe '((c) d)) => [c d]
(Efringe '((c) d)
  #'(lambda (e)
      (or (atom e) (atom (car e))))) => [((c) d)]

The value returned by Efringe can be used as a destination for alterS. However, if the entire tree is a leaf and gets altered, this will have no side-effect on the tree as a whole. In addition, altering a leaf will have no effect on the leaves enumerated. In particular, if a leaf is altered into a subtree, the leaves of this subtree will not get enumerated.

(let ((tree '((3) 4)))
  (letS ((leaf (Efringe tree)))
    (if (evenp leaf) (alterS leaf (- leaf)))
    tree) => ((3) -4)

Evector vector &optional (indices (Eup)) => elements

This function creates an OSS series of the elements of a one-dimensional array. If indices assumes its default value, Evector enumerates all of the elements of vector in order.

(Evector "BAR") => [#\B #\A #\R]
(Evector ")") => []

Looked at in greater detail, Evector enumerates the elements of vector which are indicated by the elements of the OSS series indices. The indices must be non-negative integers, however, they do not have to be in order. Enumeration stops when indices runs out, or an index greater than or equal to the length of vector is encountered. One can use Eup to create an index series which picks out a section of vector. (Since Evector takes in an OSS series it is technically a transducer, however, it is on-line and is an enumerator in spirit.)
(Evector '#(b a r) (Eup 1 :to 2)) => [a r]
(Evector "BAR" [0 2 1 1 4 1]) => [#\B #\R #\A #\A]

The value returned by Evector can be used as a destination for alterS.

(let ((v "FOOBAR"))
  (alterS (Evector v (Eup 2 :to 4)) '#\-) v) => "FO---R"

Esequence sequence &optional (indices (Eup)) => elements

The function Esequence is the same as Evector except that it will work on any Common Lisp sequence. However, since it has to determine the type of sequence at run-time, it is much less efficient than either Elist or Evector. (The value returned by Esequence can be used as a destination for alterS.)

(Esequence '(b a r)) => [b a r]
(Esequence '#(b a r)) => [b a r]

Ehash table => keys values

This function returns two OSS series containing keys and their associated values. The first element of keys is the key of the first entry, the first element of values is the value in the first entry, and so on. (There are no guarantees as to the order in which entries will be enumerated.)

(Ehash (let ((h (make-hash-table)))
  (setf (gethash 'color h) 'brown)
  (setf (gethash 'name h) 'fred)
  h)) => [color name] [brown fred] ;in some order

In the pure Common Lisp version of the OSS macro package, Ehash is rather inefficient, because Common Lisp does not provide incremental support for scanning the elements of a hash table. However, in the Symbolics Common Lisp version of the OSS macro package, Ehash is quite efficient.

Esymbols &optional (package *package*) => symbols

This function creates an OSS series of the symbols in package (which defaults to the current package). (There are no guarantees as to the order in which symbols will be enumerated.)

(Esymbols) => [foo bar baz ... zot] ;in some order

In the pure Common Lisp version of the OSS macro package, Esymbols is rather inefficient, because Common Lisp does not provide incremental support for scanning the symbols in a package. However, in the Symbolics Common Lisp version of the OSS macro package, Esymbols is quite efficient.

Efile name => items

This function creates an OSS series of the items written in the file named name. The function combines the functionality of with-open-file with the action of reading from the file (using read). It is guaranteed that the file will be closed correctly, even if an error occurs. As an example of using Efile, assume that the forms (a), (1 2), and T have been written into the file "test.lisp".
The higher-order function EnumerateF is used to create new kinds of enumerators. The `init` must be a value of some type T1. The `step` argument must be a non-OSS function from T1 to T1. The `test` argument (if present) must be a non-OSS function from T1 to boolean.

Suppose that the series returned by EnumerateF is S. The first output element $S_0$ has the value $S_0=\text{init}$. For subsequent elements, $S_i=\text{step}(S_{i-1})$.

If the `test` is present, the output consists of elements up to, but not including, the first element for which $\text{test}(S_i)$ is true. In addition, it is guaranteed that `step` will not be applied to the element for which `test` is true. If there is no `test`, then the output series will be of unbounded length. (In this situation, EnumerateF is not an early terminator.)

$$\text{EnumerateF `'(a b c d) #'cddr #'null} => [(a b c d) (c d)]$$
$$\text{EnumerateF `'(a b c d) #'cddr} => [(a b c d) (c d) nil nil ...]$$
$$\text{EnumerateF list #'cdr #'null} => (\text{Esublists list})$$

If there is no `test`, then each time an element is output, the `step` function is applied to it. Therefore, it is important that other factors in an expression cause termination before EnumerateF computes an element which `step` cannot be applied to. In this regard, it is interesting that the following equivalence is almost, but not quite true. The difference is that including the `test` argument in the call on EnumerateF guarantees that `step` will not be applied to the element which `test` fails, while the expression using TuntilF guarantees that it will.

$$(\text{TuntilF test (EnumerateF init step)) not= (\text{EnumerateF init step test})$$

The higher-order function Enumerate-inclusiveF is the same as EnumerateF except that the first element for which `test` is true is included in the output. As with EnumerateF, it is guaranteed that `step` will not be applied to the element for which `test` is true.

$$(\text{Enumerate-inclusiveF `'(a b) #'cddr #'null}) => [(a b) ()]$$

Transducers compute OSS series from OSS series and form the heart of most OSS expressions. This section and the next one present the predefined transducers that are on-line (i.e., all of their inputs and outputs are on-line). These transducers are singled out because they can be used more flexibly than the transducers which are off-line. In particular, it is impossible to violate the off-line port isolation restriction without using an off-line transducer.

$$(\text{Tprevious items &optional (default nil) (amount 1)} => \text{shifted-items})$$

This function creates a series which is shifted right amount elements. The input amount must be a positive integer. The shifting is done by inserting amount copies of default before items and discarding amount elements from the end of items. The output is always the same length as the input.
(Tprevious [a b c]) => [nil a b]
(Tprevious [a b c] 'z) => [z a b]
(Tprevious [a b c] 'z 2) => [z z a]
(Tprevious []) => []

The word previous is used as the root for the name of this function, because the function is typically used to access previous values of a series. An example of Tprevious used in this way is shown in conjunction with Tuntil below.

To insert some amount of stuff in front of a series without losing any of the elements off the end, use Tconcatenate as shown below.

(Tconcatenate [z z] [a b c]) => [z z a b c]

Tlatch items &key :after :before :pre :post => masked-items

This function acts like a latch electronic circuit component. Each input element causes the creation of a corresponding output element. After a specified number of non-null input elements have been encountered, the latch is triggered and the output mode is permanently changed.

The :after and :before arguments specify the latch point. The latch point is just after the :after-th non-null element in items or just before the :before-th non-null element. If neither :after nor :before is specified, an :after of 1 is assumed. If both are specified, it is an error.

If a :pre is specified, every element prior to the latch point is replaced by this value. If a :post is specified, this value is used to replace every element after the latch point. If neither is specified, a :post of nil is assumed.

(Tlatch [nil c nil d e]) => [nil c nil nil nil]
(Tlatch [nil c nil d e] :before 2 :post T) => [nil c nil T T]
(Tlatch [nil c nil d e] :before 2 :pre 'z) => [z z z d e]

As a more realistic example of using Tlatch, suppose that a programmer wants to write a program get-codes which takes in a list and returns a list of all of the numbers which appear in the list after the second number in the list.

(defun get-codes (list)
  (letS ((elements (Elist list)))
    (Rlist (Tselect (Tlatch (numberp elements) :after 2 :pre nil)
                    elements))))

(get-codes '(a b 3 4 c d 5 e 6 f)) => (5 6)

Tuntil bools items => initial-items

This function truncates an OSS series of elements based on an OSS series of boolean values. The output consists of all of the elements of items up to, but not including, the first element which corresponds to a non-null element of bools. That is to say, if the first non-null value in bools is the mth, the output will consist of all of the elements of items up to, but not including, the mth.

(The effect of including the mth element in the output can be obtained by using Tprevious as shown in the last example below.)

In addition, the output terminates as soon as either input runs out of elements even if a non-null element of bools has not been encountered.
(Tuntil [nil nil T nil T] [1 2 -3 4 -5]) => [1 2]
(Tuntil [nil nil T nil T] [1]) => [1]
(Tuntil (Eoss :R nil) (Eup)) => [0 1 2 ...]
(Tuntil [nil nil T nil T] (Eup)) => [0 1]
(letS ((x [1 2 -3 4 -5]))
  (Tuntil (minusp x) x)) => [1 2]
(letS ((x [1 2 -3 4 -5]))
  (Tuntil (Tprevious (minusp x)) x)) => [1 2 -3]

If the items input of Tuntil is such that it can be
used as a destination for alterS, then the output of
Tuntil can be used as a destination for alterS.

(letS* ((list '(a b 10 c))
  (x (Elist list))
  (y (Tuntil (numberp x) x)))
  (alterS y (list y))
list) => ((a) (b) 10 c)

TuntilF pred items => initial-items

This function is the same as Tuntil except that it takes a
functional argument instead of an OSS series of boolean values. The non-OSS
function pred is mapped over items in order to obtain a
series of boolean values. (Like Tuntil, TuntilF is
can be used as a destination
of alterS if items can.) The basic relationship between
TuntilF and Tuntil is shown in the last example below.

(letS* ((var items)) (Tuntil (TmapF pred var) var))

The functions Tuntil and TuntilF are both early
terminators. This can sometimes lead to conflicts with the
restriction that within each on-line subexpression, there must be a
data flow path from each termination point to each
output. To get the same effect without using an early terminator use
Tselect of Tlatch as shown below.

(TuntilF #'minusp [1 2 -3 4 -5]) => [1 2]
(TuntilF #'minusp [1]) => [1]
(TuntilF #'minusp (Eup)) => [0 1 2 ...]
(TuntilF pred items)
  => (letS ((var items)) (Tuntil (TmapF pred var) var))

TmapF function &rest items-list => items

The higher-order function TmapF is used to create simple
kinds of on-line transducers. Its arguments are a single function and
zero or more OSS series. The function argument must be a non-OSS
function which is compatible with the number of input series and the
types of their elements.

A single OSS series is returned. Each element of this series is the
result of applying function to the corresponding elements of the
input series. (That is to say, if TmapF receives a single input
series R it will return a single output S such that
S_i=function(R_i).) The length of the output is the
same as the length of the shortest input. If there are no bounded
series inputs (e.g., if there are no series inputs), then TmapF
will generate an unbounded OSS series.

\[(\text{TmapF } #'+ [1 2 3] [4 5]) \Rightarrow [5 7]\]
\[(\text{TmapF } #'\text{sqrt} []) \Rightarrow []\]
\[(\text{TmapF } #'\text{gensym}) \Rightarrow [\#:G003 \#:G004 \#:G005 ...]\]

\text{TscanF} \{\text{init}\} \text{ function items} \Rightarrow \text{ results}

The higher-order function \text{TscanF} is used to create complex kinds of on-line transducers. (The name is borrowed from APL.) The init argument (if present) must be a non-OSS value of some type \(T_1\). The function argument must be a binary non-OSS function from \(T_1\) and some type \(T_2\) to \(T_1\). The items argument must be an OSS series whose elements are of type \(T_2\). If the init argument is not present than \(T_1\) must equal \(T_2\).

The function argument is used to compute a series of accumulator values of type \(T_1\) which is returned as the output of \text{TscanF}. The output is the same length as the series input and consists of the successive accumulator values.

Suppose that the series input to \text{TscanF} is \(R\) and the output is \(S\). The basic relationship between the output and the input is that \(S_i=\text{function}(S_{i-1},R_i)\). If the init argument is specified, it is used as an initial value of the accumulator and the first output element \(S_0\) has the value \(S_0=\text{function}(\text{init},R_0)\). Typically, but not necessarily, init is chosen so that it is a left identity of function. If that is the case, then \(S_0=R_0\). It is important to remember that the elements of items are used as the second argument of function. The order of arguments is chosen to highlight this fact.

\[(\text{TscanF } 0 #'+ [1 2 3]) \Rightarrow [1 3 6]\]
\[(\text{TscanF } 10 #'+ [1 2 3]) \Rightarrow [11 13 16]\]
\[(\text{TscanF } \text{nil} #'\text{cons} [a b]) \Rightarrow [(\text{nil} . a) ((\text{nil} . a) . b)]\]
\[(\text{TscanF } \text{nil} #'(\text{lambda} (\text{state} x) (\text{cons} x \text{ state})) [a b]) \Rightarrow [(a) (b a)]\]

If the init argument is not specified, then the first element of the output is computed differently from the succeeding elements and \(S_0=R_0\). (If function is cheap to evaluate, \text{TscanF} runs more efficiently if it is provided with an init argument.) One situation where one typically has to leave out the init argument is when function does not have a left identity element as in the last example below.

\[(\text{TscanF } #'+ [1 2 3]) \Rightarrow [1 3 6]\]
\[(\text{TscanF } \#\text{max} [1 3 2]) \Rightarrow [1 3 3]\]

An interesting example of a scanning process is the operation of proration. In this process, a total is divided up and allocated between a number of categories. The allocation is done based on percentages which are associated with the categories. (For example, some number of packages might be divided up between a number of people.) One might think that this could be done straightforwardly by multiplying the total by each of the percentages. Unfortunately, this mapping approach does not work.

The proration problem is more complex than it first appears. Typically, there is a limit to the divisibility of the total (e.g., when a group of packages is divided up, the individual packages cannot be subdivided). This means that rounding must be performed each time the total is multiplied by a percentage. In addition, it is usually important that the total be allocated exactly---i.e., that the
sum of the allocations be exactly equal to the total, rather than
being one more or one less. Scanning is required in order to make sure
that things come out exactly right.

As a concrete example of proration, suppose that 99 packages need to
be allocated among three people based on the percentages 35%, 45%,
and 20%. Assuming that the percentages and the number of packages are
all represented as integers, simple mapping would lead to the
incorrect result below in which the allocations add up to 100 instead
of 99.

(prognS (round (/ (* 99 [35 45 20]) 100))) => [35 45 20]

The transducer Tprorate below solves the proration problem by
using TscanF. It takes in a total and an OSS series of
percentages and returns an OSS series of allocations. The basic action
of the program is to multiply each percentage by the total. However,
it also keeps track of how much of the total has been allocated. When
the last percentage is encountered, the allocation is set to be
everything which remains to be allocated. (This can cause a
significant distortion in the final allocation, but it guarantees that
the allocations will always add up to the total no matter what has
happened with rounding along the way.) In order to determine when the
last percentage is being encountered, the program keeps track of how
much percentage has been accounted for and assumes that the
percentages always add up to 100.

(defun prorate-step (state percent)
  (let* ((total (second state))
         (unallocated (third state))
         (unused-percent (fourth state))
         (allocation (if (= percent unused-percent) unallocated
                       (round (/ (* total percent) 100))))
         (setf (first state) allocation)
         (setf (third state) (- unallocated allocation))
         (setf (fourth state) (- unused-percent percent))
         state))

(defun Tprorate (total percents)
  (declare (type oss percents))
  (car (TscanF (list 0 total total 100) #'prorate-step percents)))

(Tprorate 99 [35 45 20]) => [35 45 19]

An interesting aspect of the function Tprorate is that the
state manipulated by the scanned function prorate-step has four
parts: an allocation, the total, the unallocated portion of the total,
and the remaining percentage not yet allocated. This illustrates the
fact that TscanF can be used with complex state objects. (The
same is true of EnumerateF and ReduceF.) However, it also
illustrates that accessing the various parts of a complex state is
awkward and inefficient.

Fortunately, it is often possible to get around the need for a complex
state object by using a compound OSS expression. For the example of
proration, this can be done as shown below. Simple mapping is
combined with two scans which keep track of cumulative values. An
implicitly mapped test is used to make sure that things come out right
on the last step. (The function Tprevious is used to access the
previous value of the series unallocated.)

(defun Tprorate-multi-state (total percents)
  (declare (type oss percents))
  (letS* ((allocation (round (/ (* percents total) 100))))
    ...
    ...
    (...)
A key feature of every on-line transducer is that it terminates as soon as any input runs out of elements. Put another way, the output is never longer than the shortest input. (If the transducer is also an early terminator, then the output can be shorter than the shortest input, otherwise it must be the same length as the shortest input.)

This effect is referred to as cotruncation, because it acts as if each input had been truncated to the length of the shortest input. If several enumerators and on-line transducers are combined together into an OSS expression, cotruncation will typically cause all of the series produced by the enumerators to be truncated to the same length. For example, in the expression below, all of the series (including the unbounded series produced by Eup) are truncated to a length of two.

\[(\text{Rlist}\ (*\ (+\ \text{Eup}\ [4\ 5])\ [1\ 2\ 3]))\Rightarrow\ (4\ 12)\]

\text{Tcotruncate}\ \text{items}\ \&\text{rest}\\text{more-items}\Rightarrow\text{initial-items}\ \&\text{rest}\ \text{more-initial-items}

It is occasionally important to specify cotruncation explicitly. This can be done with the function Tcotruncate whose only action is to force all of the outputs to be of the same length. (If any of the inputs of Tcotruncate are such that they can be used as destinations of alterS, then the corresponding outputs of Tcotruncate can be used as destinations of alterS.)

\[(\text{Tcotruncate}\ [1\ 2\ -3\ 4\ -5]\ [10])\Rightarrow\ [1]\ [10]\]
\[(\text{Tcotruncate}\ \text{Eup}\ [a\ b])\Rightarrow\ [0\ 1]\ [a\ b]\]
\[(\text{Tcotruncate}\ [a\ b]\ [])\Rightarrow\ []\ []\]

An important feature of Tcotruncate is that it has a powerful interaction with the requirement that within each on-line subexpression, there must be a data flow path from each termination point to each output. Consider the function weighted-squares below. This program is intended to take a vector of values and a vector of weights and return a list of two vectors: the squares of the values and the squares multiplied by the weights. The program violates the requirement above, because there is no data flow path from (Evector weight-vector) to (Rvector squares).

\[(\text{defun}\ \text{weighted-squares}\ (\text{value-vector}\ \text{weight-vector})\]
\hspace{1cm} (\text{let}\ast (\text{values} (\text{Evector} \\text{value-vector}))\hspace{1cm} ;\text{Signals warning 18}
\hspace{1cm} (\text{weights} (\text{Evector} \text{weight-vector}))
\hspace{1cm} (\text{squares} (* \text{values} \text{values}))
\hspace{1cm} (\text{weighted-squares} (* \text{squares} \text{weights})))
\hspace{1cm} (\text{list} (\text{Rvector} \text{squares}) (\text{Rvector} \text{weighted-squares}))))\]

\[(\text{weighted-squares}\ #(1\ 2\ 3)\ #(2\ 3\ 4))\Rightarrow\ (#(1\ 4\ 9)\ #(2\ 12\ 36))\]
\[(\text{weighted-squares}\ #(1\ 2)\ #(2\ 3\ 4))\Rightarrow\ (#(1\ 4)\ #(2\ 12))\]
\[(\text{weighted-squares}\ #(1\ 2\ 3)\ #(2\ 3))\Rightarrow\ (#(1\ 4\ 9)\ #(2\ 12))\]

It might be the case that the programmer knows that value-vector and weight-vector always have the same length. (Or it might be the case that he wants both output values to be no longer than the shortest input.) In either case, the function can be written as shown below which is much more efficient than the program above since there is no longer a restriction violation which triggers code copying. The
key difference is that the use of \texttt{Tcotruncate} makes both outputs depend on both inputs. If the inputs are known to be the same length, the use of \texttt{Tcotruncate} can be thought of as a declaration.

\begin{verbatim}
(defun weighted-squares* (value-vector weight-vector)
  (letS* (((values weights)
    (Tcotruncate (Evector value-vector)
    (Evector weight-vector)))
    (squares (* values values))
    (weighted-squares (* squares weights)))
  (list (Rvector squares) (Rvector weighted-squares))))

(weighted-squares* #(1 2 3) #(2 3 4)) => (#(1 4 9) #(2 12 36))
(weighted-squares* #(1 2) #(2 3 4)) => (#(1 4) #(2 12))
(weighted-squares* #(1 2 3) #(2 3)) => (#(1 4) #(2 12))
\end{verbatim}

\textbf{Off-Line Transducers}

This section and the next two describe transducers that are not on-line. Most of these functions have some inputs or outputs which are on-line. The ports which are on-line can be used freely. However, the off-line ports have to be isolated when they are used. (For ease of reference, the off-line ports all begin with the letter code "O".)

\textbf{Tremove-duplicates} \textbf{O}items &optional (comparator #'eql) => items

This function is analogous to remove-duplicates. It creates an OSS series that has the same elements as the off-line input \textbf{O}items with all duplicates removed. The comparator is used to determine whether or not two items are duplicates. If two items are the same, then the item which is later in the series is discarded. (As in remove-duplicates the algorithm employed is not particularly efficient, being \texttt{O(n^2)}.) (If the \textbf{O}items input of \textbf{T}remove-duplicates is such that it can be used as a destination for \textbf{alter}S, then the output of \textbf{T}remove-duplicates can be used as a destination for \textbf{alter}S.)

\begin{verbatim}
(Tremove-duplicates [1 2 1 (a) (a)]) => [1 2 (a) (a)]
(Tremove-duplicates [1 2 1 (a) (a)] #'equal) => [1 2 (a)]
\end{verbatim}

\textbf{Tchunk} amount \textbf{O}items => lists

This function creates an OSS series of lists of length amount of successive subseries of the off-line input \textbf{O}items. If the length of \textbf{O}items is not a multiple of amount, then the last (mod (Rlength \textbf{O}items) amount) elements of \textbf{O}items will not appear in any output chunk.

\begin{verbatim}
(Tchunk 2 [a b c d e]) => [(a b) (c d)]
(Tchunk 6 [a b c d]) => []
\end{verbatim}

\textbf{Twindow} amount \textbf{O}items => lists

This function creates an OSS series of lists of length amount of subseries of the off-line input \textbf{O}items starting at each element position. If the length of \textbf{O}items is less than amount, the output will not contain any windows. The last example below shows \textbf{T}window being used to compute a moving average.

\begin{verbatim}
(Twindow 2 [a b c d]) => [(a b) (c d)]
(Twindow 4 [a b c d]) => [(a b c d)]
(Twindow 6 [a b c d]) => []
(prognS (/ (apply #'+ (Twindow 2 [2 4 6 8])) 2)) => [3 5 7]
\end{verbatim}
Tconcatenate Oitems1 Oitems2 &rest more-Oitems => items

This function creates an OSS series by concatenating together two or more off-line input OSS series. The length of the output is the sum of the lengths of the inputs. (The elements of the individual input series are not computed until they need to be.)

(Tconcatenate [b c] [] [d]) => [b c d]
(Tconcatenate [] [1]) => [1]

TconcatenateF Enumerator Oitems => items

The Enumerator must be a quoted OSS function that is an enumerator. The function TconcatenateF applies Enumerator to each element of the off-line input Oitems and returns the series obtained by concatenating all of the results together. If Enumerator returns multiple values, then TconcatenateF will as well.

(TconcatenateF #'Elist [(a b) () (c d)]) => [a b c d]
(TconcatenateF #'Elist () () ) => []
(TconcatenateF #'Eplist [(a 1) (b 2 c 3)]) => [a b c] [1 2 3]

Tsubseries Oitems start &optional below => items

This function creates an OSS series containing a subseries of the elements of the off-line input Oitems from start up to, but not including, below. If below is greater than the length of Oitems, output nevertheless stops as soon as the input runs out of elements. If below is not specified, the output continues all the way to the end of Oitems. Both of the arguments start and below must be non-negative integers.

(Tsubseries [a b c d] 1) => [b c d]
(Tsubseries [a b c d] 1 3) => [b c]
(Rlist (Tsubseries (Elist list) 1 2)) == (subseq list 1 2)

If the Oitems input of Tsubseries is such that it can be used as a destination for alterS, then the output of Tsubseries can be used as a destination for alterS.

(let ((list '(a b c d e)))
  (alterS (Tsubseries (Elist list) 1 3) (Eup))
  list) => (a 0 1 d e)

The function Tsubseries terminates as soon as it has written the last output element. As a result, it is an early terminator. This can sometimes lead to conflicts with the restriction that within each on-line subexpression, there must be a data flow path from each termination point to each output. To select a subseries without using an early terminator, use Tselect, Tmask, and Eup as shown below.

(Tsubseries Oitems from below)
  == (Tselect (Tmask (Eup from :below below)) Oitems)

Tpositions Obools => indices

This function takes in an OSS series and returns an OSS series of the indexes of the non-null elements in the off-line input series.

(Tpositions [T nil T 44]) => [0 2 3]
(Tpositions [nil nil nil]) => []
Tmask  Omonotonic-indices => bools

This function is a quasi-inverse of Tpositions. The input Omonotonic-indices must be a strictly increasing OSS series of non-negative integers. The output, which is always unbounded, contains T in the positions specified by Omonotonic-indices and nil everywhere else.

(Tmask [0 2 3]) => [T nil T nil nil ...]
(Tmask []) => [nil nil ...]
(Tmask (Tpositions x)) == (Tconcatenate (not (null x)) (Eoss :R nil))

Tmerge  Oitems1 Oitems2 comparator => items

This function is analogous to merge. The output series contains the elements of the two off-line input series. The elements of Oitems1 appear in the same order that they are read in. Similarly, the elements of Oitems2 appear in the same order that they are read in. However the elements from the two inputs are intermixed under the control of the comparator. At each step, the comparator is used to compare the current elements in the two series. If the comparator returns non-null, the current element is removed from Oitems1 and transferred to the output. Otherwise, the next output comes from Oitems2. (If, as in the first example below, the elements of the individual input series are ordered with respect to comparator, then the result will also be ordered with respect to comparator. If, as in the second example below, either input is not ordered, the result will not be ordered.)

(Tmerge [1 3 7 9] [4 5 8] #'<) => [1 3 4 5 7 8 9]
(Tmerge [1 7 3 9] [4 5 8] #'<) => [1 4 5 7 3 8 9]
(Tmerge x y #'(lambda (x y) T)) == (Tconcatenate x y)

Tlastp  Oitems => bools items

This function takes in a series and returns a series of boolean values having the same length such that the last value is T and all of the other values are nil. If the input series is unbounded, then the output series will also be unbounded and every element of the output will be nil.

It turns out that this output cannot be computed by an on-line OSS function. Therefore, if Tlastp returned only the boolean values described above, the isolation restrictions would make it impossible to use the input series and the output values together in the same computation. In order to get around this problem, Tlastp returns a second output which is identical to the input. This output can be used in lieu of the input in combination with the boolean values.

(Tlastp [a b c d]) => [nil nil nil T] [a b c d]
(Tlastp [a]) => [T] [a]
(Tlastp []) => [T] [T]
(Tlastp (Eup)) => [nil nil nil ...] [0 1 2 ...]

As an example of using Tlastp, it is interesting to return to the example of proration discussed in conjunction with the function TscanF. Both of the proration functions presented earlier assume that the percentages always add up to 100. If this turns out not to be the case, then an exact allocation of the total is not guaranteed. The following program ensures that exact allocation will occur no matter what the percentages add up to. It does this by using Tlastp to detect which percentage is the last one.
(defun Tprorate-robust (total Opercents)
  (declare (type oss Opercents))
  (let* (((is-last percents) (Tlastp Opercents))
          (allocation (round (/ (* percents total) 100))))
        (unallocated (TscanF total #'- allocation)))
  (if is-last (Tprevious unallocated total) allocation)))

(Tprorate-robust 99 [35 45 20]) => [35 45 19]
(Tprorate-robust 99 [35 45 21]) => [35 45 19]
(Tprorate 99 [35 45 21]) => [35 45 21]

Selection and Expansion

Selection and its inverse are particularly important kinds of off-line transducers.

Tselect  bools &optional items => Oitems

This function selects elements from a series based on a boolean series. The off-line output consists of the elements of items which correspond to non-null elements of bools. That is to say, the nth element of items is in the output iff the nth element of bools is non-null. The order of the elements in Oitems} is the same as the order of the elements in items. The output terminates as soon as either input runs out of elements. If no items input is specified, then the non-null elements of bools are themselves returned as the output of Tselect. (If the items input of Tselect is such that it can be used as a destination for alterS, then the output of Tselect can be used as a destination for alterS.)

(Tselect [T nil T nil] [a b c d]) => [a c]
(Tselect [a nil b nil]) => [a b]
(Tselect [nil nil] [a b]) => []

An interesting aspect of Tselect is that the output series is off-line rather than having the two input series be off-line. This is done in recognition of the fact that the two input series are always in synchrony with each other. Having only one port which is off-line allows more flexibility then having two ports which are off-line.

One might want to select elements out of a series based on their positions in the series rather than on boolean values. This can be done straightforwardly using Tmask as shown below.

(Tselect (Tmask [0 2]) [a b c d]) => [a c]
(Tselect (not (Tmask [0 2])) (Eup 10)) => [11 13 14 15 ...]

A final feature of Tselect in particular, and off-line ports in general, is illustrated by the program below. In this program, the Tselect causes the first Elist to get out of phase with the second Elist. As a result, it is important to think of OSS expressions as passing around series objects rather than as merely being abbreviations for loops where things are always happening in lock step. The latter point of view might lead to the idea that the output of the program below would be ((a 1) (c 2) (d 4)).

(letS ((tag (Elist '(a b c d e)))
        (x (Elist '(1 -2 2 4 -5))))
        (Rlist (list tag (Tselect (plusp x) x)))) => ((a 1) (b 2) (c 4))

TselectF  pred Oitems => items
This function is the same as Tselect, except that it maps the non-OSS function pred over Oitems to obtain a series of boolean values with which to control the selection. In addition, TselectF has an off-line input rather than an off-line output (this is fractionally more efficient). The logical relationship between Tselect and TselectF is shown in the last example below.

(TselectF #'identity [a nil nil b nil]) => [a b]
(TselectF #'plusp [-1 2 -3 4]) => [2 4]
(TselectF pred items)
  == (letS ((var items)) (Tselect (TmapF pred var) var))

Texpand  bools Oitems &optional (default nil) => items

This function is a quasi-inverse of Tselect. (The name is borrowed from APL.) The output contains the elements of Oitems spread out into the positions specified by the non-null elements in bools---i.e., the nth element of Oitems is in the position occupied by the nth non-null element in bools. The other positions in the output are occupied by default. The output stops as soon as bools runs out of elements, or a non-null element in bools is encountered for which there is no corresponding element in Oitems.

(Texpand [nil T nil T T] [a b c]) => [nil a nil b c]
(Texpand [nil T nil T T] [a]) => [nil a nil]
(Texpand [nil T] [a b c] 'z) => [z a]
(Texpand [nil T nil T T] []) => [nil]

Splitting

An operation which is closely related to selection, is splitting. In selection, specified elements are selected out of a series. It is not possible to apply further operations to the elements which are not selected, because they have been discarded. In contrast, splitting divides up a series into two or more parts which can be individually used. Both Tsplit and TsplitF have on-line inputs and off-line outputs. The outputs have to be off-line, because they are inherently non-synchronized with each other.

Tsplit  items bools &rest more-bools => Oitems1 Oitems2 &rest more-Oitems

This function takes in a series of elements and partitions them between two or more outputs. If there are n boolean inputs then there are n+1 outputs. Each input element is placed in exactly one output series. Suppose that the nth element of bools is non-null. In this case, the nth element of items will be placed in Oitems1. On the other hand, if the nth element of bools is nil, the second boolean input (if any) is consulted in order to see whether the input element should be placed in the second output or in a later output. (As in a cond, each time a boolean element is nil, the next boolean series is consulted.) If the nth element of every boolean series is nil, then the nth element of items is placed in the last output.

(Tsplit [-1 -2 3 4] [T T nil nil]) => [-1 -2] [3 4]
(Tsplit [-1 -2 3 4] [T T nil nil] [nil T nil T]) => [-1 -2] [4] [3]
(Tsplit [-1 -2 3 4] [T T T T]) => [-1 -2 3 4] []

If the items input of Tsplit is such that it can be used as a destination for alterS, then all of the outputs of Tsplit can be used as destinations for alterS.
(let* ((list '(-1 2 -3))
       (x (Elist list))
       (x+ x-) (Tsplit x (plusp x)))
       (alterS x+ (+ x+ 10))
       (alterS x- (- x- 10))
       list) => (-11 12 -13)

TsplitF items pred &rest more-pred => Oitems1 Oitems2 &rest more-Oitems

This function is the same as Tsplit, except that it takes predicates as arguments rather than boolean series. The predicates must be non-OSS functions and are applied to items in order to create boolean values. The relationship between TsplitF and Tsplit is almost but not exactly as shown below.

(TsplitF items pred1 pred2)
not= (letS ((var items))
       (Tsplit var (TmapF pred1 var) (TmapF pred2 var)))

The reason that the equivalence above does not quite hold is that, as in a cond, the predicates are not applied to individual elements of items unless the resulting value is needed in order to determine which output series the element should be placed in (e.g., if the first predicate returns non-null when given the nth element of items, the second predicate will not be called). This promotes efficiency and allows earlier predicates to act as guards for later predicates.

(TsplitF [-1 -2 3 4] #'minusp) => [-1 -2] [3 4]
(TsplitF [-1 -2 3 4] #'minusp #'evenp) => [-1 -2] [4] [3]

Reducers

Reducers produce non-OSS outputs based on OSS inputs. There are two basic kinds of reducers: ones that combine the elements of OSS series together into aggregate data structures (e.g., into a list) and ones that compute some summary value from these elements (e.g., the sum). All the predefined reducers are on-line. A few reducers are also early terminators. These reducers are described in the next section.

Rlist items => list
This function creates a list of the elements in items in order.

(Rlist [a b c]) => (a b c)
(Rlist []) => ()
(Rlist (fn (Elist x) (Elist y))) => (mapcar #'fn x y)
(Rlist (fn (Esublists x) (Esublists y))) => (maplist #'fn x y)

Rbag items => list
This function creates a list of the elements in items with no guarantees as to the order of the elements. The function Rbag is more efficient than Rlist.

(Rbag [a b c]) => (c a b) ;in some order
(Rbag []) => ()

Rappend lists => list
This function creates a list by appending the elements of lists together in order.
Rappend  \([(a \ b) \ nil \ (c \ d)]\) => (a b c d)

(Rappend []) => ()

Rnconc  lists => list

This function creates a list by nconc-ing the elements of lists together in order. The function Rnconc is faster than Rappend, but modifies the lists in the OSS series lists.

(Rnconc [[a b] nil (c d)]) => (a b c d)
(Rnconc []) => ()
(let ((x '(a b))) (Rnconc (Eoss x x))) => (a b a b a b ...)
(Rnconc (fn (Elist x) (Elist y))) == (mapcan #'fn x y)
(Rnconc (fn (Esublists x) (Esublists y))) == (mapcon #'fn x y)

Ralist  keys values => alist

This function creates an alist containing keys and values. It terminates as soon as either of the inputs runs out of elements. If there are duplicate keys, they will be put on the alist, but order is preserved.

(Ralist [a b] [1 2]) => ((a . 1) (b . 2))
(Ralist [a b] []) => ()
(Ralist keys values) == (Rlist (cons keys values))

Rplist  indicators values => plist

This function creates a plist containing keys and values. It terminates as soon as either of the inputs runs out of elements. If there are duplicate indicators, they will be put on the plist, but order is preserved.

(Rplist [a b a] [1 2 3]) => (a 1 b 2 a 3)
(Rplist [a b] []) => ()
(Rplist keys values) == (Rnconc (list keys values))

Rhash  keys values &rest option-plist => table

This function creates a hash table containing keys and values. It terminates as soon as either of the inputs runs out of elements. The option-plist can contain any options acceptable to make-hash-table. The option-plist cannot refer to variables bound by letS.

(Rhash [color name] [brown fred]) => #<hash-table 23764432> ;;hash table containing color->brown, name->fred

(Rhash [color name] []) => #<hash-table 23764464> ;;empty hash table

Rvector  items &key :size &rest option-plist => vector

This function creates a vector containing the elements of items in order. The option-plist can contain any options acceptable to make-array. The option-plist cannot refer to variables bound by letS.

The function Rvector operates in one of two ways. If the :size argument is supplied, then Rvector assumes that items will contain exactly :size elements. A vector is created of length :size with the options specified in option-plist and the elements of items are stored in it. (If items has fewer than :size elements, some of the slots in the vector will
be left in their initial state. If items has more than
:size elements, an error will ensue.) In this mode, Rvector is
very efficient, but rather inflexible.

(Rvector [1 2 3] :size 3) => #(1 2 3)
(Rvector [#\B #\A #\R] :size 3 :element-type ‘string-char) => "BAR"
(Rvector [1] :size 4 :initial-element 0) => #(1 0 0 0)

If the :size argument is not supplied, then Rvector allows
for the creation of an arbitrarily large vector. It does this by
using vector-push-extend. In order for this to work, it forces
:adjustable to be T and :fill-pointer to be 0 no
matter what is specified in the options-list. In this mode, an
arbitrary number of input elements can be handled, however, things are
much less efficient, since the vector created is not a simple vector.

(Rvector [1 2 3]) => #(1 2 3)
(Rvector []) => #()
(Rvector [#\B #\A #\R] :element-type ‘string-char) => "BAR"

To store a series in a preexisting vector, use alterS of
Evector.

(let ((v '#(a b c)))
  (alterS (Evector v) (Eoss 1 2))
  v) => #(1 2 c)

Rfile name items &rest option-plist => T

This function creates a file named name and writes the elements
of items into it using print. The option-plist can
contain any of the options accepted by open except
:direction which is forced to be :output. All of the ordinary
printer control variables are obeyed during the printout. The value
T is always returned. The option-plist cannot refer to
variables bound by letS.

(Rfile "test.lisp" ['(a) '(1 2) T] :if-exists :append) => T
;;The output "
;;(a)
;;(1 2)
;;T " is printed into the file "test.lisp".

Rlast items &optional (default nil) => item

This function returns the last element of items. If items
is of zero length, default is returned.

(Rlast [a b c]) => c
(Rlast []) 'z) => z

Rlength items => number

This function returns the number of elements in items.

(Rlength [a b c]) => 3
(Rlength []) => 0

Rsum numbers => number

This function computes the sum of the elements in numbers.
These elements must be numbers, but they need not be integers.

(Rsum [1 2 3]) => 6
(Rsum []) => 0
(Rsum [1.1 1.2 1.3]) => 3.6

Rmax numbers => number

This function computes the maximum of the elements in numbers.
These elements must be non-complex numbers, but they need not be integers.
The value nil is returned if numbers has length zero.

(Rmax [2 1 4 3]) => 4
(Rmax []) => nil
(Rmax [1.2 1.1 1.4 1.3]) => 1.4

Rmin numbers => number

This function computes the minimum of the elements in numbers.
These elements must be non-complex numbers, but they need not be integers.
The value nil is returned if numbers has length zero.

(Rmin [2 1 4 3]) => 1
(Rmin []) => nil
(Rmin [1.2 1.1 1.4 1.3]) => 1.1

ReduceF init function items => result

This function is analogous to reduce. In addition, it is similar to TscanF except that init is not optional and the final value of the accumulator is the only value returned as shown in the last example below. If items is of length zero, init is returned. As with TscanF, function must be a non-OSS function and the value of init is typically chosen to be a left identity of function. It is important to remember that the elements of items are used as the second argument of function. The order of arguments is chosen to highlight this fact.

(ReduceF 0 #'+' [1 2 3]) => 6
(ReduceF 0 #'+' []) => 0
(ReduceF 0 #'+' x) == (Rsum x)
(ReduceF init function items) == (letS ((var init))
  (Rlast (TscanF var function items) var))

In order to do reduction without an initial seed value, use Rlast of TscanF. Note that although a seed value does not have to be specified, a value to be returned if there are no elements in items still has to be specified.

(Rlast (TscanF #'max x) nil) == (Rmax x)

Early Reducers

The following four reducers are early terminators. Each of these functions has a non-early variant denoted by the suffix "-late". The early variants are more efficient, because they terminate as soon as they have determined a result. This may be long before any of the input series run out of elements. However, as discussed at the end of this section, one has to be somewhat careful when using an early reducer in an OSS expression.

Rfirst items &optional (default nil) => item

Rfirst-late items &optional (default nil) => item
Both of these functions return the first element of items. If items is of zero length, default is returned. The only difference between the functions is that Rfirst stops immediately after reading the first element of items, while Rfirst-late does not terminate until items runs out of elements.

\[(R\text{first} [a \ b \ c]) \Rightarrow a\]
\[(R\text{first} [\ ] 'z) \Rightarrow z\]

\[\text{Rnth n items &optional (default nil) => item}\]

\[\text{Rnth-late n items &optional (default nil) => item}\]

Both of these functions return the nth element of items. If \(n\) is greater than or equal to the length of items, default is returned. The only difference between the functions is that Rnth stops immediately after reading the nth element of items, while Rnth-late does not terminate until items runs out of elements.

\[(R\text{nth} 1 [a \ b \ c]) \Rightarrow b\]
\[(R\text{nth} 1 [\ ] 'z) \Rightarrow z\]

\[\text{Rand bools => bool}\]

\[\text{Rand-late bools => bool}\]

Both of these functions compute the and of the elements in bools. As with the function and, nil is returned if any element of bools is nil. Otherwise the last element of bools is returned. The value T is returned if bools has length zero. The only difference between the functions is that Rand terminates as soon as a nil is encountered in the input, while Rand-late does not terminate until bools runs out of elements.

\[(R\text{and} [a \ b \ c]) \Rightarrow c\]
\[(R\text{and} [a \ nil \ c]) \Rightarrow nil\]
\[(R\text{and} [\ ] ) \Rightarrow T\]
\[(R\text{and} (\text{pred} (\text{Esequence} x) (\text{Esequence} y))) \Rightarrow (\text{every} #'\text{pred} x y)\]

\[\text{Ror bools => bool}\]

\[\text{Ror-late bools => bool}\]

Both of these functions compute the or of the elements in bools. As with the function or, nil is returned if every element of bools is nil. Otherwise the first non-null element of bools is returned. The value nil is returned if bools has length zero. The only difference between the functions is that Ror terminates as soon as a non-null value is encountered in the input, while Ror-late does not terminate until bools runs out of elements.

\[(R\text{or} [a \ b \ c]) \Rightarrow a\]
\[(R\text{or} [a \ nil \ c]) \Rightarrow a\]
\[(R\text{or} [\ ] ) \Rightarrow nil\]
\[(R\text{or} (\text{pred} (\text{Esequence} x) (\text{Esequence} y))) \Rightarrow (\text{some} #'\text{pred} x y)\]

Care must be taken when using early reducers. As discussed in the section on restrictions, OSS expressions are required to obey the restriction that within each on-line subexpression, there must be a data flow path from each termination point to each output. Early reducers interact with this restriction since early reducers are termination points. As a result, there
must be a data flow path from each early reducer to each output of the containing on-line subexpression.

Since reducers compute non-OSS values, they directly compute outputs of on-line subexpressions. As a result, it is impossible for there to be a data flow path from a reducer to any output other than the output the reducer itself computes. Therefore, the use of an early reducer will trigger code copying unless that reducer computes the only output of the on-line subexpression.

For example, consider the following four expressions. The first two expressions return the same result. However, the first is more efficient. This is a prototypical example of a situation where it is better to use an early reducer. In contrast, although the last two expressions also return the same results, the second of the expressions is more efficient. The problem is that in the first of these expressions, there is no data flow path from the use of Rfirst to the second output. In order to fix this problem the OSS macro package duplicates the list enumeration. It is more efficient to use a non-early reducer as in the last example.

For example, consider the following four expressions. The first two expressions return the same result. However, the first is more efficient. This is a prototypical example of a situation where it is better to use an early reducer. In contrast, although the last two expressions also return the same results, the second of the expressions is more efficient. The problem is that in the first of these expressions, there is no data flow path from the use of Rfirst to the second output. In order to fix this problem the OSS macro package duplicates the list enumeration. It is more efficient to use a non-early reducer as in the last example.

\[
\begin{align*}
\text{(letS ((x (Elist '(1 2 -3 4 5 -6 -7 8))))
\text{ (Rfirst (TselectF #'minusp x))))} & \Rightarrow -3 \\
\text{(letS ((x (Elist '(1 2 -3 4 5 -6 -7 8))))
\text{ (Rfirst-late (TselectF #'minusp x))))} & \Rightarrow -3 \\
\text{(letS ((x (Elist '(1 2 -3 4 5 -6 -7 8)))) ;Signals warning 18
\text{ (valS (Rfirst (TselectF #'minusp x))
\text{ (Rsum x))))} & \Rightarrow -3 4 \\
\text{(letS ((x (Elist '(1 2 -3 4 5 -6 -7 8))))
\text{ (valS (Rfirst-late (TselectF #'minusp x))
\text{ (Rsum x))))} & \Rightarrow -3 4
\end{align*}
\]

Series Variables

The principal way to create OSS variables is to use the form \text{letS.} (These variables are also created by the forms lambdaS and defunS.)

\text{letS var-value-pair-list {decl}* &body expr-list \Rightarrow result}

The form \text{letS} is syntactically analogous to \text{let}. Just as in a \text{let}, the first subform is a list of variable-value pairs. The \text{letS} form defines the scope of these variables and gives them the indicated values. As in a \text{let}, one or more declarations can follow the variable-value pairs. These can be used to specify the types of the variables.

The variables created by \text{letS} can be OSS variables or non-OSS variables. Which are which is determined by the type of the value that is bound to the variable. As in \text{let}, the variables are bound in parallel. In the example below, \text{y} is an OSS variable while \text{x} and \text{z} are non-OSS variables.

\[
\begin{align*}
\text{(letS ((x '(1 2 3))
\text{ (y (Elist '(1 2 3)))
\text{ (z (Rsum (Elist '(1 2 3)))))
\text{ (list x (Rmax y) z)))} & \Rightarrow ((1 2 3) 3 6)
\end{align*}
\]

Unlike \text{let}, \text{letS} does not support degenerate variable-value pairs which consist solely of a variable. (Since \text{letS} variables cannot be assigned to, see below, degenerate pairs...
would be of little value.)

(letS (x) ...) ;Signals error 9

The following example illustrates the use of a declaration in a letS. Declarations are handled in the same way that they are handled in a let.

(letS ((x (Elist '(1 2 3))))
  (declare (type integer x))
  (Rsum x)) => 6

The form letS goes beyond let to include the functionality of multiple-value-bind. A variable in a variable-value pair can be a list of variables instead of a single variable. When this is the case, the variables pick up the first, second, etc. results returned by the value expression. (If there is only one variable, it gets the first value. If nil is used in lieu of a variable, the corresponding value is ignored.) If there are fewer variables than values, the extra values are ignored. Unlike multiple-value-bind, letS signals an error if there are more variables than values. (Note that there is no form multiple-value-bindS and that the form multiple-value-bind cannot be used inside of an OSS expression to bind the results of an OSS function.)

(letS (((key value) (Ealist '((a . 1) (b . 2))))
  (Rlist (list key value))) => ((a 1) (b 2))

(letS (((key (Ealist '((a . 1) (b . 2))))
  (Rlist key)) => (a b)

(letS (((nil value) (Ealist '((a . 1) (b . 2))))
  (Rlist value)) => (a b)

(letS (((key value x) (Ealist '((a . 1) (b . 2))))
  (Rlist (list key value x))) => ;Signals error 8

The expr-list of a letS has the effect of grouping several OSS expressions together. The value of the last form in the expr-list is returned as the value of the letS. This value may be an OSS value or a non-OSS value.

In addition to placing all of the expressions in the same letS binding scope, the grouping imposed by the expr-list causes the entire body to become an OSS expression. This can alter the way implicit mapping is applied by including non-OSS functions in the OSS expression.

The restricted nature of OSS variables. There are a number of ways in which the variables bound by letS (or lambdaS and defunS) are more restricted than the ones bound by let. For the most part, these restrictions stem from the fact that when the OSS macro package transforms an OSS expression into a loop, it rearranges the expressions extensively. This forces letS variable scopes to be supported by variable renaming rather than binding. One result of this is that it is not possible to declare (or proclaim) a letS variable to be special. (Standard Common Lisp does not provide any method for determining whether or not a variable has been proclaimed special. As a result, the OSS macro package is unable to issue an error message when a special letS variable is encountered. The Symbolics Common Lisp version of the OSS macro package does issue an error message.)

(proclaim '(special z))
(letS ((z (Elist '(1 2 3)))) (Rsum z)) ;erroneous expression
Another limitation is that programmers are not allowed to assign values to letS variables in the body of a letS. (This restriction applies whether or not the variables contain OSS values.) The only time letS variables can be given a value is the moment they are bound. (Although assignment could be supported easily enough, the rearrangements introduced by the OSS macro package would make it very confusing for a programmer to figure out exactly what would happen in a given situation. In particular, naively applying implicit mapping to setq would lead to peculiar results. In addition, outlawing assignments enhances the functional nature of the OSS macro package.) An error message is issued whenever such an assignment is attempted.

\[
\begin{align*}
\text{letS*} & \text{ var-value-pair-list } \{\text{decl}\}^* & \& \text{body expr-list} & \Rightarrow \text{result} \\
\text{letS*} & \Rightarrow \text{LET*} \\
\end{align*}
\]

Another aspect of letS variables is that their scope is somewhat limited. In particular, letS variables can be referenced in a letS or mapS which is inside the letS which binds them. However, they cannot be referenced in lambda or lambdaS. (As above, this limitation is imposed in order to avoid confusions due to rearrangements. Further, it is not obvious what it would mean to refer to an OSS variable in a lambda. Should some sort of implicit mapping be applied?) No attempt is made to issue error messages in this situation. Rather, the variable reference in question is merely treated as a free variable.

\[
\begin{align*}
\text{letS} & \Rightarrow \text{LET} \\
\text{letS*} & \Rightarrow \text{LET*} \\
\end{align*}
\]

As shown below, prognS is identical to letS except that it cannot contain any variable-value pairs or declarations. It is a degenerate form whose only function is to delineate an OSS expression. This can alter the way implicit mapping is applied by including non-OSS functions in the OSS expression.

\[
\begin{align*}
\text{prognS} & \Rightarrow \text{result} \\
\end{align*}
\]

Complete OSS expressions do not return OSS values. A key point relevant to the discussion above is that syntactically complete OSS expressions are not allowed to return OSS values. This is relevant, because letS and prognS are often used in such a way that an OSS series gratuitously ends up as the return value. For example, the main intent of the expression below is to print out the elements of the list. However, as written, the expression appears to return an OSS series of the values produced by prin1. Because expressions like the one below are relatively common, it was decided not to issue an error message in this situation. Rather, the OSS value is simply discarded and no value is returned.
\begin{verbatim}
(prognS (prin1 (Elist '(1 2)))) =>
;;The output "12" is printed.

It might be the case that the programmer actually desires to have a
physical series returned in the example above. This can be done by
using a reducer such as Rlist or Rvector as shown below.

(prognS (Rlist (prin1 (Elist '(1 2))))) => (1 2)
;;The output "12" is printed.

Preventing complete OSS expressions from returning OSS values does not
limit what can be written, because programmers can always return a
non-OSS series. This can be a bit cumbersome at times, but it is
highly preferable to the large inefficiencies which would be
introduced by automatically constructing physical representations for
OSS series in situations where the returned values are not used in
further computation.

Coercion of Non-Series to Series

If an OSS input of an OSS function is applied to a non-series value, the
type conflict is resolved by converting the non-OSS value into a series
by inserting Eoss. That is to say, a non-OSS value acts the same
as an unbounded OSS series of the value.

(Ralist (Elist '(a b)) (* 2 3))
== (Ralist (Elist '(a b)) (Eoss :R (* 2 3))) => ((a . 6) (b . 6))

Using Boss to coerce a non-OSS value to an OSS series has the
effect of only evaluating the expression which computes the value
once. This has many advantages with regard to efficiency, but may not
always be what is desired. Multiple evaluation can be specified by
using TmapF or mapS.

(Ralist (Elist '(a b)) (gensym)) => ((a . #:G004) (b . #:G004))

(Ralist (Elist '(a b)) (TmapF #'gensym)) => ((a . #:G004) (b . #:G005))

Implicit Mapping

Mapping operations can be created by using TmapF. However, in the
interest of convenience, two other ways of creating mapping operations
are supported. The most prominent of these is implicit mapping. If a
non-OSS function appears in an OSS expression and is applied to one or
more arguments which are OSS series, the type conflict is resolved by
automatically mapping the function over these series.

(Rsum (car (Elist '((1) (2)))))
== (Rsum (TmapF #'car (Elist '((1) (2))))) => 3

(Rsum (* 2 (Elist '(1 2))))
== (Rsum (TmapF '#'(lambda (x) (* 2 x)) (Elist '(1 2))))) => 6

As shown in the second example, implicit mapping actually applies to
entire non-OSS subexpressions rather than merely to individual
functions. This promotes efficiency and makes sure that related
groups of functions are mapped together. However, it is not always
what is desired. For instance, in the first example below, the call
on gensym gets mapped in conjunction with the call on
list. This causes each list to contain a separate gensym
variable. It might be the case that the programmer wants to have the
same gensym variable in each list. This can be achieved by
inserting an Eoss as shown in the second example. (Inserting a
Boss here and there can promote efficiency by avoiding
\end{verbatim}
unnecessary recomputation.)

(Rlist (list (Elist '(a b)) (gensym)))
== (Rlist (TmapF #'(lambda (x) (list x (gensym))))
       (Elist '(a b)))) => ((a #:G002) (b #:G003))

(Rlist (list (Elist '(a b)) (Eoss :R (gensym))))
== (Rlist (TmapF #'list
       (Elist '(a b))
       (Eoss :R (gensym)))) => ((a #:G002) (b #:G002))

In order to be implicitly mapped, a non-OSS function must appear inside
of an OSS expression. For example, the instance of prin1 in the
first example below does not get implicitly mapped, because it is not
in an OSS expression. Implicit mapping of the prin1 can be
forced by using progNS as shown in the second example above.

(prin1 (Elist '(1 2))) => nil
;;The output "NIL" is printed.

(prognS (prin1 (Elist '(1 2)))) =>
;;The output "12" is printed.

(The result of the first example above is that NIL gets
printed. This happens because (Elist '(1 2 3)) is a
syntactically complete OSS expression and is therefore not allowed to
return a series. It returns no values instead. The function
prin1 demands a value anyway, and gets nil.)

Another aspect of implicit mapping is that a non-OSS function will not
be mapped unless it is applied to a series. This is usually, but not
always, what is desired. Consider the first expression below. The
instance of prin1 is mapped over x. However, the instance
of princ is not applied to a series and is therefore not mapped.
If the programmer intends to print a dash after each number, he has to
do something in order to get the princ to be mapped. This could
be done using TmapF or mapS. However, the best thing to
do is to group the two printing statements into a single subexpression
as shown in either of the last two examples below. This grouping
shows the relationship between the printing operations and causes them
to be mapped together.

(letS ((x (Elist '(1 2 3))))
   (prin1 x)
   (princ "]-")) => ";-"
;;The output "123-" is printed.

(letS ((x (Elist '(1 2 3))))
   (progn (prin1 x) (princ "]-"))) =>
;;The output "1-2-3-" is printed.

(letS ((x (Elist '(1 2 3))))
   (format T "]-A-" x)) =>
;;The output "1-2-3-" is printed

Ugly details.
Implicit mapping is easy to understand when applied in simple
situations such as the ones above. However, it can be applied to any
Lisp form. Things become somewhat more complicated when control
constructs (e.g., if) and binding constructs (e.g., let)
are encountered. The example below shows the implicit mapping of an
if. This creates a lambda expression containing a
conditional which is mapped over a series. A key thing to notice in
this example is that implicit mapping of if is very different
from a use of Tselect. In particular, the mapped if returns a value corresponding to every input, while the Tselect does not.

(Rlist (if (plusp (Elist '(10 -11 12))) (Eup)))
  ==( (Rlist (TmapF #'(lambda (x y) (if (plusp x) y))
               (Elist '(10 -11 12)) (Eup))) => (0 nil 2)

(Rlist (Tselect (plusp (Elist '(10 -11 12))) (Eup))) => (0 2)

Another aspect of the way conditionals are handled inside of an OSS expression is illustrated below. When an OSS expression is being processed in order to determine what should be implicitly mapped, the expression is broken up into OSS pieces and non-OSS pieces. If the argument of a conditional is an OSS expression, this argument will end up in a separate piece from the conditional itself. One result of this is that the argument will always be evaluated and the conditional will therefore lose its power to control when the argument should be evaluated. This effect will happen even if, as in the example below, the conditional does not have to be mapped. The three examples below all produce the same value, but the first two always evaluate (Rlist (abs (Elist x))) while the last may not.

(prognS (if (Ror (minusp (Elist x)))
  (Rlist (abs (Elist x)))
  x))
  ==( (prognS (funcall #'(lambda (y z) (if y z x))
                   (Ror (minusp (Elist x)))
                   (Rlist (abs (Elist x)))))

not= (if (Ror (minusp (Elist x)))
  (Rlist (abs (Elist x))))
  x)

The following example shows the implicit mapping of a let. (Among other things, this illustrates that such expressions are far from clear. In general it is better to use letS as in the second example.)

(Rlist (let ((double (* 2 (Elist '(1 2))))) (* double double)))
  ==( (Rlist (TmapF #'(lambda (x)
               (let ((double (* 2 x))) (* double double)))
               (Elist '(1 2))) => (4 16)

(letS ((double (* 2 (Elist '(1 2)))))
  (Rlist (* double double))) => (4 16)

A problem with the implicit mapping of a let (or other binding forms) is that the implicit mapping transformation potentially moves subexpressions out of the scope of the binding form in question. This can change the meaning of the expression if any of these subexpressions contain an instance of a variable bound by the binding form. For instance, in the example above, the transformation moves the subexpression (Elist '(1 2)) out of the scope of the let. This would cause a problem if this subexpression referred to the variable double.

In recognition of this problem, a warning message is issued whenever implicit mapping of a binding form causes a variable reference to move out of a form that binds it. Whenever it occurs, this problem can be alleviated by using letS as shown above.

A final complexity involves forms like return, return-from, throw, etc. These forms are implicitly mapped like any other non-OSS form. When they get evaluated, they will cause
an exit. However, the loop produced by the OSS macro does not contain a boundary which is recognized by any of these forms (e.g., it does not create a proog or catch). As a result, such a boundary must be defined which will serve as the reference point. Needless to say, the final results of the OSS expression will not be computed if the expression is exited in this way.

Nested loops.
Implicit mapping is applied when non-OSS functions receive OSS values. However, implicit mapping is not applied when OSS functions receive OSS values, even if these values are passed to non-OSS inputs. As illustrated below, whenever this situation occurs, an error message is issued.

(Elist (Elist '((1 2) (3 4)))) ;Signals error 14

There are situations corresponding to nested loops where it would be reasonable to implicitly map subexpressions containing OSS functions. For example, one might write the following expression in order to copy a list of lists.

(Rlist (Rlist (Elist (Elist '((1 2) (3 4)))))) ;Signals error 14
(Rlist (TmapF #'(lambda (x) (Rlist (Elist x)))
          (Elist '((1 2) (3 4)))))) => ((1 2) (3 4))

Nevertheless, expressions like the first one above are forbidden. This is done for two reasons. First, in more complex situations OSS expressions corresponding to nested loops become so confusing that such expressions are very hard to understand. As a result, they are not very useful. Second, experience suggests that a large proportion of situations where mapping of OSS functions might be done arise from programming errors rather than an intention to have a nested loop. Outlawing these expressions makes it possible to find these errors more quickly.

(The following example shows that there is no problem with having one loop computation following another. There are no type conflicts in this situation and no implicit mapping is required.)

(Rsum (Evector (Rvector (Elist '(1 2)))))) => 3

 Needless to say, it would be unreasonable if there were no way to write OSS expressions corresponding to nested loops. First of all, this can always be done using TmapF as shown above. However, this can be rather cumbersome. To alleviate this difficulty, an additional form (mapS) is introduced which facilitates the expression of nested computations.

mapS &body expr-list => items

The expr-list consists of one or more expressions. These expressions are treated as the body of a function and mapped over any free OSS variables which appear in them. That is to say, the first element of the output is computed by evaluating the expressions in an environment where each OSS variable is bound to the first element of the corresponding series. The second element of the output is computed by evaluating the expressions in an environment where each OSS variable is bound to the second element of the corresponding series, etc. The way mapS could be used to copy a list-of-lists is shown below. A letS has to be used, because mapS requires that the series being mapped over must be held in a variable.

(letS ((z (Elist '((1 2) (3 4))))
          (Rlist (mapS (Rlist (Elist z)))))

The following example shows that there is no problem with having one loop computation following another. There are no type conflicts in this situation and no implicit mapping is required.

 Implicit mapping is very valuable. From the above, it can be seen that although implicit mapping is simple in simple situations, there are a number of situations where it becomes quite complex. There is no question that these complexities dilute the value of implicit mapping. Nevertheless, experience suggests that implicit mapping is so valuable that, warts and all, it is perhaps the most useful single feature of OSS expressions.

Literal Series Functions

Just as it is very convenient to be able to specify a literal non-OSS function using lambda, it is sometimes convenient to be able to specify a literal OSS function.

**lambdaS** var-list {decl}* &body expr-list

The form lambdaS is analogous to lambda except that some of the arguments can have OSS series passed to them and the return value can be an OSS series. The var-list is simpler than the lambda lists which are supported by lambda. In particular, the var-list must consist solely of variable names. It cannot contain any of the lambda list keywords such as &optional and &rest. As in a letS, the variables in the var-list cannot be assigned to in the expr-list or referenced inside of a nested lambda or lambdaS.

As in a lambda, the body can begin with one or more declarations. All of the arguments which are to receive OSS values have to be declared inside the lambdaS using the declaration type oss (see below). All of the other arguments are assumed to correspond to non-OSS values. Just as in a letS, the declarations may contain other kinds of declarations besides type oss declarations. However, the variables in the var-list cannot be declared (or proclaimed) to be special.

The expr-list is a list of expressions which are grouped together into an OSS expression as in a letS or prognS. The value of the function specified by a lambdaS is the value of the last form in the expr-list. This value may or may not be an OSS series.

In many ways, lambdaS bears the same relationship to letS that lambda bears to let. However, there is one key difference. The expr-list in a lambdaS cannot refer to any free variables which are bound by a letS, defunS, or another lambdaS. Each lambdaS is processed in complete isolation from the OSS expression which surrounds it. The only values which can enter or leave a lambdaS are specified by the var-list and non-OSS variables which are bound outside of the entire containing OSS expression.

Another key feature of lambdaS is that the only place where it can validly appear is as the quoted first argument of funcallS (see below), or as an argument to a macro which will eventually expand in such a way that the lambdaS will end up as the quoted first argument of a funcallS.
The following example illustrates the use of lambdaS. It shows an anonymous OSS function identical to Rsum.

\[
(f\text{uncallS} \ #'(\text{lambdaS} (x) \\
(\text{declare (type oss x)}) \\
(\text{ReduceF} 0 \ #'+ x)) \\
(\text{Elist} \ '(1 2 3))) \Rightarrow 6
\]

\text{type oss \&rest variable-list}

This type declaration can only be used inside of a declare inside of a lambdaS or a defunS. It specifies that the variables carry OSS values.

\text{funcallS \ function \&rest expr-list => result}

This is analogous to funcall except that function can be an OSS function. In particular, it can be the quoted name of a series function, a quoted lambdaS, or a macro call which expands into either of the above. It is also possible for function to be a non-OSS function, in which case funcallS is identical to TmapF. If function is an expression which evaluates to a function (as opposed to a literal function), then it is assumed to be a non-OSS function.

\[
(f\text{uncallS} \ #'(\text{Elist} \ '(1 2))) \Rightarrow (\text{Elist} \ '(1 2)) \Rightarrow [1 2] \\
(f\text{uncallS} \ #'(\text{lambdaS} (y) \ (\text{declare (type oss y)}) \ (* \ 2 \ y)) \\
(\text{Elist} \ '(1 2))) \Rightarrow [2 4] \\
(f\text{uncallS} \ #'\text{car} [(1) (2)]) \Rightarrow [1 2] \\
(f\text{uncallS} \ #'\text{car} \ '(1 2)) \Rightarrow [1 1 1 1 \ldots]
\]

The number of expressions in expr-list must be exactly the same as the number of arguments expected by function. If not, an error message is issued. In addition, the types of values (either OSS series or not) returned by the expressions should be the same as the types which are expected by function. If not, coercion of non-series to series will be applied if possible in order to resolve the conflict.

\text{Defining Series Functions}

An important aspect of the OSS macro package is that it makes it easy for programmers to define new OSS functions. Straightforward OSS functions can be defined using the facilities outlined below. More complex OSS functions can be defined using the subprimitive facilities described in [6].

\text{defunS \ name \ lambda-list \{doc\} \{decl\}* \&body expr-list}

This is analogous to defun, but for OSS functions. At a simple level, defunS is just syntactic sugar which defines a macro that creates a funcallS of a lambdaS. The lambda-list, declarations, and expression list are restricted in exactly the same way as in a lambdaS except that the standard lambda list keywords &optional and &key are allowed in the lambda-list.

\[
(\text{defunS} \ \text{Rlast} \ \text{(items \&optional (default nil))} \\
"\text{Returns the last element of an OSS series}" \\
(\text{declare (type oss items)}) \\
(\text{ReduceF} \ \text{default \#'(lambda (state x) x) items}) \\
== (\text{defmacro Rlast \items \&optional (default \'nil)}) \\
"\text{Returns the last element of an OSS series}"
\]
'(funcallS #'(lambdaS (items default)
   (declare (type oss items))
   (ReduceF default #'(lambda (state x) x) items))
   ,items ,default))

However, at a deeper level, there is a key additional aspect to defunS. Preprocessing and checking of the resulting lambdaS is performed when the defunS is evaluated (or compiled), rather than when the resulting OSS function is used. This saves time when the function is used. More importantly, it leads to better error messages because error messages can be issued when the defunS is initially encountered, rather than when the OSS function defined is used.

Although the lambda list keywords &optional and &key are supported by defunS, it should be realized that they are supported in the way they are supported by macros, not the way they are supported by functions. In particular, when keywords are used in a call on the OSS function being defined, they have to be literal keywords rather than computed by an expression. In addition, initialization forms cannot refer to the run-time values of other arguments, because these are not available at macro-expansion-time. They are also not allowed to refer to the macro-expansion-time values of the other arguments. They must stand by themselves when computing a value. A quote is inserted so that this value will be computed at run-time rather than at macro-expansion-time. (In the example above, (default nil) becomes (default 'nil).)

It may seem unduly restrictive that defunS does not support all of the standard keywords in lambda-list. However, this is not that much of a problem because defmacro can be used directly in situations where these capabilities are desired. For example, Tconcatenate is defined in terms of a more primitive OSS function Tconcatenate2 as follows.

(defun Tconcatenate (Oitems1 Oitems2 &rest more-Oitems)
  (if (null more-Oitems)
      '(Tconcatenate2 ,Oitems1 ,Oitems2)
      '(Tconcatenate2 ,Oitems1 (Tconcatenate ,Oitems2 .,more-Oitems))))

Using defmacro directly also makes it possible to define new higher-order OSS functions. For example, an OSS function analogous to substitute-if could be defined as follows. (The Eoss ensures that newitem will only be evaluated once.)

(defun Osubstitute-if (newitem test items)
  (let ((var (gensym)))
    '(letS ((,var ,items))
      (if (funcall ,test ,var) (Eoss :R ,newitem) ,var))))

(Osubstitute-if 3 #'minusp [1 -1 2 -3]) => [1 3 2 3]

Multiple Values

The OSS macro package supports multiple values in a number of contexts. As discussed above, letS can be used to bind variables to multiple values returned by an OSS function. Faculties are also provided for defining OSS functions which return multiple values. The support for multiple values is complicated by the fact that the OSS macro package implements all communication of values by using variables. As a result, it is not possible to support the standard Common Lisp feature that multiple values can coexist with single values without the programmer having to pay much attention to what is going on. When using OSS expressions, the programmer has to be
explicit about how many values are being passed around.

\texttt{vals} &rest expr-list => &rest multiple-value-result

This is analogous to values except that it can operate on OSS values. It takes in the values returned by \( n \) different expressions and returns them as \( n \) multiple values. It enforces the restriction that the values must either all be OSS values or all be non-OSS values. The following example shows how a simple version of Eplist could be defined.

\begin{verbatim}
(defun simple-Eplist (place)
  (let ((plist (EnumerateF place #'cddr #'null)))
    (vals (car plist) (cadr plist))))
\end{verbatim}

It is possible to use values in an OSS expression. However, the results will be very different from the results obtained from using \texttt{vals}. The values will be implicitly mapped like any other non-OSS form. The value ultimately returned will be the single value returned by \texttt{TmapF}.

\begin{verbatim}
(progn (vals (Elist '(1 2)) (Elist '(3 4)))) => [1 2] [3 4]
(progn (values (Elist '(1 2)) (Elist '(3 4)))) == (progn (TmapF #'(lambda (x y) (values x y))
               (Elist '(1 2)) (Elist '(3 4)))) => [1 2]
\end{verbatim}

\texttt{pass-vals} n expr => &rest multiple-value-result

This function is used essentially as a declaration. It tells the OSS macro package that the form expr returns n multiple values which the programmer wishes to have preserved in the context of the OSS expression. (This is needed, because Common Lisp does not provide any compile-time way to determine the number of arguments that a function will return.) The first example below enumerates a list of symbols and returns a list of the internal symbols, if any, which correspond to them. The second example defines a two valued OSS function which locates symbols.

\begin{verbatim}
(let* ((names (Elist '(zots Elist zorch)))
       ((symbols statuses) (pass-vals 2 (find-symbol (string names))))
       (internal-symbols (Tselect (eq statuses :internal) symbols)))
  (Rlist internal-symbols)) => (zots zorch)
\end{verbatim}

\begin{verbatim}
(defun find-symbols (names)
  (declare (type oss names))
  (pass-vals 2 (find-symbol (string names))))

(find-symbols [zots Elist zorch]) => [zots Elist zorch] [:internal :inherited :internal]
\end{verbatim}

The form \texttt{pass-vals} never has to be used in conjunction with an OSS function, because the OSS macro package knows how many values every OSS function returns. Similarly, \texttt{pass-vals} never has to be used when multiple values are being bound by \texttt{letS}, because the syntax of the \texttt{letS} indicates how many values are returned. (As a result, the \texttt{pass-vals} in the first example above is not necessary.) However, in situations such as the second example above, \texttt{pass-vals} must be used.

\textbf{Alteration of Values}

The transformations introduced by the OSS macro package are inherently antagonistic to the transformations introduced by the macro \texttt{setf}. In particular, OSS function calls cannot be used as the
destination of a setf. In order to get around this problem, the OSS macro package supports a separate construct which is in fact more powerful than setf.

alterS destinations items => items

This form takes in a series of destinations and a series of items and stores the items in the destinations. It returns the series of items. Like setf, alterS cannot be applied to a destination unless there is an associated definition for what should be done (see the discussion of alterableS in [6]). The outputs of the predefined functions Elist, Ealist, Eplist, Efringe, Evector, and Esequence are alterable. The effects of this alteration are illustrated in conjunction with the descriptions of these functions. For example, the following sets all of the elements in a list to nil.

(let ((list '((a . 1) (b . 2) (c . 3))))
  (alterS (Elist list) nil)
list) => (nil nil nil)

As a related example, consider the following. Although setf cannot be applied to an OSS function, it can be applied to a non-OSS function in an OSS expression. In the example below, setf is used to set the cdr of each element of a list to nil.

(let ((list '((a . 1) (b . 2) (c . 3))))
  (prognS (setf (cdr (Elist list)) nil))
list) => ((a) (b) (c))

A key feature of alterS is that (in contrast to setf) a structure can be altered by applying alterS to a variable which contains enumerated elements of the structure. This is useful because the old value in a structure can be used to decide what new value should be put in the structure. (When alterS is applied to such a variable it modifies the structure being enumerated but does not change the value of the variable.)

(letS* ((v '#(1 2 3))
  (x (Evector v)))
(alterS x (* x x))
(valS (Rlist x) v)) => (1 2 3) #(1 4 9)

Another interesting aspect of alterS is that it can be applied to the outputs of a number of transducers. This is possible whenever a transducer passes through unchanged a series of values taken from an input which is itself alterable. This can happen with the transducers Tuntil, TuntilF, Tcotruncate, Tremove-duplicates, Tsubseries, Tselect, TselectF, Tsplit, and TsplitF. For example, the following takes the absolute value of the elements of a vector.

(letS* ((v '#(1 -2 3))
  (x (TselectF #'minusp (Evector v)))
(alterS x (- x))
v) => #(1 2 3)

Debugging

The OSS macro package supports a number of features which are intended to facilitate debugging. One example of this is the fact that the macro package tries to use the variable names which are bound by a letS in the code produced. Since the macro package is forced to use variable renaming in order to implement variable scoping, it cannot guarantee that these variable names will be used. However, there is a high probability that they will. If a break occurs in the
middle of an OSS expression, these variables can be inspected in order
to determine what is going on. If a letS variable holds an OSS series,
then the variable will contain the current element of the series.
For example, the OSS expression below is transformed
into the loop shown. (For a discussion of how this transformation is
performed see [6].)

(lets* ((v (get-vector user))
   (x (Evector v)))
   (Rsum x))

(let (#:index-9 #:last-8 #:sum-2 x v)
   (setq v (get-vector user))
   (tagbody (setq #:index-9 -1)
      (setq #:last-8 (length v))
      (setq #:sum-2 0)
      #:L-1 (incf #:index-9)
      (if (not (< #:index-9 #:last-8)) (go oss:END))
      (setq x (aref v #:index-9))
      (setq #:sum-2 (+ #:sum-2 x))
      (go #:L-1)
   oss:END)
#:sum-2)

showS thing &optional (format "-%S") (stream *standard-output*) => thing

This function is convenient for printing out debugging information
while an OSS expression is being evaluated. It can be wrapped around
any expression no matter whether it produces an OSS value or a non-OSS
value without disturbing the containing expression. The function
prints out the value and then returns it. If the value is a non-OSS
ting without disturbing the containing expression. The function
prints out the value and then returns it. If the value is a non-OSS
thing, it will be printed out once at the time it is created. If it
is an OSS series thing, it will be printed out an element at a time.
The format can be used to print a tag in order to identify the
value being shown.

(showS format stream)
== (let ((x thing)) (format stream format x) x)

(letS ((x (Elist '(1 2 3))))
   (Rsum (showS x "Item: ~A, ")) => 6
   ;;The output "Item: 1, Item: 2, Item: 3, " is printed.

*permit-non-terminating-oss-expressions*

On the theory that non-terminating loops are seldom desired, the
OSS macro package checks each loop constructed to see if it can
terminate. If this control variable is nil (which is the
default), then a warning message is issued for each loop which the OSS
macro package thinks has no possibility of terminating. This is
useful in the first example below, but not in the second. The form
compiler-let can be used to bind this control variable to
T around such an expression.

(Rlist 4)                   ;Signals warning 15
(block bar                 ;Signals warning 15
   (letS ((x (Eup :by 10)))
      (if (> x 15) (return-from bar x))) => 20

(compiler-let ((*permit-non-terminating-oss-expressions* T))
   (block bar
      (letS ((x (Eup :by 10)))
         (if (> x 15) (return-from bar x)))) => 20
*last-oss-loop*

This variable contains the loop most recently produced by the OSS macro package. After evaluating (or macro-expanding) an OSS expression, this variable can be inspected in order to see the code which was produced.

*last-oss-error*

This variable contains the most recently printed warning or error message produced by the OSS macro package. The information in this variable can be useful for tracking down errors.

Side-Effects

The OSS macro package works by converting each OSS expression into a loop. This allows the expressions to be evaluated very efficiently, but radically changes the order in which computations are performed. In addition, off-line ports are supported by code motion. Given all of these changes, it is not surprising that OSS expressions are primarily intended to be used in situations where there are no side-effects. Due to the change in computation order, it can be hard to figure out what the result of a side-effect will be.

Nevertheless, since side-effects (particularly in the form of input and output) are an inevitable part of programming, several steps are taken in order to make the behavior of OSS expressions containing side-effect operations as easy to understand as possible. First, when implicit mapping is applied, it is applied to as large a subexpression as possible. This makes it straightforward to understand the interaction of the side-effects within a single mapped subexpression. Several examples of this are given in the section above which discusses implicit mapping.

Second, wherever possible, the OSS macro package leaves the order of evaluation of the OSS functions in an expression unchanged. Each function is evaluated incrementally an element at a time, but on each cycle, the processing follows the syntactic ordering of the functions in the expression.

The one place where order changes are required is when handling off-line ports. However, things are simplified here by ensuring that the evaluation order implied by the order of the inputs of an off-line function is preserved.

Third, when determining whether or not each termination point is connected to every output in each on-line subexpression, functions whose outputs are not used for anything are considered to be outputs of the subexpression. The reasoning behind this is that if the outputs are not used for anything, then the function must be being used for side-effect and probably matters that the function get evaluated the full number of times it should be. For example, consider the expressions below. The first expression prints out the numbers in a list and returns the first negative number. The second expression signals a warning and the enumeration of the list is duplicated so that the prin is will be applied to all of the elements of the list.

(letS* ((x (Elist '(1 2 3 -4 5))))
  (princ x)
  (Rfirst-passive (TselectF '#`minusp x))) => -4
  ;;The output "123-45" printed.

(letS* ((x (Elist '(1 2 3 -4 5)))) ;Signals warning 10
(princ x)
  (Rfirst (TselectF '#'minusp x))) => -4
;;The output "123-45" printed.

3. Bibliography

4. Warning and Error Messages

In order to facilitate the debugging of OSS expressions, this section discusses the various warning and error messages which can be issued by the OSS macro package while processing the functions described in this document. Error messages describe problems in OSS expressions which make it impossible to process the expression correctly. Warning messages identify less serious situations which are worthy of programmer scrutiny, but which do not prevent the expression from being processed in a way which is, at least probably, correct.

Warning and error messages are both printed out in the following format. Error messages (as opposed to warnings) can be identified by the fact that the word "Error" precedes the message number. (The format is shown as it appears on the Symbolics Lisp machine and may differ in minor ways in other systems.)

Warning: {Error} message-number in OSS expression:
containing OSS expression
detailed message

For example, the following error message might be printed.

Warning: Error 1.1 in OSS expression:
(LET ((X (ELIST NUMBER-LIST))
     (Y (EUP (CAR HEADER) :TO 4 :LENGTH 5)))
     (RLIST (LIST Y X)))
Too many keywords specified in a call on Eup:
(EUP (CAR HEADER) :TO 4 :LENGTH 5)

The first line of each message specifies the number of the warning or error. This number is useful for looking up further information in the documentation below. The next part of the message shows the complete OSS expression which contains the problem. This makes it easier to locate the problem in a program. The remainder of the message describes the particular problem in detail. (The variable *last-oss-error* contains a list of the information which was used to print out the most recent warning or error message.)

The OSS macro package reports problems using warn so that processing of other parts of a program can continue, potentially finding other problems. However, each time an OSS error (as opposed to a warning) is detected, the OSS macro package skips over the rest of the OSS expression without performing any additional checks. Therefore, even if there are several OSS errors in an OSS expression, only one OSS error will be reported. When an OSS error is found, a dummy value is inserted in place of the erroneous OSS expression. As a result, it is virtually impossible for the containing program to run correctly.

The documentation below describes each of the messages which the OSS macro package can produce. Each description begins with a header line containing a schematic rendition of the message. Italics is used to indicate pieces of specific information which are inserted in the message. The number of the warning or error is shown in the left margin at the beginning of the header. For ease of reference, the messages are described in numerical order.

Local errors concerning single OSS functions. The following error messages report errors which are local in that they stem purely from the improper use of a single OSS function. These errors cover only a few special situations. Many (if not most) local errors are reported directly by the standard Common Lisp processor rather than by the OSS macro package. For example, if an OSS function
is used with the wrong number of arguments, an error message is issued by the standard macro expander.

1.1 Error: Too many keywords specified in call on Eup: call
1.2 Error: Too many keywords specified in call on Edown: call
1.3 Error: Too many keywords specified in call on Tlatch: call

Each of these errors specifies that incompatible keywords have been provided for the indicated function. The entire function call is printed out as shown above.

2 Error: Invalid enumerator arg to TconcatenateF: enumerator

This error is issued if the enumerator argument to TconcatenateF fails to be an enumerator---i.e., fails to be an OSS function that has no OSS inputs, at least one OSS output, and which can terminate.

3 Error: Unsupported &-keyword keyword in defunS arglist.

This error is issued if an &-keyword other than &optional or &key appears in the argument list of defunS. Other keywords have to be supported by using defmacro directly. (See the discussion of defunS.)

4 Error: AlterS applied to an unalterable form: call

This error is issued if alterS is applied to a value which is not alterable. Values are alterable only if they come directly from an enumerator which has an alterable value, or come indirectly from such an enumerator via one or more transducers which allow alterability to pass through.

5 Error: Malformed lambdaS argument arg.

This error message is issued if an argument of a lambdaS fails to be a valid variable. In particular, it is issued if the argument, is not a symbol, is T or nil, is a symbol in the keyword package, or is an &-keyword. (It is also erroneous for such a variable to be declared special. However, this error is only reported on the Symbolics Lisp Machine.)

6 Error: LambdaS used in inappropriate context: call

This error message is issued if a lambdaS ends up (after macro expansion of the surrounding code) being used in any context other than as the quoted first argument of a funcallS.

7 Error: Wrong number of args to funcallS: call

This error message is issued if a use of funcallS does not contain a number of arguments which is compatible with the number of arguments expected by the OSS functional argument.

8 Error: Only n return values present where m expected: call

This error message is issued if an OSS function is used in a situation where it is expected to return more values than it actually does---for example, if a letS tries to bind two values from an OSS function which only returns one, or pass-valS tries to obtain two values from an OSS function which only returns one. (Non-OSS functions return extra values of nil if they are requested to produce more values than they actually do.)
Warnings and errors concerning OSS variables.
The following warnings and errors concern the creation and use of letS and lambdaS variables. Like the errors above, they are quite local in nature and relatively easy to fix.

9 Error: Malformed letS{*} binding pair pair.
This error message is issued if a letS or letS* binding pair fails to be either a list of a valid variable and a value, or a list of a list of valid variables and a value. The criterion for what makes a variable valid is the same as the one used in Error 5, except that a binding pair can contain nil instead of a variable.

10 Warning: The variable(s) vars declared TYPE OSS in a letS{*}.
This warning message is issued if one or more variables in a letS are explicitly declared to be of type oss. The explicit declarations are ignored.

11 Warning: The letS{*} variable variable is unused in: call
This warning message is issued if a variable in a letS is never referenced in the body of the letS. Note that these variables cannot be referenced inside a nested lambda or lambdaS.

12 Error: The letS{*} variable var setq'd.
This error message is issued if a letS variable (either OSS or non-OSS) is assigned to in the body of a letS. It is also issued if any of the variables bound by a lambdaS or defunS are assigned to.

Non-local warnings and errors concerning complete OSS expressions. The following warnings and errors concern non-local problems in OSS expressions. The first two are discussed in further detail in the section on implicit mapping.

13 Warning: Decomposition moves: code out of a binding scope: surround
This warning is issued if the processing preparatory to implicit mapping causes a subexpression to be moved out of the binding scope for one of the variables in it. The problem can be fixed by using letS to create the binding scope, or by moving the binding form so that it surrounds the entire OSS expression. (The testing for this problem is somewhat approximate in nature. It can miss some erroneous situations and can complain in some situations where there is no problem. Due to this latter difficulty, the OSS macro package merely issues a warning message rather than issuing an error message.)

14 Error: OSS value carried to non-OSS input by data flow from: call to: call
As illustrated below, this error is issued whenever data flow connects an OSS output to a non-OSS input of an OSS function as in the example below. (If the expression in question is intended to contain a nested loop, the error can be fixed by wrapping the nested portion in a mapS.)

Warning: Error 14 in OSS expression:
(Rlist (Rlist (Elist (Elist '((1 2) (3 4)))))))
OSS value carried to non-OSS input by data flow from:
(Elist '((1 2) (3 4)))
to:
(Elist (Elist '((1 2) (3 4))))
The error message prints out two pieces of code in order to indicate the
source and destination of the data flow in question. The outermost part of the first piece of code shows the function which creates the value in question. The outermost function in the second piece of code shows the function which receives the value. (Entire subexpressions are printed in order to make it easier to locate the functions in question within the OSS expression as a whole.) If nesting of expressions is used to implement the data flow, then the first piece of code will be nested in the second one.

15 Warning: Non-terminating OSS expression: expr

This warning message is issued whenever a complete OSS expression appears incapable of terminating. The expression in question is printed. It may well be only a subexpression of the OSS expression being processed. A warning message is issued instead of an error message, because the expression may in fact be capable of terminating or the expression might not be intended to terminate. (This warning message can be turned off by using the variable *permit-non-terminating-oss-expressions*.)

Warnings concerning the violation of restrictions.
The following warnings are issued when an OSS expression violates one of the isolation restrictions or the requirement that within each on-line subexpression, there must be a data flow path from each termination point to each output. In each case, the violation is automatically fixed by the macro package. However, in order to achieve high efficiency, the user should fix the violation explicitly rather than relying on the automatic fix.

16 Warning: Non-isolated non-oss data flow from: call to: call

This warning is issued if an OSS expression violates the non-OSS data flow isolation restriction. As shown below, the message prints out two pieces of code which indicate the data flow in question.

Warning: 16 in OSS expression:
(LETs* ((NUMS (EVeCToR '#(3 2 8)))
    (TOTAL (REDUCEF 0 #'+ NUMS)))
    (RVeCToR (/ NUMS TOTAL)))
Non-isolated non-oss data flow from:
(REDUCEF 0 #'+ NUMS)
to:
(/ NUMS TOTAL)

The OSS macro package automatically fixes the isolation restriction violation by duplicating subexpressions until the data flow in question becomes isolated. (In the example above, the vector enumeration gets copied.) However, the macro package is not guaranteed to minimize the amount of code copied. In addition, it is sometimes possible for a programmer to fix an expression much more efficiently without using any code copying. As a result, it is advisable for programmers to fix these violations explicitly, rather than relying on the automatic fixes provided by the OSS macro package.

17.1 Warning: Non-isolated oss input at the end of the data flow from: call to: call

17.2 Warning: Non-isolated oss output at the start of the data flow from: call to: call

One of these warnings is issued if an OSS expression violates the off-line port isolation restriction. The warning message prints out two pieces of code
which indicate a data flow which ends (or starts) on the port in question. Code copying is automatically applied in order to fix the violation. It is worthwhile to try and think of a more efficient way to fix the violation. As with Warning 16, even if code copying is the only thing which can be done, it is better for the programmer to do this explicitly.

18 Warning: No data flow path from the termination point: call to the output: call

This warning is issued if a termination point in an on-line subexpression of an OSS expression is not connected by data flow to one of the outputs. Code copying is automatically applied in order to fix the violation. (However, the OSS macro package has a tendency to copy a good deal more code than necessary.)
The violation can often be fixed much more efficiently by using non-early-terminating OSS functions instead of early-terminating functions or by using Tcotruncate to indicate relationships between inputs.

Errors concerning implementation limitations.
These errors reflect limitations of the way the OSS macro package is implemented rather than anything fundamental about OSS expressions.

19 Error: LambdaS body too complex to merge into a single unit: forms

In general, the OSS macro package is capable of combining together any kind of permissible OSS expression. In particular, there is never a problem as long as the expression as a whole does not have any OSS inputs or OSS outputs. However, in the body of a lambdaS, it is possible to write OSS expressions which have both OSS inputs and OSS outputs. If such an expression has a data flow path from an OSS input to an OSS output which contains a non-OSS data flow arc, then this error message is issued. For example, the error would be issued in the situation below.

```
(funcallS #'(lambdaS (items)                      ;Signals error 19
             (declare (type oss items))
             (Elist (Rlist items)))
...)
```

An error message is issued in the situation above, because the situation is unlikely to occur and there is no way to support the situation without resorting to very peculiar code. In particular, the input items in the example above would have to be converted into an off-line input.

20 Error: The form function not allowed in OSS expressions.

In general, the OSS macro package has a sufficient understanding of special forms to handle them correctly when they appear in an OSS expression. However, it does not handle the forms compiler-let, flet, labels, or macrolet. The forms compiler-let and macrolet would not be that hard to handle, however it does not seem worth the effort. The forms flet and labels would be hard to handle, because the OSS macro package does not preserve binding scopes and therefore does not have any obvious place to put them in the code it produces. All four forms can be used by simply wrapping them around entire OSS expressions rather than putting them in the expressions.

21--27 Documentation for these errors appears in [6].
5. Index of Functions

This section is an index and concise summary of the functions, variables, and special forms described in this document. Each entry shows the inputs and outputs of the function, the page where documentation can be found, and a one-line description.

The names of OSS functions often start with one of the following prefix letters.

- E Enumerator.
- T Transducer.
- R Reducer.

Occasionally, a name will end with one of the following suffix letters.

- S Special form.
- F Function that takes functional arguments.

In addition, the argument and result names indicate data type restrictions (e.g., number indicates that an argument must be a number, item indicates that there is no type restriction). Plural names are used iff the value in question is an OSS series (e.g., numbers indicates an OSS series of numbers; items indicates an OSS series of unrestricted values). The name of a series input or output begins with "O" iff it is off-line.

- alterS destinations items => items
  Alters the values in destinations to be items.

- defunS name lambda-list {doc} {decl}* &body expr-list
  Defines an OSS function, see lambdaS.

- Ealist alist &optional (test #'eql) => keys values
  Creates two series containing the keys and values in an alist.

- Edown &optional (start 0) &key (:by 1) :to :above :length => numbers
  Creates a series of numbers by counting down from start by :by.

- Efile name => items
  Creates a series of the forms in the file named name.

- Efringe tree &optional (leaf-test #'atom) => leaves
  Creates a series of the leaves of a tree.

- Ehash table => keys values
  Creates two series containing the keys and values in a hash table.

- Elist list &optional (end-test #'endp) => elements
  Creates a series of the elements in a list.

- EnumerateF init step &optional test => items
  Creates a series by applying step to init until test returns non-null.

- Enumerate-inclusiveF init step test => items
  Creates a series containing one more element than EnumerateF.

- Eoss &rest expr-list => items
  Creates a series of the results of the expressions.

- Eplist plist => indicators values
  Creates two series containing the indicators and values in a plist.
Esequence  sequence &optional (indices (Eup)) => elements
Creates a series of the elements in a sequence.

Esublists  list &optional (end-test #'endp) => sublists
Creates a series of the sublists in a list.

Esymbols &optional (package *package*) => symbols
Creates a series of the symbols in package.

Etree  tree &optional (leaf-test #'atom) => nodes
Creates a series of the nodes in a tree.

Eup &optional (start 0) &key (:by 1) :to :below :length => numbers
Creates a series of numbers by counting up from start by :by.

Evector  vector &optional (indices (Eup)) => elements
Creates a series of the elements in a vector.

funcallS  function &rest expr-list => result
Applies an OSS function to the results of the expressions.

lambdaS  var-list {decl}* &body expr-list
Form for specifying literal OSS functions.

*last-oss-error*
Variable containing a description of the last OSS warning or error.

*last-oss-loop*
Variable containing the loop the last OSS expression was converted into.

letS  var-value-pair-list {decl}* &body expr-list => result
Binds OSS variables in parallel.

letS*  var-value-pair-list {decl}* &body expr-list => result
Binds OSS variables sequentially.

mapS  &body expr-list => items
Causes expr-list to be mapped over the OSS variables in it.

oss-tutorial-mode &optional (T-or-nil T) => state-of-tutorial-mode
If called with an argument of T, turns tutorial mode on.

pass-valS  n expr => &rest multiple-value-result
Used to pass multiple values from a non-OSS function into an OSS expression.

*permit-non-terminating-oss-expressions*
When non-null, inhibits error messages about non-terminating OSS expressions.

prognS  &body expr-list => result
Delineates an OSS expression.

Ralist  keys values => alist
Combines a series of keys and a series of values together into an alist.

Rand  bools => bool
Computes the and of the elements of bools, terminating early.

Rand-late  bools => bool
Computes the and of the elements of bools.

Rappend  lists => list
Appends the elements of lists together into a single list.
Rbag  items => list
Combines the elements of items together into an unordered list.

ReduceF  init function items => result
Computes a cumulative value by applying function to the elements of items.

Rfile  name items &rest option-plist => T
Prints the elements of items into a file.

Rfirst  items &optional (default nil) => item
Returns the first element of items, terminating early.

Rfirst-late  items &optional (default nil) => item
Returns the first element of items.

Rhash  keys values &rest option-plist => table
Combines a series of keys and a series of values together into a hash table.

Rlast  items &optional (default nil) => item
Returns the last element of items.

Rlength  items => number
Returns the number of elements in items.

Rlist  items => list
Combines the elements of items together into a list.

Rmax  numbers => number
Returns the maximum element of numbers.

Rmin  numbers => number
Returns the minimum element of numbers.

Rnconc  lists => list
Destructively appends the elements of lists together into a single list.

Rnth  n items &optional (default nil) => item
Returns the nth element of items, terminating early.

Rnth-late  n items &optional (default nil) => item
Returns the nth element of items.

Ror  bools => bool
Computes the or of the elements of bools, terminating early.

Ror-late  bools => bool
Computes the or of the elements of bools.

Rplist  indicators values => plist
Combines a series of indicators and a series of values together into a plist.

Rsum  numbers => number
Computes the sum of the elements in numbers.

Rvector  items &key (:size 32) &rest option-plist => vector
Combines the elements of items together into a vector.

showS  thing &optional (format "-%S") (stream *standard-output*) => thing
Displays thing for debugging purposes.

Tchunk  amount Oitems => lists
Creates a series of lists of length amount of non-overlapping subseries of Oitems.
Tconcatenate  Oitems1 Oitems2 &rest more-Oitems => items
Concatenates two or more series end to end.

TconcatenateF  Enumerator Oitems => items
Concatenates the results of applying Enumerator to the elements of Oitems.

Tcotruncate  items &rest more-items => initial-items &rest more-initial-items
Truncates all the inputs to the length of the shortest input.

Texpand  bools Oitems &optional (default nil) => items
Spreads the elements of items out into the indicated positions.

Tlastp  Oitems => bools items
Determines which element of the input is the last.

Tlatch  items &key :after :before :pre :post => masked-items
Modifies a series before or after a latch point.

TmapF  function &rest items-list => items
Maps function over the input series.

Tmask  Omonotonic-indices => bools
Creates a series continuing T in the indicated positions.

Tmerge  Oitems1 Oitems2 comparator => items
Merges two series into one.

Tpositions  Obools => indices
Returns a series of the positions of non-null elements in Obools.

Tprevious  items &optional (default nil) (amount 1) => shifted-items
Shifts items to the right by amount inserting default.

Tremove-duplicates  Oitems &optional (comparator #'eql) => items
Removes the duplicate elements from a series.

TscanF  {init} function items => results
Computes cumulative values by applying function to the elements of items.

Tselect  bools &optional items => Oitems
Selects the elements of items corresponding to non-null elements of bools.

TselectF  pred Oitems => items
Selects the elements of Oitems for which pred is non-null.

Tsplit  items bools &rest more-bools => Oitems1 Oitems2 &rest more-Oitems
Divides a series into multiple outputs based on bools.

TsplitF  items pred &rest more-pred => Oitems1 Oitems2 &rest more-Oitems
Divides a series into multiple outputs based on pred.

Tsubseries  Oitems start &optional below => items
Returns the elements of Oitems from start up to, but not including, below.

Tuntil  bools items => initial-items
Returns items up to, but not including, the first non-null element of bools.

TuntilF  pred items => initial-items
Returns items up to, but not including, the first element which satisfies pred.

Twindow  amount Oitems => lists
Creates a series of lists of length amount of successive overlapping subseries.
type oss &rest variable-list
Declaration used to specify that variables are OSS variables.

valS &rest expr-list => &rest multiple-value-result
Returns multiple series values.
INTRODUCTION

PACMAN is a Xerox Lisp (Medley, Lyric or Koto) implementation of the arcade game PACMAN. It is fairly faithful to the arcade version, in terms of screen appearance and game dynamics. It runs equally well on Suns, 1132's, 1108's, 1186's, and 1100's (Maikos, Dorados, Dandelions, Doves, and Dolphins). It can run in color for 1132's and 1100's with color boards. Several different methods of user input are supported.

This document describes operational details only. I assume that you know what Pacman is and how to play it.

Load PACMAN.LCOM from your local Lispusers directory. To start the game, type (PACMAN). It will prompt you via menus for input mode, speed, color, and high scores. The menus are described in the next section.

OPTIONS

Input mode: there are currently four ways to control the Pacman, depending on what hardware you have. Although you are asked to pick a mode whenever you start the game, you may switch modes freely at any point during the game.

Mouse - to use this mode, move the mouse in the direction you want the Pacman to go. You only need to move the mouse when you want to change directions.

Keyboard - uses the I, J, K, and space bar as cursor control keys. I is up, J is left, L is right, and space-bar is down. If you look at the arrangement of these keys on the keyboard, you will see that they form an approximate cross. Using the space bar for down (rather than M or ",") lets you control each key comfortably with your right hand; use your thumb for space, and index, middle, and ring fingers for J, I, and L respectively. Note that you must use the upper-case letters.

Joystick - this mode lets you connect an Atari joystick to the keyset port on the Alto keyboard of your 1100 or 1132. See the appendix below for details on constructing the interface cable needed. This is the input mode of choice, since the arcade game also uses a joystick. You can, if you want, plug a keyset (if you can find one) into the keyset port, but it is not clear that this offers any particular advantages for data input. I have heard that it is possible to kludge a keyset port on an 1108, but I don't know how to do that.

Voice - perhaps the most exotic input mode, this requires that you have an Interstate Electronics voice recognition board connected to the RS-232 port of your machine. If you possess such a device, call me for specific interfacing details. The commands are "up", "down", "left", "right", and the words "click" and "pause".
"down", "left", and "right". People walking by in the hall will wonder what’s going on in your office.

Speed: You can choose one of four speeds for the game. Some effort has gone into making these values similar across different machines, but there’s no guarantee they will stay that way. Note that the speed of the game itself will increase (just like the arcade version) as you progress from board to board.

- **Fast** - challenging.
- **Medium** - not unreasonable.
- **Slow** - mellow mode.
- **Snail** - mainly for debugging or the very patient.

*Color (y/n):* will run the game on your color display (if you have one). The b/w display is blanked out during color mode.

*Read high scores (y/n):* this option is only available to users on the Xerox Internet, since the high score repository is on this net. If you are an outside or stand-alone user, always answer no to this. The high score list contains the names and score of the top ten players. Note that with the more recent addition of a speed option, this list is somewhat bogus anyway.

Once you have selected your menu options, the game window will appear, along with the message "Insert quarter to start game". You will note a "quarter icon" in the window. Click this to start the game, or click anywhere else to exit. You can skip the introduction screen by clicking the mouse anywhere inside the window while the introduction is in progress.

All of the standard Pacman boards are supported, along with bonus fruit and relative ghost "blue times". You get the correct number of points for eating various objects. On the b/w screen, the ghosts simply invert-video when you eat an energizer; in color they turn blue.

This game is adapted from the author’s PDP-11 Fortran version. Call me if you want that one. Please direct all comments, questions, and bug reports to Denber.WBST@Xerox.COM.

**KNOWN BUGS**

- Pieces of characters are occasionally left lying about the board following collisions.
- Keyboard steering MUST be in uppercase (at least in Medley), lowercase has no effect.

**LIMITATIONS**

- No sound (that’s planned)
- The ghosts do not gain on you as they’re chasing you. (You however, can gain on them when you’re chasing them).
• The ghosts do not go around turns slower than you do.

• You can't scare ghosts off by feinting at them.

• Only the first intermission is implemented.

• The top ten score probably no longer works, since it depended on an account on {ICE}.

• Color Pacman does not currently work in the Medley release.

• Mouse steering does not currently work in the Medley release.

APPENDIX: PACMAN CONTROL VIA JOYSTICK

1. You must use a switch-closing type joystick (not a pot type). The Atari 2600 (ie. "Video Computer System") or 400/800 computer joystick works fine. The pinouts given below are for this joystick. Signal descriptions are given too, so you can use other similar devices.

2. You will need a male mouse connector (the pins are embedded in the shell, so it's hard to tell the sex of this type of connector), a 9 pin male D connector, and a short length of six conductor cable.

3. I will use the following convention for pin numbers since the connectors are not clearly labeled. The views below are from the pin-side of the connectors, ie. not the side that the wires are soldered to.

4. I recommend you check the completed assembly for shorts with a VOM and by running KeyTest (available to 1100’s and 1132’s from the NetExec) before trying it out on the game. Shorts or opens won't hurt the machine, but they will keep the joystick from working properly (obviously).

Keyset connector:

```
-----------------------------------
|  1   2   3   4   5   6     |
|  7   8   9   10  11  12  13  |
| 14  15  16  17  18  19    |
-----------------------------------
```

Atari connector:

```
----------------------
| 1   2   3   4   5 |
|  6   7   8   9  |
-------------------
```

INTRODUCTION

Loading PAGEHOLD.LCOM redefines the function PAGEFULLFN to alter the behavior that occurs when a tty window fills. Rather than inverting the window and waiting indefinitely for type-in, the PAGEHOLD module indicates the hold by an independent notification, and waits for only a specified interval before continuing. Thus, filling the window is no longer a cause for a program to hang indefinitely.

The default behavior of the PAGEHOLD module is to raise a "button" at the corner of the tty window flashing a message, alternating between

```
-- SHIFT to hold typeout --
```

and

```
{ -- Release SHIFT for more -- }
```

indicating that output to the window is being held. While in this state, you can release the hold by any of the following means:

Typing any character (of course, the window must own the tty process). This is the same as the old behavior;

Depressing the CTRL key;

Depressing and releasing either SHIFT key;

Clicking with LEFT on the button that announces the hold (clicking instead with MIDDLE gets a menu of options);

Waiting until the timeout has passed (initially, 20 seconds).

When you depress one of the SHIFT keys, the button stops flashing. Output will continue to be held indefinitely as long as one of the SHIFT keys is depressed, even if the timeout passes. If while holding down SHIFT, you depress the CTRL key for a second or so, the button will start flashing again; you may now release CTRL and then SHIFT, and the hold will be maintained without your needing to hold down SHIFT. You can release the hold by any of the means listed above.

If the CTRL key is down when a window fills, output is not held at all. Depressing the CTRL key immediately releases any hold in progress.

The remainder of this document describes ways of tailoring the behavior further.
Controlling the timeout

One of the primary motivations for the PAGEHOLD module is so that printout to a TTY window does not hang indefinitely when one "page" has filled up. The default release time is in the global variable PAGE.WAIT.SECONDS, which comes initialized to 20 seconds; a value of 0 causes immediate release (unless a SHIFT key is already depressed). If a window being held has a PAGE.WAIT.SECONDS property, then that value is used instead of the global default.

However, if PAGE.WAIT.SECONDS is set to STOP, then the hold will not be released by any automatic timeout, nor will it be sensitive to the SHIFT or CTRL key actions. This mode most closely approximates the current Lisp design, except that a pop-up button signals the hold rather than a video inversion (mousing the button will, nevertheless, still effect a release). The message “Scrolling Stopped” appears in the button rather than one of the several “holding” messages.

The Pop-up "Buttons"

A secondary motivation for this facility is to have a pop-up "button" that interactively signals the user of a holding condition on a particular window without obscuring the window’s contents, as video inversion does. In addition, the button permits the selective release of a particular window by mousing the button (note that holding down SHIFT, on the other hand, would affect all windows currently being held). There are three styles of buttons—WINKING, FLASHING, and NIL—and the selection is determined by the value of the global variable PAGE.WAIT.ACTIVITY, which comes initialized to WINKING. If a window has a PAGE.WAIT.ACTIVITY property, then that value is used instead of the global default, thus allowing different types of buttons on different windows.

A WINKING button is a fairly hefty pad—approximately 1/2" by 2 1/2"—which pops up just over the right side of the window’s title bar; it will alternately print and clear two short holding messages: one in the upper half of the "button" and one in the lower half. A FLASHING button is about the same width, but half the height, and will alternately print the two holding messages. A NIL button merely shows the message "Release SHIFT for more".

LEFT-mousing any button causes an immediate release of the hold; MIDDLE-mousing the button brings up a menu offering several options. One of these is "Release this hold!", same as using LEFT. Other menu options permit conversion of the hold to indefinite "hold" or to STOP mode; additionally, five options are offered for setting the window’s specific PAGE.WAIT.SECONDS property.

The WINKING button has a different pattern of activity when the hold is placed into indefinite hold mode, but the other button styles do not visibly distinguish this state. If there isn’t room to place the button down over the right side of the title bar (because, for example, the window is too close to the screen top), then it will be placed over another corner of the window.

Keyboard Input and Typeahead

Consistent with Lisp’s current action, there will be no holding on a window which is its process’s TtyDisplayStream and for which there is typeahead in that process’s TTY input buffer. This action can be overridden by setting PAGE.WAIT.IGNORETYPEAHEAD to a non-NIL value: typeahead does not inhibit the hold, character input does not release the hold, and no input is ever discarded (note that depressing the SHIFT and/or the CTRL keys does not generate character input). This feature is intended for those who dislike not knowing whether a keystroke will be consumed by the PAGEFULLFN—under the default behavior, if the TTY input buffer is empty, then the first character you
type will either (a) release a hold already in progress and be discarded, or (b) prevent subsequent holds and be retained, all depending on when exactly you type the character.

Requires: Lispuser package GREP

INTRODUCTION
The PHONE-DIRECTORY package provides quick and easy access to on-line phone directories.

When you load the PHONE-DIRECTORY package, an icon (■) will appear on your screen. Opening this icon will start a directory search program (see example below). To look up a person, type in a name, followed by a return. The PHONE-DIRECTORY program will search the available phone lists and print out those entries that contain the name. This can be repeated as many times as you like. When you are done, just SHRINK the window back to its icon.

Example PHONE-DIRECTORY window

Phone directory

Name:  lennon
{from {CORE}(REGISTRAR>PARCPHONELIST.TXT;1)
  4243   Lennon, John   35-1312
Name:

Variables

PHONELISTFILES [Variable]

PHONELISTFILES is a list of files that contain phone lists. This is usually set in the INIT.LISP file. The PHONELISTFILES should be unformatted files with a single entry per line. Blank lines are permitted. A typical value for PARC users (as defined in PARC-INIT) is

{{INDIGO}<REGISTRAR>PARCPHONELIST.TXT
  {INDIGO}<REGISTRAR>ISDNORTHPHONELIST.TXT).

*Phone-Directory-Pos* [Variable]
*Phone-Directory-Pos* is the initial POSITION for the PHONE-DIRECTORY icon. This is defined as an INITVAR in the file, so you can set it before loading the file. The default value is
(create POSITION XCOORD ← 15
       YCOORD ← (DIFFERENCE SCREENHEIGHT 75)).
This places the icon in the upper left corner of the screen, just above the exec window.

*Phone-Directory-Region* [Variable]

*Phone-Directory-Region* is the initial REGION for the PHONE-DIRECTORY window. This is defined as an INITVAR in the file, so you can set it before loading the file. The default value is
(CREATEREGION 15 (DIFFERENCE SCREENHEIGHT 258) 400 250).
This places the window in the upper left corner of the screen.

Notes
When you first open the PHONE-DIRECTORY window, the program will copy the PHONELISTFILES to {CORE}, significantly speeding up queries. Bugging in the title of the PHONE-DIRECTORY window with the left or middle mouse button will produce a menu with an option to recache the files from PHONELISTFILES.
INTRODUCTION

When I get frustrated trying to decide what to work on, I use 'pick' to choose a project. It has a bunch of different choices.

MODULE EXPLANATIONS

(PICK option choices) [Function]
pick option choice1 choice2 ... [Command]

<table>

<tr>
<td>issue</td>
<td>Choose an issue &amp; display it</td>
<td>open issues in Medley</td>
<td>pick issue 3</td>
</tr>
</tbody>
</table>

For now -- the code is commented, so read it :)
INTRODUCTION
This module provides two solutions to the problem of menus with too many items. Which is useful will depend on the inherent structure of the items. 1) CHUNK-MENUS: For use in which the items have the simple structure of one long list: Break the items up into chunks following the ordering of the items in the list, and then provide a menu which presents one of those pieces and a way of getting other menus containing the other pieces. 2) KEYWORD-MENUS: For use when it is possible to associate keywords with the items: Break the items up into the sets which share the same keyword, and then provide a menu which presents one of those chunks and a way of getting other menus with other keywords. As with standard Interlisp-D menus, these specialized menus are created by a "create" function (cf. (CREATE MENU)), and are used with a single "invoke" function (cf. (MENU menu)). The items and other information are as with standard menus, except that the other information is presented to the create function in the form of a Plist.

CHUNK MENUS
A Chunk Menu appears as a single menu, but is really a data structure encompassing a number of pieces, each represented by a menu, between which the operator can move to find the item desired. Each piece is in three parts: a set of "required items" which will appear in all chunks, a set of indicators for all the chunks, and the items in this piece. Each chunk has up to 30 items in it (it can be varied using the CHUNK.COUNT property). If there are fewer than one chunk's worth of items, the CHUNK-MENU behaves just like a standard menu.

(CHUNK.MENU.CREATE ITEMS PROPERTIES REQUIRED.ITEMS) [Function]
Creates and returns a Chunk Menu, a data structure of menus each containing some of the (presumably large number of) items.. All items are as with standard menus. The properties understood are: CHUNK.COUNT (see above), TITLE, CENTERFLG, MENUFONT, ITEMWIDTH, ITEMHEIGHT, MENUBORDERSIZE, and MENULAYOUTSIZE. The actual menus are created only when needed.

(CHUNK.MENU.INVOKE CHUNK.MENU POSITION ) [Function]
Carries out the interaction with the user to select and item from a Chunk Menu. If POSITION is non-NIL, the menu will appear at that position, otherwise it will appear under the mouse. All interactions are as with the standard menus. Returns the value produced when a selection is made. Selecting outside any of the menus appearing in the interaction cancels the interaction and returns NIL.

KEYWORD MENUS
A keyword menu appears as a single menu, but is really a data structure encompassing number of menus which the operator can move between to find the item desired. Each piece is in two parts: the set of keywords for all the pieces, and the items in this piece (having this keyword). Each piece is a Chunk Menu, so that if a particular keyword has many items, its piece is itself broken into pieces. The items in a keyword menu is computed from a list of objects, the things which presumably are being selected among. A function is provided for computing the keywords of each object, and another for computing an item from an object.
(KEYWORD.MENU.CREATE OBJECTS KEYWORDFN PROPERTIES ITEMFN ) [Function]
Creates and returns a Keyword Menu, a data structure of pieces associated with the keywords of the
OBJECTS as determined by KEYWORDFN. Each piece of the Keyword Menu is a Chunk Menu and
contains the items for the objects with the associated keyword. The item is computed from the object
by applying the ITEMFN to that object; ITEMFN should return an item appropriate for standard menus.
The menus are determined by the values on the PList PROPERTIES. The properties understood are:
CHUNK.COUNT (see Chunk Menus), TITLE, CENTERFLG, MENUFONT, ITEMWIDTH, ITEMHEIGHT,
mENUBORDERSIZE, and MENULAYOUTSIZE. The actual menus are created only when needed.

(KEYWORD.MENU.INVOKE KEYWORD.MENU POSITION ) [Function]
Carries out the interaction with the user to select an item from a Keyword Menu. If POSITION is non-
NIL, the menu will appear at that position, otherwise it will appear under the mouse. All interactions are
as with Chunk Menus, which is just that for standard menus for small numbers of items. Returns the
value produced by the items when a selection is made. Selecting outside any of the menus appearing
in the interaction cancels the interaction and returns NIL.
PLOT

By: Jan Pedersen (pedersen.PA @ Xerox.com)

Uses: TWODGRAPHICS and PLOTOBJECTS

PLOT is a module designed to assist in the production of analytic graphics. PLOT provides automatic scaling, labeling, incremental modification, generalized selection, and a collection of standard graphics primitives which may be combined to produce interactive plots of great diversity.

PLOT is to some degree object-oriented. The primitive components of a plot are plot objects (e.g. points, lines, etc.). A plot manager maintains a display list of plot objects which are individually responsible for displaying themselves, highlighting themselves, etc. The user constructs a plot incrementally, adding plot objects, while the plot manager handles details such as the appropriate scale for the plot. Each plot object is active, in the sense that it is selectable and may have a menu associated with it. In addition, the plot manager may be directed to modify the appearance of the entire plot through a command menu.

The module is open, in the sense that most default behaviors may be overridden by the user, although it is hoped that the defaults will be sufficient for most applications. A functional interface is provided for programmatic access to all of PLOT’s facilities.

The plot manager is abstracted as a datatype of type PLOT, along with a collection of functions which operate on PLOT’s. Functions are provided to create PLOT’s, manipulate their display lists, and modify default menus. Plot objects are abstracted as instances of datatype PLOTOBJECT. A set of default plot objects are provided, along with a mechanism of defining new plot objects.

Plots exist independently of their representation on the screen. Indeed, it is intended that plots may be displayed on ANY imagestream. However, the most common usage is to display a plot in a window, and a PLOT does have an associated WINDOW which may be opened, closed, etc.

Plots may be hard copied, made into image objects, and dumped to file.

The lispuser's module PLOTEXAMPLES contains a few examples of how PLOT may be used to create high level plotting facilities.

BASIC OPERATION

A plot is abstracted as an instance of datatype PLOT which includes a display list, a property list, and an associated window, among other things. PLOT’s may be create via the function CREATEPLOT.

(CREATEPLOT openflg region title border) [Function]

Returns a PLOT. If openflg is T then the PLOT’s associated window is opened with an empty plot. The other arguments are treated as in CREATEW.

An empty plot is initialized to have a world coordinate system extending from 0.0 to 1.0 on either axis, with no labels or tic marks displayed. As objects are added to the plot, the world coordinate system is grown to accommodate the new objects.
A PLOT has an associated window, which is closed by default. The window is used as the primary display device and may be manipulated with the following functions.

**(OPENPLOTWINDOW plot)** [Function]
Opens the plot’s associated window.
Returns the associated window.

**(CLOSEPLOTWINDOW plot)** [Function]
Closes the plot’s associated window.

**(REDRAWPLOTWINDOW plot)** [Function]
Redraws, by running down the current display list, the contents of the associated window. Opens the window if it is closed.

**(GETPLOTWINDOW plot)** [Function]
Returns the window associated with plot.

**(WHICHPLOT x y)** [Function]
Returns the PLOT associated with the window (or icon) at position (x . y), or at the current cursor position if x and y are defaulted. x may be a WINDOW, in which case the associated PLOT is returned.

A plot object is abstracted as an instance of datatype PLOTOBJECT. A point plot object is an instance of PLOTOBJECT whose data component describes a point. That is, a point plot object is a subtype of PLOTOBJECT; all plot objects satisfy (type? PLOTOBJECT FOO), but only a point plot object satisfies in addition (PLOTOBJECTSUBTYPE? POINT FOO). A collect of standard plot objects has been implemented, including point, curve, polygon, line, and filled rectangle plot objects. The module is designed so that new objects may defined at any time, but that mechanism is described in a separate document.

PLOTOBJECT’s may be added to or deleted from a PLOT. The following functions provide an add facility for the standard objects.

**(PLOTPOINT plot position label symbol menu nodrawflg)** [Function]
Only the plot and position arguments are required. Position is a POSITION in world coordinates. Label is an expression which will be PRIN1 ‘ed whenever a label is required (typically an atom or a string). Symbol is a BITMAP which will be plotted centered at position. The litatoms CROSS, CIRCLE, STAR are bound to convenient BITMAPS. Symbol defaults to STAR. Menu is either a MENU, a litatom, in which case a MENU of that name must be cached on plot (more about this later), or an item list which may be coerced into a MENU.

If nodrawflg is non-NIL then a point object will be added to the display list of plot, but the associated window will not be updated. If Nodrawflg is NIL, and the plot’s associated window is not open, it will be opened.

Returns a POINT PLOTOBJECT.

**(PLOTPOINTS plot positions labels symbol menu nodrawflg)** [Function]
As above except that positions is a list of POSITIONS and labels may also be a list. Reasonable things happen if positions and labels are of unequal length.
Returns a list of POINT PLOTOBJECT's.

(PLOTCURVE plot positions label style menu nodrawflg)  [Function]

The list of POSITION's defines a piecewise linear curve. Style may be an integer which specifies the line width (in pixels) or a list of (linewdth dashing color), any of which may be NIL; defaults to one. For convenience the atoms DOT, DASH and DOTDASH have been bound to a few dashing patterns.

Returns a CURVE PLOTOBJECT.

(PLOTPOLYGON plot positions label style menu nodrawflg)  [Function]

As in PLOTCURVE, although a polygon is a closed figure

Returns a POLYGON PLOTOBJECT.

(PLOTTEXT plot position text label font menu nodrawflg)  [Function]

Text should be a STRING to be printed at position.

Returns a TEXT PLOTOBJECT.

(PLOTFILLEDRECTANGLE plot left bottom width height label
 texture borderwidth menu nodrawflg)  [Function]

Texture must be TEXTURE. SHADE1, ..., SHADE8 are bound to some convenient textures. Defaults to SHADE3.

Returns a FILLEDRECTANGLE PLOTOBJECT.

The following two functions add analytic plot objects to the display list of a PLOT. Analytic objects differ from points, curves, etc. by having infinite extents; their appearance on a plot depends on the current world coordinate scale, but adding an analytic object to a plot will not effect the current scale.

(PLOTLINE plot slope constant label style menu nodrawflg)  [Function]

Slope and constant define an analytic line, \( y = \text{slope} \times x + \text{constant} \). If slope is NIL, it is taken to be infinite; i.e. the line is vertical.

Returns a LINE PLOTOBJECT.

(PLOTGRAPH plot graphfn nsamples label style menu nodrawflg)  [Function]

Graphfn should be a function of one variable which defines a graph (or the graph of a function) to be drawn on plot. Nsamples is the number of equispaced points along the x-axis of plot at which graphfn is to be sampled when drawn; defaults to 100.

Returns a GRAPH PLOTOBJECT.

Complex objects may be built up from the preceding primitives by defining a compound plot object, which is simply a collection of other plot objects, including other compound objects.

(PLOTCOMPOUND plot component1 ... componentn typename label
 menu nodrawflg)  [NoSpread Function]

A compound plot object is specified by listing its components. In addition, a compound plot object may have its own menu and label. The typename field is supplied to allow different compound objects to be differentiated. Drawing a compound object amounts to drawing its components recursively. In general, operations on compound objects are applied recursively.
Components 1 through n are plot objects. Typename is required and serves to tag this compound object, and is accessible via the function COMPOUNDSUBTYPE. Label and menu are as in other plot objects.

Returns a COMPOUND PLOTOBJECT.

All plot objects may be created independently of the previous functions. This is useful if it is desired to create a plot object without entering it on a PLOT’s display list. The following functions create and return the standard plot objects.

(CREATEPOINT position label symbol menu) [Function]
Returns a POINT PLOTOBJECT.

(CREATECURVE positions label style menu) [Function]
Returns a CURVE PLOTOBJECT.

(CREATEPOLYGON positions label style menu) [Function]
Returns a POLYGON PLOTOBJECT.

(CREATETEXT position text label font menu) [Function]
Returns a TEXT PLOTOBJECT.

(CREATEFILLEDRECTANGLE left bottom width height label texture style menu) [Function]
Returns a FILLEDRECTANGLE PLOTOBJECT.

(CREATELINE slope constant label style menu) [Function]
Returns a LINE PLOTOBJECT.

(CREATGRAPH graphfn nsamples label style menu) [Function]
Returns a GRAPH PLOTOBJECT.

(CREATECOMPOUND compoundtype components label menu) [Function]
Components must be a list of PLOTOBJECT’s.
Returns a COMPOUND PLOTOBJECT.

Each PLOT has a display list which is nothing more than a list of plot objects. The display list may be manipulated directly via the following functions.

(ADDPLOTOBJECT plotobject plot nodrawflg) [Function]
Interns plotobject on the display list of plot, and updates the associated window. The update is suppressed if nodrawflg is non NIL.

One might think of PLOTPOINT as being equivalent to:

(ADDPLOTOBJECT (CREATEPOINT position ....) plot nodrawflg)

Interns plotobject on the display list of plot, and updates the associated window. The update is suppressed if nodrawflg is non NIL.

Returns plotobject.
(DELETEPLOTOBJECT plotobject plot nodrawflg nosaveflg) [Function]
Deletes plotobject from the display list of plot, and updates the associated window accordingly. The update is suppressed if nodrawflg is T. If nosaveflg is T, then the deleted object will not be saved for possible later undeletion.

Returns plotobject if it was deleted from the display list, else NIL.

A PLOT has collection of properties, some of which are maintained by the plot manager, and others which may be used to cache arbitrary user data. All plot properties are accessed via the function PLOTPROP.

(PLOTPROP plot prop newvalue) [NoSpread Function]
If newvalue is absent then the current value of prop is returned. If newvalue is supplied (even if it is NIL) then the value of prop is set and the old value returned. The distinguished prop’s PLOTOBJECTS, PLOTSOURCE, SELECTEDOBJECT, PLOTWINDOW, PLOTWINDOWVIEWPORT, PLOTPROMPTWINDOW, and PLOTHIST refer system maintained properties plot, and should be treated as read only. Compiles open in some cases.

For example, The display list of plot may be accessed by the expression.

(PLOTPROP plot 'PLOTOBJECTS)

For convenience in manipulating the property list of a PLOT, the following functions are provided.

(PLOTADDPROP plot prop itemtoadd firstflg) [Function]
If the value of prop is a list then itemtoadd is added to the end of the list. If the value of prop is NIL it is set to (LIST itemtoadd). Firstflg indicates that the new item is to be the first in the list rather than the last. Works only for user defined properties.

Returns the new value.

(PLOTDELPROP plot prop itemtodelete) [Function]
If itemtodelete is a member (MEMB) of the prop value, it is deleted. Works only for user defined properties.

Returns NIL if nothing was deleted, else the new value of prop.

(PLOTREMPROP plot prop) [Function]
Destructively removes prop from property list of plot. Works only for user defined properties.

Each plot object also has a property list. As with PLOT’s, some of the properties are maintained by the system, but the rest may be used to store arbitrary data objects. The property list of a plot object is accessed through the function PLOTOBJECTPROP.

(PLOTOBJECTPROP object prop newvalue) [NoSpread Function]
As in PLOTPROP. The distinguished props are OBJECTMENU, OBJECTLABEL, and OBJECTDATA. The property, OBJECTMENU, may be set as well as read; if the newvalue is a list of items, it will be coerced into a menu.

(PLOTOBJECTADDPROP object prop itemtoadd firstflg) [Function]
As in PLOTADDPROP. Firstflg indicates that the new item is to be the first in the list rather than the last.
(PLOTOBJECTDELPROP object prop itemtodelete) [Function]
As in PLOTDELPROP.

DEFAULT MOUSE BUTTON ACTIONS

The user may interact with a plot through its associated window. A plot provides two default menu’s, the RIGHT menu, which pops up if the right mouse button is depressed within a plot’s window, and typically contains items relevant to the plot as a whole, and the MIDDLE menu, which pops up if the middle mouse button is depressed, and typically contains items relevant to the currently selected plot object. The left mouse button is used exclusively for selection. The right menu may optionally be fixed to the right hand side of the plot window for easy reference. In summary:

Left Button
While depressed will select the closest plot object.

Middle Button
Pops up a menu of default actions on the selected object

Right Button
Pops up a menu of default actions on the plot as a whole

DEFAULT MIDDLE MENU ITEMS

Label
Label the selected object. Either a default location for the label is selected (for point plot objects), or the user is queried for a location.

Unlabel
If the object is label, remove the label.

Relabel
Change the object’s label

Delete
Remove the object from the plot. May be undeleted later.

DEFAULT RIGHT MENU ITEMS

Layout
Create a SKETCH of the contents of the PLOT. Requires SKETCH and SKETCHSTREAM to be loaded.

Redraw
Redraw the plot

Rescale
Compute a new scale for both the X and the Y axis based on the objects currently displayed. May also rescale the X or Y axis separately.
Extend
Extend the axes slightly on either side so plot objects occurring on the borders may become visible. May be applied separately to either axis.

Labels
Change the marginal labels. May either Choose a margin explicitly, or respond to query.

Tics
Enable or disable marginal tics.

Undelete
Restore the last plot object deleted. Subsidiary items allow selected objects to be restored.

Deselect
Deselects the current selected object.

The default menus may be altered or superceded altogether. Each plot object may either use the default middle menu, another cached menu, or provide its own individual menu.

Menus are described by item lists of the form (label function helpstring [(subitems ...)]). Function may be a litatom in which case the function is called with one argument, plot, for right menu items, or two arguments, plotobject and plot, for all other menus. If function is a list the CAR of the list is a APPLIED to (CONS PLOTOBJECT (CONS PLOT (CDR list))), etc.

The following functions facilitate modifying existing menus, and creating new menus.

(PLOTMENU plot menuname newmenu) [NoSpread Function]
Plot and menuname are required. If newmenu is not present, then the current value of menu menuname is returned. Menu name may be RIGHT or MIDDLE, in which case the default menus are referred to, or any LITATOM, in which case the cached menu by that name is referred to. Menus other than RIGHT or MIDDLE will typically be specialized menus for particular plot objects. If present, newmenu must be a MENU.

(PLOTMENUITEMS plot menuname menuitems) [NoSpread Function]
Plot and menuname are required. If menuitems is not present, then the current item list for the MENU menuname is returned. If menuitems is present, then menu menuname is replaced with a new menu with items list menuitems. All the properties (if any) of the old menu are copied over. Menu name may be one of RIGHT or MIDDLE, in which case the operations refer to the default right or middle mouse button menus or any other LITATOM, in which case the operations refer to a menu cached on plot by that name. Menus other than RIGHT or MIDDLE will typically be specialized menus for particular plot objects.

(PLOTADDMENUITEMS plot menuname itemstoadd) [Function]
Itemstoadd must be a list of menu items. Adds each item in itemstoadd to the end of the item list for menu menuname and replaces menu menuname with a new MENU having the appropriate item list.

Returns the new item list for menuname.
(PLOTDELMENUITEM plot menuname itemstodelete) [Function]

Itemstodelete must be a list of items. For each element of itemstodelete, if it is a LITATOM, then deletes the item whose CAR is EQ to it. If it is a LISTP, then deletes the item EQUAL to it. Replaces menu menuname with a new MENU having the appropriate item list.

Returns NIL if no items were deleted, else the new item list.

(PLOT.FIXRIGHTMENU plot fixedflg) [NoSpread Function]

Fixedflg is optional. If not present that the current state of the right menu of plot is returned; T implies the right menu is fixed. If Fixedflg is supplied the right menu state is correspondingly changed.

The middle button menu for a particular plot object is a property of that plot object, and may be accessed via the function PLOTOBJECTPROP. For example, the expression,

(PLOTOBJECTPROP object 'OBJECTMENU)

will return the current middle button menu for object. If the OBJECTMENU property is NIL, then the system default MIDDLE menu is used, if it is a LITATOM, than a specialized cached menu by that name is used, finally, if it is a MENU, then that menu is used.

Two default fonts are provided, a large font for labels and a small font for tic marks. Both may be reset and that aspect of a plot will change accordingly with the next redraw.

LARGEPLOTFONT [Variable]
Default value: (Gacha 12 BRR)

SMALLPLOTFONT [Variable]
Default value: (Gacha 8 MRR)

Detailed Operation

Most visible aspects of a PLOT may be changed programmatically. The following functions allow the user to specify labels, etc., as well as override the default algorithms for drawing tics, etc.

(PLOTLABEL plot margin newlabel nodrawflg) [NoSpread Function]

Plot and position are required. Margin must be one of TOP, BOTTOM, LEFT, OR RIGHT. If newlabel is absent, then the current margin label is returned (may be NIL). If newlabel is present then the margin label is set to newlabel. The display is automatically updated unless nodrawflg is non NIL.

(PLOTTICS plot margin newvalue nodrawflg) [NoSpread Function]

Plot and margin are required. Margin must be one of TOP, BOTTOM, LEFT, OR RIGHT. If newvalue is absent, returns the tic status of that margin. NIL implies no tics or labels, T implies both. If newvalue is present, then sets margin’s tic status. The display is automatically updated unless nodrawflg is non NIL.

The appearance of the tic marks will also depend on the tic generation method employed. The default is simply to make down tics at "pretty" intervals from the max to the min of each axis in world coordinates. However, non-numeric tic marks, and other behaviors are user specifiable by the function PLOTTICMETHOD.
(PLOTTICMETHOD plot margin newmethod nodrawflg) [NoSpread Function]
Plot and margin are required. Margin must be one of TOP, BOTTOM, LEFT, OR RIGHT. If newmethod is absent, returns the current tic method for margin margin. Newmethod may be one of NIL, implying the default tic method, a list of CONS pairs (value . label), in which case label (if non-NIL) will be printed at value, or a list of numbers, which is equivalent to ((value . value) ...) or a function which will be called with args, margin plotscale plot, and should return a list as above. Plotscale is a datatype which describes the current scale of the plot.

(DEFAULTTICMETHOD margin plotscale plot) [Function]
The result depends on the ticinfo field of plotscale, which should be an instance of the PLOTSCALE datatype. The ticinfo field will be an instance of datatype TICINFO. If its ticinc field is a number (the usual case) then it returns a list of numbers, starting at ticmin and ending at ticmax in increments of ticinc, otherwise returns ticinc (should be a list).

When a plot object is added to a plot, the scale of the plot is adjusted so that the object is visible. This is accomplished by comparing the extent (in world coordinates) of the object with the current scale of the plot. If the scale needs to be enlarged, a new interval is chosen for each axis which is guaranteed to include the object and also be some multiple of a "round" increment -- in other words, a pretty tic interval. The default behavior of this scaling algorithm may be altered in several ways.

The pretty tic interval is determined by the TICFN for each axis. The default uses the function SCALE to find a suitable interval. This may be altered by supplying a TICFN other than the default.

Given a pretty tic interval, the default is to simply use the end points of that interval as the endpoints of the scale for each axis. This may be altered by supplying a SCALEFN other than the default.

In other words the actually displayed interval (for each axis) in world coordinates (what I will call the plot interval) is separated from the pretty tic interval (for each axis). The pretty tic interval is computed first, then the plot interval is computed in the presence of that information. This separation is useful if the user wishes to plot objects in a coordinate system different from the one used to display tic marks.

The current state of each axis of a PLOT is cached in the plot property plotscale, whose value is an instance of datatype PLOTSCALE. A PLOTSCALE has three fields for each axis, one which contains an instance of AXISINTERVAL, describing the actual plot interval for that axis, another which contains an instance of TICINFO, which describes the pretty tic interval for that axis, and a third which is a simply a place to cache a user supplied TICFN and SCALEFN.

(PLOTTICFN plot axis ticfn nodrawflg) [NoSpread Function]
Ticfn is optional. If not present the current ticfn for the indicated axis is returned. If supplied, the state of that axis is correspondingly updated. A ticfn is called with args min, max, and plot and should return an instance of TICINFO. If the state of plot is changed, the appropriate axis is rescaled. A value of NIL implies the default ticfn.

(DEFAULTTTICFN min max -- -- --) [Function]
The default ticfn for each axis. Uses the function SCALE to find a suitable pretty tic interval.

(PLOTSCALEFN plot axis scalefn nodrawflg) [NoSpread Function]
Scalefn is optional. If not present the current scalefn for that axis of plot is returned. If supplied, the state of that axis is updated. A scalefn is called with four arguments, the min and max extent (in world coordinates) on that axis of the plotobjects currently displayed, the TICINFO for that axis, and the plot;
the scalefn should return an AXISINTERVAL which will determine the scale for that axis of plot. A value of NIL implies the default scalefn.

(DEFAULTSCALEFN min max ticinfo)  [Function]
The default scalefn for each axis.

Returns an AXISINTERVAL with endpoints identical to the endpoints of ticinfo.

(ADJUSTSCALE? extent plot)  [Function]
Determines whether extent will fit into the current viewing area of plot. If so, returns NIL. If not, returns T and updates the plotscale of plot.

(EXTENTOFPLOT plot)  [Function]
Computes the current extent of plot by mapping EXTENTOBJECT down the display list. Returns an EXTENT.

To be precise, the scaling algorithm operates as follows; a min and max extent of the data is computed (via EXTENTOFPLOT or entered manually in the case manual rescaling), then CHOOSETICS is called, which returns an instance of TICINFO. CHOOSETICS either uses a default TICFN, or one supplied by the user. The default TICFN, calls SCALE repeatedly to find an "optimal" tic interval in world coordinates. Once the TICINFO instance has been computed, CHOOSESCALE is called with the original min, max and the TICINFO, and returns an instance of AXISINTERVAL, which will determine the actually displayed plot interval. Again, CHOOSESCALE either uses a default SCALEFN, or one supplied by the user. The default SCALEFN simply uses the end points of the passed in pretty tic interval as the end points of the AXISINTERVAL which it returns. Finally, the PLOT is redrawn with the new scale -- notice that the plot interval may either be larger or smaller than the pretty tic interval; the margin drawing routines are robust enough to deal with all cases.

For example, suppose the world coordinates are in centigrade and it is desired to produce a pretty tic interval in units of Fahrenheit (this is an easy case since the transformation between scales is linear -- more about that later). The user would then supply a TICFN which would transform the incoming min and max to Fahrenheit, apply the default TICFN on the transformed min and max, obtain a TICINFO in Fahrenheit, transform the fields of that record back to Centigrade, and return that record. Note, it is always assumed that the fields of a returned TICINFO are in the units of the world coordinate system. The rest of the machinery would then go through as before.

A tricker example is one in which it is desired to produce unequispaced tic marks. Suppose the data were plotted on a log scale (that is, log was applied BEFORE plotting the data).The default algorithm would produce a pretty tic interval in the log scale. It might be desired instead to produce one pretty in the original scale. The user would then supply a TICFN which would exponentiate the incoming min and max, apply the default TICFN on the transformed min and max, obtain a TICINFO in Fahrenheit, transform the fields of that record back to Centigrade, and return that record. Note; since equispaced tic marks in the orginal scale are not equispaced in the log scale, the TICINC field of the returned TICINFO would be a list of the unequispaced tic marks values, rather than a number.

The plot scale of each axis may be manipulated directly through the following functions.

(PLOTAXISINTERVAL plot axis newinterval nodrawflg)  [Function]
Plot and axis are required. Axis must be one of X, or Y. If newinterval is NIL, returns the current AXISINTERVAL for that axis. If newinterval is non-NIL it must be an AXISINTERVAL.
(PLOTTICINFO plot axis newticinfo nodrawflg) [Function]
Plot and axis are required. Axis must be one of X, or Y. If newticinfo is NIL, returns the current TICINFO for that axis. If newticinfo is non-NIL it must be a TICINFO.

On occasion it is useful to clean out an existing plot instead of creating a new one.

(PLOT.RESET plot xscale yscale flushmargins flushprops nodrawflg) [Function]
Returns plot to a pristine state. If xscale and yscale are provided, the scale of the plot is set accordingly.

Finer control over the behavior of plot objects is possible through the following functions.

(TRANSLATEPLOTOBJECT plotobject dx dy plot nodrawflg) [Function]
Moves plotobject dx, dy in world coordinates and updates the associated window accordingly. The update is suppressed if nodrawflg is non NIL.

(DRAWPLOTOBJECT plotobject plot) [Function]
Draw plotobject in the window associated with plot. As with all the display functions, the window should be opened beforehand. DRAWOBJECT does NOT check that the window is open.

APPLY’s the plotobject’s DRAWFN.

(ERASEPLOTOBJECT plotobject plot) [Function]
APPLY’s the plotobject’s ERASEFN

(HIGHLIGHTPLOTOBJECT plotobject plot) [Function]
Invoked when a plotobject is selected

(LOWLIGHTPLOTOBJECT plotobject plot) [Function]
Invoked when a plotobject is deselected

(EXTENTOFPLOTOBJECT plotobject plot) [Function]
Computes the extent of plotobject in world coordinates.

Returns an EXTENT, which has fields MAXX, MINX, etc.

(DISTANCETOPLOTOBJECT plotobject streamposition plot) [Function]
Returns the "distance" to plotobject from streamposition in stream coordinates. Value returned may be a FIXP or a FLOATP, but is always a distance in stream coordinates.

(CLOSESTPLOTOBJECT plot streamposition) [Function]
Returns the "closest" plotobject on plot’s display list to streamposition.

(DESELECTPLOTOBJECT plot) [Function]
Deselects the current selected object of plot

Plot objects also have "afterfns". That is, functions which are optionally invoked after some standard operation. These are stored as plot object properties with distinguished names, and invoked with at least two args, the plotobject and the plot.
WHENADDEDFN [Property]
The WHENADDEDFN is called with three arguments, plotobject, plot, and nodrawflg.

WHENDELETEDFN [Property]
The WHENDELETEDFN is called with four arguments, plotobject, plot, nodrawflg, and nosaveflg.

WHENDRAWNFN [Property]
The WHENDRAWNFN is called with three arguments, plotobject, viewport and plot.

WHENERASEDFN [Property]
WHENHIGHLIGHTEDFN [Property]
WHENLOWLIGHTEDFN [Property]
WHENTRANSLATEDFN [Property]

A PLOT has two associated windows, the mainwindow in which the graphics, labels, tics, etc. are displayed and an attached promptwindow. The mainwindow is cached as plot property and may be accessed via the function PLOTPROP. A function is provided for easy access to the prompt window.

(PLOTPROMPT text plot) [Function]
Text is output in the one character high prompt window of plot.

PLOT’s may be drawn in ANY imagestream (but only interacted with in the PLOT’s associated window). The following function is the fundamental draw primitive.

(DRAWPLOT plot stream streamviewport streamregion) [Function]
Stream is any imagestream. Streamviewport is a viewport on that stream that defines the the world to stream transformation. Streamregion is a region in stream coordinates that will contain the entire image (for a window it will be the CLIPPINGREGION). Streamviewport is usually the result of ADJUSTVIEWPORT.

For more information about viewport, consult the documentation for the TWODGRAPHICS module.

(ADJUSTVIEWPORT viewport streamregion plot) [Function]
Viewport is a VIEWPORT whose parentstream is the imagestream of interest. Streamregion is a region in stream coordinates that will contain the entire image.

Adjusts the Streamsubregion and Worldregion of viewport to reflect the current scale and margin setting of plot.

(MINSTREAMREGIONSIZE stream plot) [Function]
Returns a CONS pair (minwidth . minheight) of the plot in stream coordinates.

A plot has "afterfns" for two major operations, opening and closing the plotwindow. These are stored as plot properties with distinguished names. The values of these properties may be a single function or a list of functions which are called in sequence with the plot as an argument.

WHENOPENEDFN [Property]
WHENCLOSEDFN [Property]

PLOT’s may be copied, made into image objects, dumped onto files, sent in the mail, etc.
(COPYPLOT plot)  
[Function]

Returns a copy of plot. The user defined properties require special handling. If there exists a plot prop COPYFN, which may be function or list of functions, the function (or functions) will be invoked with the arguments newplot plot and propname for each user defined property on plot. If the function returns a non-NIL value, it will be used as the value of propname on newplot. In the case of a list of functions, the first non-NIL value (traveling from the head to the tail of the list of functions) will be used as the new prop value. Otherwise the prop will be HCOPYALL’ed.

(COPYPLOTOBJECT plotobject plot)  
[Function]

Returns a copy of plotobject. The protocol for copying objectprops is similar to plot props. The plotobject may have a COPYFN prop which may be a function or list of functions. The function (or functions) will be invoked with the arguments newplotobject plotobject plot propname. The first non-NIL value will be used as the prop value else the property will be HCOPYALL’ed.

(PRINTPLOT plot stream)  
[Function]

Writes out an HREADable symbolic representation of plot on stream. Again, user defined properties require special handling. If there exists a plot prop PUTFN, which may be function or list of functions, the function (or functions) will be invoked with the arguments plot propname and stream for each user defined property on plot. If the function returns a non-NIL value, it is assumed an HREADable representation of the prop value has been written out on stream. In the case of a list of functions, the functions will invoked one at time, starting from the head of the list, until a non-NIL result is obtained. If there is no PUTFN, or the function (or none of the functions) returns a non-NIL value, the prop is HPRINT’ed.

Lists of the form ((FUNCTION function) arg) are recognized by the inverse of PRINTPLOT, READPLOT, to imply that function should be called with plot and arg as arguments at HREAD time, and the value returned to be the prop value.

(PRINTPLOTOBJECT plotobject plot stream)  
[Function]

Writes out an HREADable symbolic representation of plotobject on stream. As in PRINTPLOT user defined object properties require special handling. The protocol is the same as in PRINTPLOT.

The following data types have HPRINT macros and need no special handling: FONTDESCRIPTOR, MENU, PLOT, and PLOTOBJECT.

A file package command has been defined to simplyfy dumping PLOT’s on files.

(PLOTS . plots)  
[FilePkgCom]

The syntax is identical to VARS.

A plot image object is fully supported.

(CREATEPLOTIMAGEOBJ plot)  
[Function]

Returns an image object which contains a copy of plot. These image objects can also be created by copy-selecting from a plot window into a host window (e.g. TEdit or Sketch) that supports image objects. Such a selection will ask whether the plot should be inserted as a bitmap or a plot, the latter case constructing a plot image object. Buttoning on the image object provides the option of reshaping the plot or creating a separate plot window in which the plot can be modified. Closing the plot window will ask whether the new plot should be reinserted in the host.
INTRODUCTION
This file redefines the plot functions BOXREGION and DRAWPLOT so that each side of the box around the plot need not be drawn. Specifically, giving a plot a non-NIL value for the properties NOLEFT, NORIGHT, NOTOP or NOBOTTOM will eliminate the respective side from the drawing of the plot.
This module contains two examples of how PLOT might be used to produce high level plotting facilities. The first example is a histogram primitive, and the second is a scatterplotter. The code is commented, and exploits most of the facilities in PLOT. The scatterplot example is the simpler of the two, and is suggested as a starting point.

(SCATPLOT y x pointlabels ylabel xlabel title symbol) [Function]
Generates a scatterplot of y vs x which are numeric lists of equal length. If x in NIL, then y is plotted vs the integers from 1 to (LENGTH y). Pointlabels is a list of labels, one for each point plotted. Ylabel and xlabel are labels for the x and y axis respectively. Title is a title for the scatterplot. Symbol is the plotting symbol to use, must be a BITMAP; defaults to STAR.

Returns a PLOT.

(HISTPLOT batch label shade) [Function]
Batch is a list of numbers, or a list of pairs (number . frequency) whose histogram will be displayed. Label is an optional label for those numbers. Shade is a shade to use to fill the bars of the histogram (defaults to SHADE3). The case of all entries in batch being integers is treated specially.

Returns a PLOT.
PLOT OBJECTS

By: Jan Pedersen (pedersen.PA @ Xerox.com)

Uses: PLOT and TWODGRAPHICS

Plot objects are the primitive quantities of the PLOT module. A plot object is abstracted as an instance of datatype PLOTOBJECT. A point plot object is an instance of PLOTOBJECT whose data component describes a point. That is, a point plot object is a subtype of PLOTOBJECT; all plot objects satisfy \( \text{type} \ PLOTOBJECT\ FOO \), but only a point plot object satisfies in addition \( \text{PLOTOBJECTSUBTYPE}? \ POINT\ FOO \).

A PLOTOBJECT is both a datatype and a collection of functions that implements a set of generic operations on that plot object. A plot object must know how to draw itself, erase itself, highlight itself, etc. The PLOT module then deals only with generic operations, and allows the plot objects to implement them as is appropriate.

PLOTOBJECT [Datatype]

OBJECTFNS [Field]

Must be an instance of PLOTFNS

OBJECTSUBTYPE [Field]

Describes the plot objects subtype

OBJECTUSERDATA [Field]

Space for a property list

OBJECTMENU [Field]

The object’s MENU

OBJECTLABEL [Field]

Something to print

OBJECTDATA [Field]

Space for a datatype that describes the subtype of this PLOTOBJECT

The field OBJECTFNS must be an instance of PLOTFNS, essentially a vector of functions which implements the generic operations.

PLOTFNS [Datatype]

DRAWFN [Field]

Implements the DRAWOBJECT generic operation

ERASEFN [Field]

etc.
The generic operations are:

(DRAWPLOTOBJECT object viewport plot) [Function]

Draw the object within viewport. A VIEWPORT may be thought of as a sub imagestream. It will usually be associated with the plot's PLOTWINDOW, but might also be associated with some other image stream. Typically this generic operation will make use of functions from TWODGRAPHICS and the position of the object in world coordinates. The plot is also passed as an argument, so that the draw operation may make use of information cached on the property list of plot.

The only operation that is expected to draw on streams other than the PLOTWINDOW is drawobject, so the drawfn may have to behave differently depending on the imagestreamtype of the stream. All other generic operations are assumed to operate on the PLOTWINDOW. The idea here is that plot's may be drawn on any stream, but may be interacted with only through the PLOTWINDOW. It is also guaranteed that an object will be drawn before it is erased, highlighted, etc.

(ERASEPLOTOBJECT object viewport plot) [Function]

Erase the object from the viewport. The inverse of DRAWOBJECT. It is guaranteed that the viewport will be on the PLOTWINDOW

(HIGHLIGHTPLOTOBJECT object plot) [Function]

Highlight the object. Used in selection.

(LOWLIGHTPLOTOBJECT object plot) [Function]

The inverse of HIGHLIGHTOBJECT. With XOR drawing the HIGHLIGHTFN and the LOWLIGHTFN can often be the same.

(MOVEPLOTOBJECT object dx dy plot) [Function]

Destructively alter the object's OBJECTDATA, so that its position is moved dx, dy units (in world coordinates).

(LABELPLOTOBJECT object plot) [Function]

If it is desired to label the object, the LABELFN will be called. Often the function LABELGENERAL will do the trick.

(EXTENTOFPLOTOBJECT object plot) [Function]

Should return an EXTENT, which expresses the range of the object in world coordinates.
EXTENT [Datatype]
MINX [Field]
Minimum extent in the X (horizontal) direction
MAXX [Field]
Maximum extent in the X (horizontal) direction
MINY [Field]
Minimum extent in the Y (vertical) direction
MAXY [Field]
Maximum extent in the Y (vertical) direction

All fields are type floating.

(DISTANCETOPLOTOBJECT object streamposition plot) [Function]
Should return a number (more efficient if it returns a SMALLP), which is some measure of the distance from the REPRESENTATION of the object to the POSITION streamposition. Note that distance is calculated in stream coordinates, NOT world coordinates. This is done for efficiency and logical consistency. Selection makes most sense as an activity in stream coordinates.

A plot object will typically cache its stream coordinates when it is drawn. Although not strictly necessary (it is always possible to backsolve to stream coordinates from world coordinates), this improves efficiency many fold by avoiding generation of floating point boxes.

The following functions are provided to allow the plot object to customize how it is copied, printed on file, etc. The generic defaults will usually be satisfactory.

(COPYPLOTOBJECT object plot) [Function]
Returns a copy of object. COPYOBJECT will create a new instance of PLOTOBJECT and copy over all the fields of object except for OBJECTDATA. The object’s COPYFN is evoked with the arguments object and plot and is expected to return a new instance of OBJECTDATUM. The objects property list is handled as follows: If object has a prop COPYFN (which may be a function or list of functions), for each property it is called with the arguments newobject, oldobject, plot, propname. If the returned value is non-nil it is used as the value for that property on newobject; else the prop value is HCOPYALL’ed. If the value of COPYFN is a list of functions, they are invoked in order head to tail, and the first non-NIL value is used as the new value.

(PRINTPLOTOBJECT object plot stream) [Function]
Writes out to stream an HREADable symbolic representation of object. As in COPYOBJECT, PRINTOBJECT takes care of all PLOTOBJECT fields except of OBJECTDATA. The objects PUTFN will be invoked with the arguments object plot stream and is expected to write out a representation of OBJECTDATUM which is HREADable. This will usually be in prop list format.

Again the prop list of object requires special handling. The special object prop PUTFN may be a function or list of functions. For each property it will be invoked with the arguments object plot propropname and stream and if it returns a non-NIL value, it is assumed that property has been written out in a HREADable format. Again, if the the PUTFN prop is a list of fn’s then if any one of them returns non-NIL then the property is assumed written out. If there is no PUTFN then the property is (HPRINT prop stream NIL T)’ed.
PUTFNS may put out special lists of the form ((FUNCTION fnname) arg) in which case fnname will be invoked at HREAD time with args object plot propname arg and fnname will be expected to return the propvalue of propname.

(READPLOTOBJECT stream) [Function]
Reads in the product of PRINTOBJECT. Calls the objects GETFN to read in the OBJECTDATA field.

An instance of PLOTFNS may be created by the function:

(CREATEPLOTFNS drawfn erasefn extentfn distancefn highlightfn lowlightfn labelfn movefn copyfn putfn getfn borrowfrom) [Function]

Returns an instance of PLOTFNS. Drawfn, erasefn, and extentfn are required. If a distancefn is supplied then so must be a highlightfn. Lowlightfn defaults to highlightfn, labelfn defaults to LABELGENERIC. The other arguments also default to some safe, if not too efficient genericfn.

A primitive inheritance scheme is implemented via the optional argument borrowfrom. If supplied, borrowfrom must be an instance of PLOTFNS. Before creating the new instance of PLOTFNS, the NIL arguments passed are filled in from the fields of borrowfrom, with the following exception; lowlightfn is only inherited if highlightfn is also NIL.

The OBJECTDATA field will typically be a datatype which holds the data characterizing the PLOTOBJECT. For example a point plot object will have an OBJECTDATA field whose value is an instance of the datatype POINTDATA (has fields position, symbol, etc). So, a point PLOTOBJECT is a specialization of PLOTOBJECT. The field OBJECTSUBTYPE is supplied to make the subtype explicit. The following macro is provided to facilitate testing for plot object subtypes.

(PLOTOBJECTSUBTYPE? subtype plotobject) [Macro]
Essentially tests if (EQ subtype (fetch OBJECTSUBTYPE of plotobject))

(PLOTOBJECTSUBTYPE plotobject) [Function]
Returns the value of the OBJECTSUBTYPE field.

PLOTOBJECTS may be created via the function:

(CREATEPLOTOBJECT objectfns objectlabel objectmenu objectdata) [Function]
Returns an instance of PLOTOBJECT. Coerces objectmenu into a MENU if it is an item list.

The following subtypes of PLOTOBJECT are currently implemented.

pointPLOTOBJECT, curvePLOTOBJECT, polygonPLOTOBJECT, linePLOTOBJECT, graphPLOTOBJECT, texttPLOTOBJECT, filledrectanglePLOTOBJECT, compound PLOTOBJECT

The functions CREATEPOINT, etc. return an instance of PLOTOBJECT, with the appropriate OBJECTFNS and OBJECTDATA. In order for this to work, some initializations must be done at load time.

The function PLOT.SETUP performs the initializations at LOAD time.

(PLOT.SETUP opstable) [Function]
Opstable must be a list of lists of the form:
(subtypename1 (opname1 function1) (opname2 function2) ....
(subtypename2 (opname1 function1) (opname2 function2) ....
.....
(subtypename n (opname1 function1) (opname2 function2) ....
)

Creates one instance of PLOTFNS for each subtypename.

In summary, to add a new plot object you need to:

• Determine the data required to describe the new subtype. This may involve declaring a new datatype.
• Write functions similar to CREATEPOINT and PLOTPOINT for the new subtype.
• Write (or borrow) the functions which implement the generic ops described above.
• Invoke MAKEPLOTFNS to create an instance of PLOTFNS for the new plot object subtype, which all objects of that subtype will refer to.
• If continued use of the new plot object is contemplated, PLOT.SETUP should be evoked at load time to effect the proper initializations.

Look at the code for existing plot objects for more details. The point plot object is the simplest example.
PLOTOBJECTS1

By: Tad Hogg (hogg.PA @ Xerox.com)

Uses: PLOT and PLOTOBJECTS

PLOTOBJECTS1 defines additional plot objects for use with PLOT.

NEW PLOTOBJECTS

ERRORPOINT - a point with vertical and/or horizontal error bars.

SAMPLESET - a set of points drawn as line segments to a specified vertical or horizontal line.

FUNCTIONS

The following functions provide an add facility for the new objects. They are similar to the corresponding functions for the standard plot objects, e.g. PLOTPOINT, etc. The allowed forms of the arguments symbol, style, menu and nodrawflg are the same as for the standard functions.

(PLOTERROPOINT plot position-range label symbol style menu nodrawflg) [Function]

Position-range is a list of the form (POSITION X RANGE Y RANGE). POSITION is the position of the point in world coordinates. X RANGE and Y RANGE control the length of the horizontal and vertical error bars respectively. If the range is NIL, no error bars are drawn. If it is a number, it is a distance (in world coords) for the error bar to extend on each side of the point. Finally, if it is a pair of numbers (NegDist . PosDist) it specifies the extent of the error bar in the negative and positive directions, respectively. Symbol is used to plot the point. Symbol defaults to STAR. Style specifies the style to use for drawing the error bars.

Returns an ERRORPOINT PLOTOBJECT.

(PLOTERROPOINTS plot position-ranges labels symbol style menu nodrawflg) [Function]

As above except that position-ranges is a list of POSITION-RANGEs as described above and labels may also be a list. Reasonable things happen if positions and labels are of unequal length.

Returns a list of ERRORPOINT PLOTOBJECT's.

(PLOTSAMPLESET plot positions constant vertical? side label style menu nodrawflg) [Function]

The list of POSITION's defines a number of sample points. Constant specifies the location of a vertical or horizontal line, depending on whether vertical? is non-NIL. Line segments are drawn from the sample points to this line. Side determines which points are actually included. If side is NIL, only those points whose coord is greater than constant will be drawn (i.e. points above or to the right of the line). If side is T, only those with coord less than constant will be drawn. Otherwise, all points will be included. Style specifies the style to use for drawing the line segments.

Returns a SAMPLESET PLOTOBJECT.

All plot objects may be created independently of the previous functions. This is useful if it is desired to create a plot object without entering it on a PLOT's display list. The following functions create and return the new plot objects.
(CREATEERRORPOINT position-range label symbol style menu) [Function]
Returns an ERRORPOINT PLOTOBJECT.

(CREATESAMPLESET positions constant vertical? side label style menu) [Function]
Returns a SAMPLESET PLOTOBJECT.

In addition there are a number of functions to aid in creating position-ranges used with the error point plot objects:

(MAKE-POSITION-RANGE position xrange yrange) [Function]
Returns a position-range suitable for use for specifying an error point. The arguments are as described above for PLOTERRORPOINT.

(LOG-ERROR-RANGE position-range axis base) [Function]
Returns a position-range corresponding to position-range converted to a log scale. base is the log base to use (defaults to 10) and axis specifies which axis to convert: :X or :Y for a specific axis, NIL for both. Note that the position, with its error bars must be positive in order to be converted to a log scale.

(LOG-ERROR-RANGE-LIST position-ranges axis base) [Function]
Converts a list of position-ranges to log scale.
PLOTOBJECTS2

By: Tad Hogg (hogg.PA @ Xerox.com)

Uses: PLOT and PLOTOBJECTS

PLOTOBJECTS2 defines an additional plot object for use with PLOT.

NEW PLOTOBJECT

FILLEDPOLYGON - a polygon with optional shading in its interior.

FUNCTIONS

The following functions provide an add facility for the new object. They are similar to the corresponding functions for the standard plot objects, e.g. PLOTPOINT, etc. The allowed forms of the arguments texture, style, menu and nodrawflg are the same as for the standard functions.

(PLOTFILLEDPOLYGON plot positions label style texture menu nodrawflg)  [Function]

The points in positions define a closed polygon. The polygon is filled with texture, and the other arguments are the same as for PLOTPOLYGON. If the linewidth specified by style is 0, the polygon perimeter will not be drawn.

Returns a FILLEDPOLYGON PLOTOBJECT.

All plot objects may be created independently of the previous functions. This is useful if it is desired to create a plot object without entering it on a PLOT’s display list. The following creates and returns the new plot object.

(CREATEFILLEDPOLYGON positions label style texture menu)  [Function]

Returns aa FILLEDPOLYGON PLOTOBJECT.

The actual drawing is done with

(CLILPPED.FILLPOLYGON clippingregion points texture stream operation windnumber draw? width drawoperation color dashing)  [Function]

which effectively does both of (FILLPOLYGON points texture stream operation windnumber) and (if draw? is non-NIL)a series of (DRAWLINE x1 y1 x2 y2 width drawoperation stream color dashing) for each edge of the polygon except they are clipped against clippingregion in stream coordinates.
This module turns on pre-emptive process scheduling. Using IL:\PERIODIC.INTERRUPT, it forces a block in whatever process is running.

(IL:PREEMPTIVE &OPTIONAL STATE) [Function]

The function PREEMPTIVE turns preemptive process scheduling on and off. (IL:PREEMPTIVE ':ON) turns it on, (IL:PREEMPTIVE ':OFF) turns it off. (IL:PREEMPTIVE) with no argument returns the current state with no change.

WARNING WARNING WARNING WARNING DANGER DANGER DANGER DANGER DANGER

PREEMPTIVE is dangerous. Many places in the system do not have monitor locks and other mechanisms to prevent one process from overwriting the data of another in the face of preemptive interrupts. (Most do, of course.)

I've run with preemptive scheduling turned on for weeks, and about once a day, my screen gets trashed, windows and menus overwritten, etc. This version of PREEMPTIVE is a little more conservative than previous versions, e.g., it checks to see if the system is running in the MENU code and doesn’t do a process switch. However:

USE AT YOUR OWN RISK. CAUTION CAUTION.

NOTE: Using SPY turns preemptive scheduling OFF.
INTRODUCTION

This module is a patch to allow Press printers to print NS characters by translating them to appropriate Press fonts. Before loading this file, make sure there are no open press streams (i.e. no hardcopy in progress to a Press printer).

CONTROLLING CHARACTER SET TRANSLATIONS

The translations are controlled by a number of variables and functions described below. These variables can be modified to provide additional or different translations.

Global character set translations

NSTOASCII TRANSLATIONS [Variable]

an ASSOC list whose elements have the form (charset translationArrayName). This specifies which translation array is to be used when translating the specified character set.

Example: `((0 ASCIIFROM0ARRAY) (38 ASCIIFROM38ARRAY))` specifies that ASCIIFROM38ARRAY is bound to the array to be used for translating charset 38.

The translationArrayName is bound to an array whose index ranges from 0 to 255. Each element of the array specifies the translation to use for the corresponding charcode in this charset.

Translations are of one of the following forms:

1. NIL -- no translation specified which will use the font as is for charset 0 and otherwise print a black box to indicate the NS character could not be translated

2. an integer in the range 0 to 255 which indicates that this value is to be used as the translated charcode, but that no font translation is required [This is mainly useful for converting NS to ASCII in charset 0.]

3. a two element translation list of the form (fontFamily charcode) which indicates that this character should be translated to charcode in a font whose family is fontFamily. Note that charcode should be in the range 0 to 255. fontFamily can also be a font descriptor or a font specification list (e.g. (Gacha 10)) of a form acceptable to FONTCREATE.

PRESSFONTFAMILIES [Variable]

a list whose elements are of the form (FAMILY . specialTranslations). The optional list specialTranslations specifies translations to use for Press fonts in charset 0. Each element is (charcode translation) which specifies that translation is to be used for charcode in this family.

Example: `((GACHA (50 (HELVETICA 40)) (51 (TIMESROMAN 45))) (TIMESROMAN) (SYMBOL))`
Note: these translations are cached in the font descriptor when PRESS fonts are created so any changes to these variables will not change the translations in previously created fonts.

**Translations in individual fonts**
The following two functions provided detailed control over the translations used in individual fonts.

(GETCHARPRESSTRANSLATION  CHARCODE FONT)  [Function]
returns the translation (a two element list) used for CHARCODE in FONT

(PUTCCHARPRESSTRANSLATION  CHARCODE FONT NEWTRANSLATION)  [Function]
sets the translation to be used for CHARCODE in FONT. NEWTRANSLATION should be a translation in one of the forms described above.

**Additional functions**

(PRESS.NSARRAY  CHARSET FAMILY ASCIIARRAY)  [Function]
This function returns a suitable translation array built as the inverse of a translation array from Press to NS characters. Such arrays are used to print Press fonts on Interpress printers and are listed in the variable ASCIITONSTRANSLATIONS. CHARSET is the character set for which to create a translation. FAMILY is the press font family for which ASCIIARRAY is the translation to NS characters. If ASCIIARRAY is not specified, the function looks through all arrays included on ASCIITONSTRANSLATIONS to fill in the translation array.

**CONTROLLING PRESS FONT COERCIONS**
There is also a mechanism for determining which press font is actually used for the translation. For example, an NS character in the Modern 8 font might translate to an ASCII character in Symbol 8. If this font does not exist on the printer, a (generally incorrect) font change will be done by the printer. The following procedure changes the actual font used, e.g. to Symbol 10 in this example.

The coercion is controlled by a coercion list which is an alist indexed by device. The font coercion scans down the element on the list for the requested device (e.g. PRESS) looking for the first entry that matches the user request. If a match is found, then the entry tells how to construct an appropriate new name from the requested specification. Fields of the newname not specified in the entry are simply copied over.

FONTCOERCIONS  [Variable]
This list allows the user to coerce fonts that he knows don't exist on the printer even tho the fonts-widths files doesn't indicate that (e.g. the desired size doesn't exist). FONTCOERCIONS is initialized simply to take all SYMBOL fonts of size less than 10 into 10, and size greater than 12 into 12.

MISSINGFONTCOERCIONS  [Variable]
If the initial coerced (or uncoerced) lookup fails, then MISSINGFONTCOERCIONS is used. This takes MODERN into HELVETICA etc--the standard press coercions.

The procedure for determining whether a user request matches a coercion entry is straightforward. If the match-part of the coercion entry is an atomic family name, it matches if it is eq to the requested family. Otherwise, the match-part must be a list of family, size, face in standard fontname order. If a component is NIL or missing, then it is assumed to match. The only funniness is in size matching. The size component can be NIL (matches anything), a particular size (EQ matches), or a list of the form (<
n) or (> n) where n is a size number. The first matches any requested size less than n, and the second matches any requested size greater than n.

FONTCOERCIONS for PRESS starts out as

((SYMBOL (< 10) ) (SYMBOL 10)) (SYMBOL (> 12))(SYMBOL 12))

MISSINGFONTCOERCIONS for PRESS starts out as

((MODERN HELVETICA) (CLASSIC TIMESROMAN) etc.)
INTRODUCTION

PRETTYFILEINDEX is a program for generating indexed listings for Lisp source files. PRETTYFILEINDEX operates by reading expressions from the file and reprettyprinting them to the output image stream, building up an index of the objects as it goes. The index is partitioned by type (e.g. FUNCTIONS, VARIABLES, MACROS, etc.); within each type, the objects are listed alphabetically by name along with the page number(s) on which their definitions appear in the listing.

PRETTYFILEINDEX also modifies the Exec's and the FileBrowser's SEE command to prettyprint the file being viewed, if it is a Lisp source file. It also modifies the PF and PF* commands to prettyprint the requested function body. Together, these features mean you can use the NEW & FAST options to MAKEFILE to speed up file creation without sacrificing the ability to get pretty listings or see the files prettily inside Lisp.

PRETTYFILEINDEX performs some additional niceties in the listing: it prints bitmaps by "displaying" them, rather than dumping their bits; it translates underscore to left arrow (for the benefit of Interlisp listings); it prints quote and backquote in a font in which they are clearly distinguishable; and it suppresses some of the "noise" in source files, such as the filemap.

The module also contains a function MULTIFILEINDEX that can be used to generate a merged index of items from a whole set of files being listed.

PRETTYFILEINDEX subsumes, and is incompatible with, the modules SINGLEFILEINDEX and PP-CODE-FILE. You can, however, load PRETTYFILEINDEX on top of either one, and it will successfully wrest control of LISTFILES from them. PRETTYFILEINDEX has several advantages over SINGLEFILEINDEX: the prettyprinter has fine control over positioning of the output stream, so things that are supposed to line up do, despite font changes and variable-width fonts; the entire page is used, rather than sacrificing the bottom quarter or so due to lack of control over page breaks; and the use of an image stream allows bitmaps to be rendered directly.

USING PRETTYFILEINDEX

For ordinary use, just load PRETTYFILEINDEX.LCOM. This redefines LISTFILES1 so that calling LISTFILES or using the File Browser's Hardcopy command invokes PRETTYFILEINDEX if the file is a Lisp source file. The listing is created by default in a single background process that handles all LISTFILES requests. The file being indexed needn't be loaded, or even noticed (in the File Manager sense) as long as the file's commands don't require customized prettyprinting defined by the file itself. The index is printed at the end of the listing; you are expected to manually transpose the index to the front of the collection of paper that emerges from the printer.

PRETTYFILEINDEX normally assumes that you are printing one-sided listings. However, if your global default is for two-sided (currently this means that EMPRESS#SIDES = 2) or you specified two-sided in the options you passed to LISTFILES, it will prepare the output as if for two-sided listing. For example, from an Interlisp exec,
causes the file FOOBAR to be listed two-sided on the print server Perfector: (the % is the Interlisp reader's escape character, needed to quote the special character #: in an XCL exec the escape character is \, and from other packages you also have to qualify the symbols LISTFILES, SERVER and #SIDES with the package prefix IL:).

For two-sided listings, the margins are symmetric, instead of being shifted a bit to the right, page numbers appear on the outside edge of the page, and a blank page is inserted at the end of the listing if necessary to ensure that the index starts on an odd page (and hence is transposable to the front).

PRETTYFILEINDEX prettyprints the file's contents and prints indexed names using the package and read table specified in the file's reader environment, which appears at the beginning of the file. It assumes, as does most of the file manager, that the reader environment is sufficient to read any expression on the file. If you have violated this assumption, for example, by referring in the file to a symbol in another package that is defined on a file that is indirectly loaded by the file somewhere in its coms, you will probably need to LOADFROM the file before you can list it.

INDEXING MULTIPLE FILES

Ordinarily, you list files and get one index per file. If a module is made up of several files, you may want a master index of the whole set of files, so that you don't have to remember which file contains a function, macro, etc. that you are looking up. This job is handled by MULTIFILEINDEX:

\[(MULTIFILEINDEX files printoptions)\] [Function]

This function lists each of the files in the list files using PRETTYFILEINDEX and then produces a master index by merging all the individual indices. The master index is appended to the output of the last file listed. The argument files can be a list of file names and/or file patterns, such as "\{FS:}<Carstairs>RED*", or a single such pattern. In the pattern, unless explicitly specified, the extension defaults to null and the version to "highest". The argument printoptions is a property-list of options, the same as the printoptions argument to SEND.FILE.TO.PRINTER or PRETTYFILEINDEX, with the addition of some options recognized by MULTIFILEINDEX, described further below.

As each file is listed, its pages are numbered with an ordinal file number plus the page number within the file; e.g., in the first file the pages are numbered 1-1, 1-2, ..., in the second file 2-1, 2-2, etc. The master index then refers to page numbers in this form, although each individual file's own index shows only the file-relative page numbers. Alternatively, you can tell MULTIFILEINDEX to number all the pages consecutively, rather than using "part numbers", by giving the option \:CONSECUTIVE, value \:T in printoptions.

In the event that some files in the set have different reader environments, the master index is printed in the environment used by the majority of the files. More specifically, MULTIFILEINDEX independently chooses the package used by the majority of the files and the readtable used by the majority; in the case of a tie, the file later in the set wins. If this default is not adequate, you can specify the environment yourself by giving the \:ENVIRONMENT option. The value should either be a reader environment object, such as produced by MAKE-READER-ENVIRONMENT, or a property list of the form used by the MAKEFILE-ENVIRONMENT property.

For example,
(MULTIFILEINDEX "<Barney>Rub*"
   '(:CONSECUTIVE T
      :ENVIRONMENT (:PACKAGE "JABBA" :READTABLE "XCL")))

would list each of the files matching "<Barney>Rub*;", numbering the pages consecutively from
the first file through the last, and printing the master index with respect to the package JABBA
and read table XCL.

INCREMENTALLY REPRINTING MULTIPLE FILES

If you have used MULTIFILEINDEX to list a group of files, and later one of the files changes, or
maybe the printer just ate part of your listing, you might want to update your listing without
reprinting the entire set of files. You have two options.

(1) You can have PRETTYFILEINDEX reprint the one file that changed (or was eaten). Specify
the print option :PART n to have it treat the single file as the nth part of a multiple listing, or the
option :FIRSTPAGE n to have it start numbering the pages at n instead of 1 (for the case where
you used the :CONSECUTIVE option to MULTIFILEINDEX). For example,

   (LISTFILES (:PART 3) "<Barney>Rubric")

would reprint <Barney>Rubric as the third file in a group. Of course, this doesn't reprint the
master index, but it only has to process the one file, which may be adequate for your needs if
things didn't move around too much.

(2) You can have MULTIFILEINDEX process the entire set of files again, but only print some of
them. You specify this by parenthesizing the files you don't want printed. That is, each element
of the files argument to MULTIFILEINDEX is a file name or a list of file name(s); those files
inside sublists are processed but not printed. You cannot specify patterns. The master index is
listed after the last file, as usual, except that if the last file was in a sublist, and hence not
printed, the master index will appear as a separate listing. Calling MULTIFILEINDEX in this
manner is nearly as computationally expensive as calling it to list the whole set for real (it omits
only the transportation to the printer), but it does save paper and printer time.

LISTING COMMON LISP FILES

Ordinarily, PRETTYFILEINDEX only processes files produced by the Lisp File Manager; it passes
all others off to the default hardcopy routines. However, you can tell it to process a plain Common
Lisp text file by passing the print option :COMMON; e.g.,

   (LISTFILES (:COMMON T) "conjugate.lisp")

PRETTYFILEINDEX still processes the file by reading and prettyprinting, just as for Lisp files.
It starts in the default Common Lisp reading environment (package USER and read table LISP),
and evaluates top-level package expressions, such as in-package and import, in order to
continue reading correctly. The index is printed in whatever the environment was at the end of
the file.

Of course, this is of fairly limited utility, as all read-time conditional syntax is lost: comments, #+,
#o, etc. The one exception is that top-level semi-colon comments are preserved—they are copied to
the output directly, rather than being read.

Customizing PRETTYFILEINDEX

The remainder of this document describes various ways in which PRETTYFILEINDEX can be
customized.
HOW TO SPECIFY INDEXING TYPES

Initially, PRETTYFILEINDEX knows about most of the standard file manager types. In addition, it handles all the types defined by DEFDEFINER. For definers with a :NAME option, it assumes that the function is free of side effects. PRETTYFILEINDEX also notices (but does not evaluate) DEFDEFINERs that appear on the file it is currently indexing, which should appear before any instances of the type so defined in order for correct indexing to occur. Of course, it can't know about definer types that are defined on some other file unless you load it.

You can augment the set of indexing types, or override the default handling of definers, by adding elements to the following variable:

*PFI-TYPES* [Variable]

A list of entries describing types to be indexed and a way of testing whether an expression on the file is of the desired type. Each entry is a list of up to 4 elements of the form (type dumpfn namefn ambiguous), the first two of which are required:

- **type**: The name of the type, e.g., MACRO. This name will appear as the name of the index for this type, e.g., "MACRO INDEX". Type is usually the name of a file package type, though it need not be. It must be a symbol.

- **dumpfn**: The name of the function that appears as the CAR of the form that defines objects of type type on the file, or a list of such names. E.g., for type TEMPLATE it is SETTEMPLATE; for type VARIABLES it is (RPAQ RPAQQ RPAQ? ADDTOVAR).

- **namefn**: A function that tests whether the expression that starts with dumpfn really is of the desired type, and returns the name of the object defined in the expression. The function takes as arguments (expr entry), where expr is the expression whose CAR matched the entry. The testfn should return one of the following:
  - NIL the expression is not of the desired type.
  - name the expression defines a single object of this name and of the type given in the entry.
  - a list the value is either a single list or a list of lists, each of the form (type . names), meaning that the expression defines each of the names as having the specified type.

If the namefn is NIL or omitted, the name of the object is obtained from the second element of the expression. If that element is a list, the name is taken to be its CAR, or its CADR if the element is a quoted atom.

- **ambiguous**: True if the expression is ambiguous, in the sense that even if namefn returns a non-NIL value, it is possible for this expression to also satisfy other entries in *PFI-TYPES*. E.g., the expression (RPAQ --) is ambiguous, because it could define either a variable or a constant. If ambiguous is true, you usually want a corresponding entry on *PFI-FILTERS* (below).
*PFI-PROPERTIES* [Variable]

A list used by the default handler for the PUTPROPS form. It associates property names with a type (something more specific than the type PROPERTY) under which objects having this property should be indexed. Each element is of the form (propname type). If type is NIL or omitted, then objects having this property are ignored. In addition, the default PUTPROPS handler treats all elements of the list MACROPROPS as implying type MACRO.

The initial value of *PFI-PROPERTIES* is

```
((COPYRIGHT)
 (READVICE ADVICE)),
```

meaning that the COPYRIGHT property should be ignored, and the READVICE property implies that the object should be indexed as type ADVICE.

*PFI-FILTERS* [Variable]

A list describing potential index entries that should be filtered out of the final index. Each element of *PFI-FILTERS* is a list (type filterfn), where type is one of the types in *PFI-TYPES* and filterfn is a function of one argument, an index entry. If filterfn returns true, then the index entry is discarded. An index entry is of the form (name . pagenumbers).

For convenience, an element of *PFI-FILTERS* can also take the form (type . subtype), meaning that if an object is already indexed as a subtype then it should not also be indexed as a type.

The initial value of *PFI-FILTERS* is

```
((VARIABLES . CONSTANTS)),
```

meaning that "variables" that successfully index as constants should not also be listed in the VARIABLES index. This extra pass is needed because the CONSTANTS File Manager command causes expressions of the form (RPAQ var value) to be dumped on the file, and at the time this expression is read, it is not known whether there will later on appear a CONSTANTS form for the same variable.

Filter functions may want to call the following function:

```
(PFI.LOOKUP.NAME name type) [Function]
```

Looks up name in the index being built for type type. If it finds an entry, it returns it. Index entries are of the form (name . pagenumbers). It is permissible for a filter function as a side effect to destructively change another index entry by adding page numbers to it. You might want to do so, for example, in the case where there is a kind of object that dumps two expressions on a file, each of which is a different type (according to *PFI-TYPES*), but you want both occurrences indexed as a single type.

MORE EXPLICIT EXPRESSION HANDLING

The functions and variables described below allow you to completely control how certain expressions in the input file are handled. You can use these hooks to perform custom
prettyprinting, to suppress the printing of some expressions, or to perform indexing more complex than that supported by *PFI-TYPES*.

*PFI-HANDLERS* [Variable]

An association list specifying explicit "handlers" for expressions that appear on the input file. Each element is a pair (car-of-form . handler), where handler is a function of one argument, an expression read from the file whose first element is car-of-form. The handler is completely in charge of indexing the expression and/or printing it to *STANDARD-OUTPUT*. Unless the handler chooses to suppress the printing altogether, it is expected to print at least one blank line first, so that expressions are attractively separated in the listing (see PFI.MAYBE.NEW.PAGE).

*PFI-PREVIEWERS* [Variable]

This list is used when PRETTYFILEINDEX is used by the SEE command. During the SEE command, real-time performance is important, so it is undesirable to have long delays while reading a very large expression. For example, all the functions in an Interlisp FNS command appear on the file inside a single DEFINEQ expression. If handled in the obvious way, the user would have to wait for the entire expression to be read before any output appeared. A previewer has the opportunity to read the expression in pieces and prettyprint it as it goes.

Each element of *PFI-PREVIEWERS* is a pair (car-of-form . previewer), where previewer is a function of one argument, the car-of-form. The previewer is called when PRETTYFILEINDEX encounters an expression of the form "(car-of-form " on the file. Its job is to read expressions from *STANDARD-INPUT* (currently positioned after the car of form) until it encounters the closing right parenthesis, which it should consume, and prettyprint the elements appropriately to *STANDARD-OUTPUT*. *PFI-PREVIEWERS* is used only from the SEE command, so indexing is not necessary (but also not harmful, other than to waste some time).

If an expression does not have a previewer, PRETTYFILEINDEX reads the rest of the expression itself and handles it normally, i.e., performs (PFI.HANDLE.EXPR (CONS car-of-form (CL:READ-DELIMITED-LIST #\)) ).

(PFI.DEFAULT.HANDLER expr) [Function]

This is the function PRETTYFILEINDEX uses to process expressions that have no explicit handler. It indexes the expression according to *PFI-TYPES* and then prettyprints the expression. You can call this function from your handler if you decide you have an expression you didn't want to handle specially.

(PFI.HANDLE.EXPR expr) [Function]

Performs PRETTYFILEINDEX's normal handling of the expression expr, including looking on *PFI-HANDLERS**. Handlers and previewers of forms that encapsulate arbitrary expressions, such as DECLARE:, typically call this to process subexpressions.
(PFI.ADD.TO.INDEX name type/ entry)  

[Function]

Adds an entry to the index for type/ entry specifying that name occurs on the current page. type/ entry is either a type or an entry from *PFI-TYPES* from which the type will be extracted.

(PFI.PRETTYPRINT expr name formflg)  

[Function]

Prettyprints expr. Optional name is the name of the object being printed; if a page crossing occurs in the middle of the prettyprinting, this name will be displayed in the page header. If formflg is true, print the expression as code; otherwise as data.

(PFI.MAYBE.NEW.PAGE expr minlines)  

[Function]

Starts a new page if the listing is currently near the bottom of the page and expr won't fit, else performs a single (TERPRI). If minlines is specified, it is an explicit estimate of how much space the expression will require, in which case expr can be NIL; otherwise, the function estimates the size. Handlers should call this before calling PFI.ADD.TO.INDEX, so that the page number in the index is correct. The typical handler calls PFI.MAYBE.NEW.PAGE, then PFI.ADD.TO.INDEX, then prints the expression, possibly via PFI.PRETTYPRINT.

OTHER VARIABLES

*PFI-INDEX-ORDER*  

[Variable]

A list of types (as in *PFI-TYPES*) in the order in which the various types should appear in the index. Types not in this list are printed in an order of the program's choosing, currently a "best fit" algorithm (print the largest type index that will fit on the page). The initial value is (FUNCTIONS), meaning that the function index will appear first, with no constraints on the order of other types.

*PFI-PRINTOPTIONS*  

[Variable]

A plist of print options that PRETTYFILEINDEX appends to the list of print options passed to LISTFILES, thus supplying some printing defaults. The initial value is (REGION (72 54 504 702)), which on standard letter size paper in portrait mode results in left, bottom, top, and right margins of 1", 3⁄4", 1⁄2" and 1⁄2", respectively. If the print options passed to LISTFILES call for a two-sided listing, the default region is shifted 1⁄4" to the left. If the print options specify LANDSCAPE mode, the default region is ignored. Any REGION option specified in *PFI-PRINTOPTIONS* must be in points; it is scaled appropriately to the actual hardcopy device being used.

*PFI-MAX-WASTED-LINES*  

[Variable]

If an expression looks like it won't fit on the current page and there are no more than this many lines remaining on the page, PRETTYFILEINDEX starts a new page before printing the expression. A floating-point value indicates a fraction of the page; an integer indicates an absolute number of lines. The initial value is 12.

*PFI-CHARACTER-TRANSLATIONS*  

[Variable]

A list specifying how certain characters should be rendered on the output stream. This is used to get around the poor rendering of certain characters in the default font. Each
element is of the form (imagetype . charpairs), where imagetype is the type of image stream being printed to and each element of charpairs is an alist whose elements are of the form (sourcecode . destcode . looks-plist), specifying the character code to use on the destination image stream for a specified character code in the input stream. If looks-plist is non-NIL, destcode is printed in a font obtained by applying FONTCOPY to the current font and looks-plist.

The initial value is

```lisp
((INTERPRESS (95 172)
             (96 169 FAMILY CLASSIC)
             (39 185 FAMILY CLASSIC)))
```

meaning if the output stream is an Interpress stream the lister should turn character 95 (underscore) into 172 (left arrow), backquote into left single quote in the Classic font (of the same size and weight), and single quote into right single quote in Classic.

*PRINT-PRETTY-FROM-FILES* [Variable]

If true, the SEE (in the Exec and Filebrowser), PF and PF* commands attempt to prettyprint to the display, rather than copying the file as it is currently formatted. The initial value is T.

*PRINT-PRETTY-BITMAPS* [Variable]

If true, then when *PRINT-ARRAY* is true and a bitmap is to be printed to an image stream, the bitmap itself is displayed as an image on the stream, rather than as the machine-readable representation of its bits (of the form #*(16 16)H@@@L...). This variable has no effect on printing to files, such as in MAKEFILE, nor on PRETTYFILEINDEX, which binds it true; thus, changing the value mainly affects the display. The initial value is T.

*PFI-DONT-SPAWN* [Variable]

If NIL, LISTFILES arranges for a separate process to do the hardcopying (whether using PRETTYFILEINDEX or not) and returns immediately; if T, it makes the listing directly, not returning until it is finished. The initial value is NIL.

LISTING ELSEWHERE THAN THE PRINTER

Ordinarily, you call LISTFILES (or uses the File Browser) to create listings. However, you can also call PRETTYFILEINDEX directly if you want to direct the output elsewhere, such as to an Interpress file:

```lisp
(PRETTYFILEINDEX filename printoptions outstream dontindex)
```

Lists filename, the name of a Lisp source file or a stream open for input on such a file, printing it and its index to outstream. outstream is either an open image stream, or NIL, in which case the output goes to (OPENIMAGESTREAM) and the stream is closed afterwards, which results in it being sent to the default printer. If filename or outstream is open on entry, it is left open on exit. printoptions is a plist of options of interest to either LISTFILES or OPENIMAGESTREAM. If dontindex is true, no index is produced; this argument is used by the SEE command.
If the file is not a File manager file, PRETTYFILEINDEX takes no action and returns NIL; otherwise, it returns the full file name. However, if filename is an open stream, then PRETTYFILEINDEX copies the remainder of the stream to outstream (which must be given) using PFCOPYBYTES, and returns the full file name. This is so that the stream does not need to be backed up after discovering that the file is not a File Manager file, an operation not possible for a sequential-access stream.

LIMITATIONS

PRETTYFILEINDEX assumes that the default font, which is used to print the index, is fixed-width.

PRETTYFILEINDEX uses the regular Interlisp prettyprinter. This means that if you have File Manager commands that produce their output in a customized way, e.g., by printing inside the E command, then the output will look different between MAKEFILE and PRETTYFILEINDEX. You can usually remedy this by supplying PRETTYPRINTMACROS for the types of expressions your command dumps (which may also let you replace the E with a simpler P command), or by defining handlers for the expressions (see *PFI-HANDLERS*). PRETTYFILEINDEX already supplies PRETTYPRINTMACROS for most of the customized printing done by the current File Manager: RPAQ, RPAQQ, RPAQ?, ADDTOVAR, PUTPROPS and COURIERPROGRAM.

With the exception of noticing the reader environment and DEFDEFINER expressions, PRETTYFILEINDEX does not interpret the contents of the file. If your file depends on itself for proper prettyprinting or indexing, you need to LOAD (or possibly just LOADFROM) the file first.
DESCRIPTION

Creates a menu which displays all printers in the global list DEFAULTPRINTINGHOST, allows selection of a default printer, and permits addition and deletion of printers from DEFAULTPRINTINGHOST. Printers are displayed in the same order as they appear in DEFAULTPRINTINGHOST. Selecting an item from the menu will highlight by inversion and move it to the top of the menu, thus becoming the default printer. Selection in the title bar of the menu with the left or middle button will allow you to add or to delete a printer from the menu.

An auxiliary process, PRINTERMENU.WATCH, monitors the value of DEFAULTPRINTINGHOST and will update the menu if this variable is changed. If PRINTERMENU.WATCH is killed, the menu will be grayed out to indicate that it may no longer be valid. Clicking left or middle buttons inside the menu will restart PRINTERMENU.WATCH and update the menu.

To use:

Load the module with:

(LOAD 'PRINTERMENU.LCOM)

Start it with:

(PRINTERMENU)

User Switches:

1. Set DEFAULTPRINTINGHOST to contain all printers from which you wish to select.

2. Prior to calling the function (PRINTERMENU), the global variable PRINTERMENU.POSITION can be set to the position, in screen coordinates, where you want the menu to appear. If not set, you will be prompted for a position for the menu window.
DESCRIPTION

PROGRAMCHAT is a Lisp function that invokes a windowless Chat process to execute a single command line on a remote host. PROGRAMCHAT requests a login if one has not been made recently to the remote host. After execution of the command, a normal logout is performed, and the Chat connection is closed.

PROGRAMCHAT was written by Eric Schoen to allow initiation of remote computation from Lisp workstations. It works with both VMS and Unix operating systems on the remote host.

To use:
Load the module with:

\[(\text{LOAD 'PROGRAMCHAT.LCOM})\]

Invoke the function with:

\[(\text{PROGRAMCHAT } \text{hostname } \text{commandString } \text{windowFlg})\]

where

\text{hostname} is the network name of the remote host,

\text{commandString} is a string which is the exact format of the command to be run from the command line interpreter of a VAX/VMS host (or from the shell of a VAX/Linux host), and

\text{windowFlg} is a variable that, when T, opens a window and displays a log of data transferred between the PROGRAMCHAT process and the remote host. PROGRAMCHAT is normally invoked with \text{windowFlg} = \text{NIL}.

Warnings:

1. When loaded, PROGRAMCHAT resets the variable NETWORKLOGININFO.
2. PROGRAMCHAT provides no error handling. If the connection to the remote host is broken, no error message is returned.
PROMPTREMINDERS

To be periodically reminded of things

By: JonL White

Revised by: Larry Masinter (Masinter.pa@Xerox.com), subsequently by Becky Burwell
(Burwell.PA@Xerox.COM)

INTRODUCTION

PROMPTREMINDERS implements a facility which schedules events to be performed, or messages to be flashed in a prompt window. Events can be periodic or once-only. The showing of a message in a prompt window has the extra facility of flashing a message, and stopping only when there has been a recent response (mouse or keyboard movement) from the user.

If the MESSAGE given for the reminder (see description of the function SETREMINDER below) is a listp, then when the reminder "goes off", that listp will be EVAL'd rather than any of the "winking", "flashing", or "hassling" mentioned above.

The global variable REMINDERSTREAM holds the stream where the message is to be displayed; if not set by the user, it defaults to PROMPTWINDOW. After the message has been displayed, the window (if indeed REMINDERSTREAM holds a window) will be closed, depending on the value of CLOSEREMINDERSTREAMFLG.

REMINDERS is a file package type, so that they may be easily saved on files, and so that the general typed-definition facilities may be used. On any file which uses the REMINDERS filepkgcom, it is advisable to precede this command with a command

(FI LE S (S Y S LO A D C O MP I L E D F R O M L IS P US E R S) P R O M P T R E M I N D E R S)

since this package is not in the initial Lisp loadup. When initially defining a reminder, it is preferable for the user to call SETREMINDER rather than PUTDEF; but HASDEF is the accepted way to ask if some name currently defines a "reminder", and DELDEF is the accepted way to cancel an existing "reminder".

EXAMPLES

(SETREMINDER NIL (ITIMES 30 60) "Have you done a CLEANUP recently?")
the user wants to be reminded every 30 minutes that he ought to save his work

(SETREMINDER 'WOOF NIL "Call home about dinner plans."
"8-Jan-83 4:00PM")
he merely wants to be told once, at precisely 4:00PM to call home
(SETREMINDER NIL 600
  '(PROGN (AND (FIND.PROCESS 'LISTFILES) (add FREQ 1))
         (add TOTAL 1)))

checks every 10 minutes to see if there is a process called LISTFILES

FUNCTIONS

(SETREMINDER NAME PERIOD MESSAGE INITIALDELAY EXPIRATION) [Function]

This will create and install a "reminder" with the name NAME (NIL given for a name will be replaced by a gensym), which will be executed every PERIOD number of seconds by winking the string MESSAGE into the prompt window; if MESSAGE is null, then NAME is winked; if MESSAGE is a listp, then it is EVAL'd and no "winking" takes place. "Winking" means alternately printing the message and clearing the window in which it was printed, at a rate designed to attract the eye's attention.

The first such execution will occur at PERIOD seconds after the call to SETREMINDER unless INITIALDELAY is non-NIL, in which case that time will be used; a numeric value for INITIALDELAY is interpreted as an offset in seconds from the time of the call to SETREMINDER, and a stringp value is an absolute date/time string.

If PERIOD is null, then the reminder is to be run precisely once. If EXPIRATION is non-null, then a fixp means that that number of seconds after the first execution, the timer will be deleted; a stringp means a precise date/time at which to delete the timer.

Optional 6th and 7th arguments -- called REMINDINGDURATION and WINKINGDURATION -- permit one to vary the amount of time spent in one cycle of the wink/flash loop, and the amount of time spent winking before initiating a "flash". The attention-attracting action will continue for REMINDINGDURATION seconds (default: the value of the global variable DEFAULT.REMINDER.DURATION which is initialized to 60), or until some keyboard action takes place.

Type-ahead does not release the winking. In case the user fails to notice the winking, then every WINKINGDURATION seconds (default: the value of the global variable DEFAULT.REMINDER.WINKINGDURATION which is initialized to 10) during the "reminding", the whole display videocolor will be wagged back and forth a few times, which effects a most obnoxious stimulus.

SETREMINDER returns the name (note above when NIL is supplied for the name).

(ACTIVEREMINDERNAMES) [Function]

ACTIVEREMINDERNAMES returns the list of active reminders.

(REMINDER.NEXTREMINDDATE NAME DATE) [Function]

REMINDER.NEXTREMINDDATE returns (and optionally sets) the date&time (in DATE format) at which the reminder is next to be executed.

(REMINDER.EXPIRATIONDATE NAME DATE) [Function]

REMINDER.EXPIRATIONDATE returns (and optionally sets) the date&time (in DATE format) at which the reminder will be automatically deleted.
(REMINDER.PERIOD NAME SECONDS) [Function]
REMINDER.PERIOD returns (and optionally sets) the period (in seconds) at which the reminder gets rescheduled.

(SHOWDEF name 'REMINDERS) [Function]
will show a reminder in a pretty format, etc.
INTRODUCTION
The Proofreader interactively looks for and corrects spelling errors in a given TEdit document. To use it, go to the TEdit menu (click the middle button while in the title bar) and invoke the menu item labeled "Proofread". This will simultaneously attach a special menu to the side of the document and start proofreading from the caret. The proofreader scans the document from the caret location and stops at the first misspelling it finds, highlighting it with a pending delete selection. Successive misspellings can be found by clicking the "Proofread" menu item in the TEdit menu or the "Proofread" menu item in the new side menu.

At this point, you can either correct the misspelled word or skip to the next misspelling. If you are not sure what the correct spelling is, you can get a menu of possible corrections by invoking the "Correct" menu item. Selecting a correction from this menu will cause it to be automatically inserted into the document in place of the misspelling. (Note: The Proofreader occasionally suggests some very bizarre spelling corrections for your misspelled word. Do not be alarmed; this is a known but unavoidable artifact of the heuristic used for checking for misspellings. (see notes at the end)) If the word was erroneously flagged as misspelled, then you can insert the word into your personal word list of acceptable words by invoking the "Insert" menu item. At the end of the editing session you can save the word list on a file with the "StoreWordList" command (see below).

If when the Proofreader is invoked the current selection has more than one word in it, then the Proofreader will only correct the words in that selection. Otherwise, the Proofreader always proofreads the text from the caret to the end of the document.

PROOFREADER SUB-COMMANDS
Under the TEdit Proofread menu item there are a number of sub-commands that the user can invoke. They are:

Proofread
The same as the top level Proofread command. Attaches a special menu to the side of the document and starts proofreading from the caret.

CountWords
Counts the number of words in the current selection. To count the number of words in the entire document, first click "All" in TEdit’s expanded menu.

SetProofreader
Gives the user a menu of proofreaders to use for proofreading. If there is only one proofreader, no menu is generated. If the user selects a remote server, a second menu may be generated of proofreaders available on the server.
StoreWordList
Allows the user to save the words that he inserted into the proofreader onto a remote file. The words from an existing version of the file will be read in first and then a new file will be generated consisting of the old file plus the new words. After the file is written, the list of newly inserted words is set to NIL.

LoadWordList
The inverse of StoreWordList. If you have a file that you want to load every time you use the proofreader, you can add it to Proofreader.AutoLoad, and it will be loaded when the proofreader is first opened. Proofreader.AutoLoad can be either a file or a list of files.

AutoCorrect
Sets the variable Proofreader.AutoCorrect so that the proofreader automatically generates a list of corrections whenever it finds a misspelled word. In the AutoCorrect mode, the proofreader will also automatically scan for the next misspelled word whenever after a correction has been selected. If you want to stop the proofreading process, click outside of the correction menu. If you want to insert the flagged word into your word list, click the menu item labeled "*INSERT*". If you want to continue proofreading without changing the flagged word, select the menu item labeled "*SKIP*".

ManualCorrect
Sets the variable Proofreader.AutoCorrect so that the proofreader will not generate a list of corrections unless the user asks for it.

PROOFREADER VARIABLES
There are a couple of variables that the user can set in his init file to change how the proofreader works. They are:

Proofreader.AutoLoad
A file or list of files to be loaded into the proofreader every time that the proofreader is initialized.

Proofreader.AutoCorrect
A boolean that determines whether or not a list of corrections is automatically generated whenever the proofreader finds a misspelled word. The default value is NIL.

Proofreader.AutoDelete
A boolean that determines whether or not to delete the old versions of a word list file when a new one is written out. The default value is T.

Proofreader.MenuEdge
The side of the window that the proofreader menu appears on (can be either LEFT or RIGHT). The default value is LEFT.

Proofreader.UserFns
A list of functions to be applied to misspelled words (as strings). If the function returns a non-NIL value, then the word is assumed to be correctly spelled. (If the function ATOMHASH#PROBES is added to Proofreader.UserFns, then any word defined as an atom becomes legal. ATOMHASH#PROBES tests whether or not a string is an atom without creating new atoms. If you want a more restricted test (i.e. "anything defined as a procedure is legal") first test that the string
exists at an atom before doing MKATOM. Otherwise, the atom space will fill up with misspelled words.)

NOTES

- The proofreader uses a heuristic to determine whether or not a word is in its word list that occasionally will produce false positives. This is most noticeable when the proofreader is generating corrections for a misspelled words. I don’t know of any way to eliminate this problem except to use a different algorithm, the fastest of which is at least twice as slow. Hopefully people will find it more of a nuisance than a real problem.

- There is no way to remove words once they have been inserted into the local dictionary. The only way to get rid of a bad word is to reload the dictionary. This can be done by reloading the SpellingArray file. If a bad word gets into one of the remote files, you can edit the file to get rid of it.

ACKNOWLEDGMENTS

The algorithm used in the Proofreader is based on the algorithm in the Cedar Spelling Tool by Bob Nix. For more information on the implementation, see the section "How it Works" in {Cyan}<CedarChest6.1>Documentation> SpellingToolDoc.tioga.
A pseudohost identifies the root of a file system that exists as a subdirectory of another pre-existing file system. This gives a shorthand way of operating on a file in the subdirectory of a particular project without having to specify in the name of that file the entire path to its location in a larger file system. For example, suppose that the variable MEDLEYDIR contains the path from {DSK} to the subdirectory that contains all Medley system files (e.g., {DSK}<Users>kaplan>Local>medley>). If not connected to that subdirectory, then the file COREIO, say, would have to be reference as

{DSK}<Users>kaplan>Local>medley>sources>COREIO.

If MED is defined as a pseudohost with MEDLEYDIR as its prefix, then that file can also be identified more succinctly as {MED}<sources>COREIO.

This package implements pseudohost file devices that allow files to be specified and manipulated in this way. The function PSEUDOHOST defines a new pseudohost whose files coincide with the files at the end of a prefix directory path:

(PSEUDOHOST HOST PREFIX)  [Function]

For the Medley example, executing (PSEUDOHOST ‘MED MEDLEYDIR) will set up MED as a (pseudo) host name that can be used to reference Medley system files. (The full filenames can also be used—the pseudohost just provides a systematic abbreviation.) If PSEUDOHOST is called with the host of a previous invocation but a different prefix, the new prefix replaces the old. If the prefix is NIL, the pseudohost is removed. If HOST is a list and PREFIX is NIL, HOST is interpreted as a (host prefix) pair.

The target host defaults to DSK if PREFIX does not have an explicit host.

When PSEUDOHOSTS is loaded, it executes

(PSEUDOHOSTS)

so that files in the login directory can always be referenced succinctly with host LI, even while connected to another directory.

(PSEUDOHOSTS)  [Function]

Returns the (host prefix) pairs of all currently defined pseudohosts.

(PSEUDOHOSTP HOST)  [Function]

Returns the (host prefix) pair for a particular pseudohost, NIL if HOST is not a pseudohost.

(TARGETHOST HOST)  [Function]

Returns the target host of a particular pseudohost, NIL if HOST is not a pseudohost.

(TRUEFILENAME FILE)  [Function]

Returns the true filename for FILE as it would be written in the host prefix's directory.
Returns the name of \texttt{FILE} in its true device, essentially replacing \texttt{FILE}'s host by its prefix if it is a pseudohost. Returns \texttt{FILE} (possibly extended with the prefix of the connected directory) if its host is not a pseudohost. \texttt{FILE} may be a stream as well as a name.

\texttt{(PSEUDOFILENAME FILE)} \hspace{1em} [Function]

Returns the name of \texttt{FILE} in its pseudo device, if any, essentially replacing \texttt{FILE}'s prefix by the hostname of a pseudodevice for that prefix. Returns \texttt{FILE} (possibly extended with the prefix of the connected directory) if it does not match a pseudohost prefix. \texttt{FILE} may be a stream as well as a name.
By: Matt Heffron (mheffron@orion.cf.uci.edu)

Requires: POSTSCRIPTSTREAM, UNIXCOMM (only on Sun)

The module PS-SEND.LCOM is required by the PostScript ImageStream driver, and will be loaded automatically when POSTSCRIPTSTREAM.LCOM is loaded. It contains the function (POSTSCRIPT.SEND) which is called by SEND.FILE.TO.PRINTER to actually transmit the file to the printer. It is, by its nature, quite site specific, so it is in a separate file to make modifying it for any site relatively simple. For Sun Medley users, code has been added to send the completed Postscript files to the local printer (whatever the UNIX environment variable "PRINTER" is set to.)

POSTSCRIPT.SEND can handle the simple cases of copying a file to a spool directory or directly to a specific device (using COPYBYTES). The information about how to send a file to a specific host is expected to be on the SPOOLDIRECTORY, SPOOLFILE, SPOOLOPTIONS, HOST.CONTROL.STRING and HOST.CONTROL.AFTER.STRING properties of the host name. It checks first for the SPOOLFILE property on the host name, which must be a full filename that can be opened (by OPENSTREAM). If there is no SPOOLFILE property, then it checks for a SPOOLDIRECTORY property, if there, it will be concatenated together with a generated filename (by (GENSYM USERNAME)) and a ".PS" extension. If either the SPOOLFILE or SPOOLDIRECTORY properties exist, then an output stream will be opened onto the specified file. The value of the SPOOLOPTIONS property on the host name (if any) will be passed as the PARAMETERS argument to OPENSTREAM, and must be an appropriately formed list. (This is useful for cases where the specified destination is an 11xx device, such as {TTY} or {RS232} where you must set additional attributes of the stream like baud rate, etc.) If there is no SPOOLFILE or SPOOLDIRECTORY properties, then nothing will be sent and a message will appear int the PROMPTWINDOW ("[Unable to send FILE to HOST."]").

After the output stream is opened, if there is a HOST.CONTROL.STRING property of the hostname, then that string will be printed (IL:PRIN1) to the output stream first, then the first line of the file being sent (for a file generated by the PostScript ImageStream driver, this is the "%! ...") line), then the value of the POSTSCRIPT.CONTROL.STRING from the PRINTOPTIONS argument to POSTSCRIPT.SEND, finally the rest of the input file. (The idea of the HOST.CONTROL.STRING is that it should be a string to control the printing host itself, or perhaps a routing device that is mid-stream between the 11xx and the printer itself. For example, using a SPOOLFILE of "{TTY}FOO.PS" and having the PostScript printer shared by several additional computers (e.g. PC’s) by use of a device like the Logical Connection from Fifth Generation Systems, it might be necessary to send a command to the Logical Connection to specify to route the output from this input to the output which is the PostScript printer.) Likewise, if there is a HOST.CONTROL.AFTER.STRING property of the hostname, then that string will be printed to the output stream last, just before closing the stream.
This module fixes some bugs in SKETCH when interacting with the PostScript driver. This will make the printing of sketches with text in them reasonable. It SYSLOADs SKETCH (from LISPUSERSDIRECTORIES) if it is not already loaded, it does not load POSTSCRIPTSTREAM.
The module PS-TTY defines a printing host named PS-TTY which sends PostScript output to a printer over the {TTY} port of the 11xx. It also puts a function onto AROUNDEXITFNS which reinitializes the {TTY} after returning from LOGOUT. The BaudRate and other parameters of the {TTY} port are controlled by the following variables.

**VARIABLES**

- **PS-TTY-BAUD**
  
  This is the BaudRate for the {TTY} port output stream. Defaults to: 4800.

- **PS-TTY-DATABITS**
  
  This is the BitsPerSerialChar for the {TTY} port output stream. Defaults to: 8.

- **PS-TTY-PARITY**
  
  This is the Parity for the {TTY} port output stream. Defaults to: NONE.

- **PS-TTY-STOPBITS**
  
  This is the NoOfStopBits for the {TTY} port output stream. Defaults to: 1.

- **PS-TTY-FLOWCONTROL**
  
  This is the FlowControl for the {TTY} port output stream. Defaults to: XOnXOff.
QEdit

INTRODUCTION

QEdit is a facility for editing queues, which are ordered lists containing arbitrary objects. QEdit provides facilities for reordering, editing and deleting current queue entries, and inserting new entries. A QEditor looks like this:

Clicking the left mouse button over a queue entry makes it the current selection. You can then select a QEdit menu operation. QEdit returns with the original list if aborted, or a new list upon normal exit. Selecting an entry that is not entirely visible causes the display to scroll until it is.

DETAILS

(QEDIT QUEUE PROPS) [Function]

Invokes a QEditor on QUEUE. Returns QUEUE if aborted, a new list otherwise. The PROPS argument is a property list which serves to customize the behavior of QEDIT for this particular invocation. Currently defined props are listed below.

<-- [QEdit command]

Moves the current selection forward, i.e., switches the current selection and the queue entry just before it.

--> [QEdit command]

Moves the current selection backward, i.e., switches the current selection and the queue entry just after it.
Insert [QEdit command]
Inserts a new entry in front of the current selection, provided \texttt{PROPS} contained an \texttt{INSERTFN}.

Edit [QEdit command]
Edits the current selection, provided \texttt{PROPS} contained an \texttt{EDITFN}.

Delete [QEdit command]
Deletes the current selection, provided \texttt{PROPS} contained a \texttt{DELETEFN}.

Abort [QEdit command]
Aborts the current QEdit session, returning the original queue.

Done [QEdit command]
Ends the current QEdit session, returning a new list containing the current queue entries.

TITLE [QEdit property]
If supplied, its value becomes the title for the QEdit window.

CONTEXT [QEdit property]
The value of the \texttt{CONTEXT} property is passed to the functions below as an extra argument. It does not affect QEdit directly. The functions below can also obtain the current queue by calling the function \texttt{QEDIT.CURRENT.QUEUE} (see below).

LABELFN [QEdit property]
If supplied, its value is a function which, when invoked on a queue entry and the user context, returns a label to use for displaying the queue entry. If not supplied, QEdit displays the queue entry itself.

LABELFONT [QEdit property]
If supplied, its value is a font specification for displaying the queue entry.

INSERTFN [QEdit property]
If supplied, its value is a function which, when invoked on the user context, returns either NIL or a new element to be inserted in front of the current selection (at the front of the queue, if there is no current selection). If not supplied, no elements can be inserted into the queue.

EDITFN [QEdit property]
If supplied, its value is a function which, when invoked on a queue entry and the user context, returns either NIL or a (possibly new) entry to be used instead of the current selection.

DELETEFN [QEdit property]
If supplied, its value is a function which, when invoked on a queue entry and the user context, returns NIL if the entry should not be deleted. If not supplied, no elements can be deleted. Hint: the function \texttt{TRUE} always returns \texttt{T}.

\texttt{(QEDIT.CURRENT.QUEUE)} [Function]
Invoked from one of the above mentioned functions, returns the queue being edited in its current form. The \texttt{INSERTFN} might use this, for example, if duplicates are not allowed.
(QEDIT.RESET) [Function]
QEdit will reuse QEditors upon reinvocation. This function will throw away any known but currently inactive QEditors. Useful if you wish to change the default QEdit props.

*QEDITPROPS* [QEdit variable]
Any props not explicitly supplied in the call to the function QEDIT are taken from this free variable. Its initial value is (TITLE "Queue Editor" LABELFONT (HELVETICA 8))

Examples
(QEDIT '(This is a test queue)) [Function]
Brings up a QEditor as shown above. Queue elements can be rearranged, but not added to, edited or deleted.

(QEDIT '(This is a test queue) '(INSERTFN READ DELETEFN TRUE)) [Function]
Brings up a QEditor as shown above. Queue elements can be rearranged, inserted or deleted, but not edited.
INTRODUCTION

AIS (array of intensity samples) is a format for color and gray-level images. The following functions allow reading and writing of AIS files from Lisp.

\[
\text{(AISBLT FILE SOURCELEFT SOURCEBOTTOM DESTINATION DESTLEFT DESTBOTTOM WIDTH HEIGHT HOW FILTER NBITS LOBITADDRESS)}
\]

[Function]

Puts the image in an AIS file into a bitmap. AISBLT checks the sample size of the AIS file and the number of bits per pixel of the DESTINATION and performs the required reduction (if any). SOURCELEFT and SOURCEBOTTOM give the left and bottom coordinates in the source file of the image to be read (default to (0,0)). DESTINATION can be a bitmap, a color bitmap, or a window.

HOW indicates what method of reduction is to be used if the sample size of the AIS file is larger than the number of bits per pixel in the destination bitmap. The recognized methods are TRUNCATE (use the high-order bits) and FSA (use the Floyd-Steinberg dithering algorithm). The default when going to a 1 bpp bit map is FSA; otherwise it is TRUNCATE.

FILTER if non-NIL should be an array that will be used to filter the samples read from the AIS file. If FILTER is given and a sample point of intensity N is read from the file, \( (\text{ELT FILTER N}) \) is used to determine the bits for the destination. The function SMOOTHHIST described below is one way of getting a filter that balances the contrast in an image.

NBITS and LOBITADDRESS allow an image to be read into one or more “planes” of a color bitmap. NBITS tells how many bits are to be taken from each image sample, and LOBITADDRESS indicates the lowest bit within each pixel that the NBITS bits are to go. (Bit address zero is the leftmost or highest-order bit. For a four-bit-per-pixel bit map, three would be the lowest-order bit.) This is used by SHOWCOLORAIS to put the different planes of a color image into the bit map.

\[
\text{(SHOWCOLORAIS BASEFILE COLORMAPINFO HOW SOURCELEFT SOURCEBOTTOM DESTINATION DESTLEFT DESTBOTTOM WIDTH HEIGHT)}
\]

[Function]

Reads a color image from three AIS files into a color bit map. The three color files are obtained by concatenating the strings “-RED.AIS”, “-GREEN.AIS”, and “-BLUE.AIS” onto the end of BASEFILE. If COLORMAPINFO is a list of three small integers, it indicates how many of the bits in the destination are allocated to each color. For example, if DESTINATION is a four-bit-per-pixel color bit map and COLORMAPINFO is (1 2 1), one bit (bit zero) will be allocated to the red image, two bits (bits one and two) will be allocated to the green image, and one bit (bit three) will be allocated to the blue image.

DESTINATION is the color bitmap the image will be stored into.

HOW, SOURCELEFT, SOURCEBOTTOM, DESTLEFT, DESTBOTTOM, WIDTH, and HEIGHT are as described in AISBLT.

An experimental feature that is available only when going to 8 bpp color bit map: if COLORMAPINFO is a color map, each pixel will be determined by finding the color in the color map that is closest to the 24 bits of color information read from the three image files. (This takes a long time.) The function
COLOR.DISTANCE (red green blue redentry greenentry blueentry) is called to calculate the distance by which “closest” color is determined.

(CMYCOLORMAP CYANBITS MAGENTABITS YELLOWBITS BITSPERPIXEL) [Function]
Returns a color map that assumes the BITSPERPIXEL bits are to be treated as three separate color planes with CYANBITS bits being in the cyan plane, MAGENTABITS bits being in the magenta plane, and YELLOWBITS bits being in the yellow plane. Within each plane, the colors are uniformly distributed over the intensity range 0 to 255. White is 0 and black is 255.

(RGBCOLORMAP REDBITS GREENBITS BLUEBITS BITSPERPIXEL) [Function]
Returns a color map that assumes the BITSPERPIXEL bits are to be treated as three separate color planes with REDBITS bits being in the red plane, GREENBITS bits being in the green plane, and BLUEBITS bits being in the blue plane. Within each plane, the colors are uniformly distributed over the intensity range 0 to 255. White is 255 and black is 0.

(GRAYCOLORMAP BITSPERPIXEL) [Function]
Returns a color map containing shades of gray. White is 0 and black is 255.

(WRITEAIS BITMAP FILE REGION) [Function]
Writes the region REGION of the color bit map BITMAP onto the file FILE in AIS format. This provides an efficient way of saving color or gray-level images.

(AISHISTOGRAM FILE REGION) [Function]
Returns a histogram array of the region REGION in the AIS file FILE. The histogram array has as its Nth element the number of pixels in the region that have intensity N.

(GRAPHAISHISTOGRAM HISTOGRAM W) [Function]
Draws a graph of a histogram array in the window W. If W is NIL, a window is created.

(SMOOTHEDFILTER HISTOGRAM) [Function]
Returns a “filter” array that maximally distributes the intensities values contained in HISTOGRAM. The filter array can be passed to AISBLT to change the contrast of the image being read.
REDAAPPLEFONT

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

Uses: READDISPLAYFONT

REDAAPPLEFONT defines a new display font type which allows Envos Lisp to use (commercially available) Macintosh™ display fonts. Although this module is primarily intended for extracting font width information for conversion programs (e.g., MacPaint™ to Sketch and vice versa) it can also be used to extend the number of display fonts available within the Envos Lisp environment.

There are no user functions in the module. In addition to this module, you need a directory of extracted Macintosh™ font files (as described below) and you must add the name of that directory to the system DISPLAYFONTDIRECTORIES list. The following function is added under the type APPLE to the list DISPLAYFONTTYPES (defined by the READDISPLAYFONT module).

(READAPPLEFONT STREAM FAMILY SIZE FACE) [Function]

The module also adds the extension APPLE to the system list DISPLAYFONTEXTENSIONS.

FONT FILES

This module only uses the FontRec portion of the font files (see Inside Macintosh™). The font resources must be extracted into individual files with appropriate names, e.g., SANFRANCISCO18-MRR-C0.APPLE. One method of doing this is to use the Font/DA Mover™ utility:

The individual font files should be moved to a Unix AUFS/CAP server (or the equivalent) and the resource forks (in the .resource directory) should be copied to the directory you added to DISPLAYFONTDIRECTORIES above.

If another method for extracting the FontRec data structure into individual files is used, the following variable will probably need to be reset:

APPLEFONTEXTCOFFSET [Variable]

The offset in bytes into the font file of where the FontRec data structure begins (initially 264).

NOTES

• This module only handles proportionally spaced fonts and ignores fractional character widths.
• The user is responsible for determining the legality of extracting the fonts in question.
READBRUSH

By: Larry Masinter (Masinter.pa@Xerox.com)

uses: BITMAPFNS

This document last edited on September 8, 1988.

INTRODUCTION

This module implements two things:

(IDLE.GLIDING.BRUSH W box wait) [Function]

Like the default IDLE.BOUNCING.BOX Idle function but glides the bitmap around the screen instead of bouncing it.

(READBRUSHFILE file) [Function]

Reads files in the "brush" format used by Mesa/Viewpoint. Returns a pair of bitmap/mask (or just bitmap) if there is no mask. Brush file names use defaults from BRUSHDIRECTORY, initially {goofy:osbu north:xerox}<hacks>data>brushes> (and of use only inside Xerox.)

(READBRUSH file) [Function]

Calls READBRUSHFILE and then creates a window with that brush in it.

BRUSHDIRECTORY [Variable]

Default location to get brushes from.

Adds an entry to IDLE.FUNCTIONS for "Gliding box", which will use IDLE.GLIDING.BOX on the brush selected from a menu created by enumerating all of the .brush files on BRUSHDIRECTORY.
READDATATYPE gives @ a read macro definition (in the INTERLISP readtable) so that it can be used to type in datatype pointers directly. For example, suppose you have lost your pointer to a window (or menu, etc.) but you have the printed representation around (eg. \{WINDOW\}#56,17470) then you can do things like:

```
90_ (INVERTW @\{WINDOW\}#56,17470)
\{WINDOW\}#56,17470
```

The read macro is only intended to be used at the read-eval-print loop. If the character following the @ is not a { then the read macro returns the @ character just as if you had typed it in so that other expressions that use @, like `(A B ,@FILELIST C D), will still work correctly.

Although the read macro does not need the data type name in the brackets (eg. \{MENU\}) to get the pointer, it does require it in order to check the pointer to make sure it is of the correct type. If the pointer is not of the type specified, then the read macro returns NIL.

The following form is used in the COMS of the file to set the syntax of @ in the INTERLISP readtable and can be used to add the capability to other readtables and/or characters:

```
(SETSYNTAX '%@ '(MACRO FIRST READDATATYPE) (FIND-READTABLE "INTERLISP"))
```
READDISPLAYFONT

By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

READDISPLAYFONT modifies the display font functions to make it possible to define new display font types.

The functions \READDISPLAYFONTFILE and FONTFILEFORMAT are modified to use the list:

DISPLAYFONTTYPES [Variable]

An ALST containing font file extensions and the functions that can read those types from a file. Its initial value is:

    ((AC \READACFONTFILE)
     (STRIKE \READSTRIKEFONTFILE))

The functions take (STREAM FAMILY SIZE FACE) as arguments and return a CHARSETINFO datum. You will (probably) need the Xerox (internal) documentation about fonts and character sets (not supplied with the standard documentation) to define a new font file reading function.

The AC and STRIKE font types are handled specially to be compatible with the existing font code, so files with extension DISPLAYFONT still work and FONTFILEFORMAT moves the file pointer to the appropriately for those two types. For all other (new) types, the type is determined solely from the file extension and FONTFILEFORMAT has no side effects.

When defining a new display font types, you will need to add the new extension to the system list DISPLAYFONTTEXTENSIONS.
REGION facilitates having multiple complex cursor behaviors in a single window without having the CURSORMOVEDFNs, CURSORINFNs, CURSOROUTFNs, and BUTTONEVENTFNs of the behaviors know about each other. In its simplest form it can be used to implement active regions.

To use, set the various window functions of the window to the REGION window functions and put a list of REGIONEVENT records on the REGIONEVENTLST property of the window. When the cursor moves over the window, REGION checks which region it is in, calls the CURSOROUTFN of the previous region and the CURSORINFN of the new region. If regions overlap, then the appropriate functions will be called on all regions affected by the mouse event.

The REGIONEVENTLST property of the window should contain a list of REGIONEVENT records which have the fields:

- **EVENTREGION**: A REGION record which is the region of the window over which the region specific functions will be invoked.
- **REGIONBUTTONFN**:
  - (WINDOW POSITION REGION REGIONEVENT)
- **REGIONMOVEDFN**:
  - (WINDOW POSITION REGION REGIONEVENT)
- **REGIONINFN**:
  - (WINDOW REGION REGIONEVENT)
- **REGIONOUTFN**:
  - (WINDOW REGION REGIONEVENT)
- **REGIONREPAINTFN**:
  - (WINDOW REGION REGIONEVENT)
- **ACTIVEREGION**: Boolean indicating if the region is active or not.
- **REGIONFLAGS**: User defined identification flags.
- **REGIONUSERDATA**: User defined field.

All of the fields in the REGIONEVENT record are optional. If a REGIONEVENT record has a NIL EVENTREGION, then it is considered the default REGIONEVENT and will be invoked whenever a mouse event occurs outside of any other region.

The REGION window functions are:

- (WINDOWPROP WINDOW ‘CURSORINFN (FUNCTION REGIONINFN))
- (WINDOWPROP WINDOW ‘CURSOROUTFN (FUNCTION REGIONOUTFN))
- (WINDOWPROP WINDOW ‘REPAINTFN (FUNCTION REGIONREPAINTFN))
- (WINDOWPROP WINDOW ‘CURSORMOVEDFN (FUNCTION REGIONMOVEDFN))
- (WINDOWPROP WINDOW ‘BUTTONEVENTFN (FUNCTION REGIONEVENTFN))
The above window properties can be set using the function:

\[
\text{\texttt{(REGION.INIT WINDOW [REGIONEVENTLST SAVE?]})}[\text{Function}]
\]

The \texttt{REGIONEVENTLST} is a list of \texttt{REGIONEVENT} records to put on the window. If \texttt{SAVE?} is non-NIL, the CURSORINFN, CURSOROUTFN, etc. of the window are put into a default region event record (one with an EVENTREGION = NIL) and added to the \texttt{REGIONEVENTLST}. The macro:

\[
\text{\texttt{(ADDREGIONEVENT REGIONEVENT WINDOW)}}[\text{Macro}]
\]

can be used to add a \texttt{REGIONEVENT} record onto the current \texttt{REGIONEVENTLST} of \texttt{WINDOW}.

The \texttt{REGIONFLAGS} field of the \texttt{REGIONEVENT} record consists of whatever atoms the user wishes to identify regions with. These allow the user to issue commands such as “turn off all regions marked GRAPH”, “activate all the MENU regions”, etc.

\[
\text{\texttt{(ACTIVATEREGIONS FLAGS WINDOW)}}[\text{Function}]
\]

\[
\text{\texttt{(DEACTIVATEREGIONS FLAGS WINDOW)}}[\text{Function}]
\]

Activate and deactivate all the \texttt{REGIONEVENT} records on \texttt{WINDOW} whose \texttt{REGIONFLAGS} have a flag in common with \texttt{FLAGS}. If \texttt{FLAGS} is T, activate or deactivates all \texttt{REGIONEVENT} records.

\[
\text{DISABLEFLG}[\text{Variable}]
\]

If set to T, disables all of the region functions for all windows using the REGION module. Alternatively, setting \texttt{DISABLEFLG} to a window, or list of windows, disables all the windows using the REGION package except for those windows. This allows selectively turning off cursor actions on parts of the screen.
Medley comes equipped with a core set of functions for specifying regions and creating the windows that occupy those regions on the screen. But it can be disruptive if not irritating to have to draw out a new ghost region for every invocation of a particular application. Thus the common applications (e.g. TEDIT, SEDIT, DINFO...) implement particular strategies to reduce the number of times that a user has to sweep out a new region. They instead default to regions that were allocated for earlier invocations that are no longer active. TEDIT for example recycles the region of a session that was recently shut down, SEDIT allocates from a list of previous regions, DINFO always uses the same region, but FILEBROWSER always prompts for a new one. Applications that do recycle their regions tend to do so indiscriminately, without regard to the current arrangement of other windows on the screen or the role that those windows may play in higher-level applications.

The REGIONMANAGER package provides simple extensions to the core region and window functions. These are aimed at giving users and application implementors more flexible and systematic control over the specification and reuse of screen regions. It introduces three new notions:

A "typed region" allows the regions of particular applications to be specified, classified, and recycled according to their types.

The size, location, and orientation of a "relative region" is specified with respect to particular screen points and the location of other windows.

A "constellation region" encloses the collection of satellite windows (prompts, menus, etc) that surround the central window of an application.

REGIONMANAGER is innocuous in that explicit user action is required to change the default behavior of any system components.

**Typed regions**

REGIONMANAGER adds overlay veneers to the core CREATEW, CLOSEW, and GETREGION functions to make it easier to predict and control how different applications arrange their windows on the screen without always needing to respond to a ghost-region prompt.

The REGION/INITREGION arguments may now be region-type atoms in addition to either NIL or particular regions as CREATEW and GETREGION otherwise allow. The type-atom will resolve to a region drawn from a predefined pool of regions associated with that type, if the pool has at least one that is not currently allocated to another window. If the pool has no available regions, then the pool will be enlarged with a region that the user produces from a normal ghost-region prompt, and the type-atom will then resolve to the newly installed region.
A typed-region is marked as "inuse" and therefore unavailable when `create` assigns it to a window, and the extended `close` marks it as again available when the window is closed.

An example of how an application can take advantage of this facility is the TEDIT-PF-SEE package. This provides lightweight alternatives to the `pf` and `see` commands that print their output to scrollable read-only Tedit windows, specifying `pf-edit` and `see-edit` as their region types. The user can predefine a preference-ordered sequence of recyclable regions that bring up multiple output windows in a predictable tiled arrangement, without region-prompting for each invocation.

The global variable `typed-regions` is an alist that maintains the relationship between atomic type-names and the list of regions that belong to each type. The list is ordered according to preferences set by the user, and a type-atom is always resolved to the first unused region in its list. If the user is asked to sweep out a new region, that region is added at the end, as the least preferable. The function `set-typed-regions` is provided to add or replace `typed-region` entries.

```
(set-typed-regions type-lists replace)  [Function]
```

`type-lists` is an alist of the form

```
((type1 . regions1)(type2 . regions2)...)  [Function]
```

where each `region_i` is a possibly empty list of regions. For convenience, if `type-lists` is just a literal `type-atom`, it is interpreted as `((type))`, and if it is a list `(type . regions)` beginning with an atom, it is interpreted as `(type . regions)`. The new regions replace preexisting regions if `replace`, otherwise they are added at the front.

Typically, a call to `set-typed-regions` would be placed in a user’s INIT file to set up the preference order for the regions that the user wants to participate in this reallocation scheme. If an application uses a type that is not on `typed-regions`, then that type-atom is treated as `nil` and always gives rise to the normal ghost-region prompting. Thus a user will observe no change in system behavior if `typed-regions` is left with its initial value `nil`. A type that is added with an empty region list (as opposed to not being on the list at all) will allow new regions to accumulate for recycling.

**Relative regions**

Two functions are provided to make it easy to create regions relative and oriented with respect to a specified reference point. These may be useful for constructing an application that includes a constellation of windows arranged in a particular relative way.

```
(recreate-region width height cornerx cornery refx refy onscreen)  [Function]
```

`recreate-region` creates a region of dimensions `width` and `height`. One of its corners is identified by `cornerx` and `cornery` and that corner will be aligned with a reference screen-point determined by `refx` and `refy`. If `onscreen`, the `width` or `height` will be adjusted with respect to that alignment so that the resulting region is entirely within the screen.

`width` and `height` can be given as absolute (natural) numbers or specified relative to the `width` and `height` of another region or of the screen. The possibilities are interpreted as follows:

- **natural number:** the number of screen points
- **list of the form** `(anchor fraction adjustment)`, where anchor is a region, window, or an atom `screen` or `tty`. The corresponding dimension of the anchor is multiplied by `fraction` and `adjustment` is added to the result. For example, specifying `(window .5 -1)` results in a `width` that is one point smaller than half the width of window’s region. `Fraction` and `adjustment` default to 1 and 0 respectively.
region/window/SCREEN/TTY: equivalent to (region/window/SCREEN/TTY 1 0).

CORNERX can be LEFT, RIGHT, or NIL=LEFT, CORNERY can be BOTTOM, TOP, or NIL=BOTTOM. If LEFT/TOP are specified, for example, the region will be splayed down and to the right of the reference point. If RIGHT/BOTTOM, then up and to the left.

The reference-point arguments REFX and REFY are interpreted as follows:

NIL: LASTMOUSEX/LASTMOUSEY

natural number: an absolute screen coordinate

(anchor fraction adjustment) or just region/window/SCREEN/TTY: the quantity determined relative to the size of anchor (as above) is added to the anchors left/bottom produce the REFX/REFY coordinate. In this case, fractions specified as LEFT/BOTTOM/NIL are interpreted as 0 and RIGHT/TOP are interpreted as 1. For example, a specification (<window> .4 -2) for REFY will produce a coordinate 2 points below the level that is 40% of the distance between the bottom and top of the window’s region.

For convenience, if REFX is a position and REFY is NIL, then the XCOORD and YCOORD of REFX are taken as absolute values for REFX and REFY.

Also for convenience, if WIDTH is a potentially a list of RELCREATEREGION arguments, then the elements of that list are spread out in a recursive call.

(RELGETREGION WIDTH HEIGHT CORNERX CORNERY REFX REFY MINSIZE) [Function]

Calls GETREGION with an initial ghost region as created by RELCREATEREGION. CORNERX and CORNERY determine the ghost region’s fixed corner, and the cursor starts at the region’s diagonally opposite corner. If MINSIZE is true, then WIDTH and HEIGHT are taken as the minimum sizes of the region, except for adjustments that may be needed to ensure that all corners of the ghost region are initially visible on the screen.

(RELCREATEPOSITION REFX REFY) [Function]

Creates a position with X and Y coordinates specified by REFX and REFY references as above.

**Constellation regions**

Applications are often set up as a constellation of windows, a central or primary window surrounded by some number of satellites for menus, headers, prompts, and secondary outputs. The main panel of a file browser, for example, displays the list of files, but above it are carefully arranged windows for the column headers, summary information, and prompts, and off to the side is the menu of file browser commands. FILEBROWSER interprets the screen region that the user sweeps out for a new browser as the region for the whole constellation, the smallest region that will enclose the central window and all of its satellites. Similarly, the screen region given to TEDIT and SEDIT is divided between the prompt window and the central editing window, again so that the whole constellation (a pair in these cases) fit within the provided region.

Each of these applications is constructed by anticipating the subregions that the satellite windows will occupy after they are attached, decreasing the constellation region by their estimated (using WIDTHIFWINDOW HEIGHTIFWINDOW) or actual sizes, and then using remainder as the region for the central window.
An alternative approach is to construct the central window first, giving it the entire constellation region, and then to have ATTACHWINDOW reshape that window to accommodate the satellite windows as they are attached in sequence. This leads to the same final configuration, but there is no need for separate calculations to pre-adjust the region of the central window.

REGIONMANAGER provides an overlay veneer for ATTACHWINDOW that implements this strategy. If the new argument TAKEFROMCENTRAL is true, then the region of the WINDOWTOATTACH will be substracted from the region of the existing central window according to the EDGE parameter of the attachment.

(ATTACHWINDOW WINDOWTOATTACH MAINWINDOW EDGE POSITIONONEDGE WINDOWCOMACTION TAKEFROMCENTRAL) [Function]

This behavior is also triggered if the UNDERCONSTRUCTION property of the central window is true. Thus, a constellation can be set up by creating all of the satellites and the central window, marking the central window as under construction, and then doing the sequence of attachments. The property can be reset to NIL when the construction is complete, so the central window does not shrink if other other attachments (e.g. expanded menus) by later user actions.

A somewhat weaker form of a constellation is a collection of windows that are not attached around a central window but stand in a parent-child relationship at least with respect to closing and moving. A parent window spawns children that respond independently to ordinary window commands (move, shape, close). But the children close when the parent closes, and the children move when the parent moves so that they continue to appear in the same relative positions. These primitives allow the construction of a tree of windows that are dependent in this way.

(CLOSEWITH CHILDREN PARENT) [Function]

Establishes a link between the PARENT window and any number of CHILDREN windows such that all CHILDREN will close when PARENT closes. The closing is accomplished by CLOSEWITH.DOIT:

(CLOSEWITH.DOIT PARENT) [Function]

Closes the close-with children of PARENT.

(MOVEWITH CHILDREN PARENT) [Function]

Establishes a link between the PARENT window and any number of CHILDREN windows such that all CHILDREN will move when PARENT closes. The closing is accomplished by MOVEWITH.DOIT:

(MOVEWITH.DOIT PARENT NEWPOS) [Function]

If NEWPOS is the new position of PARENT, moves each of the move-children so that they stand in the same relation to PARENT after it moves as before.
REMOTEPSW defines a remote process status window facility that runs on top of Courier. The remote process status window is identical to the local one except that it contains UPDATE (to get the current process status) instead of BREAK, and INFO is not implemented. Both the client and server code are contained in the module which must be loaded on both hosts. The Courier server must be running on the host you wish to monitor.

The only user function is:

(REMOTE.PROCESS.STATUS.WINDOW HOST) [Function]

which opens a remote process status window onto HOST, where HOST is any NS host specification that COURIER.OPEN accepts.
RPC
SUN REMOTE PROCEDURE CALLS

By: JFinger

Supported by Atty Mullins (Mullins.pa@Xerox.com) and Bill Van Melle (vanMelle.pa@Xerox.com).

This document last edited on August 1, 1988.

INTRODUCTION
This module implements SUN remote procedure calls as specified in the Remote Procedure Call Protocol Specification. The syntax is oriented toward Lisp users, differing greatly from Sun’s C-like syntax.

RPC2 Package
All functions and variables mentioned in this document are defined as external variables in the package RPC2, unless otherwise stated.

REMOTE PROCEDURE DEFINITION
Remote programs are defined via calls to define-remote-program.

define-remote-program name number version protocol &key :constants [Function] :types :inherits :procedures

Defines parameters and result types of the procedures of remote program (number, version, protocol). If successful, returns name, otherwise nil.

name a string or symbol that may be used by other procedures (for example, remote-procedure-call) to uniquely specify this remote program.

number is the program number of this program on the remote machine. As specified in Sun’s Remote Procedure Call Programming Guide, programs 0 - #x1fffffff are defined by Sun, #x20000000 - #x3fffffff are reserved for users, and #x40000000 - #x5ffffff are designated as transient.

version a number, is the desired version of remote program.

protocol an atom, UDP or TCP. (At the moment TCP is not supported under Medley 1.0-S).

constants a list of pairs (<constant-name> <constant-def>), where <constant-name> is a symbol and a <constant-def> is an XDR constant (See XDR Constant Definitions below).

inherits a list of name’s of other remote programs from which types and constants are inherited. Inherited types and constants are resolved by searching this list in order.

Types a list of pairs (<type-name> <typedef>), where a <type-name> is a symbol and a <typedef> is an XDR type definition (defined below).
procedures

a list of 4-tuples of the form (<procname> <procnumber> <arg-types> <result-types>), where <procname> is a symbol or string naming the procedure, <procnumber> is the procedure number on the remote machine, <arg-types> is a (possibly empty) list of XDR type definitions (see below) of the arguments to be sent to the remote procedure, and <result-types> is a (possibly empty) list of XDR type definitions of data to be returned from this remote procedure.

XDR (EXTERNAL DATA REPRESENTATION) TYPE DEFINITIONS

Because the client and server machines may represent data in different ways, a data representation common to both machines is necessary. Remote procedure calls pass data between machines in 'External Data Representation' (XDR). The XDR language implemented here is oriented toward Lisp in its syntax and is not identical to the language spelled out in the Sun XDR Protocol Specification.

XDR data types may be defined in the :types keyword argument for later reference in the :types or :procedures of this or later remote programs. When a remote program is defined (usually at load time), the needed reading and writing functions are compiled for each constructed type referenced. Note that all XDR calls are eventually resolved to a composition of Primitive and Constructed XDR Type Definitions (see below).

SYNTAX

The keywords of the XDR language may be specified as symbols of the Keyword package.

All XDR Data Types Definitions (notated here as a <typedef>), used in Remote Procedure Calls are from the following language:

1) Primitive Definition: One of the types in *xdr-primitive-types*:
   :integer
   :boolean
   :unsigned
   :hyperinteger
   :hyperunsigned
   :string
   :float (not yet implemented)
   :double (not yet implemented).

2) Constructed Definition: One of the types in *xdr-constructed-types*:
   (:enumeration (<symbol-1> <constant-1> ...) 
   (<symbol-n> <constant-n> ))
   (:union <enumeration-type> <typedef-1> ... <typedef-n>)
   (:fixed-array <typedef> <constant>)
   (:counted-array <typedef>)
   (:opaque <constant>)
   (:struct <defstruct-type> (<field-name-1> <typedef-1> ...) 
   (<field-name n> <typedef-n>))
   (:sequence <typedef>)
   (:list <typedef-1> ... <typedef-n>).

3) Local Definition: A symbol defined previously in the same remote program definition.

Example: :types ((nrec :unsigned)...) says that type 'nrec' is really only of type ':unsigned'.

4) Qualified Definition: A dotted pair of the form (<RPC program name> . <type>), where <type> is an XDR type local to <RPC program name>.
Example: 

\[ :\text{types} \ (\ (\text{count} \ (\text{myprog} \ . \ nrec)) \ldots) \] says that a 'count' is really whatever myprog defines a 'nrec' to be.

5) **Inherited Definition:** A symbol defined in the :types argument of a remote program R such that R is on the list of remote programs passed as the :inherits argument to the current remote program definition. The first such type definition found is used, that is, the list of inherited programs is scanned from left to right.

**XDR CONSTANT DEFINITIONS**

Constants in XDR are defined by the following grammar:

\[
<\text{constant-def}> ::= <\text{integer}> | <\text{defined-constant}>
\]

\[
<\text{defined constant}> ::= <\text{locally defined constant}> | <\text{inherited constant}> | <\text{qualified constant}>
\]

- **<locally defined constant>**
  - Defined in the Remote Program currently being defined.

- **<inherited constant>**
  - Defined in a remote program inherited by the current Remote Program (searched from left to right).

- **<qualified constant>**
  - A dotted pair (<rp> . <constant>), where <constant> is defined in remote program <rp>.

**SEMANTICS**

An XDR type can be defined by a bidirectional filter mapping a subset of Lisp onto a byte stream and vice-versa.

For the XDR primitive type's filter, a description is given of its argument on the Lisp and XDR sides.

- **:integer**
  - Lisp: an integer in range -2,147,483,648 to 2,147,483,648 inclusive.
  - XDR: a 4 byte two's complement integer, high order to low order.

- **:unsigned**
  - Lisp: an integer in range 0 to 4,294,967,295 inclusive.
  - XDR: a 4 byte non-negative integer, high order to low order.

- **:boolean**
  - Lisp: NIL for false, non-NIL for true. (The Lisp symbol T is returned when decoding a 1 from the XDR side.)
  - XDR: 0 for false, 1 for true.

- **:hyperinteger**
  - Lisp: an integer in range -(2^63) to 2^63 -1 inclusive.
  - XDR: a 8 byte two's complement integer, high order to low order.

- **:hyperunsigned**
  - Lisp: an integer in range 0 to 2^64-1 inclusive.
  - XDR: a 8 byte non-negative integer, high order to low order.

- **:string**
  - Lisp: a string of any length.
  - XDR: Suppose the string is of length n. The XDR representation is an :unsigned (the string length n), followed by the n bytes of the string, followed by enough 0 bytes to make a multiple of 4 bytes.

- **:string-pointer**
  - (UDP only)
  - Lisp: a dotted pair (addr . nbytes), where addr is a buffer's address and nbytes is the number of bytes in the buffer. (Should I add an offset
argument?). This is a speed hack to avoid having to copy
VMEMPAGEP’s twice.
XDR: An XDR :string, as above.

:float
Lisp: A floating point number. (NOT YET IMPLEMENTED).
XDR: A 4 byte floating point number in IEEE format.

:double
Lisp: A floating point number. (NOT YET IMPLEMENTED).
XDR: A double precision floating point number in IEEE format.

:void
Lisp: null
XDR: no bytes.

For each constructed XDR type, the declaration syntax is given along with its corresponding mapping.

(:enumeration (<symbol> <integer>) ... (<symbol> <integer>))
Lisp: a symbol
XDR: an XDR :integer.
The Lisp symbol (Each symbol is the "discriminant" for that value of the enumeration) and the XDR integer will be from a corresponding pair in the declaration. It is an error to try to encode a symbol not in the declaration or to try to decode an XDR integer for which there is not a corresponding symbol in the declaration.

(:union <enumeration-type> (<symbol-1> <typedef-1>) ... (<symbol-n> <typedef-n>))
Lisp: A list of two elements, the first being a discriminant for the enumeration type, and the second the appropriate Lisp input/output for the typedef corresponding to that discriminant’s type.
XDR: An :integer discriminant followed by the XDR input/output for the typedef corresponding to that discriminant’s type.

(:fixed-array <typedef> <constant>)
Lisp: An array of length <constant>, each element of which is an object of type <typedefLisp>. Note that since the function elt is used in encoding, any Lisp sequence could be used in place of an array.
XDR: A sequence of <constant> objects of type <typedefXDR>.

(:counted-array <typedef>)
Lisp: A list of two elements, the first of which is an integer (the number of objects to be encoded/decoded), and the second of which is an array of objects of type <typedefLisp>.
XDR: An integer (the number of objects to be encoded/decoded) followed by that number of objects of type <typedefXDR>.

(:opaque <constant>)
Lisp: A string of length <constant>.
XDR: A sequence of <constant> bytes followed by enough null bytes to round <constant> up to a multiple of four.

(:struct <defstruct-type> (<field-name-1> <typedef-1>) ...(<field-name n> <typedef-n>))
Lisp: A struct of type <defstruct-type> such that each field mentioned in the this XDR declaration has a value. Note that a separate defstruct must be executed. The fields need not be named here in the same order as those in the defstruct, nor must all the fields named in the defstruct be used here.
XDR: A sequence of objects of types <typedef1 XDR>...<typedefn XDR>.
(:sequence <typedef>)  This is fashioned after Courier 's method for encoding/decoding linked lists. This type can often be used to get around clumsy recursive definitions involving :union's of enumeration type :boolean.

Lisp: A list of objects of type <typedefLisp>.

XDR: A sequence of objects, each preceded by an XDR :boolean encoding of true. The last object in the sequence is followed by the XDR :boolean encoding of false.

Note: (:sequence <typedef>) produces the same encoding (but not the same decoding) as
(defstruct astructure this-element the-rest)
along with the declaration

(:recursive (:union :boolean
(T (:struct astructure (this-element <typedef>)
(the-rest astructure)))
(NIL :void)),

(:list <typedef-1> ... <typedef-n>)

Lisp: A list, the ith element of which is of type <typedefi Lisp>.

XDR: A sequence of objects, the ith of which is of type <typedefi XDR>.

(:skip <unsigned>)  (For decoding only)

Lisp: Nothing

XDR: Any n bytes of data, where <unsigned> = n.

Note: This is a klooge for not having to decode the fattr's that NFS returns with every single cotton-pickin' memory read.

EXAMPLE OF A REMOTE PROGRAM DEFINITION

The following call to define-remote-program defines the portmapper remote procedures described in Sun's Remote Procedure Call Specification. Note that there are two definitions of procedure 4 given. Since remote procedures may be invoked by name, it is reasonable for there to be more than one definition for how to decode and encode the arguments to a given routine. In this case, both a recursive and non-recursive definition is given for the values returned from procedure 4. Note also that mapstruct and mapsequence must be defstruct'ed before this call to define-remote-procedure.

(define-remote-program 'portmapper 100000 2 'udp
  :types '( (mapstruct (:union :boolean
    (nil :void)
    (t (:struct astructure
      (program :unsigned)
      (vers :unsigned)
      (prot :unsigned)
      (port :unsigned)
      (therest mapstruct))))
    (mapsequence (:sequence (:struct mapsequence
      (program :unsigned)

(define-remote-program 'portmapper 100000 2 'udp
  :types '( (mapstruct (:union :boolean
    (nil :void)
    (t (:struct astructure
      (program :unsigned)
      (vers :unsigned)
      (prot :unsigned)
      (port :unsigned)
      (therest mapstruct))))
    (mapsequence (:sequence (:struct mapsequence
      (program :unsigned)
UNDEFINING REMOTE PROGRAMS

undefine-remote-program name number version [Function]

MAKING REMOTE PROCEDURE CALLS

remote-procedure-call destination program procid arglist [Function]
&key destsocket version credentials protocol
dynamic-prognum dynamic-version
msec-until-timeout msec-between-tries noerrorflg

Performs a remote procedure call to program on destination. Returns
a list of the returned values.

destination Designates the host to which the procedure call is made. If Destination
is a number it is interpreted to be the ip:phostaddress of the host; if a
symbol or string, it is a name from which the net address of the host
may be found.

program Designates the remote program to be called. If Program is a number,
it is interpreted to be the remote program number. If a symbol, in
which case it is assumed to be the name of the remote procedure (as
defined in define-remote-procedure. If :version is non-nil, then
program is treated as a number rather than as a name. If version is nil
and program is a number, then the latest version of that program is
used.

procid Designates the procedure number from program to be called. If Procid
is a number it is interpreted to be the remote procedure number; if a
symbol, it is the name given that procedure in define-remote-
procedure.

arglist A list of the arguments to be serialized into XDR representation and
passed as the arguments of the remote procedure call.

:destsocket Normally, the remote socket must be looked up in the local caches
(See "rpc-socket-cache" and "rpc-well-known-sockets") or else found
by making a call to the Portmapper on the remote machine. If :
destsocket is non-nil, its value is used as the remote socket.

:version If non-nil designated the desired version of program as well as
causing program to be interpreted as a number rather than a name.
See program above.

:credentials An object of type authentication to be passed as the credentials of the
remote procedure call. (See create-unix-authentication).
:protocol
A symbol specifying the transport protocol. Currently only UDP is implemented. Defaults to UDP. The only reason for using this parameter is to specify (along with the program and version), which known remote program is to be used.

:dynprognum
If you really can’t live without it, dynprognum is used as the remote program number in spite of treating the arglist and returned values exactly as in program. Don’t ask why.

:dynamic-version
If you really can’t live without it, dynamic-version is used as the remote program version in spite of treating the arglist and returned values exactly as specified in program (and possibly version). Don’t ask why. Defaults to 1.

:msec-until-timeout
Total number of milliseconds of waiting for a reply packet before giving up on this remote procedure call. Defaults to value of *rpc-msec-until-timeout*.

:msec-between-tries
Number of milliseconds between outgoing UDP packets. Defaults to *rpc-msec-between-tries*.

:errorflg
If :noerrors, ignores remote procedure call errors. If :returnerrors, returns the error as an s-expression. Otherwise, signals a Lisp error. Default t.

LOW-LEVEL REMOTE PROCEDURE CALL FUNCTIONS

setup-rpc destination program procid [Function]
&optional destsocket version protocol dynprognum dynversion

Returns four values destaddr, socket, program and procedure (Yes, this is real, live multiple value return requiring a multiple-value-bind or something similar.) for consumption by perform-rpc. The arguments to setup-rpc are identical in meaning to the identically named arguments to remote-procedure-call.

open-rpc-stream protocol destaddr destsocket [Function]

Returns an rpcstream for use by perform-rpc. Destaddr and destsocket are as returned by setup-rpc and protocol is identical to the protocol argument to remote-procedure-call.

close-rpc-stream rpcstream protocol [Function]

Closes rpcstream, an rpc-stream of protocol protocol created by open-rpc-stream.

perform-rpc destaddr destsocket program procedure rpcstream [Function]
arglist credentials protocol &key errorflg leave-stream-open msec-until-timeout msecs-between-tries

Performs a remote procedure call returning a list of the values retruned by the remote procedure.

LISTING REMOTE PROGRAMS CURRENTLY DEFINED
list-remote-programs [Function]

Returns a list of 4-tuples (name number version protocol) for each remote program currently defined.

CREATION OF CREDENTIALS

create-unix-authentication stamp machine-name uid gid gids [Function]

Returns a Unix-type authentication suitable for use as the credentials of a call to remote-procedure-call or perform-rpc.

stamp An arbitrary unsigned integer.
machine-name A string containing the name of the calling machine.
uid User id number on the remote machine.
gid Group id number on the machine.
gids A list or array of group id numbers (on the remote machine) that contain the caller as a member.

GLOBAL VARIABLES

*xdr-primitive-types* An a-list of keywords and the corresponding function that implements that XDR primitive type.

*xdr-constructed-types* An a-list of keywords and the corresponding function that generates code to implement that XDR constructed type.

*msec-until-timeout* Number of milliseconds before giving up on receiving a reply packet. Default 1000.

*msec-between-tries* Number of milliseconds to wait before resending UDP packet. Default 100.

*rpc-ok-to-cache* If non-nil, uses *rpc-socket-cache* as a cache of socket numbers found to date.

*rpc-well-known-sockets* A list of well-known sockets. Format is
( <host address> <remote program number> <remote program version> <protocol> <socket> )

*rpc-socket-cache* A list of non-well-known sockets. Format is same as *rpc-well-known-sockets*.

*debug* If non-nil prints out debugging information. If a number, the higher the number, the more information is printed. Default nil.

### KNOWN DEFICIENCIES

- Floating point XDR types are not implemented.
- The view-packet utility is not documented and needs to be smarter about authentications.
- Fall through cases of XDR types UNION and ENUMERATE should be added.
- TCP is not supported under Medley 1.0-S, this should be in the next release.

Modified to work under Medley 1.0-S by Atty Mullins.
RS232CNetwork

By: Nick Briggs (Briggs.pa@xerox.com)

Uses: DLRS232C

This document last edited on August 10, 1988.

INTRODUCTION

The RS232C port on a Daybreak can be configured in such a way that it can be used to communicate with a Pup Gateway over a phone line to provide a network communications path equivalent in all but speed to an Ethernet connection.

USE

Load the RS232CNetwork module. It redefines a number of functions, the one of general interest being

(RS232C.INIT BAUDRATE BITS PERSERIALCHAR PARITY NOOFS STOPBITS FLOWCONTROL LINETYPE) [Function]

RS232C.INIT performs as documented in the Lisp Library modules manual, except for the addition of the LINETYPE argument. LINETYPE should be SYNC or ASYNC (also accepted are the alternate spellings SYCH and ASYNCH).

In order to use the RS232C port for communicating with a Pup Gateway it must be configured (using RS232C.INIT) in SYNC mode. In addition, the variable

*RS232C-NETWORK* [Variable]

should be set to T (which is the default setting on loading the RS232CNetwork module).

The variable

*RS232C-NETWORK-AUTODIAL* [Variable]

controls whether the system will attempt to start the network connection automatically when Lisp returns from a LOGOUT. If *RS232C-NETWORK-AUTODIAL* is set to NIL, you can cause the system to attempt to establish the connection manually by calling the function RESTART.ETHER.

The modem should be configured to dial on detecting an off to on transition of DTR. On a Codex 2260 modem this is DTR mode 108.1. Since the dialing and answering process can take a non-trivial amount of time, the variable

*RS232C-NETWORK-DIALING-TIMEOUT* [Variable]

indicates how many seconds the code will wait for the modem to signal that the connection has been established (by raising DSR) before timing out and continuing without the network connection. The default value is 30 seconds.

EXAMPLE
The very first time the code has been loaded the initialization sequence, when using Codex 2260 modems which can communicate at 9600 baud, would be

(RS232C.INIT 9600 8 'NONE 1 NIL 'SYNC)

(SETO *RS232C-NETWORK-AUTODIAL* T)

(RESTART.ETHER)

Subsequently, whenever the Daybreak boots into Lisp, the network code will attempt to establish a phone connection.

To shutdown the phone connection you can call the function TURN.OFF.ETHER. The connection will also be broken when you log out of Lisp (assuming that the modem is configured to disconnect on loss of the DTR signal, which the Codex 2260 modems will do)
SCREENPAPER

By: Larry Masinter (Masinter.pa@Xerox.com)

SCREENPAPER is an Idle hack ("Screen wallpaper"). Old fashioned wallpaper/wrapping paper from your screen.

**Global parameters:**

SCREENPAPERSIZE  size of viewport, initially 64.
SCREENPERIOD     how often to go into reflective move
SCREENREPEAT     how long to stay in reflective mode (initially 0. e.g., disable reflective mode).
INTRODUCTION

The SearchMenu package implements a user interface to the relevance search capabilities of the dictionary server. Relevance search is a technique for finding items by giving examples of what you are looking for and having the search algorithm look for "similar" items. These items are then displayed in a FreeMenu which allows you to select those items which are actually relevant. You can then iterate on the new set of examples until no new relevant items show up.

The Dictionary Server currently supports three databases that can be searched using this technique: the WordNerd (based on the American Heritage Dictionary), the EtymologyNerd (based on the etymological portion of the American Heritage Dictionary), and the IRMNerd (based on the Interlisp Reference Manual). For example, if you were looking for different types of gases, setting the database to the WordNerd and giving it example gases such as hydrogen and helium would produce oxygen, xenon, krypton, argon, neon, radon, fluorine, chlorine, and nitrogen. Or, if you were looking for Interlisp functions that tested the equality of something, setting the database to the IRMNerd and giving example procedures like EQ and EQUAL would produce EQP, IEQP, FEQP, STREQUAL, EQMEMB and EQUALALL.

HOW TO USE THE SEARCH MENU

When you load the SearchMenu package, a Search Menu will appear in the lower left corner of the screen. (The Search Menu expands to display the results of a search, so you might leave it there until you see how big it can get.) The Search Menu has a number of commands on the top line, followed by a place to type in examples.

To try your first search, click the "Examples:" field and type "lion tiger". Then click the MATCH WORDS! command just above it. A little menu of databases will appear, asking you which database you want to search in. Select "DictServer: WordNerd". A message will then appear in the prompt window saying: "Searching in DictServer: WordNerd for words like: (tiger lion)." After about 30
seconds a new Search Menu will be created with a list of items that the Dictionary Server thinks is similar to a lion and a tiger. At the top of the list lion and tiger will already be selected.

To continue the search, scan the list of items for things that are relevant to you. If you are not sure what a word means, click the "def" button to its left, and the definition will be printed out in a separate window. If you want an item to be included in the next search, simply click at it and it will become inverted, like lion and tiger. If you click at an item twice, a line will be drawn through it to indicate that any keywords that it uses should have their weights reduced. Words that are neither highlighted nor struck out are ignored. When you are through examining the items, invoke the MATCH WORDS! command. You can iterate like this as often as you like.

Clearing The Search Menu

Before you start a new search, you should invoke the "CLEAR!" command to clear the Search Menu. The Search Menu caches some information about the search you are conducting which may interfere with your next search. Therefore, to be sure that you get a clean search, you should clear the menu.

Changing Databases

When you want to search for items in a new database, all that you need to do is click the "SET DATABASE!" command. This will cause a menu of databases to appear. Clicking one of the items in the menu will cause the Search Menu to search in that database from then on. Clicking outside the menu leaves the Search Menu in its current state.

The Key Menu

To the left of the commands in the first line is a command labelled "KEY MENU!". Invoking this command will turn the Search Menu into a key menu. The key menu will have all of the keys that were used in the last search, along with their weights. The weights are editable. If you want to see what would happen if you searched using different weights, simply edit the weights and then invoke the "MATCH KEYS!" command. Weights that are set to 0 or have no value are ignored.

If you want to see all of the uses of a particular key click the "uses" button to the left of that key. To get back to the example menu, invoke the "SAMPLE MENU!" command in the upper left of the Search Menu.

Logging a Search

If you wish to keep a log of each search, set the SearchMenu.LogData variable to T. From then on, the Search Menu will write the results of its search into a private stream. When you click the "CLEAR!" command, a TEdit window will be opened on the log and the log cleared in preparation for the next search.

THE PROGRAMMER'S INTERFACE
The Dictionary Server can be accessed directly through the following procedures:

(DICTCLIENT.MATCHWORDS  POSWORDS NEGWORDS MINWORD MAXWORD DICTIONARY)
[Function]

Takes a list of words to match, plus a list of words to ignore, plus the range of words that you are interested in, plus the database. The range of words lets you look at a search one chunk at a time: the first fifty (MINWORD = 1, MAXWORD = 50), then the next fifty (MINWORD = 51, MAXWORD = 100), and so on. The DICTIONARY is the name of the database to be searched in. Currently there are three possibilities: 'WordNerd, 'EtymologyNerd, and 'IRMNerd. If no data base is specified, the default is 'WordNerd.

(DICTCLIENT.WEIGHTEDSEARCH  WEIGHTEDKEYS MINWORD MAXWORD DICTIONARY)
[Function]

Takes a list of weighted keys to match, plus the range of words that you are interested in, plus the database. The weighted keys should be of the form '((key1 weight1)(key2 weight2)...)'. The range of words lets you look at a search one chunk at a time: the first fifty (MINWORD = 1, MAXWORD = 50), then the next fifty (MINWORD = 51, MAXWORD = 100), and so on. The DICTIONARY is the name of the database to be searched in. Currently there are three possibilities: 'WordNerd, 'EtymologyNerd, and 'IRMNerd. If no data base is specified, the default is 'WordNerd.
This package advises the SEdit Editor so that when an SEdit window is opened, the SEdit Attached Command Menu is automatically opened as well (depending on the setting of the global variable IL:SEditMenuAlwaysFlg). The value of IL:SEditMenuAlwaysFlg is initialized to T as an INITVAR when the file is loaded.
The SETDEFAULTPRINTER module provides a (cleaner) mechanism for moving printer names around on your DEFAULTPRINTINGHOST list. There are no user callable functions. Access to the features of the module are through the Background menu. This module uses the DEFAULTSUBITEMFN module which redefines the DEFAULTSUBITEMFN used in menus to accept an expanded form for menu subitems.

Set Default Printer  [Background Menu Entry]

Selecting the "Set Default Printer" item off the background menu will prompt you for a new default printer, which will be added at the beginning of the DEFAULTPRINTINGHOST list. If you roll-out into the subitems for Set Default Printer it will present a submenu with the entries on DEFAULTPRINTINGHOST, and an "Other..." item. Selecting one of the printer name entries will cause it to be moved to the front of DEFAULTPRINTINGHOST, selecting "Other..." will prompt for the name of a printer in the same manner as selecting the "Set Default Printer" top level item off the background menu. If any commentary information has been supplied (see below) holding the mouse over the printer name will display the information in the prompt window.

SDP.PRINTERINFO  [Variable]

The variable SDP.PRINTERINFO is an A-list which will be used to lookup commentary information about a printer to be included as the "help" in the menu subitems. The UPPERCASE name of the printer is used as a key. An example SDP.PRINTERINFO setting might be

((QUAKE . "Press, Rm 1532") (PENTELPS:PARC:XEROX . "Interpress, Rm 1532"))

LOCATION  [Property]

The code that looks up the commentary information about a printer will also check for a LOCATION property on the UPPERCASE atom which is the printername if no entry is found on SDP.PRINTERINFO. For example

(PUTPROP ‘JEDI ‘LOCATION "FullPress, Pod 5, 2nd floor")

Would describe the location of printer Jedi.
INTRODUCTION

SHOWTIME provides a user interface to read, write, and edit bitmaps in several different formats. Among the supported formats is RES, used in VIEWPOINT Freehand Graphics. Other supported formats include Brush (Mesa Doodle format); and Lisp.

SHOWTIME has been written to readily accommodate new formats. Users may add new formats to Showtime by writing format-specific read and/or write functions and adding them to those Showtime knows about (described below).

Selecting SHOWTIME from the background will provide the user the opportunity to specify and area to use as the SHOWTIME window. After the user creates a SHOWTIME window, a left mouse button within the window will popup a menu of available options. There may only be one bitmap displayed in a SHOWTIME window at a time, but any number of SHOWTIME windows may be opened. Shrinking a SHOWTIME window will create an icon with the name of the bitmap that is displayed in the window.

Functions, Variables, and Lisp Code Examples

SHOWTIME.FORMAT.FNS [Variable]

A global association list that maintains a list of all the formats Showtime knows about and the read and write functions to use with those formats. This variable should be updated by calling the function SHOWTIME.ADD.FORMAT to ensure successful integration of any new bitmap formats.

SHOWTIME.DEFAULT.FORMAT [Variable]

A variable that is initially set to 'LISP. This format uses the binary storage routines found in the lispusers module BITMAPFNS.

(SHOWTIME.ADD.FORMAT FORMAT READFN SAVEFN) [Function]

A function that should be called when the user wants Showtime to know about new bitmap formats. FORMAT may be any descriptive atom, such as RES or LISP. READFN and SAVEFN must be functions that have as the first two arguments FILENAME and BITMAP. In addition, the READFN must return a bitmap.
For example, the READFN code for LISP format is:

(LAMBDA (FILENAME)
  (READBM (OPENFILE FILENAME (QUOTE INPUT))))

For example, the WRITEN code for LISP format is:

(LAMBDA (FILENAME BITMAP)
  (WRITEBM (OPENFILE FILENAME (QUOTE OUTPUT)) BITMAP))

ACKNOWLEDGEMENTS

SHOWTIME was originally developed to provide a user interface in the exchange of bitmaps between the VIEWPOINT and INTERLISP-D environments. Tom Wall initiated the idea to exchange bitmaps between these environments and was instrumental in developing the code to write RES files. Gary Gocek originally wrote the code to read RES files; Mitch Garnaat wrote the code to write BRUSH files; reading brush files is supported by the lispusers module READBRUSH written by Larry Masinter. The SHOWTIME icon was designed and created by Mary Baecher-Cocca.
INTRODUCTION
Like CHAT except that it works in the current window/exec instead of spawning a new window. To exit from TTYCHAT there is an escape character, control-right-bracket (^]). If you type ^], you get prompted for a Chat command. This can be one of Binary, Text, or Close. Normally TTYCHAT translates incoming characters and converts EOL; setting Binary mode disables this. Close will close the connection.

MODULE EXPLANATIONS
The CHATSERVER module advises CHAT to use TTYCHAT when the main “terminal” is not the display. This allows one to use the Lisp system as a "protocol translation gateway"; for example, on a Sun with CHATSERVER-NS loaded, you can Chat to the Sun using NS and then use UNIXCHAT to CHAT(SHELL).

(TTYCHAT &optional host logoption)
SNAPW-ICON

By: Randy Gobbel (Gobbel.pa)

Uses: nothing but basic window functionality

This document last edited on September 8, 1988.

INTRODUCTION

SNAPW-ICON creates an icon for shrunken screen snap windows. It looks like this:

Everything else about screen snaps is as before.
INTRODUCTION

This module changes the behaviour of MOVEW when no destination is given to let the whole image of a window track the mouse instead of just its outline. To avoid flickering and to give an illusion of a smooth animation, all rendering operations are done off the screen, ending with a single bitblt to the frame buffer for each cycle. This can easily be done on small windows such as icons, but the more bits there are to be moved, the longer it takes to do the animation updates and the slower it becomes to solidly move windows. Therefore, the user can control when solid vs. outline moving is to be done by setting *SOLID-MOVEW-FLAG* to an appropriate value. By default, only windows containing less than 15,000 pixels will be moved solidly; all other windows are moved using the original MOVEW method.

SOLID-MOVEW interfaces nicely with both ICONW and ATTACHEDWINDOWS by being able to move images of arbitrary shape — not just pure rectangles. It also knows about GRID-ICONS and can be made to force the icons to snap to grid positions while being moved, thus producing a kind of jagged feeling. Finally, a shadow has been added to emphasize the 2½-D property of window systems and to give a clear indication of when the window is in the process of being moved.

PROGRAMMER’S INTERFACE

When loaded, the module replaces the system MOVEW function with its own version and moves the original code to ORIGINAL-MOVEW. The control and interaction is then comes through the following variables:

*SOLID-MOVEW-FLAG* [Variable]

This variable controls whether the new MOVEW should use solid or outline moving. It should have one of the following types of values:

- a NUMBERP Only use solid moving on windows that have a total size (width x height) less than or equal to the given number of pixels.
- a POSITIONP Only use solid moving on windows that have a width and height less than or equal to the two numbers.
- ICON Only move icons solidly. A window is considered to be an icon if it either has an ICONFOR or an ICONIMAGE property.
- T Move all windows solidly.
- NIL Move all windows using outlines.

The default value for *SOLID-MOVEW-FLAG* is 15000.
These two variables define whether or not a shadow should accompany the moving image. The shadow is always directed towards south-east and the first variable, "SOLID-MOVEW-SHADOW", determines its position by taking on any of the following types of values:

- a NUMBERP: The x and y offsets of the shadow (same)
- a POSITIONP: The x and y offsets of the shadow (different)
- T: Use the default shadow offset — 3 pixels in both directions.
- NIL: Don’t show a shadow.

The second variable, "SOLID-MOVEW-SHADOW-SHADE", sets the darkness of the shadow, i.e., the texture to be added to the background where the shadow is visible.

The default values for the two variables are T and 42405, a 50% gray shadow offset by 3 pixels.

When used together with the ICON-GRIDS module, SOLID-MOVEW can be made to only move solid window images on grid positions, thus creating a kind of "jagged" feeling when interactively moving icons on the screen. If this is disabled, the icon will "snap" to the closest grid position only after the move has been completed.

The default value for "SOLID-MOVEW-GRIDDING" is NIL, thus disabling early gridding.

SOLID-MOVEW uses separate bitmaps for rendering purposes so as to produce a smooth animated move and avoid unnecessary flickering on the screen. To speed up the initial phase of the move operation, the rendering bitmaps can be cached from one invocation to another. This will use up some bitmap space, but can be freed using (GAINSPACE) if need arises.

The default value for "SOLID-MOVEW-CASHING" is T, thus enabling cached rendering bitmaps.

Because only those windows meeting the requirements of "SOLID-MOVEW-FLAG" will be moved solidly, the user has the option of calling SOLID-MOVEW. It takes the same arguments as MOVEW, but if either POSorX or Y is specified, control is again turned over to the old MOVEW.

If you get tired of all this, you can undo the behaviour of SOLID-MOVEW by typing the following form into an Interlisp Exec:

```
(MOVD 'ORIGINAL-MOVEW 'MOVEW)
```

No provision has been made to make SOLID-MOVEW work with color. If the window is closed as a side effect of the its MOVEFN or AFTERMOVEFN, it will be reopened before SOLID-MOVEW returns.
The SOLITAIRE package ia a simple graphics demonstration program that plays and animates the solitaire card game (known as ~Patience~ in English speaking countries). Solitaire is a game for one, so there is no way to play ~against~ the machine. SOLITAIRE is most effective as a background activity when the machine is doing nothing else, so it is frequently used as an IDLE hack.

TO USE

To play once

(SOLITAIRE  SOLOW REPLAY)  [Function]

Plays one hand of solitaire, which it will animate in the window SOLOW (which should be at least 700 by 700, although the program will do its best to adapt). If REPLAY is T, SOLITAIRE will use the deck from the previous shuffle, else it will deal a new hand.

To play repeatedly

(SOLO  SOLOW)  [Function]

Calls (SOLITAIRE  SOLOW) repeatedly.

The results

SOLO keeps a record of the frequency of each of its results in the array SOLORESULTS [0..52] which it plots at the end of each hand.

As an IDLE hack

Loading SOLITAIRE automatically adds SOLITAIRE as an option to the IDLE menu. If chosen, it will be given the ~whole screen~ covering window of IDLE and will use a black background, rather than its usual shaded one, to preserve the screen phosphor. Otherwise, its operation is completely normal.
STARBG

By: Gregg Foster (Foster.PA@Xerox.COM)
Upgraded for Medley by Larry Masinter (Masinter.PA@Xerox.COM)

STARBG creates a random star field for your screen background and a little flying saucer to follow your cursor when it's in space (so it doesn't get lost). It also supplies an alternate IDLE function, Cosmos.

The star field will look something like this:

![Star Field Image]

The saucer will look like this:

![Saucer Image]

**USAGE**

(STARBG) [Function]

STARBG fills a screensized bitmap with random stars, turns the saucer on, and calls CHANGEBACKGROUND. If you don't like the star pattern you get, try it again.

(Cosmos window) [Function]

Cosmos is puts an evolving universe in a window. It's intended as an IDLE function, but will entertain you for hours in any decently sized window.

(SaucerOn) [Function]

SaucerOn turns the saucer on by changing the CURSORBACKGROUND*FNs.

(SaucerOff) [Function]

SaucerOff turns the saucer off and sets the BACKGROUNDCURSOR*FNs to NIL.
CUSTOMIZATION

There are lots of user-settable parameters, all of which have reasonable defaults. Here are some of the interesting ones:

STARBGParameters [Variable]
is a list of settable parameters. Most are dotted pairs specifying ranges (e.g. stars3 defaults to (6 . 70) meaning that STARBG will make 6 to 70 type-3 stars). The others are bitmaps.

BM1, ..., BM5 [Variables]
The star bitmaps used to BLT the stars. BM1 must be a single bit.

SBM [Variable]
The starry screen bitmap. This is reused in subsequent calls to STARBG.

stars1, ..., stars5 [Variables]
Ranges for the 5 kinds of stars.

constellations [Variable]
Range for number of constellations. A constellation is a group of bright stars.

clusters [Variable]
Range for number of clusters. Clusters are tightly globular.

superClusters [Variable]
Range for number of superClusters. SuperClusters are clusters of clusters.

eventPause [Variable]
Number of milliseconds to block between events. Larger numbers have the effect of slowing down the rate of evolution..

changeStars [Variable]
Will use the IDLE-ing star field as your new background.
This package changes the function CL::STEP-COMMAND (used by CL:STEP) to call a new function (instead of IL:ASKUSER) to get its commands from a menu attached to the stepping window (depending on the setting of the CL:SPECIAL variable IL:*STEP-COMMAND-MENU*). The value of IL:*STEP-COMMAND-MENU* is initialized to T as an INITVAR when the file is loaded. The variable USER::*STEP-COMMAND-INVERT-MENU-SHADE* is the shade used to grey-out the attached menu when the stepping is not awaiting a command. The menu is attached to the Right edge (at the Bottom) of the stepping window. (If there isn’t enough room on the Right, it will be attached to the Left edge.) The menu is detached and closed when the stepping level which first attached it is exited.
STORAGE implements a bar-graph version of the Lisp STORAGE function, providing a visual summary of the amount of storage allocated to each data type.

\[
\text{(SHOWSTORAGE [PAGETHRESHOLD MODE ROTATION])}
\]

Displays the storage allocation of Lisp data types in bar graph format:

All the arguments are optional. \text{PAGETHRESHOLD} is the same as for the STORAGE function and defaults to 1. \text{MODE} determines what to display and can be one of the following:

- **ITEM** The number of items of each type that have been allocated (the default mode).
- **PAGE** The number of pages allocated for each type.
- **BOX** The number of times each type has been allocated (see \text{BOXCOUNT} in the IRM).

The mode can be changed when the window is open by clicking with the \textit{middle} mouse button. Clicking in the window with the \textit{left} mouse button will update the window. When the window is redisplayed (using the standard window menu or REDISPLAYW) it will add new data types that have been defined since the window was last redisplayed.

For the \text{ITEM} and \text{PAGE} modes, the black part of the bar represents the number of items or pages currently \textit{in use}. The gray part of the bar represents the number of \textit{free} items or pages. The total length of the bar represents the \textit{total} number of items or pages.
The \textit{ROTATION} argument can be one of \texttt{NIL} (use the rotation of the \texttt{SHOWSTORAGEFONT}), \texttt{0} (labels from bottom to top on the right, bars grow to the left) or \texttt{90} (labels from left to right and bars grow down).

The display is controlled by the following global variables:

\begin{itemize}
\item \texttt{SHOWSTORAGEWINDOWSIZE} [Variable]
  
  The width or height (depending on the rotation) of the window, initially 275 (pixels). The bars truncate at the edge of the window; the window can be reshaped to put the longer bars in perspective.

\item \texttt{SHOWSTORAGEIGNORE} [Variable]
  
  A list of data types to ignore. The information for the data types initially on this list is incorrect and/or their inclusion breaks the program.

\item \texttt{SHOWSTORAGEDEFAULTTHRESHOLD} [Variable]
  
  The default threshold used when \texttt{PAGETHRESHOLD} is \texttt{NIL}, initially 1 (page).

\item \texttt{SHOWSTORAGEPRIN2FLG} [Variable]
  
  Flag that causes \texttt{PRIN2} to be used instead of \texttt{PRIN1} when printing data type names (\texttt{PRIN2} will include package names), initially \texttt{NIL}.

\item \texttt{SHOWSTORAGEFONT} [Variable]
  
  The window font, initially one of Helvetica 5 through 10, i.e. the smallest that can be found when the file is loaded. The default font has a rotation of 90 degrees.
\end{itemize}
INTRODUCTION

Stylesheets are collections of menus. These collections pop up all at once in a group. This group does not disappear until all menus in it have been dealt with, and the user signals that he is done.

Stylesheets are intended to be used in situations wherein the computer wants an answer to several related questions all at once. One example is font selection. To select a font, the user needs to specify font family (Classic, Modern, etc.), font size (8 point, 10 point, etc.), and font style (bold, italic, etc.). Rather than prompt for each of these parameters in succession, one could use a stylesheet to prompt for it all at once.

When the stylesheet pops up, it will shade (preselect) default selections (if provided) in each of the menus. The user can either decide that the default selections are OK, or change them to suit his taste. (The default selection mechanism can be used to convey the current state of something the user is trying to change with the stylesheet: for example, the current looks of the text with which the user is dissatisfied.)

When the user is finished, he hits the DONE button and the stylesheet disappears, and the final selections are returned. There is also a RESET button. This is useful if the user has mucked up his selections and would like to reinstate the default selections. Finally, there is an ABORT button that if selected returns NIL from STYLESHEET and is intended to provide the user with a convenient way of aborting the selection. Note: This means that NIL can be returned from a call to STYLESHEET.

Menus in a stylesheet can be set up to accept exactly one selection (like a normal menu), less than two selections, or any number of selections. Menus that need not be filled in (i.e., can accept zero selections) have an attached CLEAR button, which can be used to remove selections made in that menu. Menus that can have more than one selection have an attached ALL button, which can be used to select all the items in the menu.

HOW TO MAKE A STYLESHEET

To create a stylesheet, call

(CREATE.STYLE Prop1 Value1 Prop2 Value2 ... PropN ValueN) [Function]
CREATE.STYLE accepts an arbitrary number of property-value pairs. Properties currently recognised are:

- **ITEMS** [Style Property]
  - A list of menus. Most menu format parameters contained in menu records are honored by the stylesheet package. WHENSELECTEDDFNs are, of course, ignored.

- **SELECTIONS** [Style Property]
  - A list of menu items, each one corresponding to a menu in ITEMS. The specified selections will be shaded in the appropriate menu, and will be the default selections. If not specified or too short, it will be filled out with NILs (no selection).

- **NEED.NOT.FILL.IN** [Style Property]
  - A list of T or NIL or MULTI, each one corresponding to a menu in ITEMS. T indicates that the corresponding menu need not be filled in and will be given a CLEAR button. MULTI indicates that the corresponding menu can have any number of selections and will be given both a CLEAR button and an ALL button. If the list is too short, it will be filled out with NILs. If a single T or NIL or MULTI is given instead of a list, it will be replaced by a list of Ts or NILs or MULTIs, respectively.

- **TITLE** [Style Property]
  - The title that will be given to the stylesheet. If no title is specified, the stylesheet will not have a title bar.

- **ITEM.TITLES** [Style Property]
  - A list of strings or atoms to serve as titles over the menus. Items without titles specified will not have titles.

- **ITEM.TITLE.FONT** [Style Property]
  - A fontdescriptor or other font specification which determines the font item titles will be printed in. If NIL, titles will be printed in DEFAULTFONT.

- **POSITION** [Style Property]
  - The screen position (of type POSITION) of the lower left-hand corner of the stylesheet. If position is not specified, the function STYLESHEET will prompt for the position (using GETBOXPOSITION). STYLESHEET will modify positions as necessary to ensure that the entire stylesheet will be on the screen.

Stylesheets can be modified by calling
(STYLEPROP Stylesheet Prop Newvalue)  [Function]

STYLEPROP always returns the old value of the specified property of the specified stylesheet. If Newvalue is provided (even if NIL), it replaces the old value. If not provided, the old value remains. (Just like WINDOWPROP.)

To use the stylesheet thus created, call

(STYLESHEET Stylesheet)  [Function]

This returns a list of selections the user made from the stylesheet. (If a selection is returned as NIL, that indicates that no selection was made.)

One can determine in advance of displaying a stylesheet how big it will be. (This may help in determining a reasonable screen position for the stylesheet.) The relevant functions are

(STYLESHEETIMAGEWIDTH Stylesheet)  [Function]

and

(STYLESHEETIMAGEHEIGHT Stylesheet)  [Function]

They return the width and height, respectively, of the stylesheet in pixels.

AN EXAMPLE

The package is located in STYLESHEET and STYLESHEET.DCOM. To familiarize yourself with its workings, you might want to load it and try the following example:

(SETQ FONTSTYLE
  (CREATESTYLE 'TITLE "Please select a font:"
 'ITEMTITLES '(Family Size Face)
 'ITEMTITLEFONT 'Modern 12
 'ITEMS
   (LIST
     (CREATEMENUITEMS ← 'Classic Modern Terminal))
     (CREATEMENUITEMS ← '(8 9 10 11 12 14))
     (CREATEMENUITEMS ← 'Regular Bold Italic BoldItalic))
 'SELECTIONS 'Modern 11 Regular
 'NEEDNOTFILLIN 'T]

(STYLESHEET FONTSTYLE)
SuperParentheses

By: Andrew J. Cameron, III (Cameron.pa@Xerox.com or cameron@cs.wisc.edu)

Most useful when used with: WHO-LINE (LispUsers)

This document last edited on Oct 19, 1987.

INTRODUCTION

This file, when loaded, creates a readtable (named "LISP[]") for use with CommonLisp which contain SuperParentheses, that is, the left square bracket (LEFTBRACKET syntax class) and right square bracket (RIGHTBRACKET syntax class) available in InterLisp. CommonLisp does not give these two characters their "usual" definitions, so as to allow users to easily give these character any macro/syntax definition they might desire.

This readtable will appear on, and can be selected via, the "Rdtbl" menu provided by the WHO-LINE LispUsers utility.

One can also access this new readtable with:

```lisp
(IL:FIND-READTABLE "LISP[]")
```

These facilities obviate the need to store the readtable on a variable, as was done in an earlier version of this module.

INTERNALS

- The reading and writing of files using this readtable has not been tested or explored.
- SEdit is not too friendly to SuperParentheses.
- For more information, see Section 25.8.2 in both the IRM (InterLisp Reference Manual) and the Lyric Release Notes, and Section 22.1 in Steele (CommonLisp - The Language).
SYSTATS

By: Johannes A. G. M. Koomen
(Koomen.wbst@Xerox or Koomen@CS.Rochester)

This document last edited on: October 28, 1987

SUMMARY

SYSTATS provides a functional interface to system statistics such as PageFaults, DiskIOTime, etc. Statistics are maintained in objects of type SYSTATS. Functions are provided to fetch values from these objects, and to update the objects to reflect the current system state or to compute differences. This facility provides a Lyric alternative to the (undocumented) MISCSTATS functions in Koto.

DESCRIPTION

SYSTATSPROPS [Variable]

A list of statistics maintained by SYSTATS. Changing it does not alter SYSTATS behavior.

(SYSTATSPROP prop fromstats) [Function]

If fromstats is NIL, the internal SYSTATS object is updated and used. Returns the value of the statistic named by prop, which must be a member of the variable SYSTATSPROPS.

Caveat: The value returned is a FIXP which is an element of the fromstats object and which, for the sake of performance, is reused during a SYSTATSREAD on the fromstats object. Note that there is an implicit SYSTATSREAD on the internal SYSTATS object if fromstats is NIL.

(SYSTATSREAD intostats fromstats) [Function]

If intostats is NIL, it is set to a newly created SYSTATS object. If fromstats is NIL, the internal SYSTATS object is updated and used. Copies system statistics from fromstats into intostats. Returns intostats.

(SYSTATSDIFF oldstats newstats difstats) [Function]

If oldstats is NIL, the internal SYSTATS object is updated and used in its place. If newstats is NIL, the internal SYSTATS object is updated and used in its place. If difstats is NIL, it is set to a newly created SYSTATS object. Computes the statistics differences between oldstats and newstats, and places the results in difstats. Returns difstats.

(CLOCKTICKS interval timerunits) [Function]

Returns the (machine dependent!) number of internal clock ticks over the interval. For instance, on the D'Lion, (CLOCKTICKS 2.5 'MINUTES) = 5211900.
By: Christopher Lane (Lane@Sumex-Aim.Stanford.Edu)

TALK allows users to hold conversations between machines across the Ethernet. TALK uses various services (TTY, TEdit and Sketch) and network protocols (NS and IP).

**TALK FILES**

Talk’s services and protocols are now in separate files which may be loaded independently:

**TALK** The main Talk module.

**Services**

TTYTALK Simple text conversation between machines running Lisp, XDE and Viewpoint.
TEDITTALK Uses TEDIT; allows the full capabilities of the TEdit editor in a conversation.
SKETCHTALK Uses SKETCH; allows a conversation using the Sketch graphics editor.

**Protocols**

NSTALK Uses COURIERSERVE (and optionally NSTALKGAP); allows XNS protocols.
NSTALKGAP Used by NSTALK if the GAP Courier program has not been defined (by NSCHAT).
IPTALK Uses TCP and TCPUDP; allows conversations using IP protocols.
Any Talk service can be used with any Talk protocol. The preferred order of loading is:

(FILESLOAD TALK TEDITTALK TTYTALK SKETCHTALK NSTALK IPTALK)

dropping out those services/protocols you do not use. Order of loading determines which
services/protocols are tried first; the files may be loaded in any order to force different priorities.

USING TALK

(TALK [USER.OR.HOSTNAME SERVICE PROTOCOL]) [Function]

Starts a TALK session; USER.OR.HOSTNAME, SERVICE and PROTOCOL are optional. If not
 supplied, USER.OR.HOSTNAME is prompted for (either by menu or typein or both). If SERVICE and
PROTOCOL are not supplied (the usual case), TALK will figure out which to use based on what is
available on the local and remote machines. The supported services and protocols are described
below. The service and protocol used are indicated in the title bars of the TALK window.

TALK returns a process handle if the connection is successfully opened; it returns NIL if the user
aborts out of the host/user menu and it returns an error message (as a string or list instead of breaking)
if it cannot contact the remote host (for whatever reason). TALK can also be invoked from the
background menu.

TALK MENU

The menu at the bottom of the TALK window (which is only active while the connection is open)
contains the following items:

Disconnect Closes the TALK connection. This is equivalent to closing the TALK window, but leaves
the window open in case you want to save and/or hardcopy part or all of the session.

RingBells Rings the bell on the remote workstation (if possible) and flashes the TALK window on
the local one to indicate it has done so. This is useful if you have asked a person to hold
and want to let them know you have returned.

Message Prompts for and inserts a canned message into the TALK stream. Useful if the phone
rings and you want to ask the other person to hold with a minimum of time/effort.
Messages can be added to the list, see the TALK.USER.MESSAGES variable below.
The TALK window must have the keyboard in order to use this item.

ERROR MESSAGES

The TALK function will return one of the following error messages when it fails to start a session:

Host not found! It could not find host address for the host or user name specified.

Can’t connect to host! The remote workstation does not have the appropriate server loaded
and/or running or does not have TALK loaded.

No answer from TALK service! A connection was made, but no one responded (intentionally or
otherwise). A darkened TALK icon is left on the remote screen to log
the connection attempt (unless TALK.GAG is non-NIL).

Unknown service type! An unknown type was given as the SERVICE argument.

No services available! The SERVICE argument was not supplied and it cannot find one.

Unknown protocol! An unknown protocol was given as the PROTOCOL argument.
No protocols available!  

The PROTOCOL argument was not supplied and it cannot find one.

Service and protocol errors may indicate additional files need to be loaded.

RECEIVING TALK

When your machine is contacted by another via TALK, the following icon will appear on your screen, ringing bells, flashing and showing the time, mode (service and protocol) and (when possible) the caller’s identity:

If you button the icon with the left or middle buttons, a TALK session will begin. If you either close the icon or do not button it (it will go dark (invert) in about 15 seconds if not buttoned) the TALK connection will be refused. TALK connections are automatically refused if the TALK.GAG flag is non-NIL (settable using the subitem(s) of the TALK item in the background menu). If the machine is in IDLE, TALK will wait twice the normal time out for the user to respond.

If you button a darkened (unanswered) TALK icon, it will try to reconnect you to the caller (after a mouse confirm). If a TALK connection comes in from someone who has already left an unanswered TALK icon on your screen, the icon will be reused.

TALK SERVICES

TEdit

This service allows you to use the full capabilities of TEdit in your conversation, including: correcting mistakes anywhere in the document, changing character and paragraph looks, inserting ImageObjects, etc. Along with keyboard input, mouse selections and the caret are also visible to the remote user. The GET and INCLUDE commands in the TEdit command menu will load files into both the local and remote TEdit windows, so make sure the files are accessible to both. Similarly for fonts, if your workstation has to load a font from a server, the remote workstation must also have access to the font. Since the remote workstation may also need to load the font, you may experience communication delays. The TEdit service supports NS character codes and most of the 1108 and 1186 function keys.

TTY

This service is similar to the TEdit service except that the only supported feature is backspace (but not across lines). TTY is the only service that can talk with the Talk.bcd program in XDE or the TALK application (VPTalk.bcd) in Viewpoint. You do not need to know what type of workstation you are contacting when using any of the TALK programs.
Sketch

The Sketch service is built on the Sketch graphics editor:

TALK PROTOCOLS

NS

When NSTALK is loaded, TALK will accept as a host name anything that COURIER.OPEN will accept including an NS address or the name of a workstation registered in a Clearinghouse. Additionally, user names can be used if the address of the user’s workstation is registered under the user’s name in the Clearinghouse. The following function can be used to register a user and workstation correspondence in the Clearinghouse:

(CH.USER.WORKSTATION USER WORKSTATION) [Function]

Sets (or changes) the AddressList Clearinghouse property of USER (which must already be a name or alias in the Clearinghouse) to be the address of WORKSTATION (an NS address or name). If WORKSTATION is NIL, the function removes the AddressList property from USER. To use this function, you must be logged in (via (LOGIN)) as a System Administrator for USER’s domain.

One way to register users would be to go to the individual’s workstation, login as the System Administrator and evaluate:

(CH.USER.WORKSTATION ‘UserName \MY.NSADDRESS)

Note that you cannot use the USERNAME function in this example since the (LOGIN) will change it.

NSTALK does not require or use NSCHAT, but they do share the Courier program GAP. If both NSTALK and the NS CHATSERVER modules are to be loaded, the CHATSERVER should be loaded first if possible. NSTALK is designed to allow other types of NSCHAT/GAP servers. The GAP server function determines which function to call using the service type requested (TTY = 5, TEdit = 6, Sketch = 7) and the entries on the association list GAP.SERVICETYPES which has entries of the form (ServiceNumber ServiceName ServerFunction). It is possible to have both NSTALK running and an EXEC server by adding appropriate entries to GAP.SERVICETYPES. If a GAP server already exists when NSTALK is loaded, it is made the default for all unrecognized service types.

Although NSTALK loads the COURIERSERVE LispUsers module you do not have to have a Courier server running to initiate an NS TALK connection, but you must have one running in order to receive an NS TALK connection.
IP (Interim)

When IPTALK is loaded, TALK will accept as a host name anything that DODIP.HOSTP will accept, including symbolic and numeric IP addresses. User names can be used by adding them as synonyms for local workstation hosts in the HOSTS.TXT file.

The current TALK IP interface is only temporary and will eventually be replaced by one which is compatible (for TTY service) with the TALK program which runs under BSD Unix; at that time, the allowable username format may be expanded to handle user@host. The current IP interface will probably not be compatible with the eventual, Unix-compatible one.

TALK VARIABLES

The following variables can be used to affect TALK's default behavior:

TALK.DEFAULT.REGION = (0 0 500 500) [Variable]

The LEFT and BOTTOM of this region determine where the (initial) TALK icon appears on the screen; the HEIGHT and WIDTH are the combined dimensions of the TALK windows (each uses half the HEIGHT). If this variable is set to NIL, then the icons start at (0 . 0) and the TALK window region is prompted for as needed.

TALK.USER.MESSAGES [Variable]

A list of menu items to put up when the MESSAGES item on the TALK menu is selected. Items on the list should return strings to be put into the TALK stream. If there is an entry of the form (GREETING "message") on this list, it will be printed automatically when a connection is opened.

TALK.GAG = NIL [Variable]

If non-NIL, causes the TALK server to automatically reject any TALK connections.

TALK.ANSWER.WAIT = 15 [Variable]

The number of seconds the TALK icon remains up before closing and aborting the connection.

TALK.HOSTNAMES = NIL [Variable]

A list structure containing hosts TALK has connected to along with the address used.

TALK.SERVICETYPES [Variable]

This list determines which services are tried and in what order. You only need to modify this if you wish to force an order other than the one determined by the order files were loaded or you wish to add or drop a service.

TALK.PROTOCOLTYPES [Variable]

This list determines which protocols are tried and in what order. You only need to modify this if you wish to force an order other than the one determined by the order files were loaded or you wish to add or drop a protocol.

KNOWN PROBLEMS

Talk

• Since TALK uses the Dove/DandeLion sound generator to help announce a connection, on other machines it is difficult for the user to detect connections being made during IDLE.
TTY Talk
- The TTY service cannot backspace beyond the left margin (unlike other implementations).

TEdit Talk
- Sometimes the local and remote TEdit windows will get out of sync as to what the current looks are; usually this is not serious.
- Page layout commands have not been implemented for the remote TEdit window; there are probably other commands that do not work either.
- ImageObject specific manipulations to ImageObjects already in the window do not get transmitted to the remote TEdit window.
- Inserting (other than keyboard input) into a pending delete does not echo correctly on the remote TEdit window.
- A large ImageObject inserted into the TALK window may not be seen by the remote user until some text is typed to force the remote window to scroll. The remote user may not see the ImageObject at all if it is larger than his window. These are both true of any TEdit window.
- User scrolling of the TEdit window will not cause scrolling of the remote TEdit window. System scrolling of the window (due to insertions and deletions) will be tracked in the remote window.

Sketch Talk
- When the TALK window is opened, some sketch menus will be created and then replaced. This is due to Sketch not allowing a user to specify both an existing window and an initial menu.
- When text (or a text box) is entered, only the initial character is seen in the remote window until the text is completed and the user buttons some other point in the window.
- Arrow heads do not show up at all on the remote sketch window.
- Put of a SKETCHTALK sketch gets into an infinite loop so temporarily you must copy the sketch items to another sketch if you wish to save them on a file.
- If you sweep a control point on a box past the other one (like sweeping one corner of a region past the other in RESHAPE), the remote box will not move identically.
- Since there are no functions to programmatically manipulate grouped elements the Group and UnGroup items have been disabled in the Sketch Talk window.
- For a small number of changes (text fonts, text box brushes and closed wire dashing), the entire remote sketch window is redisplayed to make the change visible.
- Setting the SKETCHINCOLOR flag to a non-NIL value will cause some operations to break.
TCPTIME

By: Christopher Lane  (Lane@Sumex-Aim.Stanford.Edu)

Uses: TCP, TCPUDP

TCPTIME implements time client and server routines under TCP/IP and UDP/IP based on RFC868. The following are the user functions; the PROTOCOL argument refers to one of TCP or UDP and defaults to the value of RFC868.DEFAULT.PROTOCOL, initially TCP. All arguments are optional:

(RFC868.SETTIME [RETFLG PROTOCOL]) [Function]
Obtains the time from the network, similar to the \\PUP.SETTIME and \NS.SETTIME functions. If RETFLG is non-NIL, the time is returned as an integer (as specified in RFC868), otherwise SETTIME is called and the new time is printed in the prompt window. Either TCP.TIME.HOSTS and/or UDP.TIME.HOSTS (see below) must be set before calling this function.

(RFC868.START.SERVER [PROTOCOL ASCIIFLG]) [Function]
Starts a network time server process for the specified (or default) PROTOCOL if one is not already running. The ASCIIFLG is discussed below.

(RFC868.STOP.SERVER [PROTOCOL]) [Function]
Deletes the network time server process for the specified (or default) PROTOCOL if one is running.

The following variables are used by the functions above:

RFC868.TIME.PORT = 37 [Variable]
Used to set the initial value of the protocol specific port variables when the file is loaded. Once the file is loaded, changing this variable has no effect, so it must be reset (if necessary) before loading the file, otherwise the protocol specific port variables should be reset directly. See TCP.TIME.PORT and UDP.TIME.PORT below.

RFC868.DEFAULT.PROTOCOL = TCP [Variable]
The default protocol to use when one is not specified.

BINARY & ASCII TIME FORMAT

Some network software implements the RFC868 standard by returning the printed (ASCII) representation of the time, rather than the binary representation as specified in the RFC. To work around this, the ASCIIFLG can be specified when starting a server to indicate that it should output the printed representation of the number. Similarly, when getting the time from the network, the following is used:

RFC868.ASCII.OSTYPES = (VMS) [Variable]
to decide based on the host's operating system whether to read the time as a binary or ASCII number. If this variable is set to NIL, the ASCII format is never used.

The ASCII format is currently only supported in the TCP protocol.
PROTOCOL SPECIFIC FUNCTIONS

(TCP.SETTIME [RETFLG]) [Function]
(UDP.SETTIME [RETFLG]) [Function]

Functions called by RFC868.SETTIME which can be called directly. The variables TCP.TIME.HOSTS and UDP.TIME.HOSTS must be set to use these functions.

(TCP.TIMESERVER [ASCIIFLG]) [Function]
(UDP.TIMESERVER) [Function]

Functions used by RFC868.START.SERVER. Can be used directly using ADD.PROCESS.

TCP.TIME.PORT = RFC868.TIME.PORT [Variable]
UDP.TIME.PORT = RFC868.TIME.PORT [Variable]

The ports to use in both the client and server functions.

TCP.TIME.HOSTS
UDP.TIME.HOSTS

Lists of host names and/or addresses (including broadcast addresses) to try to get the time from. Hosts are tried until one responds.

TCP.SETTIME.TIMEOUT = 10000 [Variable]
UDP.SETTIME.TIMEOUT = 10000 [Variable]

Length of time (in milliseconds) to wait for a host to respond to TCP.OPEN or UDP.EXCHANGE before trying the next one on the list.
TEdit-Close-On-Shrink

By: Nick Briggs (Briggs.pa@Xerox.com)

Uses: TEdit

This document last edited on August 4, 1987.

INTRODUCTION

TEdit has the unfortunate habit of keeping the file you are editing open when you shrink the TEdit window. For users of the FileCache this has the unfortunate sideeffect of preventing a newly saved file from being written out. In places where many people are editing files on file servers can lead to an excessive number of open files. TEdit-Close-On-Shrink attempts to handle some of the problem by persuading TEdit to close unmodified files when the edit window is shrunken.

USE

Load the module. It will install itself in the appropriate places (for the curious: that’s TEDIT.CREATEW, \TEDIT.CREATEW.FROM_REGION, and \TEDIT.REOPEN_STREAM; and the shrink function \TEDIT-CLOSE-ON-SHRINK).
This package defines a number of meta-keystrokes as TEdit commands, providing much of the functionality of the 1186’s expanded keyboard. An effort was made to keep the command set compatible with SEdit’s for similar functions.

In a number of cases, the meta-lower-case and meta-upper-case commands are different--typically, the lower-case command turns some attribute (like boldness) on, and the upper-case command turns it off.

Here’s the set of defined functions:

- **meta-u**
  - UNDO

- **meta-U**
  - UNDO

- **meta-f**
  - FIND

- **meta-F**
  - FIND

- **metaa**
  - ABORT (i.e., do a GET)

- **meta-s**
  - SUBSTITUTE

- **meta-S**
  - SUBSTITUTE

- **ESC**
  - REDO (note that this changes the default definition, which is EXPAND)

- **meta-x**
  - EXPAND (also on control-X)

- **meta-n**
  - EXPAND (also on control-X)

- **meta-N**
  - EXPAND (also on control-X)

- **meta-c**
  - Change margins, rotating thru centered, left, right, just.

- **meta-C**
  - Change margins, rotating thru centered, left, right, just.

- **meta-b**
  - Turn BOLD on

- **meta-B**
  - Turn BOLD off

- **meta-i**
  - Turn ITALIC on

- **meta-I**
  - Turn ITALIC off

- **meta-=**
  - Turn strike-thru on

- **meta+-**
  - Turn strike-thru off

- **meta--**
  - Turn underline on

- **meta-_-**
  - Turn underline off

- **meta-^**
  - Superscript (or de-subscript)

- **meta-|**
  - Subscript (or de-superscript)

- **meta-space**
  - Return to default font/weight/slope/etc.

- **meta-?**
  - Show current font in prompt window.

- **meta-()**
  - Insert parentheses around the current selection

- **meta-"**
  - Insert neutral double quotes (ASCII ”) around the current selection

- **meta-’**
  - Insert real double quotes (“ and ”) around the current selection
TEDITKEY is a module that provides a keyboard interface to TEdit. On a Dandelion, the interface takes advantage of the special keys to the left, top, and right of the main keyboard. On a Dorado or Dolphin, a window mimicking the Dandelion function keys provides some of the same abilities.

The abilities provided include allowing the user to alter the caret looks (the looks of characters typed in) or the selection looks. These commands are given using the Dandelion function keys and/or metacodes. (Metacodes are keys typed while a meta key is held down. The default meta key is the tab key; to alter this see "User Switches" below.) Other metacodes and control codes move the cursor within the document (beginning/end of line, back/forward a character, up/down a line, etc.).

Thus, many of the special Dandelion keys are made to function in TEdit the way they are labeled. The following keys change their behavior once TEDitKey is loaded.

**CENTER** modifies the justification of the paragraph(s) containing the current selection. If the selection was left justified, then hitting the CENTER key makes it centered. Hitting it again produces right and left justification.

**BOLD** boldfaces the selection. All other properties remain unchanged. Holding the shift key down while hitting BOLD will make the selection become un-bold.

**ITALICS** italicizes the selection. Shift-ITALICS is the opposite.

**UNDERLINE** underlines the selection. Shift-UNDERLINE is the opposite.

**SUPERSCRIPr** superscripts the selection by a constant amount. Any relative superscripts (or subscripts) are maintained. Thus if "$X_i$" is selected in "the set $X_i$ is empty" then pressing the SUPERSCRIPr button produces "the set $X_j$ is empty." See "User Switches" below for how to set the increment. Shift-SUPERSCRIPr is the same as SUBSCRIPT.

**SUBSCRIPT** is analogous to SUPERSCRIPr.

**SMALLER** decreases the font size of the selection. All relative size differences are maintained. E.g., "this is bigger than that" produces "this is bigger than that." Shift-SMALLER (labeled LARGER) does the opposite.

**DEFAULTS** makes the selection have default looks. N.B.: The default looks can be set to the current caret looks by typing shift-DEFAULTS.

The above keys all affect the caret looks if the keyboard key is held down when they are hit. Thus holding down KEYBOARD and then hitting UNDERLINE makes the caret looks be underlined.
**FONT** changes the font of the selection or caret looks according to the following table (to alter this table see "User Switches" below):

1. Times Roman
2. Helvetica
3. Gacha
4. Modern
5. Classic
6. Terminal
7. Symbol
8. Hippo

Thus, to change the font of the selection to Classic, hold down **FONT** and hit 5. To change the caret font to Classic, hold down **FONT** (to signal the font change) and **KEYBOARD** (to direct the change to the caret looks) then hit 5. Note that this table is part of the menu displayed when the **HELP** button is pressed.

On a Dorado, middle-blank is the **FONT** key.

**KEYBOARD** applies any changes that occur while this key is down to the caret looks instead of the selection. On a Dorado, bottom-blank is the **KEYBOARD** key.

**AGAIN** invokes the redo facility in TEdit. A wide variety of operations can be repeated very simply by making a selection, performing an operation (for instance, an insertion), then picking a new selection and hitting the **AGAIN** key. The **AGAIN** key is an ESCape key, which acts as the TEdit REDO syntax class. (See page 20.22 of the *Interlisp Reference Manual*.)

**OPEN** opens a blank line at the current cursor position. **OPEN** is also used to type a linefeed outside of TEdit (for example to the function FILES?).

**FIND** prompts the user for a target string, then searches from the selection forward.

**NEXT** acts as the TEdit NEXT syntax class. (It goes to the next field to be filled in. These fields are marked as follows: >>text to be substituted<<.)

**shift-NEXT** transfers the TTY (which window will receive typed characters) to the next window which can accept typein. Thus one can cycle through the open text windows (mail windows, top level lisp windows, TEdit windows, etc.) without using the mouse.

**EXPAND** expands TEdit abbreviations. (See page 20.31 of the *Interlisp Reference Manual*.)

**HELP** displays a menu of the keybindings until a mouse key is clicked.

**UNDO** acts as the TEdit UNDO syntax class. Note that it still retains its TELERAID function as does **STOP**. There are TEditKey operations (such as Transpose Characters) that are implemented with multiple TEdit operations. Since TEdit will UNDO only single operations, it does not fully UNDO these operations.

**RightArrow** enters \, and | when shifted. (Recall that **AGAIN** is an escape key.)
MARGINS indents the margins of the paragraph selected. Shift-MARGINS exdents the margins. If the right margin is a floating margin, it is left unchanged. To control the amount by which the margins are moved, see "User Switches."

As well as the previous functions available on the Dandelion's special keys, the following functions are available on the standard keyboard (thus usable on the Dandelion, Dolphin, and Dorado). Each function is shown with the key that invokes it (in conjunction with the control (denoted ^) or meta (denoted #) key). Thus, for the sixth entry, holding down the meta key and hitting f (or "F") would move the caret one word forward. (To find out how to get a meta key see "User Switches" below.)

#/ defaults the caret looks
#= queries caret looks
#9 smaller caret font
#0 larger caret font
^b back character
^f forward character
#b back word
#f forward word
^p previous line
^n next line
^a beginning of line
^e end of line
#< beginning of document
#> end of document
#s select whole document
^k kills line (delete from caret to end of line)
^o opens line
^d deletes character forward (also on shift backspace)
#d deletes word forward (as always ^w deletes word backward)
^t transpose characters
#[ indents paragraph. Also available on the MARGINS key
#] exdents paragraph. Also available as shift-MARGINS
#j justification change (same as CENTER key)
#u uppercases selection
#c capitalizes selection
#l lowercases selection
#o inserts object into document
shows keybindings (same as HELP)
#r restores the display

Note that the positions of any of these functions can be individually changed using TEDIT.SETFUNCTION (see page 20.30 of the Interlisp Reference Manual). For wholesale customization see "User Switches" below.

**INTERRUPTS**

Any operation can be aborted by typing the STOP key. This can be used to abort font changes, GETs, PUTs, etc. A stronger form of interrupt is available as shift-STOP, which prompts the user for a menu of processes to interrupt.

^G is available as a synonym for hitting the STOP key within TEditKey. Outside of TEdit, however, ^G will continue to have the meaning specified in the user's init file. This is often the HELP interrupt, which acts as shift-STOP.

Users who are accustomed to typing ^E as a soft interrupt should note that ^E moves to the end of the line. As discussed above, hitting the STOP key (or equivalently, typing ^G) accomplishes what ^E did.

Since ^H is defined to be the Backspace action in TEditKey, users cannot type ^A to erase characters even outside of TEditKey (Interlisp-D currently does not allow multiple backspace characters).

In addition to the changed functionality mentioned above (provided courtesy of TEditKey), the user should be aware of the following standard Interlisp-D/TEdit behavior:

SAME operates as a LooksCopy mode key. First make a selection. Now to copy the looks from some other text simply hold down the SAME key, then select the source for the looks. (Paragraph looks can be copied the same way, but by making the final selection while in the left margin. This is the standard way to select a whole paragraph in TEdit.)

MOVE and COPY act as mode keys for the selection mechanism. Thus the user can select the destination, then hold down the MOVE key and make a second selection. This selection will be moved (or COPY'd depending on the mode key used) to the (original) caret position.

CONTROL operates as a mode key to signal deletion. This means that holding down the CONTROL key and selecting some text will delete that text when the CONTROL key is released.

DELETE deletes the current selection when pressed.

**DORADO EQUIVALENTS**

<table>
<thead>
<tr>
<th>Dandelion Key:</th>
<th>Equivalent key on Dorado:</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN</td>
<td>^o ( or ^O)</td>
</tr>
<tr>
<td>SAME</td>
<td>META</td>
</tr>
<tr>
<td>FIND</td>
<td>finds item in TEdit menu</td>
</tr>
<tr>
<td>AGAIN</td>
<td>ESC</td>
</tr>
<tr>
<td>DELETE</td>
<td>DEL</td>
</tr>
<tr>
<td>COPY</td>
<td>SHIFT</td>
</tr>
<tr>
<td>MOVE</td>
<td>CTRL-SHIFT</td>
</tr>
<tr>
<td>PROP’S</td>
<td>META or LOCK depending on switches</td>
</tr>
</tbody>
</table>
The function keys (CENTER, BOLD, etc.) are all available on the function key window brought up when TEditKey is loaded on a Dorado.

Note that the function key window can be rebuilt on a Dorado by selecting "Function Keys" in the default TEdit menu (obtained by buttoning in the title bar of a TEdit window).

**USER SWITCHES**

**TEDITKEY.METAKEY** The user must choose a metakey to make use of TEditKey. The value of the variable **TEDITKEY.METAKEY** is the name of the key that will be your metakey. For instance to make TAB (the default) your metakey, (SETQ TEDITKEY 'TAB) before loading TEditKey. (Note that even in the standard system, TAB is available as Control-I).

The operation of TEditKey is controlled by the following (INITVARed) variables:

**TEDITKEY.LOCKTOGGLEKEY** is the key that will be turned into a lock-toggle. If it is non-NIL, that key is set to act as a lock-toggle. Thus hitting this switches the case of the type-in. For those users who have removed the spring from their lock key, **TEDITKEY.LOCKTOGGLEKEY** is usually PROP’S. The action of LOCK is then made to be ‘(CTRLDOWN, CTRLUP) providing the user with a control key where LOCK is located and a lock toggle where PROP’S is located.

**TEDITKEY.FONTS** is an eight-element list of the fonts that are invoked by meta-1 through meta-8. The defaults are listed above.

**TEDIT.DEFAULT.CHARLOOKS** defines the looks that result when the DEFAULTS key is pressed or when default caret looks are requested. It is an instance of the CHARLOOKS datatype. To preset it, for instance, to TIMESROMAN 10 type the following to the Lisp top level.

(SETQ TEDIT.DEFAULT.CHARLOOKS (CHARLOOKS.FROM.FONT (FONTCREATE 'TIMESROMAN 10)))

However, a much simpler method is to select an instance of the desired looks and type shift-DEFAULTS.

**TEDITKEY.VERBOSE** if T (the default), the functions that modify the caret looks print feedback in the (TEdit) prompt window.
**TEDITKEY.NESTWIDTH** is the distance (in points) that the indent and exdent functions move the margins. Initially 36 points (0.5 inches).

\**TK.SIZEINCREMENT** is the amount (in points) which the LARGER function increases the selection (and conversely for SMALLER). Initially 2 points.

**TEDITKEY.OFFSETINCREMENT** is the amount (in points) which the SUBSCRIPT function raises the selection (and conversely for SUPERSCRIPT). Initially 3 points.

**TEDITKEY.KEYBINDINGS** is the list that controls the mapping of keys to functions for the functions that are common to the Dandelion, Dorado, and Dolphin. It consists of triples of function name, list of CHARCODE-style character specifications, and a comment describing what the function does. (The comments are used by the automated menu-building tools and their inclusion is encouraged.)

**TEDITKEY.DLION.KEYACTIONS** is the list that specifies the key actions of the non-Alto keys (to the left and right) on the Dandelion. It is the format acceptable to MODIFY.KEYACTIONS (see page 18.9 of the *Interlisp Reference Manual*).

**TEDITKEY.DLION.KEYBINDINGS** is the list specifying the functions to be tied to the characters generated from above. The keynames in the CAR of each element are comments. Note that TEDIT.DLION.KEYACTIONS and TEDIT.DLION.KEYBINDINGS must be coordinated (similarly for TEDITKEY.FNKEYACTIONS and TEDITKEY.FNKEYBINDINGS).

**TEDIT.DLION.KEYSYNTAX** is the list of syntax classes to be applied to the Dandelion keys.

**TEDITKEY.FNKEYACTIONS** is the list that specifies the keyactions of the function keys (center, bold, etc.).

**TEDITKEY.FNKEYBINDINGS** is analogous to TEDIT.DLION.KEYBINDINGS but for the function keys.

**TEDITKEY.DORADO.KEYACTIONS** are the keyactions unique to the Dorado (and Dolphin).

**TEDITKEY.DORADO.KEYSYNTAX** is analogous to TEDIT.DLION.KEYSYNTAX.

The previous variables in conjunction with the following functions specify the effect of TEditKey.

(TEDITKEY.INSTALL *readtable*) invokes the keyactions and bindings as specified by the above variables on *readtable*. (*Readtable* defaults to TEDIT.READTABLE).

(\*TK.BUILD.MENU) is a function that automagically builds the help menu from the values of the above variables.
INTRODUCTION

TEDIT-LINE-NUMBERING enables the automatic conversion of a TEdit selection into multiple lines of specified width each ending in a carriage return and prefixed by a line number. For example, TEDIT-LINE-NUMBERING converted the following piece of transcript:

---------------
C: We have to be able to check that, within the memory I, I claim.
(1.0)
M: Check whether Tore is a graduate student? I think we can do that (.) I mean
C: Yea I know but more we have to be able to, within the memory somehow, recognize that (.) because of this constraint being in the memory, we have to check that the time matches Wednesday morning. We have to add this constraint to the time and see if (.) the time is not overconstrained.
---------------

into:

---------------
021 C: We have to be able to check that, within the memory I, I claim.
022 (1.0)
023 M: Check whether Tore is a graduate student? I think we can do that (.) I mean
024 (.)
025 C: Yea I know but more we have to be able to, within the memory somehow, recognize that (.) because of this constraint being in the memory, we have to check that the time matches Wednesday morning. We have to add this constraint to the time and see if (.) the time is not overconstrained.
026 (.)

INTERFACE
(MAKE-LINE-BREAKS TextStream WidthInInches Device StartLineNum LineNumDigits FirstLineParaLooks OtherLineParaLooks InsertExtraTabFlg InsertExtraCRFlg)

TextStream should be a TEXTSTREAM of an open TEdit. Line breaks and line numbers will be inserted for the text in the current selection. WidthInInches is the number of inches wide the resulting lines will be when printed to Device. Device should be one of the litatoms DISPLAY, INTERPRESS, or PRESS. StartLineNum will be the line number used for the first line formed. LineNumDigits is the number of digits used to print the line numbers. FirstLineParaLooks should be a standard TEdit paralooks proplist for the first line formed from every paragraph. OtherLineParaLooks will be used for the remaining lines of each paragraph. InsertExtraTabFlg, if non-nil, will cause an extra tab to be inserted after the line number. InsertExtraCRFlg, if non-nil, causes an extra carriage return to be inserted between paragraphs. (If this last Flg is on, then FirstLineParaLooks and OtherLineParaLooks are probably equal.)

For example, the conversion depicted above was done with the following call (where SS is bound to an open textstream):

(MAKE-LINE-BREAKS SS 5 'INTERPRESS 21 3 '(LINELEADING 2 PARALEADING 5) '(LINELEADING 2 PARALEADING 0) T)

The algorithm used is (pretty much) as follows: First, place a temporary marker at the end of the selection. For each paragraph in the selection, insert a line number LineNumDigits wide followed by a tab. Move one character at a time through the paragraph adding up STRINGWIDTHs until reaching WidthInInches (converted to appropriate units for Device). Then move back to last whitespace and insert a carriage return. Change the paralooks of the paragraph just formed according to FirstLineParaLooks. Insert the next line number followed by one or two tabs (depending on value of InsertExtraTabFlg) and continue adding up STRINGWIDTHs. When WidthInInches is reached, insert a carriage return and change the paralooks to OtherLineParaLooks. Continue in this manner till the end of the paragraph. If InsertExtraCRFlg is non-nil, then insert an extra carriage return. Continue with the rest of the paragraphs until encountering the marker at the end of the selection. Delete the marker and quit.

**NOTES**

It’s a good idea to have a couple of tabs set for the selected text, though MAKE-LINE-BREAKS will use the default tab setting if you don’t.

It tries to do proper measurement of embedded tabs, but this hasn’t been extensively tested.

**BUGS**

IT’S INCREDIBLY SLOW! This is because we use only calls available from the TEdit programmers interface. Things could be significantly sped up by walking the piece table like TEdit does when printing, but it’s a lot of work to figure out how to do that and anyway I’d prefer that this tool only call advertised functions.

Doesn’t handle imageobjs.
This tiny package adds alternatives to the PF and SEE commands that produce their output in scrollable read-only TEDIT windows rather than the unscrollable EXEC window. The new commands are tf (for t(edit)f(unction) and ts for t(edit)s(ee)

```
tf FUNCTION (FILELIST) (REPRINT) [command]
```

prints the definitions of FUNCTION that appear in the files in FILELIST, with a separate TEDIT allocated for each definition. If FILELIST is not provided, then WHEREIS is used to locate the definitions, just as with PF. By default the definition characters are simply copied from the source file to the TEDIT stream, but if REPRINT is T the definition is read and then reprinted. This produces useful output for definitions that were not pretty-printed. Also, if FUNCTION is not provided, definitions for the last invocation will be reprinted.

```
ts FILE (WINDOW)
```

shows the contents of FILE in a scrollable read-only TEDIT WINDOW. This uses the function TEDIT-SEE (also used for the FILEBROWSER See command), which interprets any font changes if FILE is a Lisp source file.

TEDIT-PF-SEE loads the REGIONMANAGER package, and the default regions for tf and ts are of type PF-TEDIT and SEE-TEDIT respectively. The function SET-TYPED-REGIONS can be used to redefine the regions where the output for tf and ts will appear.
INTRODUCTION

TEdit-Process-Killer provides a simple interface to removing and restoring the process of a TEdit window. The processes of TEdit windows can be killed selectively or a TEDIT-KILLER process can be started to keep the total number of active TEdit processes at or near some threshold level. TEdit processes are automatically rebuilt when you button in their windows.

INTERFACE

(KILL-PROCESS-OF-TEdit-WINDOW WINDOW) [Function]
kills the processes associated with the main window of WINDOW, and all of the attached windows. Each process is killed in such a way that the TEdit can be restarted. It is not an error to call this function on a TEdit whose process has already been killed.

(WITHOUT-PROCESS-OF-TEdit-WINDOW WINDOW) [Function]
returns T if this window does not have a process, because the process was killed by KILL-PROCESS-OF-TEdit-WINDOW, NIL otherwise.

(RESTART-PROCESS-OF-TEdit-WINDOW WINDOW) [Function]
restarts the TEdit processes for the main window of WINDOW and all attached windows if the processes have been killed by KILL-PROCESS-OF-TEdit-WINDOW.

(START-TEdit-KILLER) [Function]
starts up a process called TEDIT-KILLER which wakes up at regular intervals to kill off the least recently used TEdit processes. There are two global vars available to the user to affect its operation:

TEdit-PROCESS-LIMIT [Variable]
Defaults to 10. The preferred threshold of running TEdit processes. Every time TEDIT-KILLER wakes up, it kills off enough TEdit processes to bring the total down to this limit.

TEdit-KILLER-WAIT-TIME [Variable]
Defaults to 10000. The time in milliseconds between wake-ups of TEDIT-KILLER.

(STOP-TEdit-KILLER) [Function]
kills any running TEDIT-KILLER process.

NOTES

In order to force a TEdit to be killed off when shrunk, simply do
(WINDOWADDPROP <Win> 'SHRINKFN (FUNCTION KILL-PROCESS-OF-TEDIT-WINDOW))

and, if you like,

(WINADDPROP <Win> 'EXPANDFN (FUNCTION RESTART-PROCESS-OF-TEDIT-WINDOW))

**BUGS**

We don’t kill lafite sendmessage processes.
There are two LispUsers Modules, TEK4010 which takes an INSTREAM and OUTSTREAM as arguments and emulates a TEKTRONIX 4010 storage tube terminal, and a version called TEK4010CHAT which works with CHAT. The details on how and what a TEKTRONIX 4010 terminal does are described in a TEKTRONIX 4010 users manual. The CHAT program is described in the Interlisp Reference Manual. This document will point out the differences from the default DM2500 emulated terminal which CHAT uses, and the relevant issues unique to running the TEK4010 emulator under Interlisp.

TEK4010 is called as follows:

(TEK4010 INSTREAM OUTSTREAM)  [Function]

where OUTSTREAM must be a displaystream (or window). This version does not fully support the TEKTRONIX 4010 terminal. Specially, the graphic input mode (which displays the crosshair and waits for a key to be typed), and does not support the double column text mode. This version supports a limited scaling feature. Both the TEKTRONIX 4010 X and Y coordinates are divided by one global integer called TEKPTSPERPOINT which can be set(q) by the user. No attempt is made to scale the text or line spacing (leading) in this version, nor does reshaping the window automatically change TEKPTSPERPOINT.

The CHAT version (TEK4010CHAT) unlike the DM2500 emulator, runs in non-scroll, paint mode, with the right margin set at the width of the window. Although not elegant, this is how the TEK4010 terminal works and there may be cases where users are dependent on its inherent mode of operation. The visible implications of this on INTERLISP are: The screen is not cleared or scrolled when a linefeed is received on the last line. Graphics and text are overlayed (OR'd) using the PAINT mode in BITBLT, since selective areas on a storage tube cannot be erased. Graphics are scaled to the window size and so is the position of the second margin, but the characters in the font (GACHA 10) are not scaled. Scaling is changed when the CHAT window is reshaped. In order to get accurate positioning of both the text and graphics, the Interlisp window size should match the TEK4010 screen resolution which is 1024 horizontally by 768 vertically.

In order to run the TEK4010 emulator under CHAT, the following recipe must be followed:
1. Make sure you have the latest version of CHAT loaded.

2. Load the TEK4010 emulator module, ie, (LOAD 'TEK4010CHAT.LCOM)

3. Edit the variable CHAT.DISPLAYTYPES (ED 'CHAT.DISPLAYTYPES) to add one or more lists of the form (host number TEK4010) where host is the name of the host that you want to chat to with this emulator. Use the number 4010 for the number field which would be used by the CHAT.SETDISPLAYTYPE function. Add as many entries as there are hosts you want to use the TEK4010 emulator with.

4. Then bug CHAT in the background MENU and select or enter the host that you want to chat to.
TILED-SEDIT

By: Johannes A. G. M. Koomen
(Koomen.wbst@Xerox or Koomen@CS.Rochester)

This document last edited on: September 23, 1987

SUMMARY

TILED-SEDIT is a facility for automagically positioning SEdit windows according to a specified pattern. SEdit windows appear in any of the four corners of the screen, with overlapping windows slightly offset so they can still be brought to top (by clicking on them). Users can specify which corners, in what order, how thick a margin around the screen, and the size of the offset.

DESCRIPTION

(TILED.SEDIT.RESET  Tiling-Order  XShift  YShift  Screen)  [Function]

If Tiling-Order is NIL, this resets the SEdit window tiling facility, and SEdit reverts back to its old behavior (i.e., prompting for a window region). Otherwise Tiling-Order should be either T or a keyword or an arbitrarily long list of keywords from the following set { :TL  :TOP.LEFT  :TOP.LEFT  :TOPLEFT  :BL  :BOTTOM.LEFT  :BOTTOM.LEFT  :BOTTOMLEFT  :TR  :TOP.RIGHT  :TOP.RIGHT  :TOPRIGHT  :BR  :BOTTOM.RIGHT  :BOTTOM.RIGHT  :BOTTOMRIGHT }. If Tiling-Order is T, the list ( :TL  :BL  :TR  :BR ) is assumed. SEdit will place new windows in the corners specified by Tiling-Order (which is indefinitely repeated if necessary).

If a new SEdit window would overlap an existing SEdit window, the new one is offset by XShift pixels right and YShift pixels down. XShift and YShift default to 15. Tiled.SEdit will compute the tile size and placement on the basis of the region Screen such that you can go three times through the default four corner loop before the right or bottom windows start crossing the edge of Screen. If Screen is neither a region nor a fixp, Screen defaults to 25. If Screen is a fixp M, Screen is assumed to be (CREATEREGION M M SCREENWIDTH-M SCREENHEIGHT-M). The default setting leaves room enough for a scrollbar on the left and the bottom.

Invoking TILED.SEDIT.RESET with a non-NIL Tiling-Order will cause all currently open SEdit windows to be repositioned according to Tiling-Order.

EXAMPLES

(TILED.SEDIT.RESET  T)  [Function]

This is executed when you load TILED-SEDIT. It provides for automatic SEdit window creation in the corners TopLeft, BottomLeft, TopRight, BottomRight, TopLeft, BottomLeft, ... Each time around the loop windows are shifted 15 pixels to the right and downward. A 25 pixels margin is preserved at the left and bottom edge of the screen.

(TILED.SEDIT.RESET  :TL)  [Function]

This causes SEdit to create windows in the TopLeft corner only. Each new window is shifted 15 pixels to the right and downward. A 25 pixels margin is preserved at the left and bottom edge of the screen.
(TILED.SEDIT.RESET  `(:TR :BR) NIL 35)  [Function]

This causes SEdit to create windows in the TopRight and BottomRight corners only. Each time around the two corner loop windows are shifted 15 pixels to the right and 35 pixels downward. This has the advantage that the title of each SEdit window remains visible, but the disadvantage that each window is smaller. A 25 pixels margin is preserved at the left and bottom edge of the screen.

CAVEAT

TILED.SEDIT.RESET is independent of SEDIT.RESET. It will not invoke SEDIT.RESET, nor does it require that all SEdit windows are closed prior to invocation. It is strictly used for controlling the window tiling.
TKDorado: TEditKey for the Dorado keyboard

TKDorado makes the full range of TEditKey commands available from the Dorado keyboard. To do so it adds TEditKey bindings for a number of meta-control key combinations:

- Meta-Control-V: set to default (vanilla) looks
- Meta-Control-B: bold on
- Meta-Control-N: bold off
- Meta-Control-I: italics on
- Meta-Control-O: italics off
- Meta-Control-D: overbar on
- Meta-Control-F: overbar off
- Meta-Control-G: strikethru on
- Meta-Control-H: strikethru off
- Meta-Control-J: underlining on
- Meta-Control-K: underlining off
- Meta-Control-[: smaller font
- Meta-Control-]: larger font
- Meta-Control-^: superscript
- Meta-Control-_: subscript
- Meta-Control-C: center/justify/left this paragraph

The functions which change character looks operate on the current selection, if any characters are selected, and otherwise change the caret looks.

The new key bindings are also added to the help menu.

In addition, TKDorado rebinds the ESC key to be REDO, rather than Expand (which is still available as Control-X), and closes the DLion keys window (if TEditKey has left it lying around).
**TMAX**

**Chapter [Chapter] Introduction**

TMAX stands for Tedit Macros And eXtensions and it enhances TEdition by providing a convenient way to do things such as numbering, indexing, creating a table of contents, and more. At SUMEX these sorts of operations are done with Scribe. Scribe is a powerful document preparation language but it consumes all together too many cycles on our mainframe. Furthermore with Scribe you must hardcopy your document to see what it looks like. If you want to change the format, you must add the appropriate commands to the Scribe input file, run Scribe again, and hardcopy the output file. This sort of “batch processing” wastes both yours and the mainframe’s time. TEdition is a WYSIWYG (What You See Is What You Get) text editing and formatting system. You see what your document will look like while you are creating it.

TMAX makes no attempt to mimic Scribe in TEdition nor does it have any facility to translate a Scribe .MSS file into a TEdition file. Rather it implements some of the more commonly used features of Scribe in TEdition. Currently there are four main areas in TMAX; indices, numbering, endnotes, and forward and backward references. The TMAX features described here plus the editing and formatting features already available in TEdition make it an attractive alternative to Scribe. For more information on TEdition, please read the first part of the Text Editing section in The Lisp Library Packages Manual.

All the features described here are merely additions to a TEdition document. TMAX does not alter your text in any way. When you invoke one of these features, TMAX inserts a “special character” (i.e. an Image Object) into your document at the current cursor position. These “special characters” may appear to be strings but they are really just single characters. This means you can delete any TMAX feature you add by simply deleting the corresponding “special character” just as you would delete any other character. The features described in this document are also used throughout this document. Rather than including pictures of each menu (and there are lots of them), we have decided to show you how to pop-up these menus yourself. This document is both an explanation and example of how to use TMAX. We suggest you read this document under TMAX/TEdition and try these features as you read about them. This document was written assuming you are reading it in a TEdition window.

**Chapter [Chapter] Menus**

When you first load TMAX.DCOM, a new item called TMAX Menu is added to the main TEdition pop-up menu. Since you probably used this menu to Get this document, you may have already seen this new item. Buttoning TMAX Menu brings up the TMAX menu which is attached to the top of your TEdition window. Now you can invoke the TMAX features by simply buttoning items in this menu. You can remove this window by right buttoning the mouse in its title bar and selecting Close (just as you would remove any other TEdition menu). The small window just above this window is called the "prompt window". TMAX uses this window both to prompt you for text input and to report current values and status. Please pop up the TMAX Menu now by pointing the mouse at the black bar above this window, left or middle buttoning it, and selecting TMAX Menu.

There are three types of fields in the TMAX menu; labels, values, and commands. You select items by pointing the mouse at the item and pressing either the left or middle button.

- **Item** The fields on the far left of each line (Miscellany:, References:, etc.) are simply labels that specify the nature of the items on the rest of that line. You cannot select these label fields.

- **Item** There are eight items that are used to set values. Five of the items are toggle switches, two define output filenames, and one pops up a menu of possible settings.

  - **Subitem** The five toggle switches are Set AutoUpdate, NGROUP Menu, Text Before, Text After, and Manual Index. They are all in a bold italic font to distinguish them from other items. These 2-way toggle switches appear in normal video (as they are above) when they are off and in reverse video when they are on. Buttoning these items complements their current setting.

    - **Subitem** TOC Filename: and Index Filename: are used to define the name of the Table-Of-Contents and Index file respectively. When these items are buttoned, the cursor appears to the right of the colon and TMAX waits for you to specify a filename. On a Get these items are defaulted to the name of the input file with the extensions .TOC and .INDEX.

    - **Subitem** The last value item is Reference By and the light face field following it is its current setting. Buttoning this item pops up a menu of possible settings.

- **Item** All the other items (everything except labels and values) are commands. Buttoning these items invokes the corresponding TMAX feature. These items turn to reverse video while they are active and then return to normal video when they finish.
Many of the TMAX features use pop-up menus. Buttoning the mouse outside any pop-up menu is equivalent to no selection and will make that menu disappear. Whenever TMAX prompts you for a new value, it always displays the current value in the prompt window.

We will now discuss each item in the TMAX menu in detail. Since many of the items interact with other items, it is difficult to find a starting point. Instead we have described the TMAX menu row by row and left to right within each row. We suggest you first peruse this document to get a general idea of the features and then focus on the areas that interest you.

Chapter [Chapter] Miscellany

[Section] Update
When you use TMAX to do some sort of numbering, TMAX inserts a "marker" rather than the actual number. It does this for speed since it is much faster to insert a marker rather than figure out the corresponding numeric value each time. Buttoning **Update** will convert all these markers to their corresponding (and consecutive) numeric values. In addition, any References (see chapter <Chapter/Value>) to these numbers will be updated. Finally, if the Endnotes (see chapter <Chapter/Value>) have already been inserted, **Update** will reinsert them but this time with the actual Endnote numbers. Currently the only numbering constructs in TMAX are Endnotes, Number Groups, and References to them. Please button **Update** now and watch all the changes.

[Section] Undo Update
Buttoning this item undoes everything that **Update** does. That is it converts all the Endnote and Number Group numbers back to their corresponding markers along with any References to these numbers. If the Endnotes have already been inserted, **Undo Update** will reinsert them but this time with the Endnote numbers replaced by their markers.

[Section] Set AutoUpdate
When this toggle switch is on, all numbering markers are immediately updated to their corresponding numeric value as they are inserted. Note that it only updates inserted markers; it does not automatically update any markers in a TEdit file that you load via **Get**. We do not encourage setting this switch for large documents. This switch causes TMAX to check every number it generated in the entire document whenever a new number is inserted. For large documents this could take some time.

[Section] Current Date/Time
Buttoning this item inserts the current date into your document. For example, the date enclosed in the following parentheses (April 22, 1987) was inserted by buttoning **Current Date/Time**. Middle buttoning this inserted date pops up a Date/Time menu. If you'd like to see this menu, go ahead and middle button the date in the parentheses. This menu allows you to change the format of the date/time, replace the date with the time, or update an old date/time to the current date/time. The font is the same as the font currently in effect in your TEdit document when the date/time was inserted.

Chapter [Chapter] References

These commands allow you to reference Endnotes and Number Groups by either their numeric value or by the page number they appear on. A Reference is simply an association between a "Tag" and a reference to that Tag. To assign a Tag, middle button the Endnote or Number Group marker (or its numeric value if it has already been updated). A menu will pop up and one of the items will allow you to define a Tag for the Endnote or Number Group. If the Endnote or Number Group is already tagged, the menu will allow you to change or delete the Tag. All the Tags in a document must be unique and TMAX will not allow you to create a Tag that is already defined. If you COPY a tagged Endnote or Number Group within the same window, TMAX will remove the Tag on the copied object. If you COPY a tagged object to another TEdit window, TMAX will preserve the tag assuming that Tag name isn't defined in the other TEdit window. The font of a Reference is the same as the font currently in effect in your document regardless of what font is used to display the Endnote or Number Group.

As an example, we have tagged both the Endnotes chapter (a Number Group on page <Chapter/Page>) with "EN Chap" and the Endnote at the end of this sentence with "EN Note<Note#". Now we can reference the Endnotes chapter as <Chapter/Value> and the previous Endnote as <Note#/Value>. Also the page number of the Endnotes chapter above was generated by a Reference to "EN Chap" by page instead of by value. You will have to button **Update** to convert the "<Chapter/Value>" and "<Note#/Value>" to their respective numeric values.
Of course, if *Set AutoUpdate* was on, the "<Chapter/Value>" and "<Note#/Value>" would be converted as soon as they were inserted.

**Section** Reference

TMAX will prompt you for a Tag name when you button this item. A bare carriage return cancels this command. It doesn’t matter if the Tag you specify is defined yet or not. If the Tag is not defined, the Reference marker is "<Reference Tag/Type>" where *Tag* is the Tag name and *Type* is either Value or Page. In this case the Tag name is embedded in the marker. If the Tag is defined, the Reference marker is either <Note#/Type> for Endnotes or the Number Group marker enclosed in angle brackets (e.g. <Chapter/Type>). In this format there is no indication of what the Tag name is. If you middle button a Reference marker (whether it is updated or not), TMAX will display the corresponding Tag in the prompt window. All Reference markers that have not been updated are enclosed in angle brackets (i.e. < and >) to distinguish them for normal text.

**Section** Previous References

Buttoning this item brings up a menu of all the defined Tag names in alphabetical order. You can then create a Reference to one of these Tags by simply buttoning the corresponding Tag in this menu. Although it doesn’t matter if you define the Tags or References to these Tags first, we suggest you define the Tags first. Once the Tags are defined you can use this command to easily create the References to these Tags. If you button Previous References now you will see all the Reference Tags defined in this document.

**Section** Reference By

This item allows you to select whether you want References by numeric value (of the Endnote or Number Group) or by the page number (on which the Endnote or Number Group appear). Buttoning this item pops up a menu with three items; Ask, Value, and Page. If you select Value or Page then all References you add will be of the type you specified. If you select Ask then TMAX will prompt you for the type every time you make a Reference. As you can see in the TMAX menu above, the default Reference type is by Value.

There is one minor inconvenience with doing forward references by page. You must do a dummy hardcopy and then button **Update** before the real hardcopy. The reason is TEat only knows the current page number while it is hardcopying a document. As TMAX encounters Endnotes and Number Groups, it saves their corresponding page numbers. If you reference an Endnote or Number Group that TMAX hasn’t seen yet then it can’t possibly know the corresponding page number. In this case, TMAX will change the Reference marker to the Endnote’s or Number Group’s numeric value followed by "/Page" both enclosed in angle brackets (e.g. <1.2/Page>) to indicate that the page number is not known yet. This only applies to forward references by page. You don’t have to do a dummy hardcopy if you are referencing by value or doing backward references by page.

**Chapter** Endnotes

These commands allow you to generate a numbered list of notes. Endnotes are like footnotes except the numbers and corresponding text appear at the end of the document rather than the bottom of the page. (TMAX does not support footnotes yet.) The Endnote numbers are consecutive and always start at 1. If you add an Endnote in the middle of a document, all the following Endnote numbers will be adjusted automatically. Suppose for example you have three Endnotes and you add another between Endnotes 1 and 2. The new Endnote becomes 2 and the Endnotes that were formerly 2 and 3 are now 3 and 4. This will happen when you button **Update** (or immediately if *Set AutoUpdate* is on). The font of the Endnote numbers, text, and title line is determined by the *Set Style* command and the default font is Gacha 10 Standard.

If you middle button an inserted Endnote marker, a menu will pop up allowing you to define a Tag for this Endnote marker or edit the text associated with this Endnote marker. If this Endnote already has a Tag, this menu will give you the option of changing, deleting, or displaying the Tag or editing the Endnote text. If you choose to edit the Endnote text, you will be prompted to open another TEdit window where the text will be displayed. When you are done editing the text, move the mouse to the title bar (i.e. the thick black bar at the top of the new TEdit window) and left or middle button the mouse. A menu will pop-up giving you the option of saving or aborting the changes. There is a sample Endnote at the end of this sentence you can play with.

**Section** Endnote

Buttoning this item inserts an Endnote marker at the current cursor position. The Endnote marker is a superscript "Note#". You will also be prompted for the text associated with this Endnote.
[Section] Insert Endnotes
This item inserts the title line "Notes" followed by the Endnote numbers and their corresponding text after the last line in your TEdit document. If you have already inserted the Endnotes and button this command again, TMAX will delete the old Endnotes and then reinsert them. It does this in case you have added or deleted any Endnotes since the last time they were inserted.

[Section] Delete Endnotes
Buttoning this item undoes what Insert Endnotes does. It deletes the title line "Notes" and the Endnote numbers and text that follow from the end of your document.

If you already inserted the Endnotes and wish to add more text at the end of your document, you must first delete the Endnotes with this command. If you don’t, the additional text at the end of your document will be deleted when the Endnotes are reinserted. Suffice it to say this is due to the way Endnotes are implemented rather than a bug in TMAX. A future version of TMAX will fix this awkwardness.

[Section] Set Style
Buttoning this item pops up the Endnote Fonts menu. This menu has three items; Number, Title, and Text. You can use this pop-up menu to change the font of the Endnote numbers, title line, and text. The title line is always "Notes". When you select one of the items from this menu, the current font of that item will be displayed in the prompt window before TMAX prompts you for the new font.

Chapter [Chapter] Number Groups
The Number Group (NGroup) commands allow you to number any arbitrary objects in your TEdit document. You define the hierarchy, font, and format of each NGroup member and then insert them wherever you want something numbered. The NGroup numbers are consecutive and start at 1 by default although you can change the starting value. This allows you to number individual pieces of a document without having to load the entire document. Some NGroup values depend on other NGroup values. For example, the sections of this document each begin with the corresponding chapter number. Each time the chapter number changes, the section number is reset to its starting value. You can nest NGroups as deep as you like. If you insert a new NGroup member in the middle of a document, all the following NGroup members that depend on this new member will be adjusted when you button Update (or immediately if Set AutoUpdate is on). This makes it trivial to number (and renumber) things. All you do is insert an NGroup member wherever you want something numbered and TMAX takes care of all the rest. The default NGroup font is Gacha 10 Standard.

[Section] NGroup Menu
When this toggle switch is on, the NGroup menu "graph" is displayed in a window attached to the top of the TMAX menu window. The Number Group graph is a tree structure showing the hierarchy and order of all the Number Group members. If you haven’t buttoned NGroup Menu yet, please do so now.

[Section] New NGroup
This item allows you to create new Number Group members. When it is buttoned, TMAX first turns on NGroup Menu if it was off so you can see the NGroup graph. It then prompts you for the name of the NGroup member. Finally TMAX prompts you for the parent of this new NGroup member by popping up a menu of the known NGroup names and you select the parent from this menu. By parent we mean the node to the immediate left in the NGroup graph. If you don’t select any parent (i.e. button the mouse outside the pop-up menu) the new NGroup becomes a "top level" node. A top level node is one whose parent is the boxed NGroups (at the far left). The NGroup graph is always built from left to right. Since the first NGroup member defined will have no parents, TMAX just adds this member to the graph. You can create as many NGroup members as you like even if you don’t use them all. As long as there is at least NGroup in you document, the entire NGroup graph will be saved/restored over a Put/Get.

[Section] Text Before
When this toggle switch is on, you will be prompted for a preceding text string each time you insert a NGroup member. This text string becomes part of the inserted NGroup marker. You can use this string as a heading for the chapter, section, figure, example, etc. you have numbered. The text string is always printed in the same font as the corresponding NGroup member and TMAX always inserts one space between the preceding text string and the NGroup marker. If you would like more spaces, you must put them in the Text Before string yourself. Any tabs in this string are automatically converted to spaces. The default Text Before string is the name of the NGroup. In this document all the Chapter NGroup markers were inserted with Text Before on and the Section NGroup markers were inserted with Text Before off.

[Section] Text After
When this toggle switch on, you will be prompted for a succeeding text string each time you insert a NGroup member. This text string becomes part of the inserted NGroup marker. You can use this string as a heading for the chapter, section, figure, example, etc. you have numbered. The text string is always printed in the same font as the corresponding NGroup member and TMAX always inserts one space between the NGroup marker and the succeeding text string. If you would like more spaces, you must put them in the Text After string. Any tabs in this string are automatically converted to spaces. There is no default Text After string. In this document all the Chapter and Section NGroup markers were inserted with Text After on.

[Section] Changing the default Font and Format

Consider the Number Group graph in this document. The boxed NGroups at the far left is a special node and buttoning it does nothing. The order of the nodes in a branch is important but the order of the branches themselves isn’t. If you would like to see a more complex NGroup graph then just add some more members to this graph. Don’t worry; adding extra NGroup members doesn’t affect anything.

When you create NGroup members by buttoning New NGroup, you are actually defining "prototype" NGroups. The font and format of these prototypes determine the font and format of the NGroups you insert into your document. To change the font and/or format of a prototype NGroup member, simply point the mouse to the member name in the Number Group menu graph and middle button it. A menu will pop up with four items; Change Font, Show Font, Change Format, and Show Format. Buttoning Show Font or Show Format will display the font or format of the selected prototype NGroup in the prompt window.

Buttoning Change Font or Change Format allows you to change the font or format of the selected prototype NGroup. This is a global change. If you change the font/format of a prototype NGroup, TMAX will apply that change to every occurrence of that NGroup in your document. Before TMAX prompts you for the new font/format, it always shows you the current font/format in the prompt window. Change Font and Change Format both have subitems that allow you to change part of the font/format without changing anything else.

The subitems for Change Font are Family, Size, and Face. If you button one of these subitems, TMAX will pop up the corresponding menu and only that part of the font will be changed. If you button Change Font instead, TMAX will prompt you for all three values via pop-up menus.

There are seven subitems for Change Format. You can change any part of the format by selecting one of these subitems. If you button Change Format instead, TMAX will prompt you for all seven values. Six of the values use pop-up menus and the other requests input in the prompt window. The seven parts of the prototype format are:

[Sect Cntr] Delimiter Before
This is the delimiter that precedes the NGroup. TMAX pops up a menu of commonly used delimiters. You can select one of these or select Other in which case TMAX will prompt you for a delimiter string in the prompt window. The default Delimiter Before is a null string.

[Sect Cntr] Display Type
This is how the NGroup’s numeric value is displayed. TMAX pops up a menu of the various ways a NGroup can be displayed. These ways are as an Arabic numeral, a null string, or an upper/lowercase letter or Roman numeral. The default is as an Arabic numeral.

[Sect Cntr] Delimiter After
This is the delimiter that follows the NGroup. It uses the same mechanism as the Delimiter Before. The default Delimiter After is a period (i.e. ".").

[Sect Cntr] Abbreviate Level
Normally a NGroup’s value is the concatenation of all its parents values plus its own value. This subitem allows you to specify how far up the NGroup branch to go when computing a NGroup’s value. TMAX pops up a menu containing this NGroup name and all its parents. You control how much of the NGroup value to display by selecting the first NGroup to be used in this NGroup’s value. Note that this subitem doesn’t actually change the NGroup value; it only determines how much of this value to display. Since top level NGroups only have a single value, you cannot abbreviate them. The subitems listed here are numbered with the NGroup "Sect Cntr" which as been abbreviated such that it only prints its own value without any of its parents values.

[Sect Cntr] Starting Value
This is the starting value of the NGroup. TMAX prompts for the new value in the prompt window rather than using a menu. The default Starting Value is 1.

[Sect Cntr] Table-Of-Contents
This is a flag that says whether or not this NGroup will be included in the Table-Of-Contents file should you decide to create one. The default is to include all NGroups in the Table-Of-Contents file.

**[Sect Cntr] Manual Index**

This is a flag that says whether or not this NGroup should be included in the manual-style index. Note that this item is only offered if the **Manual Index** (see section <Section/Value>) toggle switch is on. The default is to not include any NGroups in the manual-style index.

**[Section] NGroup Delimiters**

The Delimiter Before/After construct allows TMAX to support any numbering format. Since the default Delimiter Before is a null string and the default Delimiter After is a period, the default number format is of the form "1.", "1.2.", "1.2.3." etc. You may have noticed that this document uses this default form for the Chapter numbers but not for the Section numbers. To see how we did this just middle button Chapter in the NGroup graph above and select the Show Format item from the pop up menu. Then do the same for Section. The field following "Display=" consists of the Delimiter Before, the Display Type, and the Delimiter After in that order.

There is one small anomaly with delimiters, namely the case where one NGroup has a Delimiter After (e.g. Chapter) and the following NGroup has a Delimiter Before (e.g. Section). If the Delimiter Before is not a null string then it will *always* override the Delimiter After in the preceding NGroup regardless of what the Delimiter After is. For example, if the Delimiter After for Chapter was a colon and the Delimiter Before for Section was a dash then chapter numbers would look like "1:=" and section numbers would look like "1-2.".

**[Section] Inserting Number Groups**

You create NGroup members by buttoning **New NGroup**. To insert an NGroup member into your document, simply point the mouse to the appropriate name in the Number Group menu graph and left button it. The NGroup member name enclosed in square brackets (e.g. [Chapter]) will be inserted at the current cursor position in whatever font you have specified for this member. All NGroup markers that have not been updated are enclosed in square brackets to distinguish them from normal text. TMAX will warn you if you insert NGroups out of order. For example, in this document you should not insert "Section" until you insert "Chapter" because the value of Section depends on the value of Chapter.

**[Section] Customizing inserted Number Groups**

Although the font/format of the prototype NGroup determines the font/format of the inserted NGroup, you can change the font and certain parts of the format after the NGroup is inserted. Any change you make is *local* to that particular NGroup; it does not affect any other NGroups. If you middle button an inserted NGroup, a menu will pop up allowing you to define a Tag and show/change the font and format of the selected NGroup. If the NGroup already has a Tag, this menu will give you the option of changing, deleting, or displaying the Tag. The Show Font and Change Font items work exactly the same as those for the the prototype NGroups but the Show Format and Change Format are slightly different. The Starting Value and the Table-of-Contents and Manual Index flags can only be set for the prototype NGroup. You cannot change these for a particular inserted NGroup.

There are six subitems for **Change Format**. You can change any part of the format on an inserted NGroup by selecting one of these subitems. If you button **Change Format** instead, TMAX will prompt you for all six values. Four of the values use pop-up menus and the other two request input in the prompt window. The six parts of an inserted NGroup’s format are:

- **[Sect Cntr] Delimiter Before**
  This works exactly the same as the Delimiter Before subitem for the prototype NGroups except the change doesn’t affect any other NGroups.

- **[Sect Cntr] Display Type**
  This works exactly the same as the Display Type subitem for the prototype NGroups except the change doesn’t affect any other NGroups.

- **[Sect Cntr] Delimiter After**
  This works exactly the same as the Delimiter After subitem for the prototype NGroups except the change doesn’t affect any other NGroups.

- **[Sect Cntr] Abbreviate Level**

This works exactly the same as the Abbreviate Level subitem for the prototype NGroups except the change doesn’t affect any other NGroups.

[Sect Cntr] Text Before
This allows you to add, change, or delete the text string preceding the NGroup regardless of the setting of the Text Before toggle switch. TMAX will prompt you for the new string in the prompt window. A bare carriage return deletes the text before the NGroup. If you do specify a string, remember that TMAX will always append a space to the end of the string. Unlike inserting a NGroup with Text Before on, there is no default string.

[Sect Cntr] Text After
This allows you to add, change, or delete the text string following the NGroup regardless of the setting of the Text After toggle switch. TMAX will prompt you for the new string in the prompt window. A bare carriage return deletes the text after the NGroup. If you do specify a string, remember that TMAX will always append a space to the beginning of the string.

[Section] Pruning the NGroup graph
As mentioned before, the entire NGroup graph is saved/restored over a Put/Get even if some of the NGroup members aren’t used in the document. We have described how to add members to this graph but not how to delete them. TMAX has two ways to delete unused NGroup members from the graph.

The first way is to copy text (including the inserted NGroups) from one TEdit window to another. TMAX will only copy enough of the NGroup graph to handle the NGroups in the copied text. For example, you can remove every unused NGroup member from the graph by copying the entire document to another TEdit window.

The other way is to set the global variable TMAX .PRUNE.NGRAPH to T, open a TEdit window, and then Get the document. On a Put TMAX writes out the NGroup graph data structure. On a Get, TMAX checks this flag and if it is true, it creates the NGroup graph from the NGroups that appear in the document rather than from the NGroup graph data structure. There is a potential problem with using this feature. TMAX creates the NGroup graph from the first occurrence of each NGroup in the document. If the first occurrence of a particular NGroup has been modified (see section <Section/Value>) then TMAX will use this modified format as the new prototype format. There are no problems if the first occurrence of each NGroup has not been modified.

Chapter [Chapter] Contents File
One of the benefits of using NGroups is the Table-Of-Contents (TOC). By default all NGroups are included in the TOC along with their corresponding Text Before and/or Text After strings if any. If you don’t want certain NGroup members included in the TOC, you can specify this by changing the NGroup’s prototype format. Although this document has several NGroups, we have decided to include only the Chapter and Section NGroups in the TOC. The page numbers in the TOC are always printed in the Gacha 10 Standard font.

[Section] Create TOC
Buttoning this item creates a TEdit Table-Of-Contents file. You must first specify the name of the TOC file via the TOC Filename: item. Each line in the TOC consists of the Text Before string (if any), the NGroup number, the Text After string (in any), a dotted leader, and the page number on which this NGroup appears. Note that the TOC file itself does not contain any TMAX features. It is a simple TEdit text file.

[Section] View TOC
Buttoning this item first creates the TOC file (via Create TOC) and then prompts you for a TEdit window where TMAX displays the TOC file it just created.

[Section] TOC Filename:
This item allows you to specify the name of the TOC file. When this item is buttoned, the cursor will appear just to the right of the colon. You then type the name of the TOC file and terminate it with a carriage return. You can edit this filename string anytime. If you have already terminated the string, just button the item again. The editing features available here are the same as those available in the EXEC window. If you Get a TEdit/TMAX file, the TOC Filename: defaults to that file with a .TOC extension.

NOTE... You must hardcopy your document before creating the TOC file. The reason is TMAX needs the page numbers for the TOC file but TEdit only knows the page numbers while the document is being hardcopied. During the hardcopy process, TMAX saves the page number for each NGroup member. If you create the TOC without first hardcopying your TEdit document, the page numbers in the TOC will be NIL.
Chapter [Chapter] Indices

TMAX allows you to insert index requests into your document and create a sorted file of these indices including the page number each index appears on. There are two types of index requests; simple and extended. The format of the index marker depends on the type of index request. But, regardless of the type of index, it is important to note that the index markers are only displayed in the TEdit window. If you hardcopy the TEdit document, you will not see these index markers. TMAX always encloses index requests in curly braces (i.e. { and }) to distinguish them from normal text. **Update** and **Set AutoUpdate** have no effect on index requests.

[Section] Index

When this item is buttoned TMAX will prompt you for the index "Key". It will then insert the marker "{Index key}" into your document at the current cursor position. TMAX uses these keys to sort the indices and the sorting is case independent. The key is also printed in the Index file along with the page number(s) it appears on. Currently all simple indices are printed in the Gacha 10 Standard font. For example, we have indexed the phrase "Indexing requests" in the following parentheses (). Of course you will not see this index marker if you hardcopied this document. You can change the index key by middle buttoning the index marker. TMAX will bring up a one item menu (Change Index). If you button this item, TMAX will prompt you for the new index key.

[Section] Extended Index

This is a fancy form of indexing. When this item is buttoned TMAX first prompts you for the key to sort on. TMAX then prompts you for the "Entry" and its font. This is what is printed in the Index file instead of the key. If you do not specify an entry, it defaults to whatever the key is and the font defaults to Gacha 10 Standard. Finally, TMAX prompts you for the index page number option. There are three options; print the normal page number, print a fixed page number that you supply, or don’t print any page number at all. TMAX then inserts the index marker "{Index Key=key, Entry=entry, Option}" into your document. The option is "Yes" if the page number is to be included in the index file, "No" if the page number is not included, or the numeric value if a fixed number is to be used in the index file. For example, we have (extended) indexed the word "Spies" but we want "Boris & Natasha" printed instead in the Helvetica 12 Italic font. The extended index is enclosed in the following parentheses (). Of course you will not see this extended index marker if you hardcopied this document. You can change any of the fields in an extended index request by middle buttoning the index marker. TMAX will bring up a one item menu (Change Extended Index). If you button this item, TMAX will prompt you for the new index key, entry, font, and number values.

[Section] Known Indices

Buttoning this item brings up a menu of all the indices and extended indices specified so far in alphabetical order. You can insert another Index or Extended Index request by simply buttoning the appropriate item in this pop-up menu. This makes it trivial to index the same items throughout a document. Indices are simple items but extended indices have subitems because several extended indices can have same key but completely different entries, fonts, and/or page number options. To insert an extended index, you must button the appropriate subitem; buttoning the extended index item has no effect. The extended index subitem shows the entry, font, and page number option. If you button Known Indices above, you will see the two indices used here as examples.

[Section] Manual Index

When this toggle switch is on, the page numbers in the index file are printed in "manual format". By manual format we mean something like "III:25.7" for chapter 3, section 25, page 7 (assuming the chapter’s format has been changed to print Roman numerals following by a colon). You specify which NGroup members are included in the manual index page number. To include a NGroup member in the manual format page number, first make sure this toggle switch is on. Then change the format of the NGroup members you want included. The code to change the NGroup format checks the **Manual Index** switch setting. If the switch is on, the code asks if you want the selected NGroup member included in the manual index. You can only include the members of one major branch of the NGroup graph in the manual index page numbers. Using this document’s NGroup graph as an example, you can include either or both members in the Chapter-Section branch or the single member in the NG Format branch but **not** both. TMAX will only allow you to include an NGroup member in the manual index if there are no other members included yet or the included members are in the same branch as the new member. The reason is there is no correlation between the numbers in disjoint branches in the NGroup graph. If you don’t specify manual indexing, TMAX defaults to "book format" indexing. With book format the index file page references are just the page numbers themselves.
Chapter [Chapter] Indices File

These commands allow you to write out an index file sorted by the index keys. As we mentioned before, the sorting is case independent. The page numbers (for both "book" and "manual" style) are always printed in the Gacha 10 Standard font.

[Section] Create Index
Buttoning this item creates a TEdit sorted index file. You must first specify the name of the index file via the Index Filename: item. For simple indices each line in the index file consists of the index key followed by the page number(s) on which this index key appears. Extended indices are treated a little differently. Each extended index is printed on a separate line. Note that the index file does not contain any TMAX features. It is a simple TEdit text file.

[Section] View Index
Buttoning this item first creates the index file (via Create Index) and then prompts you for a TEdit window where TMAX displays the index file it just created.

[Section] Index Filename:
This item allows you to specify the name of the index file. When this item is buttoned, the cursor will appear just to the right of this item. You then type the name of the index file and terminate it with a carriage return. You can edit this filename string anytime. If you have already terminated the string, just button the item again. The editing features available here are the same as those available in the EXEC window. If you Get a TEdit/TMAX file, the Index Filename: defaults to that file with a .INDEX extension.

NOTE... You must hardcopy your document before creating the index file. The reason is TMAX needs the page numbers for the index file but TEdit only knows the page numbers while the document is being hardcopied. During the hardcopy process, TMAX saves the page number(s) on which each index appears. If you create an index file without first hardcopying your TEdit document, the page numbers in this index file will be NIL.

Chapter [Chapter] Specifying a Font

TMAX uses the same mechanism whenever it prompts you for a font. To specify a font you must select a value from each of three different menus. The first pop-up menu is used to specify the font family. The font families are Classic, Gacha, Helvetica, Modern, and Times Roman. After you select the family, the font size menu pops up. This menu contains the sizes 6, 8, 10, 12, 14, 18, 24, and 36. After you select the size, the font face menu pops up. The font faces are Standard, Italic, Bold, and Bold Italic.

The default for any value not specified (i.e. the mouse is buttoned outside the pop-up menu) is whatever it was before. The default font always starts out as Gacha 10 Standard. Therefore, if you select a new family (say Helvetica) and button the mouse outside the font size and face menus, the new font would be Helvetica 10 Standard. Now if you were to button the mouse outside the font family and size menus and select a new face (say Bold), then the new font would be Helvetica 10 Bold.

Some TMAX functions (like Set Style) require you to select values from three different menus. Other functions (like changing a NGroup font) allow you to change one of the three fields directly without changing the other two. This is exactly equivalent to selecting a value from one menu and buttoning the mouse outside the other two menus.

Chapter [Chapter] Random thoughts and hints

- You can Copy any of the TMAX features, from one TEdit window to another and TMAX will automatically set up the internal data structures necessary to support that feature in the destination window. For example, if you Copy a NGroup marker, TMAX will automatically set up the NGroup graph. Note that it only sets up enough to support what was copied; TMAX does not set up the entire NGroup graph.

- TMAX does not support Move. If you want to move any TMAX features, you will have to Copy and then delete the features.
If you just want to select a TMAX feature, you should do so with the left mouse button. The right button will select the feature as well but it also causes TMAX to pop up a menu. Every TMAX feature pops up a menu if it’s middle buttoned.

Regarding forward page References and doing a "dummy" hardcopy, we do the dummy hardcopy to a file whose device is \{NODIRCORE\} and whose extension corresponds to the eventual hardcopy device (e.g. \{NODIRCORE\}.INTERPRESS). NODIRCORE is the bit bucket and the extension causes TEdit to load the appropriate fonts so the real hardcopy will go a little faster.

Remember that changing the font/format of a prototype NGroup will also change every occurrence of that NGroup in the document. Therefore you should settle on the font/format of the prototype NGroups before you start customizing any inserted NGroups (see section &lt;Section/Value&gt;).

Occasionally TEdit (not TMAX) has problems displaying some TMAX features. For example, if you change the prototype NGroup font then every occurrence of that NGroup also changes. Sometimes it looks like only the first occurrence has changed when in fact they all have. If you Redisplay the window, it will look like it should. It is a good idea to Redisplay the TEdit window whenever you think it doesn’t look right.
TMAX Introduction

TMAX (Tedit Macros And eXtensions) is a package that extends the capabilities of TEdit by providing a menu of commands that allow the user to do such things as indexing, writing a sorted index file, arbitrary numbering, creating a list of notes, referencing numbered objects by their numeric value, and writing a table-of-contents file. There is also an extensive help file describing all the features of TMAX. Rather than include examples of how to use these features, the help file was written using these features and is both an example and a description of using TMAX.

Before you can read the help file, you must first load the TMAX.DCOM file from the {CSLI}<LISP.KOTO> directory. Then copy {CSLI}<LISP.KOTO>TMAX.TEDIT to your local disk. Open up a TEdit window and do a TEdit Get on {DSK}TMAX.TEDIT. The reason for copying the file to the local disk is that, due to problems with the leaf server on csli, TMAX runs a lot smoother when the source files are on non-leaf hosts.

When you load the TMAX.TEDIT file, you will see the TMAX menu appended to the top of your TEdit window. You invoke TMAX commands by buttoning items in this menu. If you would like a hardcopy of the help file, first button Update and then Insert Endnotes (both in the TMAX menu). Then point the mouse at the black title bar at the top of the TEdit window and select Hardcopy from the right button menu.
The TMENU package provides the following features:

TMenus.

These are interactive menus intended for reducing the amount of typing to an Interlisp-D program. When an item is selected in a menu, an expression is inserted into the TTY input buffer. It can be used to simplify the entry of common LISP commands or long names.

Windowshades.

Windowshades are a modification that can be made to any window in order to conserve screen space. They make a window "roll up" when not in use, leaving behind only the title. When the mouse is clicked inside the remaining bar, the window unrolls for interaction, and rolls up again at completion. Windowshades can be used with TMenus.

Msgs to the Prompt window.

Two functions are provided for clearing and printing to the Interlisp-D prompt window. These functions take an arbitrary number of arguments and preserve the black background shade of the window.

INTERACTION WITH TMENUS

TMenus are placed on the display under program control using the functions described below. Once a menu is on the screen, items may be selected using the LEFT mouse button. This causes some text to be inserted into the teletype buffer. In the default case, this text is just the item in the window, but it can alternatively be the result of evaluating an expression. In the default case, the text is followed by a blank space in the buffer, but it can be followed alternatively by an arbitrary string (such as the empty string or a carriage return). Non-default cases are controlled by arguments to the TMenu function. The MIDDLE mouse button is used for user-interactions that change the menu. When the middle button is depressed inside a menu, another pop-up menu (a meta-menu!) appears that provides several options for changing the menu, such as adding or deleting items. One of the options is to recompute the set of items by evaluating an expression associated with the menu. The RIGHT mouse button is used for the usual window commands. These commands work in the standard way except that when a TMenu is reshaped, internal functions are invoked to adjust the configuration of rows and columns in order to create a menu that is visually appealing.

MAIN FUNCTIONS
TMenu (itemExpr title displaySpec windowShadeFlg buttonFn defaultTrailerString)

TMenu is the function for creating a menu in a window on the display. Its arguments are as follows:

- **itemExpr**
  - an expression for computing the list of items that is saved with the menu. In the usual case, itemExpr is a list, whose items are either atoms or lists of the form: (displayThis evalThis comment trailerString) where displayThis is the form displayed in the menu, evalThis is the form evaluated to createthe text for the input buffer, comment is displayed in the prompt window if the LEFT button is held over an item for an extended period, and trailerString is the string inserted after an expression in the input buffer. Most of these fields are optional. The default value for evalThis is the entry in displayThis. The default trailerString can be specified for a TMenu in the defaultTrailerString argument above. Otherwise it is a space if the expression is an atom, and the empty string otherwise. This definition of fields for menu items is compatible with the usual set for the Interlisp-D menu package, with the addition of the trailerString field.

- **title**
  - The title of the menu. This title is used as the title of the window containing the menu.

- **displaySpec**
  - This argument has several possible interpretations that control the display of the menu. If displaySpec is a region, then the window for the menu is placed in that region. If displaySpec is a number, that number is used as the number of columns in the menu display and a minimum size window is allocated for displaying the entire menu. The user is prompted with a ghost box to place the menu on the display. If displaySpec is T, then the number of columns is computed by TMenu assuming a maximum of 15 rows per column and the user is prompted for placement as before. If displaySpec is NIL, then the user is prompted to place a bounding box for the menu and TMenu tries to compute an arrangement of rows and columns that is visually pleasing.

- **windowShadeFlg**
  - If T, the window containing the menu is augmented with a window shade so that the menu "rolls up" if not in use. If windowShadeFlg is NIL, the menu is placed in a window on the screen.

- **buttonFn**
  - Optional argument that allows the caller to specify his own function for handling the LEFT and MIDDLE buttons.
**defaultTrailerString**  
Optional argument that allows the caller to specify the default string to follow each item printed. Can be overridden for specific items by the trailerString argument in the itemExpr.

**EXAMPLE**

The following expression: (TMenu 'MYFNS "Common Fns" T) would create a window titled "CommonFns" and display the list of functions in the window. The window would contain columns of up to 15 functions each, and would be placed on the screen under user control. If the user later used the MIDDLE button to add or delete items from the menu, then the list in the variable MYFNS would be updated as the menu is updated.

**MakeFileMenus (fileName)**  
[Function]

MakeFileMenus is the function for creating a set of menus for the functions and variables in a file. A window is created for each menu. The menus are placed under user control and are all given window shades. The argument fileName is the name of a file.

**Example**

If the file is MYFILE, then the fns on MYFILEFNS and the vars on MYFILEVARS would be displayed in menus. MakeFileMenus would look for file commands of the form (FNS * FnsLst) and (VARS * VarsLst) on the command.

**CloseFileMenus (fileName)**  
[Function]

Closes all of the TMenu windows associated with the given file.

**Window Shades**  
**MakeWindowShade (window)**  
[Function]

Modifies the given window to provide a window shade. If the window argument is NIL, then the window is selected which is under the cursor. If the window argument is T, it waits for the CTRL key to be depressed, and then selects the window under the cursor.

**Prompt Window Functions**  
**PROMPT (arg1 arg2 arg3 ...)**  
Prints an arbitrary number of arguments to the prompt window, after first clearing the window. A call with no arguments simply clears the window.

**CPROMPT (arg1 arg2 arg3 ...)**  
[Function]

Same as prompt except the arguments are printed centered in the window.
Trajectory-Follower

By: D. Austin Henderson, Jr. (AHenderson.pa@Xerox.com)

INTRODUCTION
Trajectory-Follower provides a function which causes a "snake" to crawl along a trajectory. Comments on both interface and functionality are welcomed.

FUNCTIONS

(TRAJECTORY.FOLLOW  KNOTS CLOSED N DELAY BITMAP WINDOW)  [Function]

The trajectory is specified by KNOTS (a set of knots) and CLOSED (a flag indicating whether it is an open or closed curve). N is the length of the snake in points along the curve. DELAY is the time (in milliseconds) between each move along the curve; DELAY = 0 or NIL means go as fast as you can. BITMAP is the brush to be used at each point in creating the snake. WINDOW is the window in whose coordinate system the knots are given and in which the snake is to be drawn; if NIL, then the SCREEN bitmap is used. The snake is moved by INVERTing the bitmap at the points along the curve, and then INVERTing the bitmap back out again.

Examples
A demonstration function is also provided with the module:

(TRAJECTORY.FOLLOWER.TEST)  [Function]

Interacts with the user through prompting in the promptwindow to gather up arguments for TRAJECTORY.FOLLOW and then carries it out. Closed curves are snaked around repeatedly until the left shift key is found depressed when it reaches the curve’s starting point.

Internal Functions

The internal functions used by this module are also available for use. They are:

(TRAJECTORY.FOLLOWER.SETUP WINDOW N DELAY BITMAP)  [Function]

Initializes drawing variables.

(TRAJECTORY.FOLLOWER.POINT X Y WINDOW)  [Function]

Defines the next point on the curve. Note that the argument structure of this function is appropriate for use as a BRUSH with the curve drawing functions DRAWCURVE, DRAWCIRCLE, and DRAWELLIPSE. (For an example, see the demonstration function TRAJECTORY.FOLLOWER.TEST)

(TRAJECTORY.FOLLOWER.WRAPUP)  [Function]

Finishes the job after all the points have been defined.
Interlisp-D into Xerox Commonlisp, we developed a collection of tools to automate the conversion as much as possible. These have been placed in `{parcvax.xerox.com}/lisp/exchange`. While we at Unisys have reasonable confidence in these tools, they are being made available with no promises of accuracy, completeness or support (though we would appreciate feedback).

The tools run in Xerox Lyric Common Lisp. The following files are parts of it:

TRANSOR -- A slightly modified version of Transor, to fix a few Lyric-related problems and provide the ability to emit a DEFINE-FILE-INFO expression and to use the value of TRANSOUTREADTABLE as the output readtable. We used TRANSOR because we were familiar with it, and it handles a lot of details needed to safely and surely traverse the code to be translated. The biggest impediment to adding to the transforms is that they are specified as teletype editor commands, and only old-time Interlispers have much experience with those.

TSET -- The same version dating back to 1979. This is the part of transor used for interactively developing and testing translation rules.

TRANSOR.LCOM -- contains the compilation of BOTH the above files.

TO-COMMONLISP.XFORMS -- translation rules for 428 functions, 98 remarks and 4 auxiliary functions. It covers a large portion of Interlisp, including most Clisp constructs, and specifically handles any function with the same name in both Interlisp and Commonlisp, so that holes in a translation should result in calls to undefined functions. In many cases, nice transformations are used for easy cases, and ugly ones only for hard cases. This file sets TRANSOUTREADTABLE to be a copy of the XCL readtable which is case SENSITIVE, MYLOAD below reads it case INsensitive, so the resulting file will ultimately lose most case distinctions on reloading into Xerox Lisp (or other common lisps). This was a much debated point internally, but this seemed the best of three bad possibilities (e.g. print one of

Cased AS ORIGinal which becomes CASED AS ORIGINAL on load,

|Cased| AS |ORIGinal|, or

CASED AS ORIGINAL

INTERLISP-COMMONLISP.TEDIT -- A document describing the transformations and formacro.

LOADTRAN -- contains a few functions which prevent many breaks on loading the translated file. The function MYLOAD is intended to load
a translated file.
LOADTRAN.DFASL -- compiled version

FORMACRO and FORMACRO.DFASL -- Still another portable iteration macro for commonlisp. Its main claims are almost 100% compatibility with the semantics of the Interlisp-Clisp FOR (especially when used the the XFORMS which fix a few incompatibilities); and user extensibility (unfortunately not compatible with IL:I.S.OPR). Embedded keywords (e.g. IN, COLLECT) may be in any package.

COMMON-MAKE and COMMON-MAKE.LCOM -- still another version of code to generate a more "common" source file. It handles more filepkg command types than most. Also, when used with COMMENTHACKS will successfully print ALL comments in semicolon format. Call IL:COMMON-MAKEFILE(file). It checks the MAKEFILE-ENVIRONMENT property to select a package and base.

COMMENTHACKS and COMMENTHACKS.LCOM -- patches to the prettyprinter and to the DEFUN editor. The prettyprinter patches will print Interlisp (*--*) comments as semicolon comments when *PRINT-SEMICOLON-COMMENTS* is ‘IL:ALL.
This file also redefines the ED method for DEFUNs so that the initials and date of editing get updated for DEFUNs just as Interlisp has always done for FNS.

Because of the way things developed, these tools are not as fully integrated as they could have been. If we were doing it over, the TRANSOR step could have more carefully coordinated the new COMS so that COMMON-MAKE would be able to do the right thing. As it stands, the COMS generally have to be edited to change FNS to FUNCTIONS, etc, but you tend to need a few iterations of editing things before the compiler is completely happy anyway.

The steps needed to do translations are roughly as follows:
(LOAD ‘TRANSOR.LCOM)
(LOAD ‘TO-COMMONLISP.XFORMS)
(SETQ FIXSPELLDEFAULT ‘N) ;; Otherwise DWIM gets too clever
(SETQ XlatedRecords NIL) ;; This is currently set to records specific to the system we translated.
TRANSOR files containing record declarations. The records MUST be translated before any code containing create/fetch/replace since the translation depends on the type of records. Also, the record declarations should be LOADED. In a large translation effort, save a file containing all needed declarations and the value of XlatedRecords computed by translating them.
(TRANSOR ‘file1) ... ;; results in file1.TRAN and file1.LSTRAN, see TRANSOR documentation.

To load translated files into a fresh xerox lisp system:
>From an XCL exec:
(IL:SETPROPLIST ‘*COMMENT* (IL:GETPROPLIST ‘IL:*))
(IL:PUTASSOC ‘*COMMENT* ‘IL:* IL:PRETTYEQUIVLST)
(LOAD ‘LOADTRAN)
(SETQ IL:*DEFAULT-MAKEFILE-ENVIRONMENT* ‘(:READTABLE "XCL" :PACKAGE ???))
(SETQ IL:CMLRDTBL (IL:FIND-READTABLE "XCL"))
(LOAD ‘FORMACRO.DFASL) if used interlisp for’s ;; may need to import USER:FOR depending on packages you’ve set up.
(MYLOAD ‘translated-records)
(MYLOAD ‘file1.tran) ...

A little work with ED and FILES? and you should be able to save a commonlisp version of your files (well, OK, a lot of work).
Suggestions and questions to one of:
darrelj@RDCF.SM.UNISYS.COM or darrel@CAM.UNISYS.COM,
or fritzson@bigburd.prc.UNISYS.COM

----- End Forwarded Messages -----
TRICKLE

By: Nick Briggs (Briggs.pa@Xerox.com)

Uses: PROMPTREMINDERS

INTRODUCTION
Trickle provides a very simple cover for COPYFILES to do periodic (every 24 hours) updating of one directory from another, with processing of the log files generated by COPYFILES to mail a note to some designated person indicating what COPYFILES did.

USE
There is only one function of interest to the user:

(Trickle Source Destination RootLogfileName MailAddress ScheduleAnotherOne Don'tReplaceOldVersions) [Function]

Source and Destination should be patterns acceptable to COPYFILES. RootLogfileName should be a host, directory, and partial file name to which Trickle will append the date in the form yymmdd, and the extension .CopyLog. On completion of the copy Trickle will mail a message to MailAddress if it is non-NIL. If ScheduleAnotherOne is T then another Trickle will be scheduled (randomly) between 1 am and 5:59 am of the next day, alternatively, if ScheduleAnotherOne is a time that would be acceptable to IDATE (Trickle will prepend the actual date, just give the time) then another Trickle will be scheduled at exactly that time. Don'tReplaceOldVersions signals that Trickle should not use the COPYFILES option REPLACE, use of which causes problems with NS file servers (at least in Koto).

Example
To update the directory {cf}<lispusers>koto>* from {eris}<lispusers>koto>* storing the log files starting with {core}eluk-870512.copylog, mailing notification to Briggs.pa, scheduling this to run every night, and using COPYFILES' REPLACE option one would execute:

(SETREMINDER NIL NIL
 ' (Trickle '{eris}<lispusers>koto>* '{cf}<lispusers>koto>*
 "{core}eluk-" "Briggs.pa" T)
 "12-May-87 03:00")

Two versions of the log file will be created; version 1 with the complete log output of COPYFILES, and version 2, with all the "skipped" files removed. It is this version that is mailed to the designated recipient.

The mail messages that are sent out indicate whether there were any files processed: the subject line will include the string "(Empty)" if no files were Trickled, and the string "(Error?)" if there were no files in the source directory (may not be an error, but may be worth investigating)
INTRODUCTION

Turbo-Windows does not have anything to do with speeding up primitive window operations, but rather it helps speed up your use and manipulation of windows by providing most of the right button menu functions via shift keychords. In this way one can Move, Shape, Copy, Shrink, Close, etc., a window without having to wait for the right button menu to appear and then select from it.

Also, when providing the INITIAL shape of a window, pressing the middle button yields a large default size suitable for TEdit, etc. (Recall that using the middle button during a RESIZING operation allows you to keep roughly the original window shape and then move the corner nearest the cursor when the middle button was pressed.)

One can bring up a brief cribsheet for all the TurboWindow keychord commands by holding down the HELP key and RIGHT buttoning on the background (not in any window). This can also be produce by typing (TW.HELP) to an InterLisp EXEC.

OPERATION

Before discussing how to use this utility, a description of how the key-chords were chosen is in order. They are based loosely on the effect of the shift keys in TEdit. Recall that in TEdit, pressing and holding the Shift key Copies whatever is selected. Also, pressing and holding the Control key (sometimes labeled PROPS or EDIT) Deletes whatever is selected. Pressing both Shift and Control performs both a copy and a delete, which ends up Moving the selected item. The only additional piece of information that you need to know is that the Meta key (sometimes labeled KEYBOARD or ALT) modifies an operation or in some way makes it different. With this general interpretation, most of the key-chords are rather easy to remember.

If the following keys are chorded (held down together) while the right mouse button is pressed in the region of a window which would normally bring up the right-button menu (by convention, at least the title bar should provide the right button menu), the listed operation will be invoked without actually bringing up the right button menu.

SHIFT (using the LEFT SHIFT key or CAPS LOCK key)

Makes a copy of a window by snapping it.

CONTROL

Closes (deletes) a window. (Since this is a destructive operation, a small safeguard is built into this operation. If one holds the CONTROL key and depresses the right mouse button and continues to hold them, the window to be operated on (closed) will blink. If this is not the window you want to close
you can cancel the Turbo-Close by either moving outside the window (or by releasing the CONTROL key before releasing the right mouse button). If you abort the Turbo-Close in this manner, the normal right button menu will appear. Clicking outside of the menu will make it go away. Sometimes unexpected things occur when trying to Turbo-Close windows with attached windows, e.g. FileBrowsers, but hopefully this safeguard is conservative enough to avoid inadvertent closing of the wrong window.) [Holding down CONTROL while Right Buttoning on the background activates Window Slamming, if the LispUsers utility WDHACKS is loaded.)

META
Shape (makes different) a window.

SHIFT-CONTROL
Moves a window. (Due to the design of the InterLisp window system, this operation works in a rather strange way. You press and hold both CONTROL and SHIFT and then press the right mouse button while in the appropriate part (title bar) of the window you want to move. You then need to release the right button to be able to actually move the window. In order to "drop" the window (here is the strange part) you need to press the LEFT (or middle) button. Pressing the right button merely allows you to move to a different corner of the shadow box.)

META-CONTROL
Shrinks ("deletes" in a different way) a window.

META-SHIFT
Redisplays (copies in a different way) a window.

META-SHIFT-CONTROL
Buries (moves in a different way) a window. [You might also think of this as pushing the window down to the bottom, as you are pressing down all three shift keys.]

RIGHT-SHIFT
Clears a window.

HELP
Pressing the HELP key while the cursor is in the background (or typing (TW.HELP) to an InterLisp EXEC) displays a cribsheet for the Turbo-Window KeyChords. Some addition capabilities not listed here are given on that cribsheet. The "OTHER" keychords which are marked with an asterisk (*) indicate that some side-effect (potentially quite harmful) might occur depending on where the TTY is when those alternate access methods are used. You are warned!

GETTING STARTED
[If any of the operations described below do not perform properly, it might be the case that your keys are not defined in the way that this utility expects. See INTERNALS below for more information.]

You might want to get familiar with Turbo-Windows by first bringing up the cribsheet by depressing the HELP key and right-buttoning on the background. Next, make a copy of the cribsheet by depressing SHIFT (the left shift key) and right-buttoning on the cribsheet. Drop the new copy of the cribsheet by releasing all keys and buttons and the pressing the left mouse button. [Note: The cribsheet is merely written to the TTY window, which happens to be sensitive to the right mouse button everywhere. Other windows may only be sensitive to the right button (for the purpose of bringing up the right button menu, in their title bar.] Now try moving the copied cribsheet by pressing both SHIFT and CONTROL
(PROPS or EDIT) and right-buttoning on the copy of the cribsheet. Again, release everything (well, just releasing the mouse button will do) and press the left mouse button to drop it. Press and hold both META (KEYBOARD) and CONTROL while right buttoning in the copy of the cribsheet to shrink it to an icon. Release and click the left mouse button to drop the icon. Reopen (expand) the icon by middle buttoning on it. Reshape the copy of the cribsheet by pressing META and right buttoning on the copy's window. Release and rubberband the new shape with the left mouse button. (Do you know what would happen if you used the middle button after releasing instead? Try it.) Assuming the copy of the cribsheet is overlapping another window and some part of the background (if not, Turbo-Move it so it is), press and hold all three (META, SHIFT, and CONTROL) and right button in the cribsheet copy's window to bury it. Right button (holding no other keys) in the partially exposed area of the now buried cribsheet copy to bring it back to the top. Finally, close the copied cribsheet window by pressing CONTROL while right buttoning in the copy's window. [O.K. which shift key combination hasn't been used yet? Consult the original cribsheet (or produce it again), if necessary. Give that combination a try in the original cribsheet's window. [Did you notice the message in the prompt window?] And don't forget to give the Right Shift key (Clears a window) a try as well. [Remember, the cribsheet can be brought back at any time using HELP-RightButton on the background.] To see how to cancel a Turbo-Close, depress the CONTROL key and press AND HOLD the right mouse button while in the original cribsheet window. Notice that the window blinks. Before you release the right mouse button move the cursor outside the cribsheet's window and then release the right mouse button. The cribsheet's window is not closed because releasing outside the window that flashed cancels the Turbo-Close. The normal right button menu appears instead. Click outside it to get rid of it. Now, actually close the original cribsheet window. And with that, may I welcome you to the fast paced world of Turbo-Windows.

INTERNALS

The right button events are intercepted by a piece of advice placed on DOWINDOWCOM. The middle button sizing capability is provide by advice on \GETREGIONTRACKWITHBOX.

The window snapping Turbo-Window feature (LeftShift-RightMouseButton) is also added as a submenu to the normal right button menu provided by the window system.

A common problem is that the META key is not defined to be at the proper place (attached to the key named KEYBOARD). To remedy this, type:

```
(KEYACTION 'KEYBOARD '(METADOWN . METAUP))
```

to an InterLisp EXEC. The following should also be the case:

```
(KEYACTION 'EDIT '(CTRLDOWN . CTRLUP))
(KEYACTION 'LSHIFT '(1SHIFTDOWN . 1SHIFTUP))
(KEYACTION 'RSHIFT '(2SHIFTDOWN . 2SHIFTUP))
```

These can be verified by using, for example:

```
(KEYACTION 'EDIT)
```

TW.NO-FLASH-CLOSE [Variable]

Initially NIL, if set to T, windows will not flash to indicate there impending closure.
TW.DONT-GROW-SNAP-BORDER  [Variable]
Initially NIL, if set to T, windows will be copied without a small border. The small border is quite handy in telling the original window from its Turbo-Snapped copy.

TW.SNAP-HERE  [Variable]
Initially NIL, if set to T, windows will be copied directly on top of the window they are duplicating. Normally (when NIL) the user must position the copy.

GETREGIONDEFAULT  [Variable]
This variable can be bound dynamically by an application to provide the region afforded by middle buttoning when prompted for an initial region of a window. It is initially set to roughly 7x9 inches, and is useful for TEdit windows, FileBrowsers, etc. [See the LispUsers utility RESIZE-FILEBROWSER for an even better way of dealing with FileBrowsers.]

- In order to edit/compile the source of this utility, the InterLisp Source file WINDOW must be loaded in order to provide the SCREEN record definition used by the window system internals. The loading of this source file occurs automatically when this utility’s source file is loaded.

- This utility interacts poorly with other utilities that redefine any of the shift keys. TEDITKEY and PC-Emulation (among others) are dubious in this regard.
TWODGRAPHICS implements viewports. A viewport is a subregion of a window (or image stream) within which graphics is clipped and a linear transformation from a world coordinate system to the window (or image stream) coordinates.

A given window (or image stream) may have any number of viewports defined and the viewports may be arbitrarily nested or overlapping. If a window is reshaped the subregions of all currently defined viewports are proportionately reshaped.

Viewports will operate in the context of any image stream, (Interpress printers, etc.), although not all DIG (Device independent graphics) primitives are supported.

**(CREATEVIEWPORT stream streamsubregion source)**

Creates a viewport on stream. Stream is the target stream. Streamsubregion is a region in stream coordinates that defines the extent of the viewport.

Source may be a REGION in world coordinates, in which case the world to stream linear transformation is set up to map left to left and bottom to bottom, etc., or a VIEWPORT, in which case the new viewport inherits its world to stream transformation.

Returns a VIEWPORT

**(SETWORLDREGION region viewport)**

(Re)sets the worldregion of viewport and recomputes the transformation.

**(SETSTREAMSUBREGION region viewport)**

(Re)sets the streamsubregion of viewport and recomputes the transformation.

Modified versions of selected DIG primitives are supplied to take advantage of the world to stream transformation.

**(TWODGRAPHICS.BITBLT source sourceleft sourcebottom destinationviewport destinationleft destinationbottom width height sourcetype operation texture clippingregion)**

World coordinates may be used where it makes sense. The destination must be a VIEWPORT. Destination left and bottom default to the viewport’s stream subregion left and bottom. The clippingregion argument is always in destinationviewport world coordinates. The source may be a VIEWPORT, a BITMAP, or NIL in the case of texture patterns.

In the following, all coordinates must be world coordinates.
(TWODGRAPHICS.MOVETO x y viewport) [Function]

(TWODGRAPHICS.MOVETOPT position viewport) [Function]

Here position is a POSITION in world coordinates

(TWODGRAPHICS.RELMOVETO dx dy viewport) [Function]

(TWODGRAPHICS.RELMOVETOPT dposition viewport) [Function]

(TWODGRAPHICS.DRAWTO x y width operation viewport color dashing) [Function]

(TWODGRAPHICS.DRAWTOPT position width operation viewport color dashing) [Function]

(TWODGRAPHICS.RELDRAWTO dx dy width operation viewport color dashing) [Function]

(TWODGRAPHICS.RELDRAWTOPT dposition width operation viewport color dashing) [Function]

(TWODGRAPHICS.DRAWLINE x1 y1 x2 y2 width operation viewport color dashing) [Function]

(TWODGRAPHICS.DRAWBETWEEN position1 position2 width operation viewport color dashing) [Function]

(TWODGRAPHICS.DSPRESET viewport) [Function]

Does a “DSPRESET” on the VIEWPORT

(TWODGRAPHICS.DSPFILL region texture operation viewport) [Function]

region must be in world coordinates

The following function is an extension which may be of use to those who wish to produce analytic plots.

(TWODGRAPHICS.PLOTAT position glyph viewport operation) [Function]

Bitblts glyph to position with operation, with glyph centered at position.

Several functions provide access to the world to stream transformations.

(WORLDTOSTREAM position viewport oldposition) [Function]

Position is in world coordinates. Oldposition is smashed if provided.

Returns the corresponding position in stream coordinates.

(WORLDREGIONTOSTREAMREGION region viewport) [Function]

Region is in world coordinates

Returns the corresponding region in stream coordinates

(WORLDTOSTREAMX x viewport) [Macro]

Returns x in stream coordinates.

Uses unboxed floating point arithmetic

(WORLDTOSTREAMY y viewport) [Macro]

Returns y in stream coordinates

Uses unboxed floating point arithmetic.
(WORLDXLENGTH dx viewport) [Macro]
Returns the length dx in stream coordinates.
Uses unboxed floating point arithmetic.

(WORLDYLENGTH dy viewport) [Macro]
Returns the length dy in stream coordinates.
Uses unboxed floating point arithmetic.

(STREAMTOWORLD position viewport oldposition) [Function]
Returns position in world coordinates.

(STREAMTOWORLDX x viewport) [Macro]
Returns x in world coordinates.
Uses unboxed floating point arithmetic.

(STREAMTOWORLDY y viewport) [Macro]
Returns y in world coordinates.
Uses unboxed floating point arithmetic.

(STREAMXLENGTH dx viewport) [Macro]
Returns dx in world coordinates.
Uses unboxed floating point arithmetic.

(STREAMYLENGTH dy viewport) [Macro]
Returns dy in world coordinates.
Uses unboxed floating point arithmetic.

For those who desire tighter control over the two-stage process, transform into stream coordinates, and then clip against the viewport, the following functions provide primitive clipping for line drawing and text output in any image stream.

(CLIPPED.BITBLT clippingregion source sourceleft sourcebottom
destination destinationleft destinationbottom
width height sourcetype operation texture) [Function]
As in BITBLT, although the operation is clipped against clippingregion in destination stream coordinates.

(CLIPPED.DRAWLINE clippingregion x1 y1 x2 y2 width operation stream
color dashing) [Function]
As in DRAWWLINE, although the operation is clipped against clippingregion in stream coordinates.

(CLIPPED.DRAWTO clippingregion x y width operation stream color dashing) [Function]
As in DRAWTOW, although the operation is clipped against clippingregion in stream coordinates.

(CLIPPED.DRAWBETWEEN clippingregion pt1 pt2 width operation stream color dashing) [Function]
As in DRAWBETWEEN, although the operation is clipped against clippingregion in stream coordinates.
(CLIPPED.PLOTAT clippingregion position glyph stream operation) [Function]
BITBLT glyph to stream centered at position and clipped against clippingregion.

(CLIPPED.PRIN1 clippingregion expr stream) [Function]
PRIN1 expr on stream clipped against clippingregion.
The module UNBOXEDOPS is intended to assist those interested in high-performance, scalar, floating-point arithmetic. The basic trick is to perform floating point arithmetic on the stack, utilizing special, unboxed, floating-point opcodes, an ugly but usually effective solution. This method of eliminating floating-point number boxes is likely to change, but in the interim a combination of compiler declarations and explicit evocations of unboxed operations, as described below, will allow the interested user to eliminate a high percentage of floating-point number boxes. This module and the methods described are "safe", i.e., the declarations won't cause your programs to crash, and if it works with the declarations it will also work without them.

Unboxed floating point tricks help out only 1108's with floating point hardware or 1186's with floating point microcode. Unfortunately, they may make performance even worse on 1108's without floating point hardware, although the performance degradation is probably not too severe.

There exist opcodes which perform floating point arithmetic on the stack (that is, on the bits of those numbers, rather than pointers to those bits). These opcodes are only emitted by the byte compiler if arithmetic occurs in an unboxed context. One example of an unboxed context is arithmetic on a record field defined to be of type FLOATP, another is arithmetic on a variable declared to be of TYPE FLOAT. However, the compiler will box across function boundaries and in a return context. Furthermore, there exist more unboxed opcodes than are used by the compiler (unboxed comparison springs to mind).

UNBOXEDOPS defines macros/functions so that these additional opcodes may be exploited in an unboxed context. These macros/functions include:

UFABS, UFEQP, UFGEQ, UFGREATERP, UFIX, UFLEQ, UFLESSP, UFMAX, UFMIN, UFMINUS, and UFREMAINDER,

which behave identically to there non-U namesakes, except that the operations are done on the stack without generating floating point boxes.

For those unfamiliar with unboxed compiler declarations a short description follows:

**Using (DECLARE (TYPE FLOATING x y z)) to reduce number boxes**

Consider the silly function:

```lisp
(DEFINEQ (FIE  (N)
  (bind (SETQ X 0.0) (SETQ Y 2.0) for I from 1 to N
    do (SETQ X (FPLUS X (FTIMES Y Y)))
    finally (RETURN X))))
```

```
(TIMEALL (FIE 100))
```

returns a CPU time of .025 and reports 200 FLOATP boxes produced. Now, consider
(DEFINEQ (FOO (N))
  (bind (SETQ X 0.0) (SETQ Y 2.0) for I from 1 to N)
  declare (TYPE FLOAT X Y)
  do (SETQ X (FPLUS X (FTIMES Y Y)))
  finally (RETURN X)))

(TIMEALL (FOO 100))

returns a CPU time of .003 seconds and reports just one floatp box produced.

Essentially the (TYPE FLOAT X Y) declaration is a promise to the compiler that X and Y will hold
FLOATP's, so arithmetic may be done unboxed (that is on the value itself, instead of on a pointer to
the value, which is the usual case) if possible. The key issue is what is meant by "if possible".

The compiler is conservative. It will perform unboxed arithmetic only on built-in arithmetic functions
(PLUS, TIMES, DIFFERENCE, etc), which have unboxed counter parts, and will otherwise box across
function boundaries regardless of compiler declarations.

For example:
(DEFINEQ (FOOBAR (N))
  (bind (SETQ X 0.0) (SETQ Y 2.0) for I from 1 to N)
  declare (TYPE FLOAT X Y)
  do (SETQ X (FPLUS X (LOG Y)))
  finally (RETURN X)))

then

(TIMEALL (FOOBAR 100))

returns a CPU time of .049 with 601 FLOATP boxes produced (some of which come from the LOG
(five per function call)).

Also, the compiler will box in a return context. For example
(DEFINEQ (BAR (N))
  (bind (SETQ X 0.0) for I from 1 to N)
  declare (TYPE FLOAT X)
  do (SETQ X
       (PROG ((Y 2.0))
          (DECLARE (TYPE FLOAT Y))
          (RETURN (FTIMES Y Y)))
       finally (RETURN X)))

then

(TIMEALL (BAR 100))

returns a CPU time of .022 with 301 FLOATP boxes produced -- notice that BAR seems like it should
behave like FOO.

Indeed that is the the greatest drawback of the unboxed arithmetic as it stands now -- it is not always
easy to predict what is going to happen -- there are even traps where indiscriminate uses of TYPE
FLOAT declarations will actually produce MORE boxes than without them. This is the case if, for
example, you use comparison operators (GREATERP, etc) since the compiler boxes each operand before invoking them.

The BAR example may be fixed up as follows:

```lisp
(DEFINEQ (BAR  (N)
  (bind (SETQ X 0.0) for I from 1 to N
    declare (TYPE FLOAT X )
    do (SETQ X
      (PROG ((Y 2.0) RESULT)
        (DECLARE (TYPE FLOAT Y RESULT))
        (RETURN (SETQ RESULT (FTIMES Y Y))))
    finally (RETURN X))))
```

then

```lisp
(TIMEALL (BAR 100))
```

returns a CPU time of .008 with 101 FLOATP boxes produced. Note that the compiler still boxes the result returned by the PROG.

The best way to find out what is happening is to use a combination of TIMEALL and INSPECTCODE. Unanticipated boxing behavior will show up as BOX opcodes -- if you find a sequence of opcodes UNBOX, BOX, function call, UNBOX, then you know you are in trouble. TIMEALL will report the total number of boxes produced.

Basically TYPE FLOAT declarations are best used in tight inner loops of the sort illustrated in FOO.

With all these caveats, I think it is only fair to say that considerable performance improvements can be realized with judicious use of the TYPE FLOAT declarations; my measurements indicate a factor of ten.

Additional note: TYPE FLOAT vars are by necessity LOCALVARS.

Lyric compatibility note: All the entries described for this module are in the Interlisp package. Only the Byte compiler pays attention to TYPE FLOAT declarations -- i.e. use of TYPE FLOAT declarations will be ignored by the XCL compiler.
INTRODUCTION

This Lafite package allows you to unpack an Arpa Network digest, such as AIList, into its constituent messages. An new item, "Undigest," is placed on the browser menu. When a single message (presumably a digest) is selected, clicking on this item will delete the selected message, and append the constituent messages to the end of the mail folder. If the selected message is not a digest, or is a digest in a format that cannot be parsed properly, then a message will be printed and nothing will happen to the mail folder.

USER OPTIONS

*DELETE-DIGEST-FLAG*, if T means that the digest message should be deleted if it is successfully parsed. The default is T.

*MOVE-TO-FIRST-DIGEST-MESSAGE-FLAG*, if T means to select the first constituent message, if NIL means to select the first undeleted message after the digest message. The default is NIL.

*DONT-UPDATE-HEADERS-FLAG*, if T means not to copy the To: field from the digest to each constituent message. The default is NIL.

PLANNED ENHANCEMENTS

Inserting the contained messages immediately after the digest, rather than appending.

Moving the contained messages to a different mail folder.

NOTES

Many digests are not in the correct format. The parser used in this program tries to be very forgiving, and hence, is relatively slow (about 10 seconds to parse a digest on a Dorado). If everyone adhered to RFC934, the parser could be optimized for speed, but, alas, this is not the case.

UUENCODE provides facilities for encoding files into printing ASCII characters for transfer by electronic mail. It is compatible with the UNIX™ facility of the same name. For details of the file format see the UNIX™ manual page on ‘uuencode’.

(UUENCODE FILES INTO-FILE) [Function]
Encodes the files named by FILES into INTO-FILE. FILES may be either a list or files or a single file name. Note that UNIX™ uudecode does not support multiple files encoded in one file. Thus one should only pass a single file name to UUENCODE if the file is to be decoded under UNIX™. Returns the name of the file written.

(UUDECODE FILE-OR-STREAM ONLY-ONE-FILE?) [Function]
Decode from FILE-OR-STREAM writing the decoded files in the connected directory. FILE-OR-STREAM may be either a file name or a stream. If ONLY-ONE-FILE? is non-NIL then only one file will be extracted from FILE-OR-STREAM, and an error will be reported if no encoded file is found. This can be thought of as UNIX™ compatibility mode. Returns the list of the names of the files extracted.

(UUENCODE-INTERNAL INS OUTS DECODE-NAME FILE-MODE) [Function]
Called by UUENCODE to encode one file. Encodes all bytes from the stream INS to the stream OUTS. DECODE-NAME is the name the file should be given when it is decoded. FILE-MODE is the UNIX™ file mode for the file. DECODE-NAME defaults to (FULLNAME INS) and FILE-MODE defaults to the value of the variable UU.MODE-DEFAULT. Returns OUTS.

UU.MODE-DEFAULT [Global Variable]
The default UNIX™ file mode to encode files under as an integer. UNIX™ uudecode will use this when creating the decoded file. The initial value is 644Q (read & write by owner, read by group and other).

(UUDECODE-INTERNAL INS ONE-FILE-ONLY?) [Function]
Called by UUDECODE to decode one file. INS should be a stream open for input. Returns the name of the file extracted or NIL if none is found and ONE-FILE-ONLY? is NIL.

UUENCODE was inspired by Christopher Lane’s BMENCODE package.
VSTATS

By: Johannes A. G. M. Koomen
(Koomen.wbst@Xerox or Koomen@CS.Rochester)

Uses: SYSTATS, READNUMBER

This document last edited on November 20, 1987

INTRODUCTION
Loading VSTATS will put a VStats entry on the background menu, and execute (VSTATS 'On), which will cause the following display to be created and continuously updated:

```
16-Jan-86  14:45:34

<table>
<thead>
<tr>
<th>Data</th>
<th>Atom</th>
<th>VMem</th>
<th>Disk</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.11</td>
<td>0.36</td>
<td>0.73</td>
<td>0.05</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CPU</th>
<th>I/O</th>
<th>GC</th>
<th>Swap</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.91</td>
<td>0.00</td>
<td>0.08</td>
<td>0.01</td>
</tr>
</tbody>
</table>
```

DESCRIPTION
VSTATS is a facility for continuously displaying various interesting aspects of a running system. It can display the current time of day, with or without seconds, and/or display memory and disk space utilization, and/or display machine utilization in terms of CPU, I/O, GC and swap time. The display can be regular or inverse-video. The display is updated at user settable intervals, either always or only if the display window is completely visible.

Closing the VSTATS window will remove the background update function.

Left buttoning the VSTATS window causes it to be recomputed and redisplayed entirely. Otherwise display updates only affect those parts that have actually changed, making for a visually quiet and efficient facility.

Middle buttoning the VSTATS window will bring up an Inspector window onto the VSTATS list of options. Left buttoning an option name prints an explanation of the option to the Prompt window. Left buttoning an option value selects it, and middle buttoning an option value presents a menu from which a new value can be selected. The options window looks like this:
VSTATS is highly optimized for speed and implemented as a BACKGROUNDFN rather than as a separate process so as to minimize overhead. As a result, VSTATS can easily be run with display update intervals equal to 1 second.

DETAILS

(VSTATS on/off) [Function]
If on/off is either ON, On, on, or T, the VStats display is turned on; otherwise off.

VSTATS.CLOCK.INTERVAL [Variable]
If the global variable VSTATS.CLOCK.INTERVAL is a positive number, VSTATS displays an alphanumeric clock (e.g., "1-Aug-85 14:30"), which is updated every VSTATS.CLOCK.INTERVAL seconds. If this interval is less than 1 minute VSTATS displays seconds as well. For those of you who keep their machines running overnight (say, with IDLE or BOUNCE), if the clock display is enabled, VSTATS will resynchronize the local clock with the network daily at midnight. (My machine looses about 15 minutes a week, otherwise!)

VSTATS.SPACE.INTERVAL [Variable]
If the global variable VSTATS.SPACE.INTERVAL is a positive number, VSTATS displays, both graphically and alphanumerically, the utilization of Data, Atom, and VMem spaces and optionally Disk space, which is updated every VSTATS.SPACE.INTERVAL seconds.

VSTATS.SPACE.PANIC.LEVEL [Variable]
If VStats is displaying space utilization, and VSTATS.SPACE.PANIC.LEVEL is a percentage between 1 and 100 (or a fraction between 0 and 1), and any of the memory space utilizations (other than disk) exceed this percentage, VSTATS will flash its window in proportion to the excess, whether the window is occluded or not.

VSTATS.SPACE.SHOW.DISK? [Variable]
If VStats is displaying space utilization, then if VSTATS.SPACE.SHOW.DISK? is non-NIL, Disk space utilization is displayed as well, provided VStats can figure out the total disk size. If VSTATS.SPACE.SHOW.DISK? is T, the default DSK is used, for instance {DSK19} on a Dorado, or {DSK}<LispFiles> on a Dandelion. Alternate Dorado partitions or Dandelion volumes may be assigned to VSTATS.SPACE.SHOW.DISK? as well. If assigned through the options window, VStats will figure out which volumes or partitions are displayable.

VSTATS.MUTIL.INTERVAL [Variable]
If the global variable VSTATS.MUTIL.INTERVAL is a positive number, VSTATS displays, both graphically and alphanumerically, the machine utilization in terms of CPU time, time spent on disk and
Ethernet I/O, garbage collection time, and swapping time, which is updated every VSTATS.MUTIL.INTERVAL seconds.

**VSTATS.MUTIL.HYSTERESIS**  
If VStats is displaying machine utilization and VSTATS.MUTIL.HYSTERESIS is a positive number, the relative percentages are based on the average over VSTATS.MUTIL.HYSTERESIS intervals, otherwise they are based on the total time since VSTATS was invoked.

**VSTATS.POSITION**  
If the global variable VSTATS.POSITION is a POSITION, the VSTATS display will be put there, otherwise the user is prompted for a POSITION.

**VSTATS.BLACK?**  
If the global variable VSTATS.BLACK? is non-NIL, VSTATS displays with inverse video.

**VSTATS.ALWAYS?**  
If the global variable VSTATS.ALWAYS? is non-NIL, VSTATS will always update its display when its timers expire, causing its window to come to the top if it isn't already there; otherwise, VSTATS will only update the display if its window is neither partially nor wholly occluded. If it is occluded, VSTATS will, of course, continue to update its internal timers and the display will be updated the first time the timers expire after the display becomes wholly visible again.

**Defaults**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSTATS.BLACK?</td>
<td>NIL</td>
</tr>
<tr>
<td>VSTATS.ALWAYS?</td>
<td>NIL</td>
</tr>
<tr>
<td>VSTATS.POSITION</td>
<td>top right corner of display</td>
</tr>
<tr>
<td>VSTATS.CLOCK.INTERVAL</td>
<td>1 second</td>
</tr>
<tr>
<td>VSTATS.SPACE.INTERVAL</td>
<td>300 seconds (5 minutes)</td>
</tr>
<tr>
<td>VSTATS.SPACE.PANIC.LEVEL</td>
<td>95 %</td>
</tr>
<tr>
<td>VSTATS.SPACE.SHOW.DISK?</td>
<td>T</td>
</tr>
<tr>
<td>VSTATS.MUTIL.INTERVAL</td>
<td>1 second</td>
</tr>
<tr>
<td>VSTATS.MUTIL.HYSTERESIS</td>
<td>20 intervals</td>
</tr>
</tbody>
</table>

If different values are preferred, these variables should be set by the user before loading VSTATS to affect initial display. They can of course be altered anytime using the options menu.

**Extras:**

A number of functions are required (and supplied) by VSTATS which the author believes might well be part of standard Interlisp-D, viz.,

**(COVEREDWP window)**  
Returns T if window is partially or completely covered by some other window; NIL otherwise.

**(CLOCKTICKS interval timerunits)**  
Returns the (machine dependent!) number of internal clock ticks over the interval. For instance, on the D'Lion

\[(\text{CLOCKTICKS} \ 2.5 \ \text{`MINUTES}) = 5211900\]
(ALTOPARTITIONS) [Function]

On the Dorado, returns a list of partitions set up with an Alto exec, i.e., containing a system boot file. Especially useful with the recently added Extended VMem option, where not all partitions are bootable. Returns NIL on any other machine type. Note: this list of partitions takes between 15-20 seconds to compute.

(DISKUSEDPAGES dsk recompute) [Function]

Returns the total number of disk pages in use (complementing DISKFREEPAGES). On Dorado, this is only an estimate, unless recompute is non-NIL in which case you wait ~ 8 seconds for the answer.

(DISKTOTALPAGES dsk recompute) [Function]

Returns the total number of disk pages available (sum of DISKFREEPAGES and DISKUSEDPAGES).
SUMMARY

WALKFILES is a facility for searching loaded files for arbitrary objects. It complements MasterScope, in that it can do some things that MasterScope can’t (like looking for arbitrary substrings in functions); other things Masterscope can do as well or better. WALKFILES does not require an analysis of the files prior to action.

DESCRIPTION

(WALKFILES pattern file{s} editcommands confirmflg quietflg filepackagetypes)  [Function]

Invokes WALKDEFS on all the objects on each file{s} of the types given in filepackagetypes. If file{s} is NIL, the value fo FILELST is used. If filepackagetypes is NIL, all the filepackage types in PRETTYTYPELST are used.

(WALKDEFS pattern name{s} filepkgtype editcommands confirmflg quietflg)  [Function]

Walks over the filepkgtype definition of each name in name{s} looking for pattern. Pattern can be anything acceptable to EDITFINDP. For each occurrence, first prints the name (unless quietflg = T) and then prints the occurrence if editcommands is NIL, or invokes the editor in interactive mode if editcommands is T (asking for confirmation if confirmflg = T), or applies editcommands to the name and filepkgtype if editcommands is a function, or otherwise invokes the editor with editcommands.

EXAMPLES

(WALKFILES ’elseif ’MYFILE T)  [Example]

Brings up the editor on every definition in MYFILE which contains the symbol elseif.

(WALKFILES ’$FOO$)  [Example]
Prints every occurrence of any symbols with FOO as a substring in every definition in any file in FILELST.

(LET (THEFNS)  
  (WALKFILES '(*ANY* $FOO$ BAR) NIL '(LAMBDA (FN) (PUSH THEFNS FN)) NIL T 'FNS) 
  THEFNS)  

Collects all functions containing either the symbol BAR or any symbols with FOO as a substring on every file in FILELST.
Some short hacks that make window management slightly easier.

Loading this file forces the menu entries: **SLAMWS** (in the background menu) with the subitem **INSPECTORS**, **SEDIT**, and **FILEBROWSERS**, and **POPSHAPE** (under “Close” in the window menu), and replaces the action for **SHAPE** (window menu) with its own call.

When **SLAMWS** is selected, you are asked for a region of the screen, and all of the windows that intersect that region are closed (by call to **CLOSEW**). If one of the **INSPECTORS**, **SEDIT**, or **FILEBROWSERS** subitems is selected, all open (not shrunk) windows of the indicated type are closed.

When **SHAPE** is selected, the old shape of the window is stored, and then selecting **POPSHAPE** will reshape the window to the stored shape. When **POPSHAPE** is called, the current shape is stored, so that doing **POPSHAPE** multiple times will rotate between the two shapes.

The shape/popshape hacks are useful if you want to either get something out of the way temporarily (but not lose it entirely); or to enlarge something temporarily (e.g., for doing a SEE in the typescript window).
This small file adds the ability to scroll (scrollable) windows by rotating
the wheel on a wheel mouse or by moving (2?) fingers on a track pad.

The capability is enabled when WHEELSCROLL.LCOM is loaded.

It is toggled on and off by

(ENABLEWHEELSCROLL ON)  (initially (ENABLEWHEELSCROLL T))

The vertical scrolling speed is controlled by the variable

WHEELSCROLLDELTA (initially 20)

The number of points to scroll for each click of the wheel. Higher
values give faster scrolling. A negative value reverses the scrolling
direction.

HWHEELSCROLLDELTA (initial NIL)
If non-NIL, then this is the delta used for horizontal scrolling.

Implementation:

Lisp receives a key transition on PAD1 or PAD2 for vertical scrolling when the
wheel rotates and no other keys are down.  (ENABLEWHEELSCROLL T) modifies the
keyaction table so that it maps these transitions to characters 156 and 157.
Those characters are defined as interrupts that invoke the vertical scrolling
action.  For horizontal scrolling sideways pushes of a wheel (if it has that)
produce transitions on PAD4 and PAD5, which map to interrupt-characters 158
and 159.  (156-159 are the highest right-panel characters of character-set 0
that correspond to left-panel control characters, so typically have no other
conflicting meaning.)

(ENABLEWHEELSCROLL NIL) causes PAD1, PAD2, PAD4, and PAD5 to be ignored.

Current negative features:

1. When the wheel is depressed for middle-button effect (and no other keys are
down), an accidental rotation of the wheel during the transition (up and/or
down) may cause unintended scrolling.

We need to develop a strategy, either in Lisp, Maiko, or X, to discriminate
intended middle-button pushes from intended scrolling.  This is not an issue
for track-pad scrolling.

2. When the wheel is rotated over a window that partially occludes a Tedit
window with a caret blinking in its unoccluded region, both the target window
and the partially obscured Tedit window may scroll.
This file contains two useful functions for quick crossreference:

(whocalls callee usage) [Function]
maps over all symbols in the current environment, looking for any function that mentions callee according to usage:

values for usage:

USES VAR VARS BOUND USEDFREE GLOBALS
All mean: mention as a variable

NIL CALLS
means calls as a function

(distribute.callinfo) [Function]
inverts all of the call, use global, use free, bound relations for functions, variables from compiled code. Operates by mapping over all symbols in the sysout that are defined as compiled code, and analyzing their definitions. Anything that is called has a CALLEDBY property of all of the things that call it; any variable bound has a BOUNDBY with the list of functions that bind it, variables that are used globally have a USEDGLOBALBY and variables that are used freely have a USEDFREEBY.

(References from interpreted code, etc are not detected, so it isn’t 100% guaranteed that if something doesn’t have a CALLEDBY that it isn’t called.....)
INTRODUCTION

Need to know what package you’re in? Don’t know what your connected directory is? Fret not. The Who-Line is here.

The Who-Line is a window that displays this information on your screen. It is continually updated to reflect the current state of the world (thanks to an entry on BACKGROUNDFNS). Additionally, items in the Who-Line can act as menu items, allowing you to change the state of the machine.

Defining the information displayed in the Who-Line

The values displayed in the Who-Line are determined by the setting of the variable *WHO-LINE-ENTRIES*.

*WHO-LINE-ENTRIES* [Global Variable]

*WHO-LINE-ENTRIES* is a list that describes the items that will be displayed in the who-line. Each item in the list should be a list of up to five things: the name of the item; a form that, when evaluated, will produce the value to display; the maximum number of characters in the value; an optional function to call if the item is selected (with the mouse) in the Who-Line; an optional form that will reset any internal state of the entry when evaluated; and an optional string that describes the value displayed by the entry.

[[NOTE: Since the items on the Who-Line are evaluated rather often, it is best if they are fast and efficient (= don’t CONS or allocate any space).]]

The following are standard members of *WHO-LINE-ENTRIES*.

*WHO-LINE-USER-ENTRY* [Variable]
Disables the current user in the Who-Line. Selecting this item in the Who-Line will let you change the logged in user.

*WHO-LINE-HOST-NAME-ENTRY* [Variable]
Displays the (ETHERHOSTNAME) of the machine you are running on.

*WHO-LINE-PACKAGE-ENTRY* [Variable]
Displays the (name of the) readtable of the current TTY process in the Who-Line. Selecting this item in the Who-Line will let you switch the package of the current TTY process.

*WHO-LINE-READTABLE-ENTRY* [Variable]
Displays the (name of the) readtable of the current TTY process in the Who-Line. Selecting this item in the Who-Line will let you switch the readtable of the current TTY process.
*WHO-LINE-TTY-PROC-ENTRY* [Variable]
Displays the name of the current TTY process in the Who-Line. Selecting this item in the Who-Line will let you give the TTY to a different process.

*WHO-LINE-DIRECTORY-ENTRY* [Variable]
Displays the current connected directory in the Who-Line; the directory is shown in the format "Dir>Subdir>...>Subdir on {Host}". Selecting this item in the Who-Line will let you connect to another directory: the variable *WHO-LINE-DIRECTORIES* (see below) is used to produce a menu of interesting directories. If you are holding down a SHIFT key when you select an item from this menu, the directory name will be COPYINSERTed into the current tty input stream, otherwise you will be connected to that directory.

*WHO-LINE-VMEM-ENTRY* [Variable]
Displays the percentage of the VMem file that is currently being used in the Who-Line. If the VMem file is inconsistent, the number will be preceded by an asterisk ("*"). Selecting this item in the Who-Line will let you do a (SAVEVM).

*WHO-LINE-SYMBOL-SPACE-ENTRY* [Variable]
Displays the percentage of symbol space that is currently in use.

*WHO-LINE-TIME-ENTRY* [Variable]
Displays the current time in the Who-Line. Selecting this item in the Who-Line will let you do a (SETTIME). If you hold down a shift key when you select this item, the current time will be COPYINSERTed into the current tty input stream instead.

The default value of *WHO-LINE-ENTRIES* contains all these items

Other ways to tailor the Who-Line

*WHO-LINE-ANCHOR* [Variable]
*WHO-LINE-ANCHOR* describes where the who-line will be displayed. If *WHO-LINE-ANCHOR* contains the symbol :TOP, the Who-Line will be anchored at the top of the screen; if it contains the symbol :BOTTOM it will be anchored at the bottom of the screen. If *WHO-LINE-ANCHOR* contains the symbol :LEFT, it will be anchored to the left side of the display; if it contains the symbol :CENTER it will be centered on the screen; if it contains the symbol :JUSTIFY it will run the width of the screen; if it contains the symbol :RIGHT it will be anchored to the right side of the screen. Finally, if *WHO-LINE-ANCHOR* is a POSITION, it will be used as the lower left corner of the Who-Line. The default value is (:CENTER :BOTTOM).

*WHO-LINE-NAME-FONT* [Variable]
The font used to display the names of the items in the who-line. The default is HELVETICA 8 BOLD.

*WHO-LINE-VALUE-FONT* [Variable]
The font used to display the values in the who-line. The default is GACHA 8.

*WHO-LINE-COLOR* [Variable]
The color of the Who-Line. Legal values are the keywords :WHITE and :BLACK. The default is :WHITE.
*WHO-LINE-BORDER*  [Variable]
The border width of the Who-Line window. The default is 2.

*WHO-LINE-TITLE*  [Variable]
The title of the Who-Line window. The default is NIL.

*WHO-LINE-DISPLAY-NAMES?*  [Variable]
If *WHO-LINE-DISPLAY-NAMES?* is true, the names of items in the who-line will be displayed; otherwise they will not be shown. The default value is T.

*WHO-LINE-UPDATE-INTERVAL*  [Variable]
The number of milliseconds between updates of the who-line. The default is 100 milliseconds.

Installing new Who-Line options
Changing the above variables has no direct effect on the who-line. These values need to be installed in the Who-Line before they can take effect.

(INSTALL-WHO-LINE-OPTIONS)  [Function]

The Who-Line supports an easy way to interactivly add or remove entries. If you click on the Who-Line while holding down the EDIT or CONTROL key, you will be given a chance to add or remove items from the Who-Line.

*WHO-LINE-ENTRY-REGISTRY*  [Global Variable]
A list of all known Who-Line entries. This is used to construct the menu of possible new entries for the Who-Line.

Who-Line process state
The who-line entry *WHO-LINE-TTY-STATE-ENTRY* tries to display the current state of the TTY process.

*WHO-LINE-TTY-STATE-ENTRY*  [Variable]
A Who-Line entry that displays the "state" of the current TTY process in the Who-Line. The typical state of a process is the name of the function that is currently running in that process. This simple minded result can be altered by use of the following items.

[[NOTE: Because of the nature of the Lisp scheduler, this information is almost always out of date.]]
The Who-Line "state" can be explicitly controlled from code. If the special variable `*WHO-LINE-STATE*` is bound, its value is taken to be the state of that process. You can use this feature to provide visual indication of the state of your code by using the programming idiom:

```
(LET ((*WHO-LINE-STATE* indicator)
      (BLOCK) ;Give the Who-line a chance to run
      ...your-code...)
```

This will run the ...your-code... with the Who-Line state of the process set to (the value of) indicator. The call to BLOCK insures that the Who-Line has a chance to update before ...your-code... is run.

* WHO-LINE-STATE-UNINTERESTING-FNS*  

If there is no declared who-line state (via a WITH-WHO-LINE-STATE form), then the name of the function that is currently running is used as the who-line state. However, if the function is on the list *WHO-LINE-STATE-UNINTERESTING-FNS*, the function that called it is used instead. The default value of *WHO-LINE-STATE-UNINTERESTING-FNS* is (BLOCK AWAIT.EVENT).

WHO-LINE-STATE  

If the function that is currently running has a WHO-LINE-STATE property, the value of that property is used as the who-line state. This is used to convert functions like \TTYBACKGROUND to meaningful values like "TTY wait".

(WHO-LINE-REDISPLAY-INTERRUPT)  

Updates the Who-Line. It is intended that this function be installed on an interrupt character, so that the user can easily force an update of the Who-Line. For example,

```
(ADVISE 'CONTROL-T 'BEFORE '(WHO-LINE-REDISPLAY-INTERRUPT))
```

will cause a ^T interrupt to update the Who-Line as well as its current behavior of printing state information in the Prompt window. Alternatly, you can define a new interrupt character that will force an update of the Who-Line;

```
(INTERRUPTCHAR (CHARCODE ^U) '(WHO-LINE-REDISPLAY-INTERRUPT) 'MOUSE)
```

will cause the Who-Line to be updated whenever the user hits a ^U.

Other interesting things

*WHO-LINE-DIRECTORIES*  

A list of interesting directories used to generate a pop-up menu of directories to connect to when you select the DIRECTORY item in the Who-Line. The default value is a list containing just your LOGINHOST/DIR. When the Who-Line notices that you have changed your connected directory, it updates this list to contain the new directory.

(CURRENT-TTY-PACKAGE)  

Returns the name of the package of the current TTY process. This function is used in the default value of *WHO-LINE-ENTRIES*.

(CURRENT-TTY-READTABLE-NAME)  

Returns the name of the readtable of the current TTY process, or the string "Unknown" if it can’t figure out the name. This function is used in the default value of *WHO-LINE-ENTRIES*.
(SET-PACKAGE-INTERACTIVELY) [Function]
Pops up a menu of currently defined packages. If the user selects one of them, the current package is changed to the selected package.

(SET-READTABLE-INTERACTIVELY) [Function]
Pops up a menu of currently known readtables. If the user selects one of them, the current readtable is changed to the selected readtable.
WINK

By: Larry Masinter (Masinter.pa@Xerox.com)

This is a file containing bitmap demos. To bring up a bitmap of Marilyn Monroe winking, type:

(MARILYN)

This file also has bitmaps EINSTEIN and LINCOLN:

"AL"  "ABE"
INTRODUCTION

WORDFNS is a set of functions for manipulating files of words. There are functions to do the following: sort files, manipulate sorted files, provide common i/o functions for word files, provide mapping and translation mechanisms, provide common translation functions, and provide packaged mapping utilities.

The idea behind the mapping mechanism is that you can translate a file or list of files by specifying a read function to operate on each chunk of a file (the obvious two chunks are words and lines). You can specify file specific translation functions, default functions (when file specific functions are not provided) and common translation functions for all files. The input to the first translation function is the result of applying the read function to an input stream open on a file. The output of the first translation function is passed as input to the second translation function, etc.

USE

Note: for any file, if NIL or T is specified then the results are printed in the executive window.

Sorting Files

(SORTWORDFILE IFILES OFILE COMMONTRANSFNS DEFAULTTRANSFNS READFN COMMONCOMPAREFN KEEPDUPLICATES FIELDS SEPARATOR REVERSEORDERFLG FASTFLG) [Function]

The functions sorts the words on IFILES and stores the result back on OFILE. Th duplicates are eliminated unless KEEPDUPLICATES is non-NIL. For a description of the function of the argumentsCOMMONTRANSFNS, DEFAULTTRANSFNS and READFN see the section entitled "Translation Mechanisms". The argument FIELDS is used to specify the sorting order. The separator of the fields is specified in SEPARATOR. If REVERSEORDERFLG is T the result of the sort is reversed. FASTFLG set T causes the sort to caches the fields by consing allowing for a quicker sort (but consumes memory).
FIELDS is one of: NIL, a list of field numbers or else a list of one, two or three element lists of the form: FieldNumber Type CompareFn where type is either STRING (the default) or NUMBER. The default compareFn for STRING is ALPHORDER; for NUMBER is NUMORDER  

SEPARATOR is one of the following: a character string, a bittable, a list of single character atoms or numbers or one of the special atoms WHITESPACE (indicating a space or tab) or the atom TAB. The default is WHITESPACE.

>> should I put NUMORDER and GetNthField here?<<

Note: two related functions, NUMORDER and GetNthField, are described in the miscellaneous section.

Functions for use with sorted files

In each of the following functions:

COMMENTFILE contains the details of the result of the function (for example, the number of strings that were read in from each file)  

(COMMONSORTEDFILES  file1 file2 ofile COMMENTFILE)  

Computes the intersection of two sorted files, file1 and file2 and the results are stored on ofile. The files are read a line at a time. The value is the full name of ofile.

(COMPARESORTEDFILES  file1 file2 ofile IMINUS2 2MINUS1 COMMENTFILE COMMENT)  

The two sorted files, file1 and file2, are compared a line at a time. The common lines are stored on ofile. The output is in two columns: the left column for those lines in file1 that do not exist in file2 and the right column for those lines in file2 that do not exist in file1. The two flags IMINUS2 and 2MINUS1 are used to determine how the the comparisons will be performed. If they are not specified they are both assumed to be T thus meaning that the comparison will be performed by subtracting file2 from file file1 and file2 with file1 subtracted. If only one of IMINUS2 or 2MINUS1 is specified then only the specified one way comparison will be done. COMMENT is intended to be a string which, by default, is the string "Comparison". This string is inserted at the top of the file. The value is the full name of ofile.

(DIFFSORTEDFILES  FILE1 FILE2 OUTFILE COMMENTFILE)  

The result of subtracting FILE1 from FILE2 is stored on OUTFILE. The files are read a line at a time. The value is the full name of ofile.
I/O Functions

In the two major read functions, DREADLINE and DREADWORD, the SPACE, CR, LF and ^Z in any character set are interpreted to be the corresponding character in character set zero.

(DREADLINE  stream string skipsemicolons)  [Function]

Words are read from the word-stream stream, smashing them into string, which grows as needed. Returns NIL at EOF. Skips leading and trailing separators, and if skipsemicolons is non-NIL then sequences from ";;" to EOL are treated as a composite separator or end-marker. Unlike DREADWORD (described later in this section), segments are separated only by EOL, so compounds are not split into components. Note that stream must have been set up so that BIN/READCCODE returns NULL on EOF.

(DREADLINESKIPSC  stream string skipsemicolons)  [Function]

Calls DREADLINE with skipsemicolons bound to T.

(DREADWORD  stream string)  [Function]

Words are read from the word-stream stream, smashing them into string, which grows as needed. Returns NIL at EOF. Skips leading and trailing separators, and treats sequences from ";;" to EOL as a composite separator or end-marker. Unlike DREADLINE, segments are separated by space as well as EOL, so splits compounds into components. Note that stream must have been set up so that BIN/READCCODE returns NULL on EOF.

(INPUTWORDSTREAM  FILE NOPRINT)  [Function]

Returns a stream that is guaranteed to be open for word-reading (e.g. using DREADLINE or DREADWORD) at the beginning of FILE. If NOPRINT is NIL then the fullname of the file will be output.

(OUTPUTWORDSTREAM  FILE)  [Function]

Returns and opens a stream for the output of words (sequential text) guaranteed closed when reset context is exited and deleted if there is an error.

Translation Mechanisms

Translation mechanisms are supplied to allow great flexibility in translating one or more files which may be in different formats and have unique translations applied to them. To specify how a file is to be read a read function (READFN) can be specified. Two common read functions, described previously, are DREADLINE and DREADWORD.
As mentioned earlier each file can have unique or common translation functions. A translation function is a function which takes two arguments: a string (the input to be translated) and an optional scratch string which can be destructively modified. The output of the translation function is one of the following: a string, the value T or the value NIL. Readers may wish to refer to the LispUsers module SETSTRINGLENGTH. The special value T denotes that the output is the same as the input. A value of NIL means that nothing will be kept.

>> a better name for translation set <<

>> what is the syntax? <<

**IFILES** is either a single file name, a single translation set, a list of file names or a list of translation sets. Translation sets have the form: (READFN READFN TRANFN1 TRANSFN2 ...). (Note the first element of the list is the actual atom READFN and the second element [Argument]

**READFN** is the read function that is used for reading the files. It is passed a stream. Unless specified otherwise, the default read function is DREADWORD. [Argument]

**DEFAULTTRANSFNS** is a single function or list of functions which is first applied to the first file. What is given to the translation function is determined by what the read function passed. Unless specified otherwise, the default read function is DREADWORD. The result of applying the first function in DEFAULTTRANSFNS is input to the second function in DEFAULTTRANSFNS. This result is then passed on for application to the functions in COMMONTRANSFNS. The special value T denotes that the output is the same as the input. [Argument]

**COMMONTRANSFNS** [Argument]

**DONTPRINT** is the argument which decides whether the details of the translation functions will be printed. By default it is NIL meaning that the details will be printed. [Argument]

(TRANSLATEWORDFILE IFILES COMMONTRANSFNS DEFAULTTRANSFNS READFN DONTPRINT) [Function]

TRANSLATEWORDFILE produces an output file by translating each word in (possibly a list of) **IFILES** through a translation function. List elements of files are paired with their own idiosyncratic translation function. Otherwise the **DEFAULTTRANSFNS** is used. **COMMONTRANSFNS** are applied to the results of the default or file-specific translations to produce the translation string. If any translation function returns NIL, that string is skipped. A translation function is assumed to be an identity if it returns T, which makes simple predicates easy.
(COLLECTWORDFILE IFILES COMMONTRANSFNS DEFAULTTRANSFNS READFN DONTPRINT) [Function]

Returns the list of non-NIL values of functions applied to words in IFILES.

(MAPWORDFILE IFILES COMMONTRANSFNS DEFAULTTRANSFNS MAPFN READFN DONTPRINT) [Function]

Maps mapping function over words in IFILES. Nothing is setup for output.

Packaged Mapping Utilities

(LONGESTWORDS FILES COMMONTRANSFNS DEFAULTTRANSFNS READFN DONTPRINT) [Function]

The list of longest translated words in FILES is returned.

(SEXPRCOUNT FILE RDTBL ) [Function]

Returns the number of s-expressions in FILE using RDTBL to read.

(WORDCOUNT IFILES COMMONTRANSFNS DEFAULTTRANSFNS READFN DONTPRINT ) [Function]

The total number of translated words in IFILES is returned.

(FINDPREFIXES IFILES OFILE PREFIXES BUTNOT READFN ) [Function]

FINDPREFIXES produces an output file OFILE of those strings read by READFN from IFILES which match at least one prefix in the list of prefix strings PREFIXES and do not match any prefixes in the list of prefixstrings BUTNOT.

(FINDSUFFIXES IFILES OFILE SUFFIXES BUTNOT NOCAPS READFN ) [Function]

FINDPREFIXES produces an output file OFILE of those strings read by READFN from IFILES which match at least one suffix in the list of suffix strings SUFFIXES and do not match any suffixes in the list of suffix strings BUTNOT. If NOCAPS is specified then the match succeeds if the string does not have the first letter capitalized.

(FINDSUBSTRINGS IFILES OFILE SUBSTRINGS READFN ) [Function]

FINDSUBSTRINGS produces an output file OFILE of those strings read by READFN from IFILES which match at least one substring in the list of substrings SUBSTRINGS.
Translation Functions

(MIXEDCASEP W)  [Function]

Returns W if it contains mixtures of uppercase and lowercase characters after the initial character.

(PROPERP W)  [Function]

Returns T if the first characters of W is uppercase.

(NOTPROPERP W)  [Function]

Returns T if the first characters of W is not uppercase.

(REVERSESTRING W STR)  [Function]

Reverses W into STR and returns STR.

Examples

This example will printout all the lines that have either the prefix "re" or "no" but not the prefix "non".

(FINDPREFIXES '{dsk}Myfile T ('re" "no") ('"non") (FUNCTION DREADLINE))

This example will output to file (Phylum)<Project>Suffixes all the words in the files {dsk}File1 and {dsk}File2 that end in "ion" that do not have the first letter capitalized.

(FINDSUFFIXES '{(dsk}File1 {dsk}File2) '{Phylum}<Project>Suffixes "ion" NIL T (FUNCTION DREADWORD))

Miscellaneous Functions

(GETNTHFIELD STRING N SEPARATOR FIELDTYPE)  [Function]

The Nth field in STRING is returned using SEPARATOR as the field separator and the field type is coerced to type FIELDTYPE.

N is a simple positive integer  [Argument]

SEPARATOR is the same as that for SORTWORDFILE  [Argument]

FIELDTYPE is either the atom NUMBER or the atom STRING and indicates how the type that the field should be coerced to. The default FIELDTYPE is STRING.
Example

(GETNTHFIELD "So long and thanks for all the fish" 4 'WHITESPACE 'STRING)
returns the string "thanks".

(GETNTHFIELD "Joe Smith/5551212/12 Pleasant Lane/" 2 "/' NUMBER)
returns the integer 5551212.

(DCOPYSTRING W STR) [Function]
Copies string W into string STR and returns STR.

(NUMORDER NUMBER1 NUMBER2) [Function]
Returns >>??<<

Example

(SETQ MyString (ALLOCSTRING 1))

(DCOPYSTRING "This is a much longer string" MyString)
XCL-BRIDGE

By: Jan Pedersen (pedersen.PA @ Xerox.com)

XCL-BRIDGE is a module that assists in the transformation of ascii Common Lisp source files to Lisp managed files and vice versa. In the text-to-managed-file direction, user interaction is employed to repair read-in forms before establishing a resident image of a Lisp managed file. In the managed-to-text-file direction, a few simple transforms are employed to translate common filepackagecoms to equivalent Common Lisp forms.

All entry points are external to the "XCL" package.

(XCL:TEXT-TO-MANAGED-FILE pathname filename &key (package "USER") (readtable "XCL") (read-base 10) (combine-comments t)) [Function]

Reads an ascii lisp source file named by "pathname" and converts it to a managed file with rootname "filename". The package, readtable, and read-base employed to read the ascii file may be specified via keywords arguments, or defaulted, as shown. If the reader environment arguments are defaulted and the source file has a emacs-style "mode line", then the package and read-base will be as indicated by the "mode line". The "combine-comments" keyword controls whether adjacent comments at the same ";" level should be combined when generating sedit-style comments for the converted file.

Note that forms are only read from the ascii lisp source file, not evaluated. It is assumed that the converted file should be made (via "il:makefile") and compiled before any evaluation should be attempted.

Text-to-managed-file proceeds incrementally and interactively to convert the specified file. First all the forms are read, and presented to the user for editing (via Sedit). If the user accepts this primary phase, a filecoms is generated and again, presented to the user for editing. If the user accepts the generated filecoms, a file (and its contained definitions) is instantiated, completing the conversion.

(XCL:MANAGED-TO-TEXT-FILE filename pathname &key (package "USER") (readtable "XCL") (print-base 10)) [Function]

Prints a managed file, with rootname "filename", whose source definitions must be resident, to an ascii file "pathname" in a form suitable for reading by any Common Lisp reader. The read-print environment of the managed file may be overwritten via the keyword arguments "package", "readtable", and "print-base". Many Interlisp "filepackagecoms" are translated to their Common Lisp equivalents. For example, "il:declare:" forms are transformed to "eval-when" forms and "il:files" forms are transformed to "require" forms. As an additional convenience, defdefiners are printed as equivalent defmacros.
Subject: Converter for Xerox Bitmaps to X bitmaps.
To: Lispusers^x
cc: Rao.pa

{ERINYES}<LispUsers>medley>xerox-to-xbm.lisp
{ERINYES}<LispUsers>medley>xerox-to-xbm.dfasl

I assume soon to trick to PHYLUM.

One function

(xerox-to-xbm outpath xerox-bm &optional name)

Generates a bitmap in the "include" format used by X applications. You can test these by making them into your background in X with:

xsetroot -bitmap outpath

-- Ramana
INTRODUCTION

This module allows the 1186/Daybreak (only) users to twiddle the hardware bits so that they can have an inverting cursor (white on black and black on white instead of black on everything) and provides a patch to keep the system from undoing the effect when calling VIDEOCOLOR to reset the screen.

USE

(DOVE.XOR.CURSOR  FLG)  [Function]

The argument FLG, if T, will switch to the inverting cursor mode. If FLG is NIL it will switch back to normal mode. If FLG is a number between 0 and 15 then it is used as the ‘mix-in rule’ and has an effect according to the table below.

Mix-in rules

<table>
<thead>
<tr>
<th>Screen</th>
<th>Source</th>
<th>Cursor Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 All Black</td>
<td>None</td>
<td>Paint</td>
</tr>
<tr>
<td>1 Normal</td>
<td>Normal</td>
<td>Paint</td>
</tr>
<tr>
<td>2 Normal</td>
<td>Inverted</td>
<td>Paint</td>
</tr>
<tr>
<td>3 Normal</td>
<td>None</td>
<td>None</td>
</tr>
<tr>
<td>4 Inverted</td>
<td>Normal</td>
<td>Erase</td>
</tr>
<tr>
<td>5 All Black</td>
<td>Inverted</td>
<td>Paint</td>
</tr>
<tr>
<td>6 Inverted</td>
<td>Normal</td>
<td>Invert</td>
</tr>
<tr>
<td>7 Normal</td>
<td>Inverted</td>
<td>Erase</td>
</tr>
<tr>
<td>8 Inverted</td>
<td>Inverted</td>
<td>Erase</td>
</tr>
<tr>
<td>9 Normal</td>
<td>Inverted</td>
<td>Paint</td>
</tr>
<tr>
<td>10 All White</td>
<td>Inverted</td>
<td>Paint</td>
</tr>
<tr>
<td>11 Normal</td>
<td>Normal</td>
<td>Erase</td>
</tr>
<tr>
<td>12 Inverted</td>
<td>None</td>
<td>None</td>
</tr>
<tr>
<td>13 Inverted</td>
<td>Inverted</td>
<td>Paint</td>
</tr>
<tr>
<td>14 Inverted</td>
<td>Normal</td>
<td>Paint</td>
</tr>
<tr>
<td>15 All White</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Note

This table is relative to the normal mode of the display (1), normal screen, normal cursor in paint screen, normal cursor in paint (VIDEOCOLOR T), would be 13, inverted screen and inverted cursor in paint mode. There is probably a more precise or logical way to notate these modes, but this should give you a rough idea of what's available.
The function is set up such that when trying different modes, you must do a (DOVE.XOR.CURSOR) (no argument) between calls.

No warranty expressed or implied, but we have been using it locally without problem (at least as far as I know). Enjoy.
One of the key components of CLOS is inheritance. The CLOS Browser provides functionality for displaying this structure and for extending it. It also provides functions for displaying and changing the class definitions and method definitions which make up a system written in CLOS.

Creating a Browser

A browser can be createded in two ways:

- Via a menu option from the Background Menu
- By calling the function CLOS-BROWSER:BROWSE-CLASS on a class

Creating a browser via the Background Menu

When the CLOS-BROWSER module is loaded, an entry is added to the Background Menu, as shown below:

```
BrowseClass
  Idle
  SaveVM
  Snap
  Hardcopy
  EXEC
  PSW
```

Selecting the menu item BrowseClass brings up a window, with a prompt for the name of the class to use as the root of the browser as shown below.

```
Class> ^

CLOS-browser
```

Type in the name of the class you wish to browse at the flashing cursor, and the class graph will be drawn in the window.
Creating a browser programatically

Browsers can also be created by calling the function BROWSE-CLASS:

\[
\text{(BROWSE-CLASS &OPTIONAL CLASS-NAME-OR-LIST &KEY :WINDOW-OR-TITLE :GOOD-CLASSES :POSITION)} \quad \text{[Function]}
\]

This function brings up a browser on the class named or the list of classes named. If a window is supplied for the :WINDOW-OR-TITLE argument, then the browser is created in that window, else an appropriately sized window is created. The window is positioned at the :POSITION argument or, if not supplied, then the position is set via the mouse. If a text string is supplied for the :WINDOW-OR-TITLE argument, then that string is used for the window title, else the string “CLOS-browser” is used. If :GOOD-CLASSES is supplied, then only those classes in the list are displayed.

Using the Class browser

Instances of CLOS-BROWSER are operated on through a mouse-based interface.

Buttoning on the browser will cause one of the following menus to be popped up:

- One menu appears when the left or middle button is pressed while the mouse is in the title bar. This menu has operations that apply to the browser itself.
- The other menu appears when the middle button is pressed when the mouse is on one of the nodes in the browser.

If the left button is pressed when the mouse is on a node, that node is boxed. This marks the node for some operations.

Options in the title bar menu

The following menu appears when you left- or middle-button in the title bar.

Recompute and it’s suboptions

Selecting the Recompute option and dragging the mouse to the right causes the following submenu to appear:
Most of these items change the appearance of the browser, not the contents.

Recompute
Recomputes the browser from the starting objects. It does not recompute the labels for each node if those labels are cached in the Label-Cache slot of the browser.

Recompute Labels
Recompute the browser from the starting objects, including the labels.

Recompute inPlace
Recompute the browser without affecting the scrolled location of the lattice within the window.

Clear caches
Clear the caches of the nodes.

Browser looks and it’s suboptions

Selecting the Browser looks menu item and sliding to the right causes the following submenu to appear:

- Shape to hold
- Change font size
- Change format

Selecting one of these options changes the looks of the browser.

Shape to hold
Make the window for the browser just large enough to contain the browser.

Change font size
Causes a menu of alternative font sizes to pop up. Selecting one of these causes the browser to be redrawn with the nodes at that font size.

Change format
Causes the following menu to appear:

- Horizontal/Lattice
- Vertical/Lattice
- Horizontal/Tree
- Vertical/Tree

Horizontal/Lattice Lays out the grapher as an horizontal lattice.

Vertical/Lattice Lays out the grapher as a vertical lattice.

Horizontal/Tree Lays out the grapher as a horizontal tree.

Vertical/Tree Lays out the grapher as a vertical tree.

Options in the Middle-button menu
The following menu appears when you middle-button over a node in the graph:

```
Edit
Add method
Browse
Print
Specialize
......
slots
methods
```

**Edit and its suboptions**

Selecting **Edit** causes an editor on the class definition to be brought up. Sliding the mouse to the right causes the following menu to appear:

```
Edit
Add method
Browse
Print
Specialize
......
slots
methods
```

- **Edit** Edits the class named by the node
- **Inspect** Inspects the class object named by the node.

**Add Method**

Selecting the **Add Method** option brings up an editor window with a template for a method to be added to that class. When the editor is done the method is installed for that class and the menu updated.

**Browse**

Selecting the **Browse** option causes a browser to be created starting with that class as the root.

**Print and its suboptions**

Selecting **Print** prints out the class definition. Sliding the mouse to the right causes the following menu to appear:
Print's the class definition

Describe
Describes the class, listing its metaclass, its superclasses, its subclasses, its CPL, and the number of methods specialized to it.

Documentation
Print's the documentation string for the class

Specialize

Selecting the Specialize option brings up an editor window with a template for a subclass to be added to that class. When the editor is done the class is installed and the browser updated.

Slots

Selecting the Slots option is the same as selecting the Edit option, it brings up an editor on the class definition.

Methods

The Methods option allows you to edit one of the methods defined for that class. Selecting it and sliding to the right brings up the following sub-menu:

Local
Bring up a menu of the local methods, i.e., methods directly defined for this class.

Inherited
Bring up a menu of the methods this class inherits from its superclasses.

All
Bring up a menu of all the methods defined for this class, both local and inherited.
Selecting an item with the left button from the resulting menu brings up an editor on that method. If there are multiple methods that apply, a gray triangle appears in the right edge of the menu next to that item. Sliding to the right brings up a menu of method specializers to select the appropriate method.
This directory contains fonts and font information which are to be used for Xerox internal uses only. Under no circumstances can these fonts be released for customer use. For information, contact Frank Shih, Lisp Development, Xerox Artificial Intelligence Systems.

The screen fonts labelled ITCBauhaus are in fact just renamed copies of the font Modern. This is because ITCBauhaus is not yet available at 72 dpi, and so the generic Modern is substituted instead. Printers containing the font ITCBauhaus should be able to correctly render the file, however.
This document last edited on December 27, 1988

SUMMARY

This module provides the function HOSTUP? which attempts to find out if a given host is currently available. Contrast this to the system function HOSTNAMEP, which returns T if it has at any time successfully opened a connection to given host, whether or not it is currently available.

DETAILS

(HOSTUP? hostname) [Function]

Returns T if and only if the given host is currently responding. No distinction is made between dead and non-existing hosts.

HOSTUP.TIMEOUT [Global variable]

The function HOSTUP? returns NIL if no response is received from the given host within HOSTUP.TIMEOUT milliseconds. Default value is 15,000.

HOSTUP.RETRYCNT [Global variable]

This variable indicates the number of times the function HOSTUP? sends requests to the given host. Each time through the loop the function waits longer by a geometrically increasing amount if time, such that the total time does not exceed HOSTUP.TIMEOUT. Default value is 5. Hence, in the default case, a call to HOSTUP? with a dead host ends up sending a request to the host 5 times, waiting for an answer about 500, 1000, 2000, 4000 and 8000 milliseconds, respectively.
INTRODUCTION

The LispUsers module IRIS is a collection of functions for using an IRIS (Integrated Raster Imaging System) with Interlisp-D. The IRIS is a sophisticated 3-d color graphics workstation produced by Silicon Graphics Incorporated. Much of its imaging system is implemented in special purpose VLSI, making it a very powerful graphics engine.

IRIS provides three separate ways to exploit the IRIS in Interlisp-D. The first is to use the IRIS as an Interlisp-D imagestream. In this capacity the IRIS serves as the output device for a program which needn't even know that it is outputting to the IRIS. Thus standard system utilities (such as GRAPHER, SKETCH, and TEDIT) can make use of the IRIS without change. The images produced by these system utilities can then be manipulated with the special abilities of the IRIS (3-d rotation, color updates, double buffering, object definitions, etc.)

The second mode of use for the IRIS is to directly access the IRIS graphics library. In this mode, Interlisp-D provides stubs for the functions in the IRIS graphics library. Thus, Interlisp-D provides the illusion of having the IRIS as a direct device like the standard screen. However, it is actually a separate computer accessible across the 10-MB Ethernet.

The third mode is to use the view controller to interactively view scenes created with either of the two modes. The view controller allows the user to create an object once (interactively or via program) but then view the object many times on the IRIS without recreating the object. This object downloading allows real-time rotation of the object displayed on the IRIS.

This package also implements boot service for the IRIS workstation. The D-machine supplies the boot program to the IRIS over the Ethernet, eliminating the need for a floppy-disk on the IRIS.

This package benefited substantially from comments and improvements by Stu Card, Michel Desmerais and Lennart Lovstrand.

FILE DESCRIPTION

The implementation includes the following files:
after loading this file, the user will be prompted to place the IRIS icon. Buttoning this icon will produce a menu including the choice "create loadup panel". Choosing this item will produce a panel which can load the IRIS files. Button the "Standard" entry in the loadup panel, then button on the small SGI logo next to "Load". Prior to being able to run any applications, the IRIS must be running the terminal program. This can be booted from the floppy on the IRIS or from the Lisp workstation. To use the workstation as a bootserver, the boot file for the IRIS terminal program (see msg below) must be copied to (DSK)irisbootfile (or a directory in the list IRISBOOTDIRECTORIES) on the Dandelion that is to be the bootserver. At that point, hit the reset button on the IRIS and type 'n' to the monitor prompt on the iris. That will initiate a net boot from the Dandelion.

The file which contains the Interlisp-D imagestream definition for the IRIS. Thus, the standard Interlisp-D graphics facilities can be applied to an open IRIS imagestream. After this is loaded, images which are processed through the standard hardcopy menu can be sent to the IRIS. "Iris" will appear as a printer when the "to a printer" choice is made from the roll-off menu entry "Hardcopy".

this file contains the stubs for the functions in the IRIS library. For instance, corresponding to the function circf (found in the IRIS documentation), there is a function IRIS.CIRCF. The arguments are as listed in the IRIS documentation with the addition of the argument SPPstream. This is the SPP connection opened to the IRIS. (If omitted, it defaults to the value of IRISCONN, which is set by OPEN.IRISCONN). Where an argument is a matrix, it is passed to the lisp function as a list of the rows, each row itself a list. When a library fn returns a matrix, the appropriate (usually floatp) matrix is passed in and the elements are set.

this file contains the communication primitives which are used by the fns on IRISLIB.

this file contains the network support for the iris. The IRIS must be on the same network as the D machine (the IRIS doesn’t handle routing through the gateway properly). If the IRIS is being bootserved from the Lisp workstation, the boot server software will set IRISNSHOSTNUMBER automatically. (The diagnostic messages can be inhibited by setting \IRIS.VERBOSE to NIL. They are left in because they can be useful when initially getting the IRIS to boot). This file contains the functions supporting the interactive viewing menu, together with the object definition facility it uses.

This file contains an example 3-d function for the IRIS. It is a function called TETRA which draws a colored, 3-d recursive tetrahedron.

This file.

GETTING STARTED

N.B. All variables and functions in this document are written as in the old Interlisp readtable. To type in the examples in this document, bring up an "Old-Interlisp" Exec. (available from the background menu by rolling off "exec" and then "Interlisp".)

-1) type (FILESLOAD LOADIRIS)

It will ask you to position the following (SGI) icon:
0) Next type (FILESLOAD IRISSTREAM IRISVIEW)

1) Boot the IRIS

If you have a floppy drive for your IRIS, use it to boot the IRIS GL2 (XNS) Terminal program. (If your IRIS is a workstation, not a terminal, you need to run the WSIRIS program available from SGI).

If you do not etherboot, you must set the variable IRISNSHOSTNUMBER. (see variables section below.)

If you have no floppy, you are going to "etherboot" the IRIS. To begin ensure that IRISBOOTDIRECTORIES is set properly. (see Magic Variables section below).

Press a mouse button in the SGI icon. Choose "Enable bootserver". Now boot the IRIS (by pressing the black button labelled "reset" on the IRIS display). To the prompt on the IRIS, type (on the iris keyboard) N (followed by carriage return). To the eventual prompt "connect to which host?" type < (carriage return). Etherbooting will automatically set the variable IRISNSHOSTNUMBER. Status messages will be printed to the promptwindow. The IRIS will beep when it is finished booting.

2) Open an IRIS stream

Button in the IRIS stream and choose "Create IRISView panel". Confirm the command by clicking left button of the mouse. "Connected" should print on the IRIS screen, and then the screen should turn black and display axes. (N.B. If at any time the screen goes completely blank, touch any key on the IRIS keyboard. The IRIS has a dubious screen-saver "feature".)

Modes

The modes of use of the IRIS are as follows:

Interlisp-D display stream

In this mode, the IRIS is acting like a window on the Lisp machine. To see updates as they occur toggle the "Double Buffer" button on the IRISView Controller. It will respond "Single buffering". Then press the "2D-Home" button on the IRIS. To demonstrate this, try the use of commands like
(PROGN (DSPCOLOR 'BLUE \IRISSTREAM)
    (PRINTOUT \IRISSTREAM T "Let's here it for ")
    (DSPCOLOR 'RED \IRISSTREAM)
    (PRINTOUT \IRISSTREAM "COLOR." T)
    (DSPCOLOR 'BLUE \IRISSTREAM))

NOTE that the first time a font family is defined it will download the font after loading the spline font definitions. This will take a few minutes.

(DRAWLINE 0 0 400 200 2 NIL \IRISSTREAM 'RED)

(FORCEOUTPUT IRISCONN)

Since the SPP stream buffers, sometimes it will be necessary to (FORCEOUTPUT IRISCONN). (There is a function simply called F that will do this for you.)

These simple instructions indicate the use of the IRIS as an Interlisp Device Independent Graphics (DIG) stream. See the IRM for further examples common to all DIG devices. For interactive graphics, the following sections contain other uses of the IRIS.

Output stream for Sketch and TEdit

TEdit and Sketch can make use of the above display stream facilities. To see an example color document, do the following. (If you don’t want to see the sketch in the document, you may omit loading sketch and sketchcolor, since they are slow to load.)

(FILELOAD COLOROBJ SKETCH SKETCHCOLOR)

(TEDIT 'IRIS-EG.TEDIT)

To print a TEdit (or sketch) to the IRIS

First time: Press "2D-Home". In the title bar of the window, use the right button to bring up the default window menu. Pick the roll-off item Hardcopy. Rolloff into "hardcopy to printer", then choose "Iris". Choose "yes" to the menu saying “Make this the default printer”.

Later times: The IRIS will now be the default printer, so just press "2D-Home" and choose Hardcopy from the default window.

To use Sketch
From the background menu, choose "SKetch". Build a closed polygon (with the entry in the sketch menu). Choose "change" in the sketch menu. Pick a control point of the polygon you just built. Pick "filling color" from the menu that appears. From the menu that appears, pick a filling color.

**Clearing the IRIS**

In the IRIS icon is an entry "clear IRIS". It will return the IRIS to the original state with the white screen, etc.

**Defining new colors**

At any time the color menu is presented, "new color" may be selected. RGB will provide color sliders and CNS will provide an English description of colors. A window will pop up asking for a name for the color. Type in a name, and that name will appear in the color menu from then on.

**Using the IRISVIEW controller**

![IRISView Controller](image)

N.B. When an IRISview controller is initially opened, the IRIS will be double buffering. This means that any drawing on the iris occurs on the back of two buffers. "Swap Buffers" must be chosen to bring the back buffer to the front. This includes "Clear IRIS" and other drawing commands. Double buffering can be turned off with the "Double Buffer" button, but moving images are much smoother with it turned on.
This window allows you to define objects on the IRIS and control your view of them.

Changing the scene:

First, select "change scene". You will be prompted with the predefined scenes as examples. Choose "axes". After a moment (during with "defining object for axes" is printed), an XYZ axes picture will appear on the screen. Try choosing each of the 3 home buttons to see the effect.

Press the "2d Home" button. (This actually means to move the view such that the IRIS simulates an 1108 screen in size and view). Now change the scene to "SKULL". Again after a delay, a Grateful Dead logo will be displayed.

Defining a scene:

We are going to define a scene that calls a function on the file IRISDEMOFNS so type

(FILESLOAD IRISDEMOFNS)

Button "Change Scene". Choose "New Scene" from the Menu. In response to "Scene Name", type "TETRA". In response to "Form to eval" click in the window the message is printed in and then type

(TETRA) [carriage return]

When the object is displayed, press each of the "Home" buttons to see different home positions. (2D-Home is perhaps best).

Viewing the scene:

Before viewing the scene, choose the "Double Buffer" option. Now hold the left button down on the item marked "Background:" in the view controller. Choose the background color for the object. White is often a good choice. (Note that sliding off the menu at this point will display "none" as the background. This means that each time the scene is drawn will be on top of the previous result. This can give very pleasing, flashy results. Experiment a bit. It’s great fun (and you are probably being payed for it!))

Adjusting the view:

Bug the part of the free menu marked . This will move the image in the positive x axis. Similarly with the other hand icons. Holding down the shift key will reverse the direction in the same axis. Bugging the entry in the view controller will let you change the "delta" for translation.
Now bug the part of the free menu marked \( \Theta \). This will rotate the image in that axis. Holding down the shift key will reverse the direction of rotation.

Bugging the \( \Theta \) entry will let you choose a new "theta" for rotation (in degrees).

**Home:**

Bugging "home" will return the scene to the original view. It is often a good idea to choose "Home" before changing scenes.

**Axes:**

Bugging the "axes" entry in the menu will superimpose a set of three dimensional axes on the view for reference purposes. It defines the axes of rotation controlled by the view controller and the directions of translation. (The axes look best against a black background, I think)

**Forgetting a Scene:**

Reclaims the space inside the IRIS and removes scene names from the scene menu. All but one scene may be deleted.

**Defining a scene containing a sketch (or Tedit):**

Button "Change Scene". Choose "New Scene" from the Menu. In response to "Scene Name", type "IRIS-EG". In response to "Form to eval", click in the window the message is printed in and then type a carriage return.

The view controller will prompt with "Make object then type RETURN". Now, hardcopy the sketch exactly as above. (periodically the view controller will flash the screen to remind you that you are still making the object). When you are finished, type carriage return as before. The current scene name will be printed in the view controller.

**Troubleshooting:**

"Iris Terminall SPP not responding" printing in prompt window

This may occasionally print when the Dlion is too busy to service the SPP connection to the IRIS. If it repeats, however, this means that a previous IRIS stream has been lost. Bring up a process status window by choosing PSW in the background, then choose the process (Iris Terminal SPP#2 for instance) and bug "kill" in the PSW. Be sure to kill the correctly numbered process. "Iris Terminal SPP" is not the same as "Iris Terminal SPP#3".

**Magic Variables**
IRISNSHOSTNUMBER [Variable]

contains the 48 bit etherhostnumber of the IRIS. If you are etherbooting, this will be set automatically. Otherwise, set it to a string like "0#4000.12000.41504#0" as described on page 31.9 of the IRM.

\IRIS.DEBUG [Variable]

Defaults to NIL. If T, when fonts are created, only the first lowercase letters will be defined. This is much faster than loading the whole font.

IRISBOOTDIRECTORIES [Variable]

For users still running with the R1B version of the IRIS terminal program, the file concerned is called xiris. This is the file that should be copied to {core}irisbootfile. However, for users running R1C (also referred to as GL2), it is necessary to obtain an updated version of the terminal program from SGI. (It was named simply "iris" on the tape we received.) This variable must contain the list of directories where the boot files are to be found. (For instance, very fast booting may be obtained by copying the boot files to the {core} device and putting {core} at the front of IRIS.BOOTDIRECTORIES.)

IRIS.VERBOSE [Variable]

 Defaults to T. Says whether or not status messages are printed during font creation etc.

\IRISSTREAM [Variable]

contains the IRIS stream that is current.

IRISCONN [Variable]

contains the SPP connection that is current.
INTRODUCTION

Makes a Koto-style logo window.

(KOTOLOGOW string where title angledelta)  [Function]

Works like LOGOW did in Koto. Put string as the main logo name, with title in the window title. angledelta is the angle at which the little windows go. where is either a position or an old window. For example (KOTOLOGOW "the string" NIL "the title" 30) produces:
LispNerd

By: Maxwell (Maxwell.pa)

DICTCLIENT, DINFO

INTERNAL

INTRODUCTION

The LispNerd provides a menu-based interface to the Interlisp Reference Manual. The data for the LispNerd is stored on the Dictionary Server, and is accessed via DICTCLIENT. Because of certain licensing agreements we have with Houghton-Mifflin, the Dictionary Server should only be used by people within PARC. Hence LispNerd has not been released as a LispUsers package.

HOW TO USE THE LISPNERD

When you load the LISPNERD, it adds a new menu item called "Search IRM" to the background menu. Bugging "Search IRM" causes the LispNerd to prompt the user for keywords in the prompt window. It then produces a menu of items that have at least two of the keywords in their definitions (perhaps with submenus, if there is more than one class of items). Bugging one of these items will cause the LispNerd to fetch the documentation for that item using DInfo.

For example, if you type the input "draw line function", you will get the following menu:

```
<table>
<thead>
<tr>
<th>IRM Entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>draw line function</td>
</tr>
<tr>
<td>line function</td>
</tr>
<tr>
<td>draw function</td>
</tr>
<tr>
<td>draw line</td>
</tr>
</tbody>
</table>
```

where each of the entries has a sub-menu of the items that have the keywords listed in the entry.

If you type the input "date", you will get a menu all of the items in the Interlisp Reference Manual that have the word "date" in them. Putting parenthesis around items means that the items should all be treated as one keyword for the purposes of sorting them into groups. For instance, the input "(draw draws)(line lines) function" will look for all of the items that have "draw" OR "draws" in their definition.

LispNerd only fetches 50 entries at a time, so sometimes you will see an entry in the menu that says something like ". . . + 103 more". Clicking this item will cause the LispNerd to fetch the next 50 entries. Also, when there is more than one class of entries, sometimes a sub-menu will only list the number of
entries it has, and not the entries themselves. To get the entries, click the menu item with the keywords in it, and LispNerd will recompute the menu with just those keywords.

Please send all bug reports to Maxwell.pa.
INTRODUCTION

MICROTEK is an image processing software package that enables you to operate Microtek Models-300 and 300A Intelligent Image Scanners with the Xerox 1108 and 1186 workstations. The Microtek MS-300, 300A, and MSF-300C are high-resolution optical scanners that can convert text, artwork, photographs, etc., into digital form for processing by computer. The digitized images that are output to the computer contain up to 300 black and white dots for every linear inch of the original document. Page size can be as large as 8.5 by 14 inches. Sophisticated firmware in this scanner enables the user to set the scanning area and control brightness, contrast, scaling, shading and other characteristics of the scanned images through simple commands transmitted from the 1108 or 1186. Two basic scanning modes are supported: Line Art mode for accurate capture of completely black-and-white material, and Halftone mode for faithful reproduction of material with varied shading. Mixed-mode scanning is also available.

With the MICROTEK software package you will be able to: Set the scanner to capture images of all kinds, with desired visual effects, and transmit them to the 1108/1186, save scanned images to disk, floppy or file server for later reloading to recreate images and print scanned images to a Xerox 4045 or 8044 laser printer.

SOFTWARE REQUIRED

MICROTEK.DFASL
MICROTEKPRINT.DFASL (if you have a Xerox 4045 or 8044 laser printer)
DLRS232C.LCOM
EDITBITMAP.LCOM
READNUMBER.LCOM
4045XLPSTREAM.DFASL (if you have a Xerox 4045 laser printer)

FONTS USED

MODERN 10, 12 BOLD

Other useful software for manipulating the scanned image:

Lispuser’s Packages:

ACTIVEREGIONS, ACTIVEREGIONS2, AIREGIONS, FILLREGION

HARDWARE REQUIRED

Xerox 1108 with RS232C port (E-30 upgrade kit). It is also recommended that the 1108 have 3.5 meg of memory and a floating point processor (CPE board) to enable faster scanning and creation of bitmaps.
Xerox 1186. It is also recommended that the 1186 have 3.7 meg of memory. Microtek MS-300, MS-300A, or MSF-300C Intelligent Image Scanner with optional serial port.

**CABLE CONFIGURATION**

Note that the cable configuration is DIFFERENT for the MSF-300C scanner. Plugging a standard RS232C cable into the MSF-300C DB25 connector may result in damage to the equipment.

<table>

</tbody>
</table>

**DOCUMENTATION REQUIRED**

Microtek MS-300, MS-300A, or MSF-300C Intelligent Image Scanner Operation Manual

**LOADING MICROTEK**

Make sure that DIRECTORIES contains the directory where the required software is located. When the file MICROTEK.DFASL is loaded, the item “MicrotekScanner” will be added to the Background menu. If you have a Xerox 4045 or 8044 laser printer load MICROTEKPRINT.DFASL. If you have a Xerox 4045 laser printer load 4045XLPSTREAM.DFASL. Your 4045 laser printer should be connected to the TTY/DCE port.

**RUNNING MICROTEK**

The process of running the Microtek scanner software consists of three phases: Scanner initialization, scanning, and creating a bitmap of the scanned image that can eventually be printed. Each of these are controlled by different menus within the Microtek Scanner Control Window.

**SCANNER INITIALIZATION**

Set the Microtek scanner so that it is operating at 19200 baud by setting its internal DIP switches (See Microtek Operating Manual for details). Turn on the Microtek scanner. Select “MicrotekScanner” from the background menu and the Microtek Scanner Control window (figure 1) and Microtek Scanner Pagemap window (figure 2) will be created. (Note you may have do a control-E and retry if cursor flashes while trying to create the control window). The scanner pagemap window is used to select the area of the image to be scanned and to select the page length. The scanner control window is used to set all other scanner parameters, start and stop scanning as well as to initiate creation and printing of scanned image bitmaps. After these windows have been created, the RS232 port will be initialized to...
19200 baud and an attention command will be sent to the scanner. If all cables are connected properly and the scanner is on, the message “MICROSCAN 300(A) V# is ready” will be displayed in the Microtek Status Window. If the cable is configured incorrectly or the scanner is not on or ready the message “Microtek Not Responding ... Check scanner and cable” will appear instead.

**FIGURE 1 - MICROTEK SCANNER CONTROL WINDOW**

Before scanning can be initiated, a number of parameters have to be set by the user via the Microtek Command Menu and Microtek Configuration Menu as follows:
Microtek Command Menu:

Output FileName  Left buttoning on this item allows you enter the name of the file on disk, floppy or fileserver where the scanned data is to be saved. Be sure to type a carriage return to terminate this entry.

Microtek Configuration Menu:

Reduction  Left button on the number next to the item Reduction and a menu will appear. Reduction can be changed from 0%, which corresponds to scanning at 300 dots per inch (DPI) to 75%, which corresponds to 75 DPI.

GrayLevel  Left button on the number next to the item GrayLevel and a menu will appear allowing you to choose from a selection of gray levels based on grain size and number of gray levels within that grain size.

Contrast  Left button on either the the left or right arrow to either decrease or increase the contrast setting.

Brightness  Left button on either the the left or right arrow to either decrease or increase the brightness setting.

FIGURE 2 - MICROTEK SCANNER PAGEMAP WINDOW

BackGround  Select either HALFTONE or LINEART as the primary scanning mode for the image. Line Art mode is for accurate capture of completely black-and-white material, and Halftone mode for faithful reproduction of material with varied shading.

Pagelength  Move the cursor to the vertical ruler of the page map (figure 2). The cursor will change to a right pointing triangle. Position this triangle and left-button to select the pagelength. The page length will also show up in the configuration menu. The page length should be set so that it is longer
than the actual page length of the document to be scanned. Otherwise you will get a paper jam message at the completion of scanning. The minimum page length is 3 inches and the maximum page length is 14 inches.

**Frame** The scanning frame is an area within the document that will be scanned. The maximum scanning frame is 8.5" by 14". Left button on the item Frame and you will be prompted to sweep out an area on the scanner page map to select the primary area to be scanned. The horizontal and vertical rulers and the page map grid dots can be used as a guide in determining the dimensions of the scanning frame. When the the scanning frame has been swept out, a box of the scanned area will be drawn on the page map and the actual X and Y coordinates of the top lefthand corner and lower righthand corner will appear next to corresponding items on the configuration menu (See Figure 2).

**Windows 1-4** Windows are areas within the scanning frame that are scanned in a different mode from the rest of the frame. If LINEART mode is selected as the background, all material in any windows you set will be scanned in Halftone mode, and vice versa.

The method used to set the windows is similar to that used to set the scanning frame except that you first need to specify whether the window is to be selected or not. This is done by left buttoning on the YES/NO indicator next to each window. A menu will pop-up and will allow you select “yes” or “no”. After making your selection, left buttoning on the appropriate Window # will cause you to be prompted to sweep out an area within the scanning frame. Each selected window will be displayed and have a unique shade to it (See Figure 2). The only restriction is that the scanning mode must not change more than twice in one 8.5" horizontal scan line. Thus, if two windows lie across the same scan line they must extend to the edges of the page setting area. (Note that material to the left and right of the frame is scanned but not transmitted to the 1108.) You can select different windows for halftone vs lineart mode by switching between backgrounds. The item above WINDOW1 indicates which window mode is selected. An illegal window setting will result in an error message when you attempt to scan. Also note that the windows will be displayed on the scanner pagemap only if there is a “yes” next to the window number.

**SCANNING**

After the Microtek scanning parameters have been initialized, the document to be scanned should be placed in the scanner top-first with the image to be scanned facing away from the user. Scanning is initiated by left-buttoning SCAN on the Microtek Command Menu. The software first creates a scratch file in {CORE} for storage of the incoming data. It then sends the scanning parameters to the scanner and if all are valid the scanning process starts as indicated by movement of the rollers. You have up to 5 minutes to insert a document before the scanner automatically stops. After scanning has been completed you will be notified in the status window that it is saving the core file to the file specified in Output Filename. It takes approximately 20 minutes to scan an 8.5" x 11" document at 300 DPI.

You may stop the scanning at any time by selecting STOP. The document will be ejected and the scanner reset. You can also explicitly reset the scanner by selecting RESET. This closes the scanner scratch file if it is open, sends a reset command to the scanner and then sends the attention command. If everything is reset properly, you will get the message "MICROSCAN 300(A) V# is ready" in the status window.

**CREATING BITMAPS OF SCANNED IMAGES**

The Microtek Display Menu is used to create bitmaps from a file that contains scanned data. Select SOURCE FILENAME and enter the name of the file that contains the scanned data. Select BITMAP NAME and enter the name of a variable that you would like the bitmap bound to. **Be sure to type a carriage return to terminate the entry of each of these items.** Left button on the number next to
SHRINKFACTOR and choose a factor by which you want the bitmap shrunk. The default value is 1. Left button on the item next to ROTATION and choose how you want the scanned image to be rotated. The default is “none.” After these items have been set, you can then select CREATE BITMAP to start the bitmap creation process. The status window will be updated as it proceeds to create the bitmap and finally, you will be prompted to sweep out a scrollable window to display the bitmap.

NOTE: Depending on the size of the bitmap, rotation may take a “very” long time and will look like your machine has frozen...be patient, it will come back. If you desire to save the bitmap(s) on a file you can do the following:

```
(SETQ filenameCOMS '((VARS bitmapname1 bitmapname2 etc))).
(MAKEFILE '{device}<directory>filename)
```

PRINTING BITMAPS OF SCANNED IMAGES TO A XEROX LASER PRINTER

If you have the package MICOTEKPRINT loaded you will have a MicrotekPrint Menu under your display menu (See Figure 1). Select BITMAPNAME on the display menu and enter the name of the bitmap that you would like to print. To select where on the page the bitmap is printed, left button XPOS and YPOS and enter a number. For the 4045 laser printer the values of XPOS can be between 0 - 2550 and YPOS, between 0 - 3300. 1” = 300 print units. For an 8044 Interpress laser printer the values of XPOS can be between 0 - 21590 and YPOS, between 0 - 27940. 1” = 2540 Interpress units. The scale that an image is printed at is dependent upon its initial scanned reduction/DPI. You can increase or decrease the scale at which the bitmap is printed by buttoning on the number next to the item SCALE and selecting a scaling factor. On an 8044 Interpress printer a scale of 8:1 will magnify an image by 8 times on printing, 1:1 will print at true size and 1:8 reduce the image by 8 times. Values in between are also available. On a 4045 laser printer only a limited number of scale factor are available and is dependent upon the original scan reduction as shown in the table below.

<table>
<thead>
<tr>
<th>REDUCTION (%)</th>
<th>RESOLUTION (DPI)</th>
<th>SCALES ALLOWED</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>300</td>
<td>1:1, 2:1, 4:1</td>
</tr>
<tr>
<td>5</td>
<td>285</td>
<td>1:1, 2:1, 4:1</td>
</tr>
<tr>
<td>10</td>
<td>270</td>
<td>1:1, 2:1, 4:1</td>
</tr>
<tr>
<td>15</td>
<td>255</td>
<td>1:1, 2:1, 4:1</td>
</tr>
<tr>
<td>20</td>
<td>240</td>
<td>1:1, 2:1, 4:1</td>
</tr>
<tr>
<td>25</td>
<td>225</td>
<td>1:1, 2:1, 4:1</td>
</tr>
<tr>
<td>33</td>
<td>200</td>
<td>1:1, 2:1, 4:1</td>
</tr>
<tr>
<td>35</td>
<td>195</td>
<td>1:1, 2:1, 4:1</td>
</tr>
</tbody>
</table>
Select PRINT to initiate the printing process. NOTE: The amount of reduction that you will be able to do is dependent upon the number bits that were originally scanned in. If you make the scale too small nothing will be printed out.

OTHER ITEMS AND GENERAL COMMENTS

On the Microtek Command Menu, left buttoning the item PAGEMAP will alternately open and close the scanner pagemap window. Left buttoning on the item QUIT will close the input and output streams to the scanner, shutdown the RS232C port and close the scanner pagemap and control windows. The following icon will be displayed if you shrink the Microtek Scanner Control window.

The Microtek Pagemap window will close when you shrink the Microtek Scanner Control window and has to be expicitely opened when the Microtek Scanner Control window is expanded again. This is done by buttoning on PAGEMAP in the Microtek Command Menu window.

Within Interlisp you normally cannot create bitmaps larger than approximately 2.1 million pixels (about 1400 x 1400). The Microtek scanner software allows you to create bitmaps much larger than this but at the cost of using a correspondingly large amount of virtual memory. If you are near your maximum vmemsize, as determined by comparing (VMEMSIZE) to (VOLUMESIZE 'volumename), there is a good chance you could crash your system if you create a very large bitmap...caveat emptor. In addition you will not be able to call the function EDITBM to edit bitmaps larger than 2.1 million pixels.

The reduction % used to scan the original image is stored on the property list of the atom that the bitmap is bound to. It is saved as the property "Resolution" and is in %. This is used to determine the appropriate values that will make an image 1:1 when printed. If you attempt to print a bitmap to an Interpress printer that was not created by use of the Microtek scanner software you will be prompted to enter a scale explicitely. The following table indicates the 8044 laser printer scale used for scanned images and can be used as a guide when attempting to print bitmaps not created by the Microtek software.

Further information about the Microtek scanner can be obtained from:

Microtek Lab Inc
16901 South Western Avenue
Gardena, California 90247
Tel: 213-321-2121, 800-654-4160
The module NSCOPYFILE modifies COPYFILE so that if both the source and destination files are on NS file servers, the copying is done by an NSFiling-specific copy routine. This routine copies all attributes of the source, including non-standard ones, such as those used by Viewpoint. Thus, you can safely copy Viewpoint files from inside Lisp without losing information. In addition, if the copy is from an NS file server to itself, the copy is performed by the server itself, which is considerably faster than shipping the file over the Ethernet.

In addition, you can also copy entire directories, by specifying directory names as the source and destination, e.g.,

(COPYFILE "{FS:}<Carstairs>Lisp>" "{FS:}<Calvin>Lisp>Current>"

The destination directory must not already exist, since this operation creates an entirely new directory, whose contents are a copy of all the source directory’s offspring, to all levels. If the destination directory happens to exist but has no children, it is considered vestigial and is quietly deleted first (Lisp usually suppresses such directories when performing a directory enumeration).

You can also use RENAMEFILE in the same manner to either rename a directory, or to move an entire directory and its descendants to a new node in the file server’s hierarchy, or to a new server altogether. You must, of course, have access rights to delete the source directory and all its children, and the destination must be on an NS file server.

A word about protection: when a file is copied or moved, the new file is given "defaulted" access rights, i.e., its protection is set as specified by its new parent (sub)directory, just as if you had created the file afresh by any other means. Thus, if the original file happened to have its own explicit protection, that protection is ignored. When copying or moving an entire directory, only the top-level directory receives default protection, so if any individual descendent file had non-default protection, that protection is copied verbatim. This can lead to confusion—you may want to use the NSPROTECTION module to change the new directory’s descendants to default protection. See the documentation of NSPROTECTION for more discussion about protection issues. Note that if a file/directory is renamed within the same parent directory, the operation is considered merely “changing the name”, and its protection is left unchanged.

Note: If you are using the FILEWATCH module, be aware that files being copied between NS servers do not appear (because the files are not opened by the normal Lisp file system).
INTRODUCTION

The module NSPROTECTION provides a tool that enables you to easily change the protection of files and directories on Xerox NS file servers.

To install the module, load the file NSPROTECTION.LCOM. Also, Your NS file server must be running Services release 10.0 or later.

THE PROTECTION MECHANISM

An NS File Server maintains a protection for each file and (sub)directory on the server. In most cases, the protection is not specified explicitly, but rather is inherited from a file’s parent directory, making it easy to maintain consistent protection over an entire branch of the file system hierarchy.

The protection is specified as a set of pairs <access rights, name>. The name can be the name of an individual user or a group. The name can also be a pattern of the restricted form *:domain:organization, *:*:organization, or *:*:. The access rights granted to any particular user are the most general of those in the pairs that match the user’s name (by exact match, pattern or membership).

The following five kinds of access rights are independently specified (the term “file” here can also denote a directory in the places where that makes sense):

- **Read**  The user may read the file’s content and attributes. In the case of a directory, the user may enumerate files in it.

- **Write**  The user may change the file’s content and attributes, and may delete the file. In the case of a directory, the user may change the protection of any of the directory’s immediate children.

- **Add** (Applies only to directories) The user may create files in the directory (i.e., add children).

- **Delete** (Applies only to directories) The user may delete files from the directory (i.e., remove children).

- **Owner**  The user may change the file’s access list.

In the case of directories, it is also possible to independently specify the directory’s own protection and the protection that its children inherit by default. In most cases, the latter simply defaults to the former, and it is usually best to keep it that way for simplicity. However, there might conceivably be cases where, for example, you would want a user to be able to read the files in a directory, but not be able to enumerate it, or vice-versa.

Note that there can be problems when giving a more lenient protection to a file or directory than to its parents, depending on what software is going to be used to gain access to the file. For example, if your default directory protection grants access only to you, and you want to allow a user to read a
particular file stored in your directory, then you can change the protection on just that file to allow Read access. However, the user will have to know the exact name of the file in order to read it, since she won’t be able to enumerate the directory to search for the file. Specifying the exact file name works fine from Lisp, but other software that gets to a file by starting at the top and working its way down through the hierarchy would be unable to get to the file.

USER INTERFACE

To use the tool, select "NS Protection" from the background menu (if your menu has a "System" item, it’s a subitem underneath it), or call the function (NSPROTECTION). You are prompted for a place to position the tool’s window. Be sure to leave space below the window for the protection information that will follow.

<table>
<thead>
<tr>
<th>NS File Protection Tool</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show    New Entry   Apply   Set to Default</td>
</tr>
<tr>
<td>Type: Principal  Check: New Names Only</td>
</tr>
<tr>
<td>Host:         Dir/File:</td>
</tr>
</tbody>
</table>

The tool window has four command buttons across the top, two switches labeled Type and Check, and two fill-in fields for the host and file name. Holding a mouse button down over any of these items for a couple of seconds will display a help message in the prompt window.

To view or change the protection of a file or directory, first fill in the Host and Dir/File fields. You can edit these fields by clicking with the mouse anywhere inside the existing text (if any), or by clicking with the LEFT button on the boldface label. If you click with RIGHT on the label, then any existing text is first erased. Typing the Next or Return key moves to the next field. [See the FreeMenu documentation for more information about text editing.]

You can either enter the host and directory separately, e.g.,

```
Host: Phylex
Dir/File: Carstairs>Lisp
```

or enter a file name in the usual Lisp syntax in the Dir/File field, e.g.,

```
Host: 
Dir/File: {Phylex:}<Carstairs>Lisp>
```

This latter form is intended to make it easy to copy-select the name of the directory or file from another source, such as a FileBrowser window; the host in the full name overrides any name in the Host line.

To see the protection of a file or directory, click on the command Show. The protection is displayed as a series of editable one-line windows beneath the main window. In each line is a set of access rights and a Clearinghouse name or pattern to which those rights are granted; for example,
The highlighted buttons indicate which of the five access rights (Read, Write, Add, Delete, Owner) are granted to the name on the right. If the displayed protection was inherited from its parent subdirectory, rather than having been explicitly set, this fact is noted in the prompt window.

To change the protection of a file or directory, set up the protection entries as desired, then click on the command **Apply**. The usual procedure is to use the **Show** command to see the current protection, then edit one or more entries. Clicking on one of the first five buttons toggles it; clicking on **All** either sets all five (if **All** was previously unhighlighted) or clears all five. In addition, setting either **Write** or **Add** also sets **Read**, since they are of little use without read access (you can, however, clear **Read** if you really meant it). The name following **to** is edited in the same manner as the **Host** and **Dir/File** items above. As with most other places in the system, the name you type can omit the domain and organization, in which case the tool will fill in the local defaults; you can also use nicknames, which will be replaced by the Clearinghouse full names (assuming checking is on).

To add an additional entry, click on the command **New Entry**. This adds a new line to the existing set of protection entries, which you can edit as appropriate. To remove a set of access rights completely for an existing name, either clear all five access buttons (most easily done by clicking once or twice on **All**), or clear the name from the **to** field (by clicking on it with the RIGHT mouse button). Any such cleared lines will be removed by the **Apply** command.

You can also change the protection of a file back to "default" by clicking on the command **Set to Default**. Following this command, the protection of the specified file is inherited from its parent directory. This is usually the best way to "undo" a changed protection, because then any changes to the protection of its parent, or parent’s parent, etc., will have the expected effect on all its children.

For the **Apply** and **Set to Default** commands, you may also specify a group of files, rather than a single file, by giving a file pattern—a name with asterisks serving as wild cards to match zero or more characters. Any pattern acceptable to the File Browser can be used. The tool enumerates the specified set of files and applies the specified protection to each. The enumeration is made to all levels (infinite depth), so affects files both in the immediate directory and also in its subdirectories, and subdirectories of those, etc. The enumeration does not, however, include the top-level subdirectory itself; e.g., "<Carstairs>Lisp>**" matches all files (including subdirectories) anywhere in the directory <Carstairs>Lisp>, but does not include <Carstairs>Lisp> itself.

Note that applying a protection to a directory is different from applying the same protection to the files in it, because of defaulting. If you apply a protection to <Carstairs>Lisp>*, it changes the protection of every file currently in the directory, but any new files added after the change still inherit the protection of the directory <Carstairs>Lisp>. On the other hand, applying a protection to the directory <Carstairs>Lisp> itself affects all current and future files in the directory, except any files that already have an explicit protection currently set. To reduce confusion, it is thus preferable to apply protections

**Read**  **Wrt**  **Add**  **Del**  **Own**  **All**  **to:** *:Research:ACME
to subdirectories, rather than individual files, if you want to control a whole group of files. If you have a subdirectory containing files of miscellaneous protection that you would like to make uniform, the best procedure is to set the desired protection on the subdirectory itself, and then use the **Set to Default** command with a pattern (e.g., `<Carstairs>Lisp>*`) to reset all the individual files to defaulted.

The **Apply** command looks up in the Clearinghouse each of the names in the individual protection entries to make sure that they are valid, and replaces aliases (nicknames) with the canonical names. It then tells the file server to change the protection as indicated. The extent to which the **Apply** command checks names is controlled by the **Check** item in the second line of the tool window. It has four possible settings:

- **New Names Only**
  This is the default setting. The tool checks any names that you have entered or changed, but assumes that names returned by the Show command were correct.

- **All Names**
  The tool checks all names, regardless of source. You might want to do this to convert an existing protection entry into canonical form, or check that all the names are still valid.

- **Never**
  The tool never checks names; it assumes you meant exactly what you typed. You might want this setting, for example, if one of the names you are entering is registered only in a distant Clearinghouse not currently accessible.

- **I really mean it**
  Not only does the tool not check the names, it also doesn’t balk if you tell it to take certain unlikely actions, such as changing a top-level directory to default protection, setting a completely null protection, or setting a protection in which nobody has Owner rights (which means the protection can only be changed by someone with Write access to the parent, if any). This setting is “one-shot”—it reverts to “New Names Only” after you issue the next command.

The **Type** item in the second line of the tool window controls which of a directory’s two protection attributes is displayed or set. The initial setting is “Principal” and is the one that should normally be used (it coincides with the Lisp file attribute **PROTECTION**, or “Access List” in NS Filing parlance). The other setting is “Children Only”. When the protection type is set this way, the tool deals with the protection that is inherited by default by the directory’s children, the attribute called “Default Access List” in NS Filing parlance. Ordinarily, this attribute is defaulted, in which case the directory’s principal protection is also used as its children’s default protection. Using the **Apply** command changes the Default Access List to the value you specify; using the **Set to Default** command changes it back to defaulted. The **Show** command displays the directory’s Default Access List if it has one; otherwise, it displays the principal protection and notes this fact in the prompt window.

The **Type** item is irrelevant for non-directory files (and, in fact, the tool sets it back to “Principal” if it has been changed). When the file is a pattern, the tool always sets the Principal protection; in the case of any subdirectories matching the pattern, it sets the Principal protection to that specified in the window and the Default Access List to “default”.

As an additional convenience feature, when you request to **Show** the “Principal” protection of a top-level directory, the tool also displays in the prompt window the directory’s current page usage and allocation.
INTRODUCTION

The PostScript package defines a set of imageops for printers which understand the PostScript page
description language by Adobe. At Beckman we have successfully used TEdit, Sketch, LISTFILES,
and HARDCOPYW to an Apple LaserWriter and an AST TurboLaser PS. The PostScript imagestream
driver installs itself when it is loaded. All symbols in the PostScript driver are located in the
INTERLISP: package.

VARIABLES

POSTSCRIPT.FONT.ALIST [InitVariable]

POSTSCRIPT.FONT.ALIST is an ALIST mapping Xerox Lisp font names into the root names of
PostScript font files. It is also used for font family coercions. The default value should be acceptable
for any of the fonts which are built into the Apple Laserwriter.

POSTSCRIPTFONTDIRECTORIES [InitVariable]

POSTSCRIPTFONTDIRECTORIES is the list of directories where the PostScript .PSCFONT font files
can be found. The default value is: ("{DSK}<LISPFILES>FONTS>PSC>").

\POSTSCRIPT.SHORTEDGE.SHIFT [InitVariable]

\POSTSCRIPT.SHORTEDGE.SHIFT is the distance (in points) to shift the image perpendicular to the
short edge of the paper. A positive value gives a shift upward in portrait mode, and to the right in
landscape mode. The default value is: 0.

\POSTSCRIPT.LONGEDGE.SHIFT [InitVariable]

\POSTSCRIPT.LONGEDGE.SHIFT is the corresponding variable for shifts perpendicular to the long
edge of the paper. A positive value here gives a shift to the right in portrait mode and downward in
landscape mode. The default value is: 0.

\POSTSCRIPT.SHORTEDGE.PTS [InitVariable]

\POSTSCRIPT.SHORTEDGE.PTS indicates the printable region of the page (in points) along the short
edge of the paper. It should be adjusted to allow for any shifts of the image (see above). The default
value is: 576 (= 8 inches).

\POSTSCRIPT.LONGEDGE.PTS [InitVariable]
\POSTSCRIPT.LONGEDGE.PTS indicates the printable region of the page (in points) along the long edge of the paper. It should be adjusted to allow for any shifts of the image (see above). The default value is: 786.24 (= 10.92 inches).

**HINT**

The AST TurboLaser PS has an imageable area on the page which is a different size than that of the Apple LaserWriter. The values of \POSTSCRIPT.SHORTEDGE.PTS and \POSTSCRIPT.LONGEDGE.PTS for the AST are 575.76 and 767.76, respectively.

\POSTSCRIPT.MAX.WILD.FONTSIZE [InitVariable]

\POSTSCRIPT.MAX.WILD.FONTSIZE indicates the maximum point size that should be returned from FONTAVAILABLE when the SIZE argument is wild (i.e. `*`). All integer point sizes from 1 to \POSTSCRIPT.MAX.WILD.FONTSIZE will be indicated as available. The default value is: 72.

POSTSCRIPT.PREFER.LANDSCAPE [InitVariable]

POSTSCRIPT.PREFER.LANDSCAPE indicates if the OPENIMAGESTREAM method should default the orientation of output files to LANDSCAPE. It can have one of three values: NIL, T, or ASK. NIL means prefer portrait orientation output, T means prefer landscape, and ASK says to bring up a menu to ask the preferred orientation if it wasn’t explicitly indicated in the OPENIMAGESTREAM call (with the ROTATION option). The default value is: NIL.

POSTSCRIPT.TEXTFILE.LANDSCAPE [InitVariable]

POSTSCRIPT.TEXTFILE.LANDSCAPE indicates if the printing of TEXT files (e.g. LISTFILES, ...) should force the orientation of output files to LANDSCAPE. The default value is: NIL.

POSTSCRIPT.BITMAP.SCALE [InitVariable]

POSTSCRIPT.BITMAP.SCALE specifies an independent scale factor for display of bitmap images (e.g. window hardcopies). Values less than 1 will reduce the image size. (I.e. a value of 0.5 will give a half size bitmap image.) The position of the scaled bitmap will still have the SAME lower-left corner (i.e. the scaled bitmap is not centered in the region of the full size bitmap image). The default value is: 1.

**HINT**

Setting POSTSCRIPT.BITMAP.SCALE to 0.96, instead of 1, will give cleaner BITMAP images on a 300 dpi printer. (This corrects for the 72 ppi imagestream vs. the 75 dpi printer, using 4x4 device dots per bitmap pixel.) Also, values of 0.24, 0.48 and 0.72, instead of 0.25, 0.5 and 0.75, will also give cleaner images for reduced size output. In general, use integer multiples of 0.24 for a 300 dpi printer.

POSTSCRIPT.TEXTURE.SCALE [InitVariable]
POSTSCRIPT.TEXTURE.SCALE specifies an independent scale for the display of bitmap textures. The value represents the number of device space units per texture unit (bitmap bit). The default value is 4, which represents each bit of the texture as a 4x4 block, so that textures are approximately the same resolution as on the screen (for 300 dpi output devices, such as the Apple Laserwriter).

The PostScript package extends the allowed representations of a texture, beyond 16-bit FIXP and 16x16 bitmap, to ANY square bitmap. (If the bitmap is not square, its longer edge is truncated from the top or right to make it square.) Use this feature with caution, as large bitmap textures, or sizes other than multiples of 16 bits square, require large amounts of storage in the PostScript interpreter (in the printer controller), and can cause limitcheck errors when actually printing.

Anywhere that a texture or color can be used on an imagestream or in the specification of a BRUSH, you can instead give a FLOATP between 0.0 and 1.0 (inclusive) to represent a PostScript halftone gray shade. (0.0 is black and 1.0 is white. Specifically, the value sets the brightness of the shade.) The value you specify will not be range checked, and will be passed directly through to the PostScript setgray operator. (E.g. you can pass 0.33 as the color to DRAWLINE to get a dark gray line with approximately 67% of the pixels in the line black.)

POSTSCRIPT.IMAGESIZEFACTOR

POSTSCRIPT.IMAGESIZEFACTOR specifies an independent factor to change the overall size of the printed image. This re-sizing affects the entire printed output (specifically, it superimposes its effects upon those of POSTSCRIPT.BITMAP.SCALE and POSTSCRIPT.TEXTURE.SCALE). Values greater than 1 enlarge the printed image, and values less than 1 reduce it. An invalid POSTSCRIPT.IMAGESIZEFACTOR (i.e. not a positive, non-zero number) will use a value of 1. The BITMAPSCALE function for the POSTSCRIPT printer type does NOT consider the POSTSCRIPT.IMAGESIZEFACTOR when determining the scale factor for a bitmap.

MISCELLANEOUS

The SCALE of a PostScript imagestream is 100. This is to allow enough resolution in the width information for fonts to enable TEdit to correctly fill and justify text.

The first time any PostScript imagestream is created (even if only to hardcopy a bitmap or window) the DEFAULTFONT is instantiated (unless a FONTS option was given to the OPENIMAGESTREAM, in which case the initial font for the imagestream will be set to that font, or to the CAR if a list).

The PostScript imagestream method for FILLPOLYGON uses the global variable FILL.WRULE as the default value for the WINDINGNUMBER argument. (This is the same variable which is used by the DISPLAY imagestream method for FILLPOLYGON.)

The PostScript imagestream method for OPENIMAGESTREAM (and, therefore, SEND.FILE.TO.PRINTER), supports an IMAGESIZEFACTOR option to change the size of the printed image. The IMAGESIZEFACTOR re-sizing is combined with the POSTSCRIPT.IMAGESIZEFACTOR to produce an overall re-sizing of the printed image. A HEADING option is also supported to give a running header on each page of output. The value of the HEADING option is printed at the top left of the page, followed by "Page " and the appropriate page number. They are printed in the
DEFAULTFONT (unless a FONTS option was given to the OPENIMAGESTREAM, in which case it will be that font, or to the CAR if a list).

The PostScript package is contained in the files: POSTSCRIPT.LCOM & PS-SEND.LCOM, with the source in the files: POSTSCRIPT & PS-SEND. The module PS-SEND.LCOM is required and will be loaded automatically when POSTSCRIPT.LCOM is loaded. It contains the function which is called by SEND.FILE.TO.PRINTER to actually transmit the file to the printer. It is, by its nature, quite site specific, so it is in a separate file to make modifying it for any site relatively simple. System record declarations required to compile POSTSCRIPT can be found in EXPORTS.ALL.

Including Other PostScript Operations

If you wish to insert your own specific PostScript operations into a PostScript imagestream, you can do so with the following functions:

**(POSTSCRIPT.OUTSTR STREAM STRING)** [Function]

POSTSCRIPT.OUTSTR outputs a string or value to the imagestream. **STREAM** must be an open PostScript imagestream. **STRING** is the value to output (STRINGP and LITATOM are most efficient, but any value can be output (its PRIN1 pname is used)).

**(POSTSCRIPT.PUTCOMMAND STREAM STRING1 ... STRINGn)** [NoSpread Function]

POSTSCRIPT.PUTCOMMAND is more general for sequences of commands and values. It calls POSTSCRIPT.OUTSTR repeatedly to output each of the **STRINGi** arguments to **STREAM**.

**(\POSTSCRIPT.OUTCHARFN STREAM CHAR)** [Function]

\POSTSCRIPT.OUTCHARFN is used to output the characters forming the text of a PostScript string (e.g. the argument to a show or charpath operator). **STREAM** is the open PostScript imagestream to output to, and **CHAR** is the CHARCODE of the character to output. The / (slash), ( and ) (parenthesis) characters will be quoted with /, and characters with ASCII values less than 32 (space) or greater than 126 (tilde) will be output as /nnn (in octal). \POSTSCRIPT.OUTCHARFN will output the ( character to open the string, if necessary. Use POSTSCRIPT.CLOSESTRING (below) to close the string.

**(POSTSCRIPT.CLOSESTRING STREAM)** [Function]

POSTSCRIPT.CLOSESTRING closes a PostScript string (e.g. the argument to a show or charpath operator). **STREAM** is the open PostScript imagestream. It is important to use POSTSCRIPT.CLOSESTRING to output the ) character to close the string, because it also clears the stream state flag that indicates that a string is in progress (otherwise, the next POSTSCRIPT.PUTCOMMAND would output the commands to close the string and show it).

**Warning**
Do not attempt to create a PostScript font larger than about 600 points, as much of Interlisp’s font information is stored in SMALLP integers, and too large a font would overflow the font’s height, or the width for any of the wider characters. (I know that 600 points is a ridiculously large limit (about 8.3 inches), but I thought I’d better mention it, or someone might try it!)

Changes from the Lyric Release

The Medley release of this PostScript imagemstream driver changed the default value of POSTSCRIPT.TEXTFILE.LANDSCAPE from T to NIL. It also added the support for the HEADING option.

Known Problems/Limitations

The output generated for a PostScript imagemstream is rather brute force. It isn’t particularly careful to generate the smallest output file for a given sequence of operations. Specifically, it often generates extra end-of-lines between PostScript operator sequences (this has no effect on the printed output, only on the file size).

Using BITMAPs or Functions as BRUSH arguments to the curve drawing functions is not supported, nor is using a non-ROUND BRUSH with DRAWCIRCLE or DRAWELLIPSE.

There is no support for NS character sets other than 0, and there is no translation of the character code values from NS encoding to PostScript encoding.

There is no support for color.

\POSTSCRIPT.OUTCHARFN is pretty wimpy in its handling of TAB characters. It just outputs 8 SPACEs for the TAB.

I haven’t yet documented how to build the .PSCFONT files for any new fonts that become available, I’ll do that eventually.
This module fixes some bugs in software other than postscript. If you are going to load sketch, load it BEFORE you load this patch. If you load sketch after loading this patch, evaluate the following form in an Interlisp Executive:

\[
\text{(MOVD (QUOTE NEW-SK-PICK-FONT) (QUOTE SK.PICK.FONT) NIL T)}
\]

This will make the printing of sketches with text in them reasonable.
The module PS-RS232 defines a printing host named PS-RS232 which sends PostScript output to a printer over the (RS232) port of the 11xx. It also puts a function onto AROUNDEXITFNS which reinitializes the (RS232) port after returning from LOGOUT. The BaudRate and other parameters of the (RS232) port are controlled by the following variables.

**VARIABLES**

PS-RS232-BAUD [InitVariable]

This is the BaudRate for the (RS232) port output stream. Defaults to: 9600.

PS-RS232-DATABITS [InitVariable]

This is the BitsPerSerialChar for the (RS232) port output stream. Defaults to: 8.

PS-RS232-PARITY [InitVariable]

This is the Parity for the (RS232) port output stream. Defaults to: NONE.

PS-RS232-STOPBITS [InitVariable]

This is the NoOfStopBits for the (RS232) port output stream. Defaults to: 1.

PS-RS232-FLOWCONTROL [InitVariable]

This is the FlowControl for the (RS232) port output stream. Defaults to: XOnXOff.
UPCSTATS

By: Larry Masinter (Masinter.pa@Xerox.com)

INTERNAL

This document last edited on 11 October 84

UPCSTATS is for gathering statistics about where Dorado microcode is spending its time. (It only
works on Dorados.) It samples the microcode’s PC while running something, and then plots it in a
histogram. It really doesn’t help much unless you are familiar with the organization of the Dorado
Interlisp-D microcode, and want to analyze it.

(UPCSTATS form dolistflg) [Function]

will EVAL form while gathering statistics, and then print out a histogram. If dolistflg is NIL, the output
will go to the current output file (NIL). The first time you run UPCSTATS, it will ask you for the name of
a ".MB" file. This is a Dorado Microcode Binary, and you need to get the version of "DoradoLisp.MB"
that corresponds to the "DoradoLispMC.EB" that is on your local disk. Normally this is on the "Basics"
release subdirectory.

Once you’ve done a UPCSTATS, you can print the output again, merely by calling (PLOTPCS).

SAMPLE OUTPUT:

Microcode PC Sample: Each * = 11 count, or .03%

The following notes explain my (woz) idea of what the edit-interface should be responsible for, and what constitutes and "editor".

An editor is a symbol who’s function takes the args (structure props options) and starts an interactive editor on the structure. PROPS is a property list, and OPTIONS is a list of keywords, both affecting the behavior of the editor. The property :completion-fn specifies the function to be called when the user completes the edit. The completion-fn will be called with the arguments (structure props options changed?), where structure is the edited structure (even on abort, so that the edit interface could implement "undo abort"), props and options are as specified on the call to the editor and will be used to figure out what to do with this completion, and changed? is NIL (no changes made), T (changes made), or :ABORT (user wants to abort changes). It is then up to the completion function to do the right thing with the result of the edit.

The goal is that the editor doesn’t know anything about who started it, where the structure came from, or what to do with it when it’s done. And the edit-interface doesn’t know anything about the editor’s data structures.

In the case of open edit sessions (open or shrunk):
If the editor is told to start an edit, the editor must look for one already existing that matches (this can’t be the responsibility of the edit interface, because it doesn’t know about existence of open edits). the editor should restart the existing edit, processing any new props or options appropriately.

The markaschanged issue:
Since the editor knows it may have open edits, it needs to provide a hook for when the world gets changed underneath the editor. in this world this means markaschanged. in this case the editor should try to restart itself with the new structure. in other words, sedit::markaschangedfn should call edit-definition to start a new edit. the editor will then notice it has a matching edit open and restart itself with the new info.

This model is complicated by the fact that markaschanged gets called as a result of completion. Presently *ignore-changes-on-completion* controls the behavior in this case. Ideally, the editor would just say "i know it got changed, i just changed it!", and it would ignore the call.

The new version of SEdit (1/25/91) is very close to this definition, with the following exceptions, which can be fixed upon implementation of this edit interface design:
- the completion-fn is called with (context structure changed?) since all of SEDITE’s completion-fns expect these args. this should be fixed in handle-completion.
- in the abort case, undo is run until there are no more changes to undo, since sedit is sometimes handed structures "in place", destructive edits need to be undone, and thus the completion-fn never gets to see the edits. this can be fixed in the function complete.

To make this editor active, call (il:editmode editor-name), where editor-name is the symbol defined above. The function xcl::edit will then start the active editor.

xcl::edit-expression provides an example of starting the editor on an unnamed structure, where eqness is expected upon completion.

xcl::edit-definition provides a replacement for il:editdef, if il:getdef and il:putdef work correctly on all types.
:dontwait

the editor (sedit) should not wait. don’t wait is part of the editinterface features. if its going to wait, the editinterface should create the event and bind it in the completionfn to the notified by the completionfn.

need published edit-expression command. same as ed, but takes and expression, waits for once-only completion, and returns the expression. eg for FIX

sedit should provide a published interface to creating gaps, for use by make-prototype-defn.
edit interface may need a way to ask editor if it has an open edit for name/type

deal with editdates

an editor used to install itself by replacing EDITL and EDITE, then editmode was created to look for Definition-for-EDITE property on the symbol returned by editmode. now an editor is defined as a function which takes (expr props options) and implements at least the props :completion-fn and :root-changed-fn. EDITMODE then returns the name of this function so the current editor can be applied.
Notes on making a Sun Loadup

update Jan. 25, 1990 by osamu

In a medley sysout on cottonmouth do the following:

-- Now, if you are on the "loadup" machine, exit medley and go to another
-- machine. RLOGIN to the loadup machine and do the following:

-- Build an init-specific lde note: you must have a directory under
-- the maiko directory called init.ARCH where ARCH is the architecture
-- of the machine you will run the lde on. On a sun4, it would be init.sparc.

cd ~/maiko/bin
makeinitlde -e

-- connect back to your home directory and make a link to the lde and
-- ldeether (fill in yourname and machine os and arch in the proper
-- slots below

cd ~
ln -s /users/YOURNAME/maiko/init.ARCH/lde
ln -s /users/YOURNAME/maiko/init.ARCH/ldeether

-- make sure you don't have LDEDESTSYSOUT set as you want the sysout on your
-- directory.
-- You will need dbxinit.txt available
-- YOU MUST USE A FRESH COPY OF XREM.CM EVERY TIME YOU TRY THIS AS IT
-- GETS SMASHED AT STARTUP

```
cp ~/XREM.CM ~/REM.CM

-- start lde under dbx
-- init lde can’t treat ‘LDEDESTSYSOUT’
unsetenv LDEDESTSYSOUT

```

```
dbx lde

-- load the dbxinit
source /users/maiko/working/bin/dbxinit.txt

-- now set up to stop on error (before URAID, which loses ‘cause
-- it can’t find the keyboard.)

err

```

```
run ~/INIT.DLINIT -INIT -NF

-- this is going to run and eventually log itself out. when dbx returns, quit
-- from dbx and presto! You’ve built the beginnings of a loadup.

---

-- go to the loadup machine and connect to the place where you normally
-- get your lde from

cd ~/maiko/sunos4.sparc/

-- Get the new REM.CM: (YOU MUST DO THIS EVERYTIME AS
-- REM.CM gets wasted on startup!!)

```

```
cp ~/LOADUP-REM.CM ~/REM.CM
ldeether

-- Now this is going to march happily through loading files. When it turns
-- on the windowworld, you may have to hit the space bar to make it continue.

-- I don’t know how to make PUP and LEAF load at this point, but I’m working
-- on it.

-- I am also working on integrating the changes to the emulator with the
-- latest
-- stuff.

-- closure caching is still off.

-- Questions or comments?

BACKGROUND-MENU-BUTTONS

By: Doug Cutting (Cutting.PA@Xerox.COM)

This document last edited on January 28, 1988.

INTRODUCTION

BACKGROUND-MENU-BUTTONS makes it easy for the Rooms user to make buttons which do the same things as entries on the background menu.

EXPLANATION

When this module is loaded a button labelled "Make Background Button" is placed on the screen. When this button is pressed a menu which looks just like the background menu is raised. Selecting an entry from this menu will create a button which does the same thing as this entry.
September, 1988

Dear ROOMS User:

Attached is the documentation for the Rooms User’s modules.

Note that most of these modules include source code. Thus besides being useful in themselves, these modules provide good examples of programmatic use of ROOMS.

Rooms User modules are user-contributed software, and as such are not supported Envos products. We merely distribute these modules in hope that they will prove useful.

Please direct questions, suggestions and problems with Rooms User’s modules directly to their authors. We have included the ARPAnet addresses of the authors in the documentation for this purpose.

We encourage you to contribute more Rooms User’s modules. The same policies which apply to Lisp User’s modules apply here. For more information see the Lisp User’s guidelines distributed with the Medley release.

INTRODUCTION

>>This paragraph should be replaced by an overview of your module.<<

MODULE EXPLANATIONS

>>Functions, Variables, and Lisp Code Examples<<

It is usual to first give the name of a function, then describe its purpose and each of its arguments. When the name of a function is first given, it is set off like this:

(IMAGEFNSCREATE DISPLAYFN IMAGEBOXFN PUTFN GETFN COPYFN)  [Function]

The function name is in 10-point regular Modern, all caps. Arguments are in 10-point italic Modern, in all caps, mixed case, or lowercase, as they appear in the system. Variables look like functions, except that the word “Variable,” enclosed in square brackets, follows the variable name. Please note that these are the characters [], not the parentheses.

This is an example of code. It is in 10-point Terminal font.

Function names, commands, file names, and the like are in 10-point modern.

Be sure to include the following information in any module explanations:

• any file dependencies
• definitions of all arguments
• module, function variable, etc. limitations
• a liberal number of examples for all functions, variables, etc.
HYPERDESK and HYPERDESK-INIT

The HyperDesk (or "MobyDesk") sysout is a "Swiss Army Sysout" that includes much of the best local functionality. This includes Sketch, DictTool, PCL, CommonLens, Rooms, and Notecards. The HyperDesk-INIT file provides a powerful init file for HyperDesk Users as well as those that may use other sysouts but would like convenient access to HyperDesk functionality. This Init file can make life easier for those who don’t hack their own init files by making it easier on those that are called in to do so. A reasonable goal is that users of this class wouldn’t need separate init files and instead will be able to tailor their environment through a control panel and automatic profile saving.
HYPERDESK

The HyperDesk.SYSOUT is available from <LISP>LYRIC>BASICS> on your favorite Lisp Servers (i.e. IE: and PHYLUM). It contains the SKETCH, DICTTOOL, ROOMS, PCL, COMMON-LENS, and NOTECARDS.

\CC-HYPERDESK-MSG [Variable]

When HYPERDESK is greeted, it automatically sends a LAFITE message to the maintainer. By default this message is CC’ed to the person using the sysout; this CC’ing can be disabled by setting the variable \CC-HYPERDESK-MSG to NIL in the users Init File.

Loading HYPERDESK-INIT

The HYPERDESK-INIT file is available to PARC users of the Lyric release of Xerox Lisp. It can be found on the directory {EG:PARC:<RAO>HYPERDESK}. Including the file command

(FILE (FROM LISPUSERS) "HYPERDESK-INIT")

in your personal INIT file will automatically load HYPERDESK-INIT when you start up a new Lisp.

HYPERDESK-INIT is essentially wrapping around GENERIC-INIT, so users of HYPERDESK-INIT should understand the essentials of GENERIC-INIT. Documentation for it is available from {EG:<LANNING>LISP>USERS>GENERIC-INIT.TEDIT}. Both of these centralized init files set variables and invoke operations that tailor the environment. Much of this behavior can be controlled or preempted by setting user parameters or special control variables either before or after the load of HYPERDESK-INIT. Two variables, LOGINHOST/DIR and HOME-MACHINE-NAME, must be set before the load of HYPERDESK-INIT (or at least setting them should be considered explicitly). These are used as control variables to GENERIC-INIT and are documented there.

An example of a minimal init file can be found on {EG:<RAO>HYPERDESK>LYRIC-INIT. Any of these INIT files (HYPERDESK-INIT, GENERIC-INIT, LYRIC-INIT, my {EG:<RAO>LISP>INIT-LYRIC or Stan’s {EG:<LANNING>LISP>LYRIC-INIT) can be
loaded prop into your sysout without any thing happening so you can see what would happen. The one caveat is that they will smash filecoms of files with the same name.

Tailoring HYPERDESK-INIT

There are a number of variables that can be set before and after loading HYPERDESK-INIT to tailor its behavior to ones liking. In addition, users can also tailor GENERIC-INIT by setting variables documented in the GENERIC-INIT documentation. A few of the GENERIC-INIT variables (*LOAD-UTILITY-OPTIONS*) are used by HYPERDESK-INIT, so users should use the variables provided by HYPERDESK-INIT as described below before resorting to GENERIC-INIT variables. Unless otherwise noted, all symbols described are in the INTERLISP package.

Things you MAY do before loading

*HYPERDESK-FULL-INIT-P* [Variable]
When HYPERDESK-INIT is loaded, it will ask if it should do a full initialization. By default this message will time out, set this variable and continue to a full initialization. This is especially convenient for starting non-hyperdesk sysouts where you don’t want to wait for special status hyperdesk functionality to be loaded.

*HYPERDESK-BASE-MODULES* [Variable]

*HYPERDESK-MODULES* [Variable]

*HYPERDESK-EXTRA-MODULES* [Variable]
These variables control what modules are loaded automatically by GENERIC-INIT. HYPERDESK-INIT initvars *LOAD-UTILITY-OPTIONS* to the append of these three variables in the order listed. *HYPERDESK-MODULES* is initilized to the special status hyperdesk modules (ROOMS, PCL, and COMMON-LENS, and a bunch of window types for ROOMS) unless *HYPERDESK-FULL-INIT-P* is NIL in which case *LOAD-UTILITY-OPTIONS* will not be touched. Note that these should all be lists of strings where the strings are the name of the package as seen on the Load Utility Menu (i.e. the name of the top level or only file of the module e.g. LoadPCL or COMMON-LENS). See GENERIC-INIT *LOAD-UTILITY-OPTIONS*.
HYPERDESK

*HYPERDESK-SUITES-P*  [Variable]

*HYPERDESK-AX-POCKETS-P*  [Variable]

*HYPERDESK-AX-ORIGINAL-P*  [Variable]

*HYPERFLOOR-SUITE-P*  [Variable]

*HYPERDESK-SUITE-P*  [Variable]

*HYPERDESK-USER-SUITES*  [Variable]

HYPERDESK-INIT provides some mechanisms for setting up initial suites. Setting *HYPERDESK-SUITES-P* to NIL will disable this facility altogether. Setting *HYPERDESK-AX-POCKETS-P* and *HYPERDESK-AX-ORIGINAL-P* to NIL will disable deletion of POCKETS and ORIGINAL rooms respectively. Setting *HYPERFLOOR-SUITE-P* and *HYPERDESK-SUITE-P* to NIL will disable loading of these two default suites respectively (note that disabling HYPERFLOOR suite will also disable the HYPERDESK Suite). Finally *HYPERDESK-USER-SUITES* should be a list of fully qualified file names that determine which suites get loaded initially.

HyperFloor and HyperDesk Suites

HyperFloor and HyperDesk Suites provide a basic framework for working with Rooms and other HyperDesk functionality.

HyperFloor provides three rooms: HyperPanel which is basic inclusion room, Help where eventually various buttons for getting documentation will be put, and the Boiler Room where buttons for fixing things and dealing with the HyperDesk in general will be put. One particularly important button in the Boiler Room is one that allows you to reload the HyperFloor so you can import any recent additions to the Boiler or Help Rooms.

HyperDesk provides two rooms: Mail Room and Office. Users should copy these rooms to make suites of their own and avoid working in these if they want to build their own suite.
INTRODUCTION
This module provides window types for Lafite windows. Lafite is the Interlisp-D mail program. Loading this module enables you to save Lafite windows in your suite files.

EXPLANATIONS
We provide window types for Lafite browsers and for the Lafite status window.

Note: we do not provide window types for message windows, as these are far more transient than the status window and browsers.
INTRODUCTION

This is a sample suite file.

Beginning Rooms users might load this, augment it as desired, and then use the “Dump Suite” command to save their own version of it.

This suite also gives some ideas about how one might use the facilities which Rooms provides.

INSTALLATION

Load the file OFFICE.SUITE. This file (like all suite files) will load ROOMS if it is not already loaded. It will then create the rooms in the OFFICE suite. Use the Overview to see these rooms.
This module contains window type definitions for many LispUsers modules.

These definitions serve two purposes. Their primary purpose is to allow one to save windows created by these modules in suites. Secondarily they provide good examples of window type definitions for the programmer attempting to define his own.

Modules covered are:

WHO-LINE
CALENDAR
PRINTERMENU
CROCK
BICLOCK
ADDRESSBOOK
PHONE-DIRECTORY
GRID-ICONS

In addition, support is provided for the FILEWATCH LispUsers module. This works by adding a property to each room which notes whether FILEWATCH is on in that room. This property is not inherited, i.e. including a room in which FILEWATCH is does not turn FILEWATCH on.

A listing of RANDOM-WINDOW-TYPES can be found in Appendix A of this document.
Interrupted
Overview

ROOMS is a powerful interface to the Medley lisp environment window management system. ROOMS effectively increases the size of the screen and allows you to organize the work environment to facilitate management of complex parallel tasks.

For example a user may be developing and debugging a program, writing a paper, doing background research, reading mail, and filing all more or less at the same time. With limited screen space a user performing all these activities loses productivity shuffling through windows, icons, and other assorted screen clutter in order to reestablish the context of a task. ROOMS solves this problem of context switching by allowing users to create workspaces (called rooms), each one analogous to another screen, and containing only those tools needed for a specific task. Moreover, ROOMS provides methods for easily moving from one room to another and customizing the "look" of each room further aiding in efficient task-switching.

By providing dedicated workspaces, ease of navigation between workspaces, and a graphical link between each workspace and its related task, ROOMS helps users minimize context recovery time caused by task switching. In addition ROOMS provides an easy means to develop highly graphical custom interfaces for end-user applications. The overall result of this seamless integration of form and functionality is increased productivity in performing tasks in the Envos Software Development Environment.
Research Background

The ROOMS system design resulted from the following observations by members of the Xerox Palo Alto Research Labs:

1) Most intellectual work requires coordinating many sources of information, e.g. notes, drafts, spreadsheets, program listings, etc.

2) Before the widespread dissemination of desktop workstations and personal computers, knowledge workers typically spread paper containing these items out on a desk (or dining room table). But the small screens of computer workstations do not allow such a lavish use of space when working on many concurrent tasks. For example, it takes 22 average PC screens or 10 19” workstation screens to equal the area of a typical desk.

3) The result for overlapped windows systems is a kind of electronic messy desk, where the user spends large amounts of time moving, shrinking, and resizing windows in order to switch tasks.

4) An interface designed to assist a user to work on concurrent tasks rather than assume linear work habits would have the following features:
   - Fast task switching and fast task resumption
   - Easy to re-acquire mental task context
   - Access to a large amount of information
   - Fast Access to information
   - Low user overhead
   - Engaged tools shareable among several tasks
   - Collections of engaged-tools shareable among tasks
   - Task-specific presentation of shared-engaged tools.

How Envos’ implementation of ROOMS accomplishes these goals is described in the next section “The ROOMS Design”.

The ROOMS Design

Rooms solves the problem of user task switching by allowing users to create a number of screen-sized workspaces called Rooms. The figure below shows two Rooms.

Two example Rooms (a) used for programming and (b) used for reading mail
In each room, there are a number of small icon-like objects called Doors. When a door is selected with the mouse, the user has the illusion of transiting to a new room containing windows. Each room is related to a different major task, such as working on a particular project, reading mail or file management. In the room are a number of engaged tools related to the task. When a user re-enters a room it appears exactly as when it was left.

The basic notion of the Rooms scheme is simple. But in order for this basic notion to be successful the ROOMS system design has many features to help manage window interaction among rooms and to keep the user from getting lost.

**Task Interaction**

When working in ROOMS, there are usually a number of engaged tools that the user wants to share among different tasks. Examples of these might include a code editor, a text editor or a clock. The following ROOMS design features allow for the sharing of engaged tools:

**Placements**  
A window in a room has a specific location and shape. This is known as a Placement. The same window can exist in several rooms, with different locations, shapes, etc., in each room. Actions done on a shared window in one room are reflected in another room. Note that the black promptwindow in the Mail and Project rooms has a different location and shape in each room.

**Inclusions**  
Rooms can be included within other rooms. This allows collections of rooms to share a common set of windows, known as Inclusions. The band of windows and icons common in both parts of the Mail and Project rooms is a control panel, shown below, implemented as an included room.

![Example of an included room called Office Panel](image)

**Baggage**  
When moving between rooms you may carry windows with you. For example, you may wish to bring program code from one workspace to a workspace where you are doing documentation. This is accomplished by holding down the Move or Copy key when selecting a door. You will then be prompted to select the windows you wish to carry with you to the next room. The windows will have the same presentation in the new room.

**Pockets**  
You can also have a constant piece of baggage called a Pocket. A Pocket is a room dynamically included in all rooms. Whichever windows are placed in your Pocket (a clock say) will automatically occur (at the same location and presentation attributes) in all rooms.
Navigation

The organization of the user’s workspace into a number of workspaces creates a potential navigational problem. ROOMS solves this problem with a number of navigational aids.

Doors
Doors provide the basic link mechanism between rooms. Selecting a door with the mouse “moves” you to the new room containing windows associated with that room.

Back Doors
Rooms allows you to create a Back Door in a room. If you have created a Back Door you can easily move back to the task you were previously working on before you entered the present room.

Rooms Menu
Selecting the Go To Room sub-item from the ROOMS background menu presents you with a list of Room names. Selecting one will move you to that Room.

Overview
The main feature of the Overview is a set of Room pictographs as shown in the opening diagram. From the Overview you can see the overall layout of a room and the tools it contains. The room pictographs can be instantly expanded one at a time, allowing you to browse through the windows in the entire set of rooms. In addition you can enter any room directly via the Overview.

Tailorability

Several mechanisms are provided to help users tailor rooms. First, simply creating, moving, deleting and shaping windows in the usual way causes things to exist in rooms. Thus ROOMS preserves the natural interaction with the user. Second, special background entries are provided to allow the user to create new doors and other conveniences of construction. Below is an example of the standard set of Doors available to users.

At the Overview level, it is possible to copy, move or delete window pictographs within a room and between rooms and have the changes reflected in the rooms themselves. And finally, Rooms has a simple layout language for creating unique backgrounds for Rooms. By using the structure editor, SEdit, on this layout language, users can run arbitrary procedures on the entrance and exit of a room and can compute
specialized backgrounds for rooms. Below is an example of a SEEdit of a rooms layout expression for the Project room shown earlier.

```
SEEdit Project Package: XCL-USER
( :INCLUSIONS ("Office Panel") :BACKGROUND
  ( ( :REGION (0 1/4 1.0 3/4) :SHADE
      ( :EVAL ROOMS:RENAISSANCE-BITMAP)
      :BORDER 2 )
  ( :TEXT "Project" :FONT
    ( IL:HELVETICA 36 IL:BOLD)
    :POSITION (10 , 10)))
```

**Suites**

Having designed an environment to suit your needs, ROOMS allows you to restore that state if there is a need to reload your system. Subsets of rooms can be grouped together to form Suites. Suites can be saved to a file and later restored to a new environment or shared with other users. Most system windows have a ROOMS window-type specification which allows them to be saved and restored from a suite. Thus a Filebrowser window that you have open on a particular system can be saved and the window placement and contents will be restored when you reload the suite onto a new system.

**Buttons**

Buttons are a unique user-interface device that provides for the execution of any lisp command at the click of the mouse. Buttons can be of any shape and size. Doors are examples of buttons that move you from one room to another. For example selecting the following button will perform a directory listing of the local disk.

```
Directory
```

The button definition is shown below:

```
SEEdit Directory Package: XCL-USER
( :TEXT "Directory" :FONT
  ( IL:HELVETICA 12
    ( IL:BOLD IL:REGULAR
      IL:REGULAR))
  :SHADOWS :ARK :TYPE :STRETCHY-ROUND-ARK
  :HELP "Bring up local disk directory"
  :ACTION (DIR "{dsk}\lisp\files")
  :INVERTED? NIL)
```

**Customization of Rooms**

When used as the interface to an application, ROOMS provides you with a complete programmatic interface to allow application specific customization. This includes the ability to have applications create and switch rooms under programmatic control as well as enable users to design custom buttons and window-types.

Mountain View, California 94043
(415) 966-6200

ROOMS is a trademark of Xerox Corporation
ROOMS is licensed to Envos by Xerox for use in the Envos Software Development Environment
This document describes the rules and procedures for "Rooms Users" modules. This document is mainly for Rooms Users’ module writers, but users should also understand the rules.

DEVELOPING A ROOMS USERS’ MODULE

A Rooms Users’ module is a useful program made available to the general Rooms community. Neither the author nor the custodian of Rooms Users’ imputes any warranty of suitability or responsibility for errors.

Rooms Users’ modules should be easily distinguishable from released library and Lisp Users’ modules. In particular, this means that a Rooms Users’ module may not have the same name as a Library or Lisp Users’ module and should be visibly different. Rooms Users’ modules derived from released software should be announced to the public only after communicating with the organization responsible for that released software.

Testing is important. If you make significant changes to a Rooms Users’ module, enlist users at your site as alpha testers. A Rooms Users’ module is not shoddy software; it is software made available outside the regular release channels.

ROOMS USERS’ MODULE OWNERSHIP

A module submitted for Rooms Users’ remains the “property” of the submitter. Others may not make changes, except for their own private use, without negotiating with the owner (who may already be making similar or incompatible changes).

As the owner of a module, you are not required to fix bugs, but if not, you must be willing to transfer ownership (permanently) to someone who volunteers to fix them. Ownership may pass back and forth among several people as long as they agree.

SUBMITTING ROOMS USERS’ MODULES

If you are not an internal user, you should submit your new module to us through e-mail or on a floppy or tape. External users should make sure that they include all relevant information, such as documentation containing an e-mail or US mail address where he/she can be reached.

SUBMITTING FILES TO ROOMS USERS’

As with released software, it is important to submit not just the resulting product, but all the files needed to build and maintain a Rooms Users’ module:

1. the file to load (.LCOM or .dfasl or .SUITE)
2. documentation describing it, following the formatting rules (see below)
3. a source file that can be released (optional)
4. data files, if needed

Modules submitted once are released once. Do not assume that a module submitted for one release will be automatically released in subsequent releases.
DOCUMENTATION

No modules will be released without documentation. Documentation can be as simple as a paragraph describing what the module does and how to use it, or it can be as extensive as a dozen-page user manual. All modules should have a file with a .TEDIT extension. Formatting should be done according to the rules outlined in the Rooms Users' Template, included on the Rooms Users floppy or tape as EASYTEMPLATE.TEDIT and also printed in this document. All users, external users included, should follow the Rooms Users' Template rules. If the documentation is large and formatting time consuming, you can also produce an interpress file (with the .ip extension), as well as submitting a .TEdit file. (Be sure to update the interpress file if you update the documentation!) Documentation should include the full address of the submitter.

COMPATIBILITY

Any submitted Rooms Users' files should be compilable in a "vanilla" Rooms environment. The file itself should load in any auxiliary modules when necessary.

Thanks for your cooperation.

TOUCHY BUTTONS

By: Ramana Rao (Rao.pa)

Uses: Rooms

INTRODUCTION

This Rooms Users Package provides a number of “touchy” buttons i.e. buttons that visually depend on
the state of the world and change the state of the world when touched. Right now I provide three types
of touchy buttons: includer, toggler, and once-only. You can make a touchy button by calling
rooms::make-<touchy-type>. I will take suggestions for any others that people think may be useful
since I’m trying to abstract the touchy technology.

BUTTON CONSTRUCTORS

(ROOMS::MAKE-INCLUDER ROOM-NAME) [Function]

Includers allow you to conveniently mixin or mixout rooms. For example, you can have "Notecards-
Mixin" and "Programming-Mixin" Rooms and have includer buttons in your personal "Pockets.” Then
you can include these functionality traits whenever you need them no matter the room.

(ROOMS::MAKE-TOGGLER VARIABLE-NAME) [Function]

Toggle buttons allow you to toggle boolean variables. This should obviously be generalized to
something that allows you to select or circulate through value settings.

(ROOMS::MAKE-ONCE-ONLY FORM INITIAL-TEXT FINAL-TEXT) [Function]

A once-only button evaluates a form exactly once in a sysout and then displays that it is exhausted.
For Example:

(ROOMS::MAKE-ONCE-ONLY (IL:PROMPTPRINT "Hello, World") "Fire..."
"Exhausted")
ROOMS changes the window system such that open windows are not always visible. Some applications presume that open windows are visible. This module attempts to amend this situation.

Often when an application decides to start using a window which is not visible it gives that window the caret. CHAT is an example of such an application. When IL:CLOSECHATWINDOWFLG is NIL (the default) CHAT windows are left open after their connection is closed. If one leaves such a CHAT window in another room and then attempts to open a CHAT connection, CHAT will merrily re-use the hidden window. But as CHAT takes the caret when it opens a connection, we can identify that window and pull it into the current room.

(ROOMS:UN-HIDE-TTY) [Function]

If the window with the caret is not in the current room, it is brought into the current room with a call to ROOMS:UN-HIDE-WINDOW. If the window with the TTY is already visible on the screen then it is flashed. If there is no TTY window (i.e. the process with the keyboard has no TTY window) then a message to this effect is printed to the prompt window.

One can use this function in the action of a button, e.g.:

(ROOMS:MAKE-BUTTON-WINDOW
  (ROOMS:MAKE-BUTTON :TEXT "Un-Hide TTY" :ACTION '(ROOMS:UN-HIDE-TTY)))

Control-Y [Interrupt]

Brings the window with the caret into the current room by calling ROOMS:UN-HIDE-TTY. This interrupt is installed when UN-HIDE-TTY is loaded. This will not work with applications which have their own interrupt tables, e.g. TEdit and CHAT.
INTRODUCTION

ROOMS User's modules are written by users of Envos ROOMS. They are supported by the individuals who wrote them, not by Envos. Envos takes no responsibility for the reliability and maintenance of these modules.

Each module is documented, some in detail, others with only enough information to get the user started. At the top of each document, the name of the author is written, along with his electronic mail or U.S. mail address. Please contact the author with any problems you may have.

Note that most of these modules include source code. Thus besides being useful in themselves, these modules provide good examples of programmatic use of ROOMS.

This document contains explanations of each module, written by the author of each. It also contains an explanation of how to submit your own ROOMS User' module. Please read these instructions carefully if you wish to submit a module.
WALLPAPER

By: Doug Cutting (Cutting.PA@Xerox.COM) and Larry Masinter (Masinter.PA@Xerox.COM)

Uses: SCREENPAPER

INTRODUCTION
This module provides an easy way to create distinctive backgrounds for your rooms.
All symbols described in this document are in the package ROOMS.

FUNCTIONS

(MAKE-WALLPAPER-WINDOW &OPTIONAL REGION) [Function]
Makes and returns a Wallpaper window. When the LEFT or MIDDLE mouse button is pressed over Wallpaper windows the user is asked to select a tile size, then a position for the tile. Positions are selected with the LEFT button. Each tile is displayed in the window. If the user presses the MIDDLE button then the background of the current room is changed to be the current tile. The user can abort this process at any time by pressing the RIGHT mouse button.

There is a window type definition for Wallpaper windows so they may be saved in Suites.

(HACK-BACKGROUND SHADE &OPTIONAL ROOM) [Function]
Changes the first background shade specified for ROOM to be SHADE. If ROOM does not paint the background then this function adds a command to the background specification for ROOM which paints the whole screen with SHADE. ROOM defaults to the current room.
New architecture for character input-output and alternative external formats

Ron Kaplan, May 2021

The Medley system was built with the Xerox Character Coding standard as the target for multi-byte input and output and for the internal mapping of character codes to glyphs.

This is now quite out of date, and our goal is to move to more modern conventions like Unicode and UTF-8.

The coding conventions are embodied in macros that test a stream to see if it is XCCS, and to do special open-coded processing (often with the help of locally bound variables for encoding information) if it is.

If it isn’t XCCS, then the macros instead apply functions that are obtained from fields in the stream. This is optimized for the default XCCS set up because in that case a separate function call is avoided, the action itself is open coded.

The new architecture recognizes that there may be an advantage to specifying a system default for character processing that avoids function calls but that doesn’t depend on support (binding of special variables as opposed to accessing stream fields on each call) to get that last measure of efficiency.

Thus, there are 4 generic macros corresponding to the 4 character IO operations:

\INCCODE
\OUTCHAR
\BACKCHAR
\PEEKCCODE

Each of these is defined to fetch a corresponding field from the stream (OUTCHARFN, INCCODEFN, PEEKCCODEFN, BACKCHARFN). If that field is NIL, then each of these passes to a corresponding default macro:

\DEFAULTINCCODE
\DEFAULTOUTCHAR
\DEFAULTBACKCHAR
\DEFAULTPEEKCCODE

These default macros can then be redefined to make a wholesale switch of the default encoding standard.

The macro \OUTCHAR, for example, is defined as

if the stream has an OUTCHARFN, apply it. Otherwise do the \DEFAULTOUTCHAR
and so on for each of the others.

For the current XCCS default, \DEFAULTOUTCHAR is defined to call \XCCSOUTCHARFN.

The corresponding stream fields can be set directly, but the preferred interface is to wrap up the 4 functions for a given format in an EXTERNALFORMAT datastructure. The function

(\EXTERNALFORMAT stream formatname)

applies the information in the format into the stream. A particular (non-default) format can be specified as an optional parameter when a stream is opened, and each file device can have its own default external format. Then there is also a variable that holds the name of the name of the system-wide default, currently :XCCS.
If the default external format is applied to a stream, the relevant function fields are set to NIL to kick off the default macro for that particular function, otherwise the function is copied from the external format to the stream.

An external format has the following fields:

- NAME
- INCCODEFN
- PEEKCODEFN
- BACKCHARFN
- OUTCHARFN
- EOL

The function (\INSTALL.EXTERNALFORMAT format) registers the given format under its name, so it can be retrieved when the name is given to \EXTERNALFORMAT.

If EOL is not NIL, then it is an end-of-line convention that will override whatever a stream might have had by default. (The value of EOL is one of the constants LF.EOLC, CR.EOLC, CRLF.EOLC.)

The system now includes external formats for
- :XCCS   (the global default)
- :THROOUGH   (untransformed bytes)

It probably would make sense to also include a :KEYBOARD external format, to generalize that as well.

UNICODE defines external formats for UTF8 with or without character translation, and also UTF16 (big-end and little-end). When we finally make the swap, we would make :UTF8 be the default, redefine the macros, and recompile all the callers.

The Japanese external formats that used to be included in the basic system are now provided by a JAPANESE in the library.

Finally, there is another macro \INCHAR that applies \CHECKEOLC to the result of \INCCODE.
Free Menus are powerful and flexible menus that are useful for applications that need menus with different types of items, including command items, state items, and editable items. A Free Menu lives in a window, which can be opened and closed as desired, or attached as a control menu to the application window.

Making a Free Menu

A Free Menu is built from a description of the contents and layout of the menu. As a Free Menu is simply a group of items, a Free Menu Description is simply a specification of a group of items. Each group has properties associated with it, as does each Free Menu item. These properties specify the format of the items in the group, and the behavior of each item. The function FREEMENU takes a Free Menu Description, and returns a closed window with the Free Menu in it.

Probably the easiest way to make a Free Menu is to define your own function which calls FREEMENU with the Free Menu Description right there in your function. This function can then also set up the Free Menu window as required by the application. The Free Menu Description is then saved as part of your function when you save your application.

Alternatively, you can save the Free Menu Description as a variable in your file, and then just call FREEMENU with the name of the variable. This may be a more difficult alternative if you want to use the backquote facility to built your Free Menu Description. See the section Free Menu Item Descriptions.

Free Menu Formatting

A Free Menu can be formatted in one of four ways. The items in any group can be automatically layed out in rows, in columns, or in a table, or else the application can specify the exact location of each item in the group. Additionally, Free Menu keeps track of the region that a group of items occupies, and items can be justified within that region. This way an item can be automatically positioned at one of the nine justification locations, top-left, top-center, top-right, middle-left, etc.

Free Menu Description

A Free Menu Description, specifying a group of items, is a list structure. The first thing in the list is an optional list of the properties of this group of items, in the form:

```
(PROPS <PROP> <VALUE> <PROP> <VALUE> ...)  
```
The key word PROPS determines whether or not the optional group props list is specified. The section Free Menu Group Properties describes each group property. For now, the important property is FORMAT. The type of formatting determines the syntax of the rest of the Free Menu Description, in a very simple way.

When using EXPLICIT formatting, the rest of the description is any number of Item Descriptions, which have LEFT and BOTTOM properties specifying the position of the item in the menu. The syntax is:

```
((PROPS FORMAT EXPLICIT ...) <ITEM DESCRIPTION> ...
```

When using ROW or TABLE formatting, the rest of the description is any number of item groups, each group corresponding to a row in the menu. These groups are identical in syntax to an EXPLICIT group description, with an optional PROPS list and then any number of Item Descriptions, except that the items need not have LEFT and BOTTOM properties, as the location of each item is figured out by the formatter. But the order of the rows and items is important. The menu is laid out top to bottom by row, and left to right within each row. The syntax is (the comments are not part of the description):

```
((PROPS FORMAT ROW ...) ; props of this group
 <ITEM DESCRIPTION> ; items in first row
 <ITEM DESCRIPTION> ...)

((PROPS ...) ; props of second row
 <ITEM DESCRIPTION> ; items in second row
 <ITEM DESCRIPTION> ...))
```

When using COLUMN formatting, the syntax is identical to that of ROW formatting. However each group of items corresponds to a column in the menu, rather than a row. The menu is laid out left to right by column, top to bottom within each column.

Finally, a Free Menu Description can have recursively nested groups. Anywhere the description can take an Item Description, it can take a group, marked by the key word GROUP. A nested group inherits all of the properties of its mother group, by default. However, any of these properties can be overridden in the nested groups PROPS list, including the FORMAT. The syntax is:

```
(<ITEM DESCRIPTION> ; first in row
 (GROUP ; nested group, second in row
  (PROPS FORMAT COLUMN...) ; optional props
  (<ITEM DESCRIPTION> ...) ; first column
  (<ITEM DESCRIPTION> ...))
 <ITEM DESCRIPTION>)) ; third in row
```
Here is an example of a simple Free Menu Description, for a menu which might provide access to a simple data base:

```
(((LABEL LOOKUP SELECTEDFN MYLOOKUPFN) (LABEL EXIT SELECTEDFN MYEXITFN))
 ((LABEL Name: TYPE DISPLAY) (LABEL "" TYPE EDIT ID NAME))
 ((LABEL Address: TYPE DISPLAY) (LABEL "" TYPE EDIT ID ADDRESS))
 ((LABEL Phone: TYPE DISPLAY)
  (LABEL "" TYPE EDIT LIMITCHARS MYPHONEP ID PHONE)))
```

This menu has two command buttons, LOOKUP and EXIT, and three edit fields, with ID's NAME, PHONE, and ADDRESS. The Edit items are initialized to the empty string, as in this example they need no other initial value. The user could click after the Name: prompt, type a person's name, and then press the LOOKUP button. This would cause the function MYLOOKUPFN to be called, which could look at the NAME Edit item, lookup that name in the data base, and then fill in the rest of the fields appropriately. Note that the PHONE item has MYPHONEP as a LIMITCHARS function. This function would be called when editing the phone number, in order to restrict input to a valid phone number. After looking up Perry, the Free Menu might look like:

```
LOOKUP EXIT
Name: Herbert Q Perry
Address: 13 Middleperry Dr
Phone: (411) 767-1234
```

Here is a more complicated example:

```
((PROPS FONT (MODERN 10))
 ((LABEL Example FONT (MODERN 10 BOLD) HJUSTIFY CENTER))
 ((LABEL NORTH) (LABEL SOUTH) (LABEL EAST) (LABEL WEST))
 ((PROPS ID ROW3 BOX 1)
  (LABEL ONE) (LABEL TWO) (LABEL THREE))
 ((PROPS ID ROW4)
  (LABEL ONE ID ALPHA)
  (GROUP (PROPS FORMAT COLUMN BACKGROUND 23130 BOX 2 BOXSPACE 4)
   ((TYPE NWAY LABEL A BOX 1 COLLECTION COL1 NWAYPROPS (DESELECT T))
    (TYPE NWAY LABEL B BOX 1 COLLECTION COL1)
    (TYPE NWAY LABEL C BOX 1 COLLECTION COL1))
   ((TYPE STATE LABEL "Choose Me" BOX 1 MENUITEMS (BRAVO DELTA)
     INITSTATE DELTA LINKS (DISPLAY (GROUP ALPHA)))
    (TYPE DISPLAY ID ALPHA LABEL "" BOX 1 MAXWIDTH 35))))
 (LABEL THREE)))
```

which will produce the following Free Menu:
And if the Free Menu were formatted as a Table, instead of in Rows, it would look like:

```
<table>
<thead>
<tr>
<th>NORTH</th>
<th>SOUTH</th>
<th>EAST</th>
<th>WEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>ONE</td>
<td>TWO</td>
<td>THREE</td>
<td></td>
</tr>
</tbody>
</table>
```

### Free Menu Group Properties

Each group has properties. Most group properties are relevant, and should be set, in the group's PROPS list in the Free Menu Description. User properties can freely be included in the PROPS list. A few other properties are setup by the formatter. After the Free Menu is created, group properties can be accessed by the macro FM.GROUPPROP or FM.MENUPROP.

- **ID**: The identifier of this group. Setting the group ID is desirable, for example, if the application needs to get handles on items in particular groups, or access group properties.
- **FORMAT**: One of ROW, COLUMN, TABLE, or EXPLICIT. The default is ROW.
- **FONT**: A font description of the form (FAMILY SIZE FACE), or a FONTDESCRIPTOR data type. This will be the default font for each item in this group. The default font of the top group is the value of the variable DEFAULTFONT.
- **COORDINATES**: One of GROUP, or MENU. This property applies only to Explicit formatting. If GROUP, then the items in the explicit group are positioned in coordinates relative to the lower left corner of the group, as determined by the mother group. If MENU, which is the default, then the items are positioned relative to the lower left corner of the menu.
- **LEFT**: Specifies a left offset for this group, pushing the group to the right.
- **BOTTOM**: Specifies a bottom offset for this group, pushing the group up.
- **ROWSPACE**: The number of bits between rows in this group.
- **COLUMNSPACE**: The number of bits between columns in this group.
- **BOX**: The number of bits in the box around this group of items.
- **BOXSHADE**: The shade of the box.
- **BOXSPACE**: The number of bits between the box and the items.
- **BACKGROUND**: The background shade of this group. Nested groups will inherit this background shade, but items in this group and nested groups will not. This is because in general it is difficult to read text on a
background, so items appear on white background by default. This can be overridden by the BACKGROUND Item Property.

**Other Group Properties**

The following group properties are setup and maintained by Free Menu. The application should probably not change any of these properties.

- **ITEMS**
  A list of the items in the group.

- **REGION**
  The region that is the extent of the items in the group.

- **MOTHER**
  The ID of the group that is the mother of this group.

- **DAUGHTERS**
  A list of ID of groups which are daughters to this group.

**Free Menu Items**

Each Free Menu Item is stored as an instance of the Data Type FREEMENUITEM. Free Menu Items can be thought of as objects, each item having its own particular properties, such as its type, label, and mouse event functions. A number of useful item types, described in the section Free Menu Item Types, are predefined by Free Menu. New types of items can be defined by the application, using Display items as a base.

Each Free Menu Item is created from a Free Menu Item Description when the Free Menu is created.

**Free Menu Item Descriptions**

A Free Menu Item Description is a list in property list format, specifying the properties of the item. For example:

```
(LABEL Refetch SELECTEDFN MY.REFETCHFN)
```

describes a command (Momentary) item labelled 'Refetch', with the function MY.REFETCHFN to be called when the item is selected.

None of the property values in an item description are evaluated. When constructing Free Menu descriptions that incorporate evaluated expressions, for example labels that are bitmaps, it is helpful to use the backquote facility. For example, if the value of the variable MYBITMAP is a bitmap, then

```
(FREEMENU '((LABEL A) (LABEL ,MYBITMAP)))
```

would create a Free Menu of one row, with two items in that row, the second of which has the value of MYBITMAP as its label.

**Free Menu Item Properties**

The following Free Menu Item Properties can be set in the Item Description. Any other properties given in an Item Description will be treated as user properties, and will be saved on the USERDATA property of the item.

- **TYPE**
  The type of the item. Choose from one of the Free Menu Item type keywords MOMENTARY, TOGGLE, 3STATE, STATE, NWAY, EDITSTART, EDIT, NUMBER, or DISPLAY. The default is MOMENTARY.
LABEL: An atom, string, or bit map. Bit maps are always copied, so that the original won’t be changed. This property must be specified for every item.

FONT: The font that the item will appear in. The default is the font specified for the group that this item is in. Can be a font description of the form (FAMILY SIZE FACE), or a FONT_DESCRIPTOR data type.

ID: May be used to specify a unique identifier for this item, but is not necessary.

LEFT and BOTTOM: When Row, Column, or Table formatting, these specify offsets, pushing the item right and up, respectively, from where the formatter would have put the item. In Explicit formatting, these are the actual coordinates of the item, in the coordinate system given by the group’s COORDINATES property.

HJUSTIFY: One of LEFT, CENTER, or RIGHT. Specifies that this item is to be horizontally justified within the extent of its group. Note that the main group, as opposed to the smaller row or column group, is used.

VJUSTIFY: One of TOP, MIDDLE, or BOTTOM. Specifies that this item is to be vertically justified.

HIGHLIGHT: Specifies the highlighted looks of the item, that is, how the item changes when a mouse event occurs on it. See the section Free Menu Item Highlighting, below.

MESSAGE: A string that will be printed in the prompt window after a mouse button is held down over this item for MENUHELDWAIT milliseconds. Or, if an atom, treat as a function to get the message. The function is applied to ITEM WINDOW BUTTONS, and should return a string. The default is a message appropriate to the type of the item.

INITSTATE: The initial state of the item. This is only appropriate to TOGGLE, 3STATE, and STATE items.

MAXWIDTH: The width allowed for this item. The formatter will leave enough space after the item for the item to grow to this width without collisions.

MAXHEIGHT: Similar to MAXWIDTH, but in the vertical dimension.

BOX: The number of bits in the box around this item. Boxes are made around MAXWIDTH and MAXHEIGHT dimensions. If unspecified, no box is drawn.

BOXSHADE: The shade that the box is drawn in. The default is BLACKSHADE.

BOXSPACE: The number of bits between the box and the label. The default is one bit.

BACKGROUND: The background shade on which the item appears. The default is WHITESHADE, regardless of the group’s background.

LINKS: Can be used to link this item to other items in the Free Menu. See the section Free Menu Item Links.

Mouse Properties

The following properties provide a way for application functions to be called under certain mouse events. These functions are called with the ITEM, the WINDOW, and the BUTTONS depressed as
arguments. These application functions do not interfere with any Free Menu system functions that take care of handling the different item types. In each case, though, the application function is called after the system function. The default for all of these functions is NILL. The value of each of the following properties can be the name of a function, or a lambda expression.

**SELECTEDFN** The function to be called when this item is selected. Note that Edit and EditStart items cannot have a selectedfn. See Edit items, below.

**DOWNFN** The function to be called when a mouse button goes down over this item, or when the mouse moves over the item with buttons depressed.

**HELDFN** The function to be called repeatedly while the mouse is held down over this item.

**MOVEDFN** The function to be called when the mouse moves off this item with buttons still depressed.

**System Properties**

The following Free Menu Item properties are set and maintained by Free Menu. The application should probably not change these properties directly.

**GROUPID** The ID of the smallest group that the item is in. For example, in a row formatted group, the item’s GROUPID will be set to the ID of the row that the item is in, not the ID of the whole group.

**STATE** The current state of TOGGLE, 3STATE, or STATE items. The state of an NWAY item behaves like that of a toggle item.

**BITMAP** The bitmap from which the item is displayed.

**REGION** The region of the item, in window coordinates. This is used for locating the display position, as well as determining the mouse sensitive region of the item.

**MAXREGION** The maximum region the item may occupy, determined by the MAXWIDTH and MAXHEIGHT properties. This is used by the formatter and the display routines.

**SYSDOWNFN** **SYSMOVEDFN** **SYSSELECTEDFN** These are the system mouse event functions, setup by Free Menu according to the type of the item. These functions are called before the users mouse event functions, and are used to implement highlighting, state changes, editing, etc.

**USERDATA** Any other properties are stored on this list in property list format. This list should probably not need to be manipulated directly.

**Predefined Item Types**

**Momentary**

Momentary items are like command buttons. When the button is selected, its associated function is called.

**Toggle**

Toggle items are simple two-state buttons. When depressed the button is highlighted, and it stays that way until pressed again. The states of a toggle button are T and NIL, initially NIL.
3State

3State items rotate through NIL, T, and OFF, states each time they are pressed. The default looks of the OFF state are with a diagonal line through the button, while T is highlighted, and NIL is normal. The default initial state is NIL.

The following Item Property applies to 3State items:

OFF Specifies the looks of a 3STATE item in its OFF state. Similar to HIGHLIGHT. The default is that the label gets a diagonal slash through it.

State

State items are general multiple state items. The following Item Property determines how the item changes state:

CHANGESTATE This Item Property can be changed at any time to change the effect of the item. If a MENU datatype, then this menu is popped up when the item is selected, and the user can select the new state. Otherwise, if this property is given, it is treated as a function name, which is applied to ITEM WINDOW BUTTONS. This function can do whatever it wants, and is expected to return the new state (an atom, string, or bitmap), or NIL, meaning don't change state.

The state of the item can automatically be indicated in the Free Menu, by setting up a DISPLAY link to a Display item in the menu (see Free Menu Item Links below). If such a link exists, the label of the DISPLAY item will be changed to the new state. Note that the possible states are not restricted at all, except that if a popup menu is used, of course the possible selections are restricted. The state can be changed to any atom, string, or bitmap, manually via FM.CHANGESTATE.

The following Item Properties are relevant to State items when building a Free Menu:

MENUITEMS If specified, should be a list of item to go in a popup menu for this item. Free Menu will build the menu and save it as the CHANGESTATE property of the item.

MENUFONT The font of the items in the popup menu.

MENUTITLE The title of the popup menu. The default title is the label of the State item.

Nway

NWay items provide a way to collect any number of items together, in any format within the Free Menu. Only one item from each Collection can be selected at a time, and that item is highlighted to indicate so.

The following Item Properties are particular to NWay items:

COLLECTION An identifier that specifies which NWay Collection this item belongs to.

NWAYPROPS A property list of information to be associated with this collection. This property is only noticed in the Free Menu Description on the first item in a Collection.

NWay Collections are formed by creating a number of NWay items with the same COLLECTION property. Each NWay item acts individually as a Toggle item, and can have its own mouse event functions.

Each NWay Collection itself has properties, its state for instance. After the Free Menu is created, these Collection properties can be
accessed by the macro FM.NWAYPROPS. Note that NWay Collections are different from Free Menu Groups.

There are three NWay Collection properties that Free Menu looks at:

DESELECT If given, specifies that the Collection can be deselected, yielding a state in which no item in the Collection is selected. When this property is set, the Collection can be deselected by pressing the Right mouse button on any item in the Collection.

STATE The current state of the Collection, which is the actual item selected.

INITSTATE Specifies the initial state of the Collection. The value of this property is an item Link Description (see the section Free Menu Item Links.)

Edit

Edit items are textual items that can be edited. The label for an Edit item cannot be a bitmap. When the item is selected an edit caret appears at that cursor position within the item, allowing inserting and deleting characters at that point. If selected with the Right mouse button, the item is cleared before editing starts. While editing, the Left mouse button moves the caret to a new position within the item. The Right mouse button deletes from the caret to the cursor. Control-W deletes the previous word.

Editing is stopped when another item is selected, when the user clicks in another tty window, or by the Free Menu function FM.ENDEDIT, which is called when the Free Menu is reset, or the window is closed. Additionally, the Free Menu editor will time out after about a minute, returning automatically. Because of the many ways in which editing can terminate, Edit items are not allowed to have a Selectedfn, as it is not clear when this function should be called.

Each Edit item should have an ID specified, which is used when getting the state of the Free Menu, since the string being edited is defined as the state of the item, and thus cannot distinguish edit items. The following Item Properties are particular to Edit items:

MAXWIDTH Specifies the maximum string width of the item, in bits, after which input will be ignored. If MAXWIDTH is not specified, the items becomes "infinitely wide" and input is never restricted.

INFINITEWIDTH This property is set automatically when MAXWIDTH is not specified. This tells Free Menu that the item has no right end, so that the item becomes mouse sensitive from its left edge to the right edge of the window, within the vertical space of the item.

LIMITCHARS The input characters allowed can be restricted in two ways: If this item property is a list, it is treated as a list of legal characters; any character not in the list will be ignored. If it is an atom, it is treated as the name of a test predicate, which is applied to ITEM WINDOW CHARACTER when each character is typed. This predicate should return T if the character is legal, NIL otherwise. The LIMITCHARS function can also call FM.ENDEDIT to force the editor to terminate, or FM.SKIPNEXT, to cause the editor to jump to the next edit item in the menu.

ECHOCHAR This item property can be set to any character. This character will be echoed in the window, regardless of what character is typed. However the item’s label contains the actual string typed. This is useful for operations like password prompting. If ECHOCHAR is used, the font of the item must be fixed pitch.
Unrestricted Edit items should not have other items to their right in the menu, as they will be edited over. If the item is boxed, input is restricted to what will fit in the box. Typing off the edge of the window will cause the window to scroll appropriately. Control characters can be edited, including CR and LF, and they are echoed as a black box. While editing, the Skip/Next key ends editing the current item, and starts editing the next Edit item in the Free Menu.

Number

Number items are Edit items that are restricted to numerals. The state of the item is coerced to the number itself, not a string of numerals.

There is one Number specific Item Property:

NUMBERTYPE

If FLOATP (or FLOAT), then decimals are accepted. Otherwise only whole numbers can be edited.

EditStart

EditStart items serve the purpose of starting editing on another item when they are selected. The associated Edit item is linked to the EditStart item by an EDIT link (see Free Menu Item Links below). If the EditStart item is selected with the Right mouse button, the Edit item is cleared before editing is started. Similar to Edit items, EditStart items cannot have a Selectedfn, as it is not clear when the associated editing will terminate.

Display

Display items serve two purposes. First, they simply provide a way of putting dummy text in a Free Menu, which does nothing when selected. The item's label can be changed, though. Secondly, Display items can be used as the base for new item types. The application can create new item types by specifying DOWNFN, HELDFN, MOVEDFN, and SELECTEDFN for a Display item, making it behave as desired.

Free Menu Item Highlighting

Each Free Menu Item can specify how it wants to be highlighted. First of all, if the item doesn't specify a HIGHLIGHT property, there are two default highlights. If the item is not boxed, the label is simply inverted, as in normal menus. If the item is boxed, it is highlighted in the shade of the box.

Alternatively, the value of the HIGHLIGHT property can be a SHADE, which will be painted on top of the item when a mouse event occurs on it. Or the HIGHLIGHT property can be an alternate label, which can be an atom, string, or bitmap. If the highlight label is a different size than the item label, the formatter will leave enough space for the larger of the two.

In all of these cases, the looks of the highlighted item are determined when the Free Menu is built, and a bitmap of the item with these looks is created. This bitmap is stored on the item's HIGHLIGHT property, and simply displayed when a mouse event occurs. The value of the highlight property in the Item Description is copied to the userdata list, in case it is needed later for a label change.
Free Menu Item Links

Links between items are useful for grouping items in abstract ways. In particular, links are used for associating Editstart items with their item to edit, and State items with their state display. The Free Menu Item property LINKS is a property list, where the value of each Link Name property is a pointer to another item.

In the Item Description, the value of the LINK property should be a property list as above. The value of each Link Name property is a Link Description.

A Link Descriptions can be one of the following forms:

- `<ID>` Simply an ID of an item in the Free Menu. This is okay if items can be distinguished by ID alone.
- `<GROUPID> <ID>` A list whose first element is a GROUPID, and whose second element is the ID of an item in that group. This way items with similar purposes, and thus similar ID's, can be distinguished across groups.
- `(GROUP <ID>)` A list whose first element is the keyword GROUP, and whose second element is an item ID. This form describes an item with ID, in the same group that this item is in. This way you don’t need to know the GROUPID, just which group you’re in.

Then after the entire menu is built, the links are setup, turning the Link Descriptions into actual pointers to Free Menu Items. There is no reason why circular Item Links cannot be created, although such a link would probably not be very useful. If circular links are created, the Free Menu will not be garbage collected after it is not longer being used. The application is responsible for breaking any such links that it creates.

Free Menu Window Properties

- **FM.PROMPTWINDOW** Specifies the window that Free Menu should use for displaying the item’s messages. If not specified, PROMPTWINDOW is used.
- **FM.BACKGROUND** The background shade of the entire Free Menu. This property can be set automatically by specifying a BACKGROUND argument to the function FREEMENU. The window border must be 4 or greater when a Free Menu background is used, due to the way the Window System handles window borders.
- **FM.DONTRESHAPE** Normally Free Menu will attempt to use empty space in a window by pushing items around to fill the space. When a Free Menu window is reshaped, the items are repositioned in the new shape. This can be disabled by setting the FM.DONTRESHAPE window property.

Free Menu Interface Functions

(FREEMENU DESCRIPTION TITLE BACKGROUND BORDER) [Function]
Creates a Free Menu from a Free Menu Description, returning the window. This function will return quickly unless new display fonts have to be created. See the example above.

Accessing Macros

These Accessing Macros are provided to allow the application to get and set information in the Free Menu data structures. They are implemented as macros so that the operation will compile into the actual access form, rather than figuring that out at run time.

(FM.ITEMPROP ITEM PROP {VALUE})  [Macro]
Similar to WINDOWPROP, this macro provides an easy access to the fields of a Free Menu Item. A handle on the item can be gotten from the Free Menu by the function FM.GETITEM, described below. VALUE is optional, and if not given, the current value of the PROP property will be returned. If VALUE is given, it will be used as the new value for that PROP, and the old value will be returned.

When a call to FM.ITEMPROP is compiled, if the PROP is known (quoted in the calling form), the macro figures out what field to access, and the appropriate Data Type access form is compiled. However, if the PROP is not known at compile time, the function FM.ITEMPROP, which goes through the necessary property selection at run time, is compiled.

The TYPE and USERDATA properties of a Free Menu Item are Read Only, and an error will result from trying to change the value of one of these properties.

(FM.GROUPPROP WINDOW GROUP PROP {VALUE})  [Macro]
Provides access to the Group Properties set up in the PROPS list for each group in the Free Menu Description. GROUP specifies the ID of the desired group, and PROP the name of the desired property. If VALUE is specified, it will become the new value of the property, and the old value will be returned. Otherwise, the current value is returned.

(FM.MENUPROP WINDOW PROP {VALUE})  [Macro]
Provides access to the group properties of the top-most group in the Free Menu, that is to say, the entire menu. This provides an easy way for the application to attach properties to the menu as a whole, as well as access the Group Properties for the entire menu.

(FM.NWAYPROP WINDOW COLLECTION PROP {VALUE})  [Macro]
This macro works just like FM.GROUPPROP, except it provides access to the NWay Collections.

Accessing Functions

(FM.GETITEM ID GROUP WINDOW)  [Function]
Get a handle on item ID in GROUP of the Free Menu in WINDOW. This function will search the Free Menu for an item whose ID property matches, or secondly whose LABEL property matches ID. If GROUP is NIL, then the entire Free Menu is searched. If no matching item is found, NIL is returned.

(FM.GETSTATE WINDOW)  [Function]
Return in property list format the ID and current STATE of every NWay Collection and item in the Free Menu. If an item’s or Collection’s state is NIL, then it is not included in the list. This provides an easy way of getting the state of the menu all at once. If the state of only one item or Collection is needed, the application
can directly access the STATE property of that object using the Accessing Macros above. Note that this function can be called when editing is in progress, in which case it will provide the label of the item being edited at that point.

Changing Free Menus

Many of the following functions operate on Free Menu Items, and thus take the item as an argument. The ITEM argument to these functions can be the Free Menu Item itself, or just a reference to the item. In the second case, FM.GETITEM will be used to find the item in the Free Menu.

The reference can be in one of the following forms:

- `<ID>`
  Specifies the first item in the Free Menu whose ID or LABEL property matches `<ID>`.

- `(<GROUPID> <ID>)`
  Specifies the item whose ID or LABEL property matches `<ID>` within the group specified by `<GROUPID>`.

(FM.CHANGELABEL ITEM NEWLABEL WINDOW UPDATEFLG) [Function]

This function changes an item’s label after the Free Menu has been created. It works for any type of item, and state items will remain in their current state. If the window is open, the item will be redisplayed with its new appearance. NEWLABEL can be an atom, a string, or a bit map (except for Edit items), and will be restricted in size by the MAXWIDTH and MAXHEIGHT Item Properties. If these properties are unspecified, the item will be able to grow to any size. UPDATEFLG specifies whether or not the regions of the groups in the menu are recalculated to take into account the change of size of this item. The application should not change the label of an Edit item while it is being edited.

The following Item Property is relevant to changing labels:

- `CHANGELABELUPDATE`
  Exactly like UPDATEFLG except specified on the item, rather than as a function parameter.

(FM.CHANGESTATE X NEWSTATE WINDOW) [Function]

Programmatically changes the state of items and NWay Collections. X is either an item or a Collection name. For items NEWSTATE is a state appropriate to the type of the item. For NWay Collections, NEWSTATE should be the desired item in the Collection, or NIL to deselect. For Edit and Number items, this function just does a label change. If the window is open, the item will be redisplayed.

(FM.RESETSTATE ITEM WINDOW) [Function]

Set an item back to its initial state.

(FM.RESETMENU WINDOW) [Function]

Reset every item in the menu back to its initial state.

(FM.RESETSHAPE WINDOW ALWAYSFLG) [Function]

Reshapes the window to its full extent, leaving the lower-left corner unmoved. Unless ALWAYSFLG is T, the window will only be increased in size as a result of resetting the shape.

(FM.RESETGROUPS WINDOW) [Function]

Recalculate the extent of each group in the menu, updating group boxes and backgrounds appropriately.
(FM.HIGHLIGHTITEM ITEM WINDOW) [Function]
This function provides a way of programmatically forcing an item to be highlighted. This might be useful for items which have a direct effect on other items in the menu. The item will be highlighted according to its HIGHLIGHT property, as described in the section Free Menu Item Highlighting. Note that this highlight is temporary, and will be lost if the item is redisplayed, by scrolling for example.

Editor functions

(FM.EDITITEM ITEM WINDOW CLEARFLG) [Function]
Start editing an Edit or Number item at the beginning of the item, as long as the window is open. This function will most likely be useful for starting editing of an item that is currently the null string. If CLEARFLG is set, the item is cleared first.

(FM.SKIPNEXT WINDOW CLEARFLG) [Function]
This function causes the editor to jump to the beginning of the next Edit item in the Free Menu. If CLEARFLG is set, then the next item will be cleared first. If there is not another Edit item in the menu, this function will simply cause editing to stop. If this function is called when editing is not in progress, editing will begin on the first Edit item in the menu. This function can be called from any process, and can also be called from inside the editor, in a LIMITCHARS function.

(FM.ENEDIT WINDOW WAITFLG) [Function]
Stop any editing going on in WINDOW. If WAITFLG, then block until the editor has completely finished. This function can be called from another process, or from a LIMITCHARS function.

(FM.EDITP WINDOW) [Function]
If an item is in the process of being edited in the Free Menu WINDOW, that item is returned. Otherwise, NIL is returned.

Miscellaneous

(FM.REDISPLAYMENU WINDOW) [Function]
Redisplays the entire Free Menu in its window, if the window is open.

(FM.REDISPLAYITEM ITEM WINDOW) [Function]
Redisplays a particular Free Menu Item in its window, if the window is open.

(FM.SHADE X SHADE WINDOW) [Function]
X can be an item, or a group ID. SHADE is painted on top of the item or group. Note that this is a temporary operation, and will be undone by redisplaying. For more permanent shading, the application may be able to add a REDISPLAYFN and SCROLLFN for the window as necessary to update the shading.

(FM.WHICHITEM WINDOW POSorX Y) [Function]
Gets a handle on an item from its known location within the window. If WINDOW is NIL, (WHICHW) is used, and if POSorX is NIL, the current cursor location is used.

(FM.TOPGROUPID WINDOW) [Function]
Return the ID of the top group of this Free Menu.
**Free Menu Changes:**

This document describes the incompatible changes from the old version to the new version of Free Menu. This document does not describe any of the new features of Free Menu. Some of the terminology used in these notes is introduced in the Free Menu documentation. You should read the Free Menu documentation first.

The function FREEMENU is used to create a Free Menu, replacing and combining the functions FM.MAKEMENU and FM.FORMATMENU.

**In the Description of the Free Menu:**

There is no longer a WINDOWPROPS list in the Free Menu Description. Instead, the window properties TITLE and BORDER that used to be set in the WINDOWPROPS list can now be passed to the function FREEMENU. Other window properties (like FM.PROMPTWINDOW) can be set directly after FREEMENU returns the window using the system function WINDOWPROP. See the section in the documentation entitled *Free Menu Window Properties*.

Setting the initial state of an item is now done with the item property INITSTATE in the item description, rather than the STATE property.

**Free Menu Items:**

3STATE items now have states OFF, NIL, and T (instead of a NEUTRAL state). They appear by default in the NIL state.

STATE items are general purpose items which maintain state, and replace the functionality of NCHOOSE items. To get the functionality of NCHOOSE items, specify the property MENUITEMS (a list of items to go in a popup menu), which instructs the STATE item to popup the menu when it is selected. STATE items do not display their current state by default, like NCHOOSE items used to. Instead, if you want the state displayed in the Free Menu, you have to link the STATE item to a DISPLAY item using a Free Menu Item Link named "DISPLAY". The current state of the STATE item will then automatically be displayed in the specified DISPLAY item. The item properties MENUFONT and MENUTITLE also apply to the popup menu.

NWAY items are declared slightly differently. There is now the notion of an NWay Collection, which is a collection of items acting as a single nway item. The Collection is declared by specifying any number of NWay items, each with the same COLLECTION property. NWay Collections have properties themselves, accessible by the macro FM.NWAYPROPS. These
properties can be specified in property list format as the value of the NWAYPROPS Item Property of the first NWay item declared for each Collection. NWay Collections by default cannot be deselected (a state in which no item selected). Setting the Collection property DESELECT to any non-nil value changes this behavior. The state of the NWay Collection is maintained in its STATE property.

EDIT items no longer will stop at the edge of the window. Editing is either restricted by the MAXWIDTH property, or else it is not restricted at all. The EDITSTOP property is obsolete. Starting editing with the Right mouse button causes the item to be cleared first.

EDITSTART items now specify their associated edit item (there can only be one, now) by a Free Menu Item Link named "EDIT" from the EDITSTART item to the EDIT item.

TITLE items are replaced by DISPLAY items, which work the same way.

**Free Menu Interface functions:**

(FREEMENU DESCRIPTION TITLE BACKGROUND BORDER) replaces FM.MAKEMENU and FM.FORMATMENU. The desired format is not specified as the value of the FORMAT property in the group’s PROPS list.

(FM.GETITEM ID GROUP WINDOW) replaces FM.ITEMFROMID. Searches within GROUP for an item whose ID property is ID. ID is matched against the item ID and then the item LABEL. If GROUP is NIL, the entire menu is searched.

(FM.GETSTATE WINDOW) replaces FM.READSTATE. Returns a property list of the selected item in the menu. This list now also includes the NWay Collections and their selected item.

(FM.CHANGETITLE ITEM NEWLABEL WINDOW UPDATEFLG) new argument order.
Now works by rebuilding the item label from scratch, taking the original specification of MAXWIDTH and MAXHEIGHT into account. NEWLABEL can be an atom, string, or bitmap. If UPDATEFLG is set, then the Free Menu Group’s regions are recalculated, so that boxed groups will be redisplayed properly.

(FM.CHANGEITEM X NEWSTATE WINDOW) new argument order.
X is either an item or an NWay Collection ID. NEWSTATE is an appropriate state to the type of item. If an NWay collection, NEWSTATE is the actual item to be selected, or NIL to deselect. Toggle items take either T or NIL as NEWSTATE, and 3STATE items take OFF, NIL, or T, and STATE items take any atom, string, or
bitmap as their new state. For EDIT items, NEWSTATE is the new label, and FM.CHANGELABEL is called to change the label of the EDIT item.

(FM.RESETSHAPE WINDOW ALWAYSFLG) replaces FM.FIXSHAPE

(FM.HIGHLIGHTITEM ITEM WINDOW) replaces FM.SHADEITEM and FM.SHADEITEMBM. FM.HIGHLIGHTITEM will programmatically highlight an item, as specified by its HIGHLGIHT property. The highlighting is temporary, and will be undone by a redisplay or scroll. To programmatically shade an item an arbitrary shade, use the new function FM.SHADE.
This is a package of functions for building small windows of arbitrary shape, principally for use as icons for shrinking windows; i.e., these functions are likely to be invoked from within the ICONFN of a window.

An icon is specified by supplying its image (a bit map) and a mask that specifies its shape. The mask is a bit map of the same dimensions as the image whose bits are on (black) in those positions considered to be in the image, off (white) in those positions where the background should "show through." By using the mask and appropriate window functions, the icon package maintains the illusion that the icon window is nonrectangular, even though the actual window itself is rectangular. The illusion is not complete, of course. For example, if you try to select what looks like the background (or an occluded window) around the icon but still within its rectangular perimeter, the icon window itself is selected. Also, if you move a window occluded by an icon, the icon never notices that the background changed behind it.

Icons created with this package can also have "titles"; some part of the image can be filled with text computed at the time the icon is created, or even changed after creation.

### Creating Icons

(ICONW IMAGE MASK POSITION NOOPENFLG) [Function]

Creates a window at POSITION, or prompts for a position if POSITION is NIL. The window is borderless, and filled with IMAGE, as cookie-cut by MASK. If MASK is NIL, the image is considered rectangular (i.e., MASK defaults to a black bit map of the same dimensions as IMAGE). If NOOPENFLG is T, the window is returned unopened.

(TITLEDICONW ICON TITLE FONT POSITION NOOPENFLG JUST BREAKCHARS OPERATION) [Function]

Creates a titled icon at POSITION, or prompts for a position if POSITION is NIL. If NOOPENFLG is T, the window is returned unopened. The argument ICON is an instance of the record TITLEDICON, which specifies the icon image and mask, as with ICONW, and a region within the image to be used for displaying the title. Thus, the ICON argument is usually of the form

(create TITLEDICON ICON someIconImage

MASK_iconMask TITLEREG_someRegionWithinICON).

The title region is specified in icon-relative coordinates, i.e., the lower-left corner of the image bit map is (0, 0). The mask can be NIL if the icon is rectangular. The image should be white where it is covered by the title region (in any event, TITLEDICONW clears the region before printing on it).
The title is printed into the specified region in the image, using FONT, which if NIL defaults to the value of DEFAULTTICONFONT, initially Helvetica 10. The title is broken into multiple lines if necessary; TITLEDICONW attempts to place the breaks at characters that are in the list of character codes BREAKCHARS. BREAKCHARS defaults to (CHARCODE (SPACE ÿ)). In addition, line breaks are forced by any carriage returns in TITLE, independent of BREAKCHARS. BREAKCHARS is ignored as needed if a long title would not otherwise fit in the specified region. For convenience, BREAKCHARS = FILE means the title is a file name, so break at file name field delimiters.

The argument JUST indicates how the text should be justified relative to the region—it is an atom or list of atoms chosen from TOP, BOTTOM, LEFT, or RIGHT, which indicate the vertical positioning (flush to top or bottom) and/or horizontal positioning (flush to left edge or right). Where not indicated, the text is centered.

The argument OPERATION is a display stream operation indicating how the title should be printed. If OPERATION is INVERT, then the title is printed white-on-black. The default OPERATION is REPLACE, meaning black-on-white. ERASE is the same as INVERT; PAINT is the same as REPLACE.

For convenience, TITLEDICONW can also be used to create icons that consist solely of a title, with no special image. If the argument ICON is NIL, TITLEDICONW creates a rectangular icon large enough to contain TITLE, with a border the same width as a regular window. The remaining arguments are as described above, except that a JUST of TOP or BOTTOM is not meaningful.

Modifying Icons

(INCONW.TITLE ICON TITLE) [Function]

Returns the current title of the window ICON, which must be a window returned by TITLEDICONW. Additionally, if TITLE is non-NIL, makes TITLE be the new title of the window and repaints it accordingly. To erase the current title, make TITLE be a null string.
GRAPHICS

(ICONW.SHADE WINDOW SHADE) [Function]
Returns the current shading of the window ICON, which must be a window returned by ICONW or TITLEDICONW. Additionally, if SHADE is non-NIL, paints the texture SHADE on WINDOW. A typical use for this function is to communicate a change of state in a window that is shrunk, without reopening the window. To remove any shading, make SHADE be WHITESHADE.

Default Icons

When you shrink a window that has no ICONFN, the system currently creates an icon that looks like the window’s title bar. You can make the system instead create titled icons by setting the global variable DEFAULTICONFN to the value TEXTICON.

(TEXTICON WINDOW TEXT) [Function]
Creates a titled icon window for the main window WINDOW containing the text TEXT, or the window’s title if TEXT is NIL.

DEFAULTTEXTICON [Variable]
The value that TEXTICON passes to TITLEDICONW as its ICON argument. Initially NIL, which creates an unadorned rectangular window, but you can set it to a TITLEDICON record of your choosing if you would like default icons to have a different appearance.

Sample Icons

The file <LispUsers>StockIcons contains a collection of icons and their masks usable with ICONW, including:

FOLDER, FOLDERMASK—a file folder
PAPERICON, PAPERICONMASK—a sheet of paper with the top right corner turned
FILEDRAWER, FILEDRAWERMASK—the front of a file drawer
ENVELOPEICON, ENVELOPEMASK—an envelope
TITLED.FILEDRAWER—a TitledIcon of the filedrawer front (Capacity, about three lines of 10-pt. text)
TITLED.FILEFOLDER—a TitledIcon of the file folder (Capacity, about three lines of 10-pt. text)
TITLED.ENVELOPE—a TitledIcon of the envelope (Capacity, one short line of 10-pt. text)
SEdit is the Xerox Lisp structure editor. It allows you to edit Xerox Lisp code directly in memory. This editor replaces DEdit in Chapter 16, Structure Editor, of the Interlisp-D Reference Manual. First introduced in Lyric, the SEdit structure editor has been greatly enhanced in the Medley release. Medley additions are indicated with revision bars in the right margin.

All symbols referenced in this appendix are external in the package named "SEdit", unless otherwise qualified.

### 16.1 SEdit - The Structure Editor

As a structure editor, SEdit alters Lisp code directly in memory. The effect this has on the running system depends on what is being edited.

For Common Lisp definitions, SEdit always edits a copy of the object. For example, with functions, it edits the definition of the function. What the system actually runs is the installed function, either compiled or interpreted. The primary difference between the definition and the installed function is that comment forms are removed from the definition to produce the installed function. The changes made while editing a function will not be installed until the edit session is complete.

For Interlisp functions and macros, SEdit edits the actual structure that will be run. An exception to this is an edit of an EXPR definition of a compiled function. In this case, changes are included and the function is unsaved when the edit session is completed.

SEdit edits all other structures, such as variables and property lists, directly. SEdit installs all changes as they are made.

If an error is made during an SEdit session, abort the edit with an Abort command (see Section 16.1.7, Command Keys). This command undoes all changes from the beginning of the edit session and exits from SEdit without changing your environment.

If the definition being edited is redefined while the edit window is open, SEdit redisplays the new definition. Any edits on the old definition will be lost. If SEdit was busy when the redefinition occurred, the SEdit window will be gray. When SEdit is no longer busy, position the cursor in the SEdit window and press the left mouse button; SEdit will get the new definition and display it.

#### 16.1.1 An Edit Session

The List Structure Editor discussion in Chapter 3, Language Integration, explains how to start an editor in Xerox Lisp.
Whenever you call SEdit, a new SEdit window is created. This SEdit window has its own process, and thus does not rely on an Exec to run in. You can make edits in the window, shrink it while you do something else, expand it and edit some more, and finally close the window when you are done.

Throughout an edit session, SEdit remembers everything that you do through a change history. All edits can be undone and redone sequentially. When an edit session ends, SEdit forgets this information and installs the changes in the system.

The session ends with an event signalling to the editor that changes are complete. Three events signal completion:

- Closing the window.
- Shrinking the window.
- Typing one of the Completion Commands, listed below.

Each of these commands has the effect of installing your changes, completing the edit, and returning the TTY process to the Exec. They vary in what is done in addition to completing. Using these commands the definition that you were editing can be automatically compiled, the edit window can be closed, or both.

A new edit session begins when you come back to an SEdit after completing. The change history is discarded at this point.

If the Exec is waiting for SEdit to return before going on, complete the edit session using any of the methods above to alert the Exec that SEdit is done. The TTY process passes back to the Exec.

### 16.1.2 SEdit Carets

There are two carets in SEdit, the edit caret and the structure caret. The edit caret appears when characters are edited within a single structure, such as an atom, string, or comment. Anything typed in will appear at the edit caret as part of the structure that the caret is within. The edit caret looks like this:

\[
(a^b_c)
\]

The structure caret appears when the edit point is between structures, so that anything inserted will go into a new structure. It looks like this:

\[
(a\triangle b)
\]

SEdit changes the caret frequently, depending on where you are in the structure you are editing, and how the caret is positioned. The left mouse button allows an edit caret position to be set. The middle mouse button allows the structure caret position to be set.
16.1.3 The Mouse

In SEdit, the mouse buttons are used as follows. The left mouse button positions the mouse cursor to point to parts of Lisp structures. The middle mouse button positions the mouse cursor to point to whole Lisp structures. Thus, selecting the Q in LEQ using the left mouse button selects that character, and sets the edit caret after the Q:

\[(\text{LEQ}, n, 1)\]

Any characters typed in at this point would be appended to the atom LEQ.

Selecting the same letter using the middle mouse button selects the whole atom (this convention matches TEdit's character/word selection convention), and sets a structure caret between the LEQ and the n:

\[(\text{LEQ}, n, 1)\]

At this point, any characters typed in would form a new atom between the LEQ and the n.

Larger structures can be selected in two ways. Use the middle mouse button to position the mouse cursor on the parenthesis of the desired list to select that list. Press the mouse button multiple times, without moving the mouse, extends the selection. Using the previous example, if the middle button were pressed twice, the list \((\text{LEQ} ... )\) would be selected:

\[(\text{LEQ}, n, 1)\]

Pressing the button a third time would cause the list containing the \((\text{LEQ} n, 1)\) to be selected.

The right mouse button positions the mouse cursor for selecting sequences of structures or substructures. Extended selections are indicated by a box enclosing the structures selected. The selection is extended in the same mode as the original selection. That is, if the original selection were a character selection, the right button could be used to select more characters in the same atom. Extended selections also have the property of being marked for pending deletion. That is, the selection takes the place of the caret, and anything typed in is inserted in place of the selection.

For example, selecting the E by pressing the left mouse button and selecting the Q by pressing the right mouse button would produce:

\[(\text{LEQ} n, 1)\]

Similarly, pressing the middle mouse button and then selecting with the right mouse button extends the selection by whole structures. Thus, in our example, pressing the middle mouse button to select LEQ and pressing the right mouse button to select the 1 would produce:
This is not the same as selecting the entire list, as above. Instead, the elements in the list are collectively selected, but the list itself is not.

16.1.4 Gaps

The SEdit structure editor requires that everything edited must have an underlying Lisp structure, even if the structure is not directly displayed. For example, with quoted forms the actual structure might be (QUOTE GREEN), although this would be displayed as 'GREEN. Even when the user is in the midst of typing in a form, the underlying Lisp structure must exist.

Because of this necessity, SEdit provides gaps to serve as dummy Lisp objects during typing. SEdit does not need a gap for every form typed in, but gaps are necessary for quoted objects. When something is typed that requires SEdit to build a Lisp structure and thus create a gap, as the quote character does, the gap will appear marked for pending deletion. This means it is ready to be replaced by the structure to be typed in. In this way it is possible to type special structures, like quotes, directly, while SEdit maintains the structure.

A gap looks like: –X–

A gap displayed after a quote has been typed in would look like this:

, –X–

with the gap marked for pending deletion, ready for typein of the object to be quoted.

16.1.5 Special Characters

A few characters have special meaning in Lisp, and are treated specially by SEdit. SEdit must always have a complete structure to work on at any level of the edit. This means that SEdit needs a special way to type in structures such as lists, strings, and quoted objects. In most instances these structures can be typed in just as they would be to a regular Exec, but in a few cases this is not possible.

Lists- ( and )

Lists begin with an open parenthesis character (. Typing an open parenthesis gives a balanced list, that is, SEdit inserts both an open and a close parenthesis. The structure caret is between the two parentheses. List elements can be typed in at the structure caret. When a close parenthesis, ) is typed, the caret will be moved outside the list (and the close parenthesis), effectively finishing the list. Square bracket characters, [ and ], have no special meaning in SEdit, as they have no special meaning in Common Lisp.

Quoted Structures:

SEdit handles the quote keys so that it is possible to type in all quote forms directly. When typing one of the following quote keys
at a structure caret, the quote character typed will appear, followed by a gap to be replaced by the object to be quoted.

**Single Quote – ’** Use to enter quoted structures.

**Backquote – ‘** Use to enter backquoted structures.

**Comma – ,** Use to enter comma forms, as used with a Backquote form.

**At Sign – @** Use after a comma to create a comma-at-sign gap. This allows type-in of comma-at forms, e.g. ,@list, as used within a Backquote form.

**Dot – .** Use the dot (period) after a comma to create a comma-dot gap. This allows type-in of comma-dot forms, e.g. ,.list, as used within a Backquote form.

**Hash Quote – #’** Use this two character sequence to enter the CL:FUNCTION abbreviation hash-quote (#’).

**Dotted Lists:** The dot, or period, character (.) is used to type dotted lists in SEdit. After typing a dot, SEdit inserts a dot and a gap to fill in for the tail of the list. To dot an existing list, point the cursor between the last and second to the last element in the list, and type a dot. To undot a list, select the tail of the list before the dot while holding down the SHIFT key.

**Escape- \ or %** Use to escape from a specific typed in character. Use the escape key to enter characters, like parentheses, which otherwise have special meaning to the SEdit reader. Press the escape key then type in the character to escape. SEdit uses the escape key appropriate to the environment it is editing in; it depends on the readtable that was current when the editor was started. The backslash key (\) is used when editing Common Lisp, and the percent key (%) is used when editing Interlisp.

**Multiple Escape- |** Use the multiple escape key, the vertical bar character (|), to escape a sequence of typed in characters. SEdit always balances multiple escape characters. When one multiple escape character is typed, SEdit produces a balanced pair, with the caret between them, ready for typing in the characters to be escaped. If you type a second vertical bar, the caret moves after the second vertical bar, and is still within the same atom, so that you can add more unescaped characters to the atom.

**Comments- ;** The comment key, a semicolon (;), starts a comment. When a semicolon is typed, an empty comment is inserted with the caret in position for typing in the comment. Comments can be edited like strings. There are three levels of comments supported by SEdit: single, double, and triple. Single semicolon comments are formatted at the comment column, about three-quarters of the way across the SEdit window, towards the right margin. Double semicolon comments are formatted against the left margin of the SEdit window. The level of a comment can be increased or decreased by pointing after the semicolon, and either typing another semicolon, or backspacing over the preceding semicolon. Comments can be placed anywhere in your Common Lisp code. However, in Interlisp code, they must follow the placement rules for Interlisp comments.
Strings- "  
Enter strings in SEdit by typing a double quote ("'). SEdit balances the double quotes. When one is typed, SEdit produces a second, with the caret between the two, ready for typing the characters of the string. If a double quote character is typed in the middle of a string, SEdit breaks the string into two smaller strings, leaving the caret between them.

16.1.6 Commands  

SEdit commands are most easily entered through the keyboard. When possible, SEdit uses a named key on the keyboard, for example, the DELETE key. The other commands are either Meta, Control, or Meta-Control key combinations. For the alphabetic command keys, either uppercase or lowercase will work.

There are two menus available, as an alternative means of invoking commands. They are the middle button popup menu, and the attached command menu. These menus are described in more detail below.

16.1.6 Editing Commands  

<table>
<thead>
<tr>
<th>Command</th>
<th>Key Sequence</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redisplay</td>
<td>Control-L</td>
<td>Redisplays the structure being edited.</td>
</tr>
<tr>
<td>Delete Selection</td>
<td>DELETE</td>
<td>Deletes the current selection.</td>
</tr>
<tr>
<td>Delete Word</td>
<td>Control-W</td>
<td>Deletes the previous atom or whole structure. If the caret is in the middle of an atom, deletes backward to the beginning of the atom only.</td>
</tr>
</tbody>
</table>

16.1.7 Completion Commands  

<table>
<thead>
<tr>
<th>Command</th>
<th>Key Sequence</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abort</td>
<td>Meta-A</td>
<td>Aborts. This command must be confirmed. All changes since the beginning of the edit session are undone, and the edit is closed.</td>
</tr>
<tr>
<td>Control-X</td>
<td></td>
<td>Signals the system that this edit is complete. The window remains open, though, so the user can see the edit and start editing again directly.</td>
</tr>
<tr>
<td>Control-C</td>
<td></td>
<td>Signals the system that this edit is complete and compiles the definition being edited. The variable <em>compile-fn</em> determines the function to be called to do the compilation. See the Options section below.</td>
</tr>
<tr>
<td>Meta-Control-X</td>
<td></td>
<td>Signals the system that this edit is complete and closes the window.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Meta-Control-C</td>
<td>Signals the system that this edit is complete, compiles the definition being edited, and closes the window.</td>
<td></td>
</tr>
<tr>
<td>16.1.8 Undo Commands</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Undo: Meta-U or UNDO</td>
<td>Undoes the last edit. All changes since the beginning of the edit session are remembered, and can be undone sequentially.</td>
<td></td>
</tr>
<tr>
<td>Redo: Meta-R or AGAIN</td>
<td>Redoes the edit change that was just undone. Redo only works directly following an Undo. Any number of Undo commands can be sequentially redone.</td>
<td></td>
</tr>
<tr>
<td>16.1.9 Find Commands</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Find: Meta-F or FIND</td>
<td>Finds a specified structure, or sequence of structures. If there is a current selection, SEdit looks for the next occurrence of the selected structure. If there is no selection, SEdit prompts for the structure to find, and searches forward from the position of the caret. The found structure will be selected, so the Find command can be used to easily find the same structure again. If a sequence of structures is selected, SEdit will look for the next occurrence of the same sequence. Similarly, when SEdit prompts for the structure to find, you can type a sequence of structures to look for. The variable <em>wrap-search</em> controls whether or not SEdit wraps around from the end of the structure being edited and continues searching from the beginning.</td>
<td></td>
</tr>
<tr>
<td>Reverse Find: Control-Meta-F</td>
<td>Finds a specified structure, searching in reverse from the position of the caret. The variable <em>wrap-search</em> controls whether or not SEdit wraps around from the beginning of the structure being edited and continues searching from the end.</td>
<td></td>
</tr>
</tbody>
</table>
## Find Gap: Meta-N or SKIP-NEXT

Skips to the next gap in the structure, leaving it selected for pending deletion.

## Substitute: Meta-S or SHIFT-FIND

Substitutes one structure, or sequence of structures, for another structure, or sequence, within the current selection. SEdit prompts you in the SEdit prompt window for the structures to replace, and the structures to replace with.

The selection to substitute within must be a structure selection. To get a structure selection, click with the middle mouse button (not the left), and extend it, if necessary, with the right mouse button. If you begin with the left button, you will get an informational message "Select the structure to substitute within", because the selection was of characters, rather than structures.

## Delete Structure: Meta-Control-S

Removes all occurrences of a structure or sequence of structures within the current selection. SEdit prompts the user in the SEdit prompt window for the structures to delete.

### 16.1.9 General Commands

**Arglist: Meta-H or HELP**

Shows the argument list for the function currently selected, or currently being typed in, in the SEdit prompt window. If the argument list will not fit in the SEdit prompt window, it is displayed in the main Prompt Window.

**Convert Comments: Meta-**

Converts old style comments in the selected structure to new style comments. This converter notices any list that begins with an asterisk (*) in the INTERLISP package (IL:* ) as an old style comment. Section 16.1.11, Options, describes the converter options.

**Edit: Meta-O**

Edits the definition of the current selection. If the selected name has more than one type of definition, SEdit asks for the type to be edited. If the selection has no definition, a menu pops up. This menu lets the user specify either the type of definition to be created, or no definition if none needs to be created.

**Eval: Meta-E or Do-It**

Evaluates the current selection. If the result is a structure, the inspector is called on it, allowing the user to choose how to look at the result. Otherwise, the result is printed in the SEdit prompt window. The evaluation is done in the process from which the edit session was started. Thus, while editing a function from a break window, evaluations are done in the context of the break.

**Expand: Meta-X or EXPAND**
Replaces the current selection with its definition. This command can be used to expand macros and translate CLISP.

**Extract:** Meta- / [Editor Command]

Extracts one level of structure from the current selection. If the current selection is an atom, or if there is no selection, the next largest structure containing this atom, or caret, is used. This command can be used to strip the parentheses off a list or a comment, or to unquote a quoted structure.

**Inspect:** Meta-I [Editor Command]

Inspect the current selection.

**Join:** Meta-J [Editor Command]

Joins. This command joins any number of sequential Lisp objects of the same type into one object of that type. Join is supported for atoms, strings, lists, and comments. In addition, SEdit permits joining of a sequence of atoms and strings, since either type can easily be coerced into the other. In this case, the result of the Join will be an atom if the first object in the selection is an atom, otherwise the result will be a string.

**Mutate:** Meta-Z [Editor Command]

Mutates. This command allows the user to do arbitrary operations on a LISP structure. First select the structure to be mutated (it must be a whole structure, not an extended selection). When the user presses Meta-Z SEdit prompts for the function to use for mutating. This function is called with the selected structure as its argument, and the structure is replaced with the result of the mutation.

For example, an atom can be put in upper case by selecting the atom and mutating by the function U-CASE. You can replace a structure with its value by selecting it and mutating by EVAL.

**Quote:** Meta-’
Meta-’
Meta-,
Meta-.
Meta-@ or Meta-2
Meta-# or Meta-3 [Editor Command]

Quotes the current selection with the specified kind of quote, respectively, Single Quote, Backquote, Comma, Comma-At-Sign, Comma-Dot, or Hash-Quote.

**Parenthesize:** Meta- ) or Meta-0 [Editor Command]

Parenthesizes the current selection, positioning the caret after the new list.

**Parenthesize:** Meta- ( or Meta-9 [Editor Command]

Parenthesizes the current selection, positioning the caret at the beginning of the new list. Only a whole structure selection or an extended selection of a sequence of whole structures can be parenthesized.
16.1.10 Miscellaneous

<table>
<thead>
<tr>
<th>Change Print Base: Meta-B</th>
<th>[Editor Command]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes Print Base. Prompts for entry of the desired Print Base, in decimal. SEdit redisplay fixed point numbers in this new base.</td>

<td>M·M</td>
</tr>
</tbody>
</table>
16.1.9 Command Menu

The SEdit Attached Command Menu contains the commonly used commands. Use the Meta-M keyboard command to bring up this menu. The menu can be closed, independently of the SEdit window, when desired. The menu looks like:

```
<table>
<thead>
<tr>
<th>EXIT</th>
<th>DONE</th>
<th>ABORT</th>
<th>PAREN</th>
<th>QUOTE</th>
<th>EXTRACT</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNDO</td>
<td>REDO</td>
<td>ARGLIST</td>
<td>EDIT</td>
<td>EVAL</td>
<td>EXPAND</td>
</tr>
<tr>
<td>PRINT-BASE</td>
<td>10</td>
<td>PACKAGE</td>
<td>XCL-USER</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FIND:</td>
<td>SUBSTITUTE:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

All of the commands in the menu function identically to their corresponding keyboard commands, except for Find and Substitute.

When Find is selected with the mouse cursor, SEdit prompts in the menu window, next to the Find button, for the structures to find. Type in the structures then select Find again. The search begins from the caret position in the SEdit window.

Similarly, Substitute prompts, next to the Find button, for the structures to find, and next to the Substitute button for the structures to substitute with. After both have been typed in, selecting Substitute replaces all occurrences of the Find structures with the Substitute structures, within the current selection.

To do a confirmed substitute, set the edit point before the first desired substitution, and select Find. Then if you want to substitute that occurrence of the structure, select Substitute. Otherwise, select Find again to go on.

Selecting either Find or Substitute with the right mouse button erases the old structure to find or substitute from the menu, and prompts for a new one.

16.1.11 SEdit Window Region Manager

SEdit provides user redefinable functions which control how SEdit chooses the region for a new edit window.

```
(Get-Window-Region CONTEXT REASON NAME TYPE) [Function]
```

This function is called when SEdit wants to know where to place a window it is about to open. This happens whenever the user starts a new SEdit or expands an Sedit icon. The default behavior is to
pop a window region off SEdit’s stack of regions that have been used in the past. If the stack is empty, SEdit prompts for a new region.

This function can be redefined to provide different behavior. It is called with the edit CONTEXT, a REASON for needing a region, the NAME of the structure to be edited, and the TYPE of the structure to be edited. The edit CONTEXT is SEdit’s main data structure and can be useful for associating particular edits with specific regions. The REASON argument specifies why SEdit wants a region, and will be one of the keywords :CREATE or :EXPAND.

(Save-Window-Region CONTEXT REASON NAME TYPE REGION)  [Function]

This function is called whenever SEdit is finished with a region and wants to make the region available for other SEdits. This happens whenever an SEdit window is closed or shrunk, or when an SEdit Icon is closed. The default behavior is simply to push the region onto SEdit’s stack of regions.

This function can be redefined to provide different behavior. It is also called with the edit CONTEXT, the REASON, the NAME, the TYPE, and additionally the window REGION that is being released. The REASON argument specifies why SEdit is releasing the region, and will be one of the keywords :CLOSE, :SHRINK, or :CLOSE-ICON.

Keep-Window-Region  [Variable]

Default T. This flag determines the behavior of the default SEdit region manager, explained above, for shrinking and expanding windows. When set to T, shrinking an SEdit window will not give up that window’s region; the icon will always expand back into the same region. When set to NIL, the window’s region is made available for other SEdits when the window is shrunk. Then when an SEdit icon is expanded, the window will be reshaped to the next available region.

This variable is only used by the default implementations of the functions Get-Window-Region and Save-Window-Region. If these functions are redefined, this flag is no longer used.

16.1.12 Options

The following parameters can be set as desired.

*Wrap-Parens*  [Variable]

This SEdit pretty printer flag determines whether or not trailing close parenthesis characters, ), are forced to be visible in the window without scrolling. By default it is set to NIL, meaning that close parens are allowed to "fall off" the right edge of the window. If set to T, the pretty printer will start a new line before the structure preceding the close parens, so that all the parens will be visible.

*Wrap-Search*  [Variable]

This flag determines whether or not SEdit find will wrap around to the top of the structure when it reaches the end, or vice versa in the case of reverse find. The default is NIL.
*Clear-Linear-On-Completion* [Variable]

This flag determines whether or not SEdit completely re-pretty prints the structure being edited when you complete the edit. The default value is NIL, meaning that SEdit reuses the pretty printing.

**Convert-Upgrade** [Variable]

Default 100. When using Meta-; to convert old-style single- asterisk comments, if the length of the comment exceeds **Convert-Upgrade** characters, the comment is converted into a double semicolon comment. Otherwise, the comment is converted into a single semicolon comment.

Old-style double-asterisk comments are always converted into new-style triple-semicolon comments.

### 16.1.13 Control Functions

**(Reset)** [Function]

This function recomputes the SEdit edit environment. Any changes made in the font profile, or any changes made to SEdit’s commands are captured by resetting. Close all SEdit windows before calling this function.

**(Add-Command** **KEY-CODE** **FORM** &OPTIONAL **KEY-NAME** **COMMAND-STRING** **HELP-STRING**) [Function]

This function allows you to write your own SEdit keyboard commands. You can add commands to new keys, or you can redefine keys that SEdit already uses as command keys. If you mistakenly redefine an SEdit command, the function **Reset-Commands** will remove all user-added commands, leaving SEdit with its default set of commands.

**KEY-CODE** can be a character code, or any form acceptable to `il:charcode`.

**FORM** determines the function to be called when the key command is typed. It can be a symbol naming a function, or a list, whose first element is a symbol naming a function and the rest of the elements are extra arguments to the function. When the command is invoked, SEdit will apply the function to the edit context (SEdit’s main data structure), the charcode that was typed, and any extra arguments supplied in **FORM**. The extra arguments do not get evaluated, but are useful as keywords or flags, depending on how the command was invoked. The command function must return T if it handled the command. If the function returns NIL, SEdit will ignore the command and insert the character typed.

The optional arguments are used to add this command to SEdit’s middle button menu. When the item is selected from the menu, the command function will be called as described above, with the charcode argument set to NIL.

**KEY-NAME** is a string to identify the key (combination) to be typed to invoke the command. For example “M-A” to represent the Meta-A key combination, and “M-C-A” for Meta-Control-A.
COMMAND-NAME is a string to identify the command function, and will appear in the menu next to the KEY-NAME.

HELP-STRING is a string to be printed in the prompt window when a mouse button is held down over the menu item.

After adding all the commands that you want, you must call Reset-Commands to install them.

For example:

```
(add-command "^U" (my-change-case t))
(add-command "^Y" (my-change-case nil))
(add-command "1,r" my-remove-nil
    "M-R" "Remove NIL"
    "Remove NIL from the selected structure"))
(reset-commands)
```

will add three commands. Suppose my-change-case takes the arguments CONTEXT, CHARCODE, and UPPER-CASE?. UPPER-CASE? will be set to T when my-change-case is called from Control-U, and NIL when called from Control-Y. my-remove-nil will be called with only CONTEXT and CHARCODE arguments when Meta-R is typed.

Below are some SEdit functions which are useful in writing new commands.

(Reset-Commands) [Function]

This function installs all commands added by Add-Command. SEdits which are open at the time of the Reset-Commands will not see the new commands; only new SEdits will have the new commands available.

(Default-Commands) [Function]

This function removes all commands added by Add-Command, leaving SEdit with its default set of commands. As in Reset-Commands, open SEdits will not be changed; only new SEdits will have the user commands removed.

(Get-Prompt-Window CONTEXT) [Function]

This function returns the attached prompt window for a particular SEdit.

(Get-Selection CONTEXT) [Function]

This function returns two values: the selected structure, and the type of selection, one of NIL, T, or :SUB-LIST. The selection type NIL means there is not a valid selection (in this case the structure is meaningless). T means the selection is one complete structure. :SUB-LIST means a series of elements in a list is selected, in which case the structure returned is a list of the elements selected.

(Replace-Selection CONTEXT STRUCTURE SELECTION-TYPE) [Function]
This function replaces the current selection with a new structure, or multiple structures, by deleting the selection and then inserting the new structure(s). The \textit{SELECTION-TYPE} argument must be one of T or :SUB-LIST. If T the \textit{STRUCTURE} is inserted as one complete structure. If :SUB-LIST, the \textit{STRUCTURE} is treated as a list of elements, each of which is inserted.

16.1.13 Programmer’s Interface

This programmer’s interface to SEdit provides a way to call SEdit directly. This interface is sketchy and will change in the future.

\textbf{*Getdef-Fn*} \hfill [Variable]

This function is called with the arguments \textit{NAME}, \textit{TYPE}, and \textit{OLDDEF}, when SEdit needs to refetch the definition for the named object being edited. When SEdit is first started it gets passed the structure, so this function doesn’t get called. But after completion, SEdit refetches because it doesn’t know if the Edit Interface (File Manager) changed the definition upon installation. The function returns the new definition.

\textbf{*Fetch-Definition-Error-Break-Flag*} \hfill [Variable]

This flag, along with the error options listed below, determines what happens when the Getdef-Fn errors. The default value is NIL, causing errors to be suppressed. When set to T, the break will be allowed.

\textbf{*Getdef-Error-Fn*} \hfill [Variable]

This function is funcalled with the arguments \textit{NAME}, \textit{TYPE}, \textit{OLDDEF}, and \textit{PROMPT-WINDOW}, when the Getdef-Fn errors, independent of whether or not the break is suppressed. This function should return the structure to be used in place of the unavailable new definition.

\textbf{*Edit-Fn*} \hfill [Variable]

This function is funcalled with the selected structure as its argument from the Edit (M-O) command. It should start the editor as appropriate, or else generate an error if the selection is not editable.

\textbf{*Compile-Fn*} \hfill [Variable]

This function is funcalled with the arguments \textit{NAME}, \textit{TYPE}, and \textit{BODY}, from the compile completion commands. It should compile the definition, \textit{BODY}, and install the code as appropriate.

\textbf{(SEdit \textit{STRUCTURE PROPS OPTIONS})} \hfill [Function]

This function provides a means of starting SEdit directly. \textit{STRUCTURE} is the structure to be edited.

\textit{PROPS} is a property list, which may specify the following properties:

- \textit{:name} - the name of the object being edited
- \textit{:type} - the file manager type of the object being edited. If NIL, SEdit will not call the file manager when it tries to refetch the
definition it is editing. Instead, it will just continue to use the
structure that it has.

:completion-fn - the function to be called when the edit session is
completed. This function is called with the CONTEXT, STRUCTURE,
and CHANGED? arguments. CONTEXT is SEdits main data structure.
STRUCTURE is the structure being edited. CHANGED? specifies if any
changes have been made, and is one of NIL, T, or :ABORT, where :ABORT
means the user is aborting the edit and throwing away any
changes made. If the value of this property is a list, the first
element is treated as the function, and the rest of the
elements are extra arguments that the function is applied to
following the main arguments above.

:root-changed-fn - the function to be called when the entire
structure being edited is replaced with a new structure. This
function is called with the new structure as its argument. If the
value of this property is a list, the first element is treated as
the function, and the rest of the elements are extra arguments
that the function is applied to following the structure argument.

OPTIONS is one or a list of any number of the following keywords:

:fetch-definition-suppress-errors - If this option is provided, any
error under the Getdef-Fn will be suppressed, regardless of
the :fetch-definition-allow-errors option or the value of "Fetch-
Definition-Error-Break-Flag".

:fetch-definition-allow-errors - If this option is provided, any error
under the Getdef-Fn will be allowed to break.

:dontwait - This option specifies that the call to SEdit should
return as soon as the editor is started, rather than waiting for a
completion command.

:close-on-completion - This option specifies that SEdit cannot
remain active for multiple completions. That is, the SEdit
window cannot be shrunk, and the completion commands that
normally leave the window open will in this case close the
window and terminate the edit.

:compile-on-completion - This option specifies that SEdit should
call the "Compile-Fn" to compile the definition being edited
upon completion, regardless of the completion command
used.

**Fixed ARS**

**AR 7471** ---- You no longer have to Ctrl-X out of SEdit to compile.
To compile, select either of two new SEdit commands. The C-C
command (Ctrl-C) compiles and leaves the SEdit window open.
The M-C-C command (Meta-Ctrl-C) compiles and closes the
window.

**AR 7783** ---- After typing Meta-O, you are prompted to "Select a
type of dummy definition to install." The first option is "Optimizers".
This title refers to XCL:DEFOPTIMIZERS, and has nothing to do
with CL:OPTIMIZE.
AR 7786 ---- Square bracket characters '[' and ']' are not treated as special characters by SEdit, just as in Common Lisp.
Test script for SEdit version  February 24, 1987

SEE CHANGE CONTROL FOR THE FILE SEDIT

FIXED:
7692 M-E breaks on numbers
7682 Ctrl-W with pending delete selection breaks
7705 M-H with extended selection breaks
7717 M-J breaks when nothing selected
7759 forgets package of mutator candidate
7731 M-J breaks with a sequence of numbers
7509 SEDIT.RESET needs IP fonts
7576 SEDIT.RELOAD should not be part of SEdit

Select a number and hit M-E, the result will be the number.

CTRL-W when there is a pending delete selection will do nothing. The easy test case is single-quote then ctrl-w.

Make an extended selection and hit M-H (help). Sedit will now say "Select function you want the arguments for"

Just after Starting SEdit, or any other time nothing is selected and/or there is no point, M-J used to break. Will now say "Select items to join."

SEdit now remembers the package of the mutate function candidate. Type in the atom abc. Get into the LISP package (M-P, LISP). Select the atom abc. Hit M-Z, and type IL:U-\CASE, cr. Now hit M-Z again, the old SEdit would prompt with U-\CASE, the new sedit will prompt with IL:U-\CASE.

Select a sequence of numbers, or any sequence with a number first. Hit M-J. SEdit will say "Can’t join numbers". SEdit will join AB 123 CD, though, as it used to.

With INTERPRESSFONTDIRECTORIES set to NIL, call SEDIT.RESET. It won’t try to create IP fonts, and thus won’t break.

The function SEDIT.RELOAD is not longer in the sysout.

,. wasn’t recognized as a quote type. (SEDIT ’(BQUOTE (A \, FOO) B) used to display as ‘(A \, FOO) B) and now will display as ‘(A ,FOO B).

And now for all the shift selecting stuff:

Weren’t able to Move select a structure into a pending delete selection. Now you can unless the structure overlaps the pending delete selection in some way. SEdit will say "Can’t move a structure which overlaps the selection” if you try.

Can move select an object out of a quote, into any destination (exec, same sedit, different sedit), and the object will be replaced by a gap, which is selected pending delete.

Shift selecting something into a string didn’t use to be completely undoable. Try Move selecting an atom into a string, then hit undo.

Move selecting something into a different destination when there is a main selection used to leave the selection messed up. Now it doesn’t.
The TWODINSPECTOR package provides a two-dimensional inspector window abstraction, very similar in form to the standard one-dimensional inspector but laid out in rows and columns, instead of just rows.

The top level function is TWODINSPECTW.CREATE

(TWODINSPECTW.CREATE  DATEUM  ROWPROPS  COLUMNPROPS  FETCHFN  
STOREFN  VALUECOMMANDFN  ROWPROPCOMMANDFN  
COLUMNPROPCOMMANDFN  TITLE  TITLECOMMANDFN  
WHERE  TOPRIGHT)  [Function]

Datum is the object to be inspected. Rowprops is a list of properties of the datum which will be laid out vertically, or a function which will be called with datum as an argument and returns such a list. Similarly, columnprops is a list of properties of the datum which will be laid out horizontally, or a function which will be called with datum as an argument and returns such a list. Each pair (rowprop, columnprop) specifies a cell of the twodimensional inspector window. Fetchfn is a function which if called with arguments datum, rowprop, and columnprop returns the value in that cell. Storefn is a function which if called with arguments newvalue, datum, rowprop, and columnprop stores newvalue in the cell.

The cells of the inspector window are selectable. If valuecommandfn is given, it must be a function which will be called with arguments cellvalue, rowprop, columnprop, datum, and twodinspectwindow when the cell specified by (rowprop, columnprop) is selected. A default valuecommandfn is provided which allows the cellvalue to be inspected, set, or bound to the litatom IT.

Similarly the rowprops and the columnprops themselves are selectable. If rowpropcommandfn is given it must be a function which will be called with args rowprop, datum, and twodinspectwindow when rowprop is selected. If columnpropcommandfn is given it must be a function which will be called with args columnprop, datum, and twodinspectwindow when columnprop is selected. No default rowpropcommandfn or columnpropcommandfn is provided. If rowpropcommandfn is not given, the rowprops will not be selectable. Similarly, if columnpropcommandfn is not given, the columnprops will not be selectable.

Title will be the title for the window -- a default is provided. Titlecommandfn is a function which will be called with the single argument twodinspectwindow if the middle button is depressed in the title bar of the window.

Where may be a window, in which case it will be used as at least part of the twodinspector (the twodinspector is composed of five window). This is especially useful if where is the result of a previous
call to TWODINSPECTW.CREATE. The dimensions of where will not be used to position the twodinspector unless topright is NIL.

Where may also be region or a position specifying the lower left hand corner of the twodinspector. If where is NIL, the user will be prompted for a position.

Topright allows the user to specify the top right-hand corner of the twodinspector. Topright must be a position, and if given overrides any specification which may have been provided by the argument where.

Returns the main window of an attached window group.

The arguments to TWODINSPECTW.CREATE are cached on windowprops of the same name on the returned main window.

Several functions are provided for use in the various command functions.

(TWODINSPECT.REDISPLAY  TWODINSPECTW SOMEROWPROPS*  
SOMECOLUMNPROPS)  [Function]

Redisplays selected cells of twodinspectw. Somerowprops may either be a single rowprop, a list of rowprops, or NIL. Somecolumnprops may either be a single columnprop, a list of columnprops, or NIL. If either are NIL the entire twodinspectw is recomputed and redisplayed. Otherwise, the cells specified by the cross product of somerowprops and somecolumnprops are redisplayed, possibly forcing the entire twodinspectw to redisplay if the printed representation of a cell overflows its column width.

(TWODINSPECT.REPLACE  TWODINSPECTW ROWPROP COLUMNPROP*  
NEWVALUE)  [Function]

Replaces the cell specified by (rowprop, columprop) with newvalue and updates the display.

(TWODINSPECT.SELECTITEM  TWODINSPECTW ROWPROP COLUMNPROP]  [Function]

Selects the cell specified by (rowprop, columprop). That cell is inverted and put on the window prop SELECTION of twodinspectw. If either of rowprop or columprop is NIL, then the current selection is simply deselected.

(TWODINSPECT.SELECTROWPROP  TWODINSPECTW ROWPROP)]  [Function]

Selects rowprop. If rowprop is NIL, then the currently selected rowprop is deselected.
(TWODINSPECT.SELECTCOLUMNPROP  TWODINSPECTW COLUMNPROP)   [Function]

Selects columprop. If rowprop is NIL, then the currently selected columprop is deselected.

Note: there is no provision for redisplaying selected row or column props -- although this may be effected by redisplaying the entire twodinspectw.

Since the Twodinspector windows differ stylistically from the standard inspector windows, a stylistically similar onedinspector window is also provided.

(ONEDINSPECTW.CREATE  DATUM PROPS FETCHFN STOREFN VALUECOMMANDFN
     PROPCOMMANDFN TITLE TITLECOMMANDFN WHERE TOPRIGHT)   [Function]

Datum is the object to be inspected. Props is a list of properties of the datum which will be laid out horizontally, or a function which will be called with datum as an argument and returns such a list. Each prop specifies a cell of the onedimensional inspector window. Fetchfn is a function which if called with arguments datum, and prop returns the value in that cell. Storefn is a function which if called with arguments newvalue, datum, and prop stores newvalue in the cell.

The cells of the inspector window are selectable. If valuecommandfn is given, it must be a function which will be called with arguments cellvalue, prop, datum, and onedinspectwindow when the cell specified by prop is selected. A default valuecommandfn is provided which allows the cellvalue to be inspected, set, or bound to the litatom IT.

Similarly the props themselves are selectable. If propcommandfn is given it must be a function which will be called with args prop, datum, and onedinspectwindow when prop is selected. No default propcommandfn is provided. If propcommandfn is not given, the props will not be selectable.

Title will be the title for the window -- a default is provided. Titlecommandfn is a function which will be called with the single argument onedinspectwindow if the middle button is depressed in the title bar of the window.

Where may be a window, in which case it will be used as at least part of the onedinspector (the onedinspector is composed of three window), This is especially useful if where is the result of a previous call to ONEDINSPECTW.CREATE or TWODINSPECTW.CREATE. The dimensions of where will not be used to position the onedinspector unless topright is NIL.

Where may also be region or a position specifying the lower left hand corner of the onedinspector. If where is NIL, the user will be prompted for a position.

Topright allows the user to specify the top right-hand corner of the onedinspector. Topright must be a position, and if given overrides any specification which may have been provided by the argument where.

Returns the main window of an attached window group.
The arguments to ONEDINSPECTW.CREATE are cached on windowprops of the same name on the returned main window.

(ONEDINSPECT.REDISPAY ONEDINSPECTW SOMEPROPS) [Function]

Redisplay selected cells of onedinspectw. Someprops may either be a single prop, a list of props, or NIL, in which case the entire onedinspectw is recomputed and redisplayed. Otherwise, the cell(s) specified by the someprops are redisplayed, possibly forcing the entire someprops to redisplay if the printed representation of a cell overflows the column width.

(ONEDINSPECT.REPLACE ONEDINSPECTW PROP NEWVALUE) [Function]

Replaces the cell specified by prop with newvalue and updates the display.

(ONEDINSPECT.SELECTITEM ONEDINSPECTW PROP) [Function]

Selects the cell specified by prop. That cell is inverted and put on the window prop SELECTION of onedinspectw. If prop is NIL, then the current selection is simply deselected.

(ONEDINSPECT.SEVEREPROP ONEDINSPECTW PROP) [Function]

Selects prop. If prop is NIL, then the currently selected prop is deselected.
EASTASIA:
The CDROM came with CJK cross reference mappings for standards such as KSC5601, GB2312, JIS0208, etc. to Unicode 2.0. However, these particular mappings are now obsolete and have been removed as per this note from Unicode.org:
The entire former contents of this directory are obsolete and have been moved to the OBSOLETE directory. The latest information may be found in the Unihan data files in the latest Unicode Character Database. August 1, 2001.
The current set of mappings are available from https://unicode.org/Public/UNIDATA/Unihan.zip.
The format of these files is given in https://unicode.org/reports/tr38/
This Unicode directory contains mapping files extracted from the CDROM that came with the Unicode 3.0 book (2000).

The Xerox subdirectory contains mappings from the Xerox character encoding (version XC1-3-3-0, 1887) into Unicode 3.0. That is the version of XCCS corresponding to the fonts in the Medley system. The Xerox mappings did not come from the Unicode CDROM, they were constructed by combining and constrasting information from a binary file (xerox>XCCStoUni) of unknown provenance with code mappings scraped from the Wikipedia page https://en.wikipedia.org/wiki/Xerox_Character_Code_Standard in July 2020. Both sources were errorful and incomplete, so many of the mappings were hand corrected. There are still missing mappings, and there still may be errors.
