| (STREAMYLENGTH <i>dy viewport</i> )                                                                                                                                                                                                              | [Macro]    |
| Returns dy in world coordinates.                                                                                                                                                                                                                 |            |
| Uses unboxed floating point arithmetic.                                                                                                                                                                                                          |            |
| For those who desire tighter control over the two-stage process, transform into stream coordinates, and then clip against the viewport, the following functions provide primitive clipping for line drawing and text output in any image stream. |            |
| (CLIPPED.BITBLT <i>clippingregion source sourceleft sourcebottom<br/>destination destinationleft destinationbottom<br/>width height sourcetype operation texture</i> )                                                                           | [Function] |
| As in BITBLT, although the operation is clipped against clippingregion in destination stream coordinates.                                                                                                                                        |            |
| (CLIPPED.DRAWLINE <i>clippingregion x1 y1 x2 y2 width operation stream<br/>color dashing</i> )                                                                                                                                                   | [Function] |
| As in DRAWLINE, although the operation is clipped against clippingregion in stream coordinates.                                                                                                                                                  |            |
| (CLIPPED.DRAWTO <i>clippingregion x y width operation stream color dashing</i> )                                                                                                                                                                 | [Function] |
| As in DRAWTO, although the operation is clipped against clippingregion in stream coordinates.                                                                                                                                                    |            |
| (CLIPPED.DRAWBETWEEN <i>clippingregion pt1 pt2 width operation stream color dashing</i> )                                                                                                                                                        | [Function] |
| As in DRAWBETWEEN, although the operation is clipped against clippingregion in stream coordinates.                                                                                                                                               |            |

(CLIPPED.PLOTAT *clippingregion position glyph stream operation*)

[Function]

BITBLT glyph to stream centered at position and clipped against clippingregion.

(CLIPPED.PRIN1 *clippingregion expr stream*)

[Function]

PRIN1 expr on stream clipped against clippingregion.

---

## UNBOXEDOPS

---

---

By: Jan Pedersen(Pedersen.PA @ Xerox.com] and Larry Masinter (Masinter.PA @ Xerox.com]

The module UNBOXEDOPS is intended to assist those interested in high-performance, scalar, floating-point arithmetic. The basic trick is to perform floating point arithmetic on the stack, utilizing special, unboxed, floating-point opcodes, an ugly but usually effective solution. This method of eliminating floating-point number boxes is likely to change, but in the interim a combination of compiler declarations and explicit evocations of unboxed operations, as described below, will allow the interested user to eliminate a high percentage of floating-point number boxes. This module and the methods described are "safe", i.e., the declarations won't cause your programs to crash, and if it works with the declarations it will also work without them.

Unboxed floating point tricks help out only 1108's with floating point hardware or 1186's with floating point microcode. Unfortunately, they may make performance even worse on 1108's without floating point hardware, although the performance degradation is probably not too severe.

There exist opcodes which perform floating point arithmetic on the stack (that is, on the bits of those numbers, rather than pointers to those bits). These opcodes are only emitted by the byte compiler if arithmetic occurs in an unboxed context. One example of an unboxed context is arithmetic on a record field defined to be of type FLOATP, another is arithmetic on a variable declared to be of TYPE FLOAT . However, the compiler will box across function boundaries and in a return context. Furthermore, there exist more unboxed opcodes than are used by the compiler (unboxed comparison springs to mind).

UNBOXEDOPS defines macros/functions so that these additional opcodes may be exploited in an unboxed context. These macros/functions include:

UFABS, UFEQP, UFGEQ, UFGREATERP, UFIX, UFLEQ, UFLESSP, UFMAX, UFMIN, UFMINUS, and UFREMAINDER,

which behave identically to there non-U namesakes, except that the operations are done on the stack without generating floating point boxes.

For those unfamiliar with unboxed compiler declarations a short description follows:

### Using (DECLARE (TYPE FLOATING x y z)) to reduce number boxes

Consider the silly function:

```
(DEFINEQ (FIE (N)
 (bind (SETQ X 0.0) (SETQ Y 2.0) for I from 1 to N
 do (SETQ X (FPLUS X (FTIMES Y Y)))
 finally (RETURN X)))
 (TIMEALL (FIE 100))
```

returns a CPU time of .025 and reports 200 FLOATP boxes produced. Now, consider

```
(DEFINEQ (FOO (N)
 (bind (SETQ X 0.0) (SETQ Y 2.0) for I from 1 to N
 declare (TYPE FLOAT X Y)
 do (SETQ X (FPLUS X (FTIMES Y Y)))
 finally (RETURN X)))
 (TIMEALL (FOO 100))
```

returns a CPU time of .003 seconds and reports just one floatp box produced.

Essentially the (TYPE FLOAT X Y) declaration is a promise to the compiler that X and Y will hold FLOATP's , so arithmetic may be done unboxed (that is on the value itself, instead of on a pointer to the value, which is the usual case) if possible. The key issue is what is meant by "if possible".

The compiler is conservative. It will perform unboxed arithmetic only on built-in arithmetic functions (PLUS , TIMES, DIFFERENCE, etc), which have unboxed counter parts, and will otherwise box across function boundaries regardless of compiler declarations.

For example:

```
(DEFINEQ (FOOBAR (N)
 (bind (SETQ X 0.0) (SETQ Y 2.0) for I from 1 to N
 declare (TYPE FLOAT X Y)
 do (SETQ X (FPLUS X (LOG Y)))
 finally (RETURN X)))
```

then

```
(TIMEALL (FOOBAR 100))
```

returns a CPU time of .049 with 601 FLOATP boxes produced (some of which come from the LOG (five per function call)).

Also, the compiler will box in a return context. For example

```
(DEFINEQ (BAR (N)
 (bind (SETQ X 0.0) for I from 1 to N
 declare (TYPE FLOAT X)
 do (SETQ X
 (PROG ((Y 2.0))
 (DECLARE (TYPE FLOAT Y))
 (RETURN (FTIMES Y Y))))
 finally (RETURN X)))
```

then

```
(TIMEALL (BAR 100))
```

returns a CPU time of .022 with 301 FLOATP boxes produced -- notice that BAR seems like it should behave like FOO.

Indeed that is the the greatest drawback of the unboxed arithmetic as it stands now -- it is not always easy to predict what is going to happen -- there are even traps where indiscriminate uses of TYPE FLOAT declarations will actually produce MORE boxes than without them. This is the case if, for

example, you use comparison operators (GREATERP, etc) since the compiler boxes each operand before invoking them.

The BAR example may be fixed up as follows:

```
(DEFINEQ (BAR (N)
 (bind (SETQ X 0.0) for I from 1 to N
 declare (TYPE FLOAT X)
 do (SETQ X
 (PROG ((Y 2.0) RESULT)
 (DECLARE (TYPE FLOAT Y RESULT))
 (RETURN (SETQ RESULT (FTIMES Y Y))))
 finally (RETURN X)))
```

then

```
(TIMEALL (BAR 100))
```

returns a CPU time of .008 with 101 FLOATP boxes produced. Note that the compiler still boxes the result returned by the PROG.

The best way to find out what is happening is to use a combination of TIMEALL and INSPECTCODE . Unanticipated boxing behavior will show up as BOX opcodes -- if you find a sequence of opcodes UNBOX , BOX , function call, UNBOX , then you know you are in trouble. TIMEALL will report the total number of boxes produced.

Basically TYPE FLOAT declarations are best used in tight inner loops of the sort illustrated in FOO.

With all these caveats, I think it is only fair to say that considerable performance improvements can be realized with judicious use of the TYPE FLOAT declarations; my measurements indicate a factor of ten.

Additional note: TYPE FLOAT vars are by necessity LOCALVARS.

Lyric compatibility note: All the entries described for this module are in the Interlisp package. Only the Byte compiler pays attention to TYPE FLOAT declarations -- i.g. use of TYPE FLOAT declarations will be ignored by the XCL compiler.

**UNDIGESTIFY**

---

---

By: Steven C. Bagley (Bagley.pa)

This document last edited on May 27, 1986

**INTRODUCTION**

This Lafite package allows you to unpack an Arpa Network digest, such as AList, into its constituent messages. A new item, "Undigest," is placed on the browser menu. When a single message (presumably a digest) is selected, clicking on this item will delete the selected message, and append the constituent messages to the end of the mail folder. If the selected message is not a digest, or is a digest in a format that cannot be parsed properly, then a message will be printed and nothing will happen to the mail folder.

**USER OPTIONS**

\*DELETE-DIGEST-FLAG\*, if T means that the digest message should be deleted if it is successfully parsed. The default is T.

\*MOVE-TO-FIRST-DIGEST-MESSAGE-FLAG\*, if T means to select the first constituent message, if NIL means to select the first undeleted message after the digest message. The default is NIL.

\*DONT-UPDATE-HEADERS-FLAG\*, if T means not to copy the To: field from the digest to each constituent message. The default is NIL.

**PLANNED ENHANCEMENTS**

Inserting the contained messages immediately after the digest, rather than appending.

Moving the contained messages to a different mail folder.

**NOTES**

Many digests are not in the correct format. The parser used in this program tries to be very forgiving, and hence, is relatively slow (about 10 seconds to parse a digest on a Dorado). If everyone adhered to RFC934, the parser could be optimized for speed, but, alas, this is not the case.

## UUENCODE

---

---

By: Doug Cutting (Cutting.PA@Xerox.COM)

This document last edited on October 7, 1987.

UUENCODE provides facilities for encoding files into printing ASCII characters for transfer by electronic mail. It is compatible with the UNIX™ facility of the same name. For details of the file format see the UNIX™ manual page on 'uuencode'.

(UUENCODE *FILES INTO-FILE*) [Function]

Encodes the files named by FILES into INTO-FILE. FILES may be either a list of files or a single file name. Note that UNIX™ uuencode does not support multiple files encoded in one file. Thus one should only pass a single file name to UUENCODE if the file is to be decoded under UNIX™. Returns the name of the file written.

(UUDECODE *FILE-OR-STREAM ONLY-ONE-FILE?*) [Function]

Decode from FILE-OR-STREAM writing the decoded files in the connected directory. FILE-OR-STREAM may be either a file name or a stream. If ONLY-ONE-FILE? is non-NIL then only one file will be extracted from FILE-OR-STREAM, and an error will be reported if no encoded file is found. This can be thought of as UNIX™ compatibility mode. Returns the list of the names of the files extracted.

(UUENCODE-INTERNAL *INS OUTS DECODE-NAME FILE-MODE*) [Function]

Called by UUENCODE to encode one file. Encodes all bytes from the stream INS to the stream OUTS. DECODE-NAME is the name the file should be given when it is decoded. FILE-MODE is the UNIX™ file mode for the file. DECODE-NAME defaults to (FULLNAME INS) and FILE-MODE defaults to the value of the variable UU.MODE-DEFAULT. Returns OUTS.

UU.MODE-DEFAULT [Global Variable]

The default UNIX™ file mode to encode files under as an integer. UNIX™ uuencode will use this when creating the decoded file. The initial value is 644Q (read & write by owner, read by group and other).

(UUDECODE-INTERNAL *INS ONE-FILE-ONLY?*) [Function]

Called by UUDECODE to decode one file. INS should be a stream open for input. Returns the name of the file extracted or NIL if none is found and ONE-FILE-ONLY? is NIL.

UUENCODE was inspired by Christopher Lane's BMENCODE package.

## VSTATS

---

---

By: Johannes A. G. M. Koomen  
(Koomen.wbst@Xerox or Koomen@CS.Rochester)

Uses: SYSTATS, READNUMBER

This document last edited on November 20, 1987

### INTRODUCTION

Loading VSTATS will put a VStats entry on the background menu, and execute (VSTATS 'On), which will cause the following display to be created and continuously updated:

### DESCRIPTION

VSTATS is a facility for continuously displaying various interesting aspects of a running system. It can display the current time of day, with or without seconds, and/or display memory and disk space utilization, and/or display machine utilization in terms of CPU, I/O, GC and swap time. The display can be regular or inverse-video. The display is updated at user settable intervals, either always or only if the display window is completely visible.

Closing the VSTATS window will remove the background update function.

Left buttoning the VSTATS window causes it to be recomputed and redisplayed entirely. Otherwise display updates only affect those parts that have actually changed, making for a visually quiet and efficient facility.

Middle buttoning the VSTATS window will bring up an Inspector window onto the VSTATS list of options. Left buttoning an option name prints an explanation of the option to the Prompt window. Left buttoning an option value selects it, and middle buttoning an option value presents a menu from which a new value can be selected. The options window looks like this:

| VStats Options        |          |
|-----------------------|----------|
| Display.Color         | Normal   |
| Update.Always?        | No       |
| Show.Disk.Space?      | DSK1     |
| MUtil.Hysteresis      | 20       |
| Space.Panic.Level     | Disabled |
| Clock.Update.Interval | 1        |
| Space.Update.Interval | 300      |
| MUtil.Update.Interval | 1        |

VSTATS is highly optimized for speed and implemented as a BACKGROUNDFN rather than as a separate process so as to minimize overhead. As a result, VSTATS can easily be run with display update intervals equal to 1 second.

## DETAILS

(VSTATS *on/off*) [Function]

If *on/off* is either ON, On, on, or T, the VStats display is turned on; otherwise off.

VSTATS.CLOCK.INTERVAL [Variable]

If the global variable VSTATS.CLOCK.INTERVAL is a positive number, VSTATS displays an alphanumeric clock (e.g., "1-Aug-85 14:30"), which is updated every VSTATS.CLOCK.INTERVAL seconds. If this interval is less than 1 minute VSTATS displays seconds as well. For those of you who keep their machines running overnight (say, with IDLE or BOUNCE), if the clock display is enabled, VSTATS will resynchronize the local clock with the network daily at midnight. (My machine loses about 15 minutes a week, otherwise!)

VSTATS.SPACE.INTERVAL [Variable]

If the global variable VSTATS.SPACE.INTERVAL is a positive number, VSTATS displays, both graphically and alphanumerically, the utilization of Data, Atom, and VMem spaces and optionally Disk space, which is updated every VSTATS.SPACE.INTERVAL seconds.

VSTATS.SPACE.PANIC.LEVEL [Variable]

If VStats is displaying space utilization, and VSTATS.SPACE.PANIC.LEVEL is a percentage between 1 and 100 (or a fraction between 0 and 1), and any of the memory space utilizations (other than disk) exceed this percentage, VSTATS will flash its window in proportion to the excess, whether the window is occluded or not.

VSTATS.SPACE.SHOW.DISK? [Variable]

If VStats is displaying space utilization, then if VSTATS.SPACE.SHOW.DISK? is non-NIL, Disk space utilization is displayed as well, provided VStats can figure out the total disk size. If VSTATS.SPACE.SHOW.DISK? is T, the default DSK is used, for instance {DSK19} on a Dorado, or {DSK}<LispFiles> on a Dandelion. Alternate Dorado partitions or Dandelion volumes may be assigned to VSTATS.SPACE.SHOW.DISK? as well. If assigned through the options window, VStats will figure out which volumes or partitions are displayable.

VSTATS.MUTIL.INTERVAL [Variable]

If the global variable VSTATS.MUTIL.INTERVAL is a positive number, VSTATS displays, both graphically and alphanumerically, the machine utilization in terms of CPU time, time spent on disk and

Ethernet I/O, garbage collection time, and swapping time, which is updated every VSTATS.MUTIL.INTERVAL seconds.

VSTATS.MUTIL.HYSTERESIS [Variable]

If VStats is displaying machine utilization and VSTATS.MUTIL.HYSTERESIS is a positive number, the relative percentages are based on the average over VSTATS.MUTIL.HYSTERESIS intervals, otherwise they are based on the total time since VSTATS was invoked.

VSTATS.POSITION [Variable]

If the global variable VSTATS.POSITION is a POSITION, the VSTATS display will be put there, otherwise the user is prompted for a POSITION.

VSTATS.BLACK? [Variable]

If the global variable VSTATS.BLACK? is non-NIL, VSTATS displays with inverse video.

VSTATS.ALWAYS? [Variable]

If the global variable VSTATS.ALWAYS? is non-NIL, VSTATS will always update its display when its timers expire, causing its window to come to the top if it isn't already there; otherwise, VSTATS will only update the display if its window is neither partially nor wholly occluded. If it is occluded, VSTATS will, of course, continue to update its internal timers and the display will be updated the first time the timers expire after the display becomes wholly visible again.

#### Defaults

|                          |                             |
|--------------------------|-----------------------------|
| VSTATS.BLACK?            | NIL                         |
| VSTATS.ALWAYS?           | NIL                         |
| VSTATS.POSITION          | top right corner of display |
| VSTATS.CLOCK.INTERVAL    | 1 second                    |
| VSTATS.SPACE.INTERVAL    | 300 seconds (5 minutes)     |
| VSTATS.SPACE.PANIC.LEVEL | 95 %                        |
| VSTATS.SPACE.SHOW.DISK?  | T                           |
| VSTATS.MUTIL.INTERVAL    | 1 second                    |
| VSTATS.MUTIL.HYSTERESIS  | 20 intervals                |

If different values are preferred, these variables should be set by the user before loading VSTATS to affect initial display. They can of course be altered anytime using the options menu.

#### Extras:

A number of functions are required (and supplied) by VSTATS which the author believes might well be part of standard Interlisp-D, viz.,

(COVEREDWP *window*) [Function]

Returns T if *window* is partially or completely covered by some other window; NIL otherwise.

(CLOCKTICKS *interval timerunits*) [Function]

Returns the (machine dependent!) number of internal clock ticks over the interval. For instance, on the D'Lion

(CLOCKTICKS 2.5 'MINUTES) = 5211900

(ALTOPARTITIONS)

[Function]

On the Dorado, returns a list of partitions set up with an Alto exec, i.e., containing a system boot file. Especially useful with the recently added Extended VMem option, where not all partitions are bootable. Returns NIL on any other machine type. Note: this list of partitions takes between 15-20 seconds to compute.

(DISKUSEDPAGES *dsk recompute*)

[Function]

Returns the total number of disk pages in use (complementing DISKFREEPAGES). On Dorado, this is only an estimate, unless *recompute* is non-NIL in which case you wait ~ 8 seconds for the answer.

(DISKTOTALPAGES *dsk recompute*)

[Function]

Returns the total number of disk pages available (sum of DISKFREEPAGES and DISKUSEDPAGES).

---

WALKFILES

---

---

Johannes A. G. M. Koomen  
(Koomen.wbst@xerox or Koomen@cs.rochester.edu)

October 27, 1989

## SUMMARY

WALKFILES is a facility for searching loaded files for arbitrary objects. It complements MasterScope, in that it can do some things that MasterScope can't (like looking for arbitrary substrings in functions); other things Masterscope can do as well or better. WALKFILES does not require an analysis of the files prior to action.

## DESCRIPTION

(WALKFILES *pattern file{s} editcommands confirmflg quietflg filepackagetypes*) [Function]

Invokes WALKDEFS on all the objects on each *file{s}* of the types given in *filepackagetypes*. If *file{s}* is NIL, the value of FILELST is used. If *filepackagetypes* is NIL, all the filepackage types in PRETTYTYPEELST are used.

(WALKDEFS *pattern name{s} filepkgtype editcommands confirmflg quietflg*) [Function]

Walks over the *filepkgtype* definition of each name in *name{s}* looking for *pattern*. Pattern can be anything acceptable to EDITFINDP. For each occurrence, first prints the name (unless *quietflg* = T) and then prints the occurrence if *editcommands* is NIL, or invokes the editor in interactive mode if *editcommands* is T (asking for confirmation if *confirmflg* = T), or applies *editcommands* to the name and *filepkgtype* if *editcommands* is a function, or otherwise invokes the editor with *editcommands*.

## EXAMPLES

(WALKFILES 'elseif 'MYFILE T) [Example]

Brings up the editor on every definition in MYFILE which contains the symbol elseif.

(WALKFILES '\$FOO\$) [Example]

Prints every occurrence of any symbols with FOO as a substring in every definition in any file in FILELST.

(LET (THEFNS) [Example]  
 (WALKFILES '(\*ANY\* \$FOO\$ BAR) NIL '(LAMBDA (FN) (PUSH THEFNS FN)) NIL T 'FNS)  
 THEFNS)

Collects all functions containing either the symbol BAR or any symbols with FOO as a substring on every file in FILELST.

---

---

**WDWHACKS**

---

---

By: Atty Mullins (Mullins.pa@Xerox.com)

Revised by: Ron Kaplan (kaplan@parc.xerox.com)

Some short hacks that make window management slightly easier.

Loading this file forces the menu entries: **SLAMWS** (in the background menu) with the subitem **INSPECTORS**, **SEDIT**, and **FILEBROWSERS**, and **POPSHAPE** (under "Close" in the window menu), and replaces the action for **SHAPE** (window menu) with its own call.

When **SLAMWS** is selected, you are asked for a region of the screen, and all of the windows that intersect that region are closed (by call to **CLOSEW**). If one of the **INSPECTORS**, **SEDIT**, or **FILEBROWSERS** subitems is selected, all open (not shrunken) windows of the indicated type are closed.

When **SHAPE** is selected, the old shape of the window is stored, and then selecting **POPSHAPE** will reshape the window to the stored shape. When **POPSHAPE** is called, the current shape is stored, so that doing **POPSHAPE** multiple times will rotate between the two shapes.

The shape/popshape hacks are useful if you want to either get something out of the way temporarily (but not lose it entirely); or to enlarge something temporarily (e.g., for doing a SEE in the typescript window).

---

---

# WHEELSCROLL

---

---

By Ron Kaplan

This document was last edited in June 2023.

This small file adds the ability to scroll (scrollable) windows by rotating the wheel on a wheel mouse or by moving (2?) fingers on a track pad. The capability is enabled when `WHEELSCROLL.LCOM` is loaded. It is toggled on and off by

`(ENABLEWHEELSCROLL ON)` [Function]

Initially `(ENABLEWHEELSCROLL T)`.

The vertical scrolling speed is controlled by the variable

`WHEELSCROLLDELTA` [Variable]

The number of points to scroll for each click of the wheel. Higher values give faster scrolling. A negative value reverses the scrolling direction. Initially value: 20.

`HWHEELSCROLLDELTA` [Variable]

If non-NIL, this is the delta used for horizontal scrolling.

## Implementation:

Lisp receives a key transition on `PAD1` or `PAD2` for vertical scrolling when the wheel rotates and no other keys are down. `(ENABLEWHEELSCROLL T)` modifies the keyaction table so that it maps these transitions to characters 156 and 157. Those characters are defined as interrupts that invoke the vertical scrolling action. For horizontal scrolling sideways pushes of a wheel (if it has that) produce transitions on `PAD4` and `PAD5`, which map to interrupt-characters 158 and 159. (156-159 are the highest right-panel characters of character-set 0 that correspond to left-panel control characters, so typically have no other conflicting meaning.)

`(ENABLEWHEELSCROLL NIL)` causes `PAD1`, `PAD2`, `PAD4`, and `PAD5` to be ignored.

## Current negative features:

1. When the wheel is depressed for middle-button effect (and no other keys are down), an accidental rotation of the wheel during the transition (up and/or down) may cause unintended scrolling.

We need to develop a strategy, either in Lisp, Maiko, or X, to discriminate intended middle-button pushes from intended scrolling. This is not an issue for track-pad scrolling.

2. When the wheel is rotated over a window that partially occludes a Tedit window with a caret blinking in its unoccluded region, both the target window and the partially obscured Tedit window may scroll.

## WHOCALLS

---

---

By: Bill van Melle (vanMelle.pa@Xerox.com)

This file contains two useful functions for quick crossreference:

(whocalls *callee usage*) [Function]

maps over all symbols in the current environment, looking for any function that mentions callee according to usage:

values for usage:

USES VAR VARS BOUND USEDFREE GLOBALS

All mean: mention as a variable

NIL CALLS

means calls as a function

(distribute.callinfo) [Function]

inverts all of the call, use global, use free, bound relations for functions, variables from compiled code. Operates by mapping over all symbols in the sysout that are defined as compiled code, and analyzing their definitions. Anything that is called has a CALLED BY property of all of the things that call it; any variable bound has a BOUND BY with the list of functions that bind it, variables that are used globally have a USED GLOBAL BY and variables that are used freely have a USED FREE BY.

(References from interpreted code, etc are not detected, so it isn't 100% guaranteed that if something doesn't have a CALLED BY that it isn't called.....)

## WHO-LINE

---

---

By: SML (Lanning.pa@Xerox.com)

### INTRODUCTION

Need to know what package you're in? Don't know what your connected directory is? Fret not. The Who-Line is here.

The Who-Line is a window that displays this information on your screen. It is continually updated to reflect the current state of the world (thanks to an entry on BACKGROUNDFNFS). Additionally, items in the Who-Line can act as menu items, allowing you to change the state of the machine.

### Defining the information displayed in the Who-Line

The values displayed in the Who-Line are determined by the setting of the variable `*WHO-LINE-ENTRIES*`.

`*WHO-LINE-ENTRIES*` [Global Variable]

`*WHO-LINE-ENTRIES*` is a list that describes the items that will be displayed in the who-line. Each item in the list should be a list of up to five things: the name of the item; a form that, when evaluated, will produce the value to display; the maximum number of characters in the value; an optional function to call if the item is selected (with the mouse) in the Who-Line; an optional form that will reset any internal state of the entry when evaluated; and an optional string that describes the value displayed by the entry.

[[NOTE: Since the items on the Who-Line are evaluated rather often, it is best if they are fast and efficient (= don't CONS or allocate any space).]]

The following are standard members of `*WHO-LINE-ENTRIES*`.

`*WHO-LINE-USER-ENTRY*` [Variable]

Displays the current user in the Who-Line. Selecting this item in the Who-Line will let you change the logged in user.

`*WHO-LINE-HOST-NAME-ENTRY*` [Variable]

Displays the (ETHERHOSTNAME) of the machine you are running on.

`*WHO-LINE-PACKAGE-ENTRY*` [Variable]

Displays the package of the current TTY process in the Who-Line. Selecting this item in the Who-Line will let you switch the package of the current TTY process.

`*WHO-LINE-READTABLE-ENTRY*` [Variable]

Displays the (name of the) readtable of the current TTY process in the Who-Line. Selecting this item in the Who-Line will let you switch the readtable of the current TTY process.

**\*WHO-LINE-TTY-PROC-ENTRY\*** [Variable]

Displays the name of the current TTY process in the Who-Line. Selecting this item in the Who-Line will let you give the TTY to a different process.

**\*WHO-LINE-DIRECTORY-ENTRY\*** [Variable]

Displays the current connected directory in the Who-Line; the directory is shown in the format "Dir>Subdir>...>Subdir on {Host}". Selecting this item in the Who-Line will let you connect to another directory: the variable **\*WHO-LINE-DIRECTORIES\*** (see below) is used to produce a menu of interesting directories. If you are holding down a SHIFT key when you select an item from this menu, the directory name will be COPYINSERTed into the current tty input stream, otherwise you will be connected to that directory.

**\*WHO-LINE-VMEM-ENTRY\*** [Variable]

Displays the percentage of the VMem file that is currently being used in the Who-Line. If the VMem file is inconsistent, the number will be preceded by an asterik ("\*"). Selecting this item in the Who-Line will let you do a (SAVEVM).

**\*WHO-LINE-SYMBOL-SPACE-ENTRY\*** [Variable]

Displays the percentage of symbol space that is currently in use.

**\*WHO-LINE-TIME-ENTRY\*** [ Variable]

Displays the current time in the Who-Line. Selecting this item in the Who-Line will let you do a (SETTIME). If you hold down a shift key when you select this item, the current time will be COPYINSERTed into the current tty input stream instead.

The default value of **\*WHO-LINE-ENTRIES\*** contains all these items

### **Other ways to tailor the Who-Line**

**\*WHO-LINE-ANCHOR\*** [Variable]

**\*WHO-LINE-ANCHOR\*** describes where the who-line will be displayed. If **\*WHO-LINE-ANCHOR\*** contains the symbol :TOP, the Who-Line will be anchored at the top of the screen; if it contains the symbol :BOTTOM it will be anchored at the bottom of the screen. If **\*WHO-LINE-ANCHOR\*** contains the symbol :LEFT, it will be anchored to the left side of the display; if it contains the symbol :CENTER it will be centered on the screen; if it contains the symbol :JUSTIFY it will run the width of the screen; if it contains the symbol :RIGHT it will be anchored to the right side of the screen. Finally, if **\*WHO-LINE-ANCHOR\*** is a POSITION, it will be used as the lower left corner of the Who-Line. The default value is (:CENTER :BOTTOM).

**\*WHO-LINE-NAME-FONT\*** [Variable]

The font used to display the names of the items in the who-line. The default is HELVETICA 8 BOLD.

**\*WHO-LINE-VALUE-FONT\*** [Variable]

The font used to display the values in the who-line. The default is GACHA 8.

**\*WHO-LINE-COLOR\*** [Variable]

The color of the Who-Line. Legal values are the keywords :WHITE and :BLACK. The default is :WHITE.

**\*WHO-LINE-BORDER\*** [Variable]

The border width of the Who-Line window. The default is 2.

**\*WHO-LINE-TITLE\*** [Variable]

The title of the Who-Line window. The default is NIL.

**\*WHO-LINE-DISPLAY-NAMES?\*** [Variable]

If **\*WHO-LINE-DISPLAY-NAMES?\*** is true, the names of items in the who-line will be displayed; otherwise they will not be shown. The default value is T.

**\*WHO-LINE-UPDATE-INTERVAL\*** [Variable]

The number of milliseconds between updates of the who-line. The default is 100 milliseconds.

### Installing new Who-Line options

Changing the above variables has no direct effect on the who-line. These values need to be installed in the Who-Line before they can take effect.

**(INSTALL-WHO-LINE-OPTIONS)** [Function]

INSTALL-WHO-LINE-OPTIONS installs the above options in the Who-Line, and updates the Who-Line accordingly.

The Who-Line supports an easy way to interactively add or remove entries. If you click on the Who-Line while holding down the EDIT or CONTROL key, you will be given a chance to add or remove items from the Who-Line.

**\*WHO-LINE-ENTRY-REGISTRY\*** [Global Variable]

A list of all known Who-Line entries. This is used to construct the menu of possible new entries for the Who-Line.

### Who-Line process state

The who-line entry **\*WHO-LINE-TTY-STATE-ENTRY\*** tries to display the current state of the TTY process.

**\*WHO-LINE-TTY-STATE-ENTRY\*** [Variable]

A Who-Line entry that displays the "state" of the current TTY process in the Who-Line. The typical state of a process is the name of the function that is currently running in that process. This simple minded result can be altered by use of the following items.

[[NOTE: Because of the nature of the Lisp scheduler, this information is almost always out of date.]]

The Who-Line "state" can be explicitly controlled from code. If the special variable `*WHO-LINE-STATE*` is bound, its value is taken to be the state of that process. You can use this feature to provide visual indication of the state of your code by using the programming idiom:

```
(LET ((*WHO-LINE-STATE* indicator))
 (BLOCK) ;Give the Who-line a chance to run
 ...your-code...)
```

This will run the `...your-code...` with the Who-Line state of the process set to (the value of) *indicator*. The call to BLOCK insures that the Who-Line has a chance to update before `...your-code...` is run.

`*WHO-LINE-STATE-UNINTERESTING-FNS*` [Global Variable]

If there is no declared who-line state (via a WITH-WHO-LINE-STATE form), then the name of the function that is currently running is used as the who-line state. However, if the function is on the list `*WHO-LINE-STATE-UNINTERESTING-FNS*`, the function that called it is used instead. The default value of `*WHO-LINE-STATE-UNINTERESTING-FNS*` is (BLOCK AWAIT.EVENT).

WHO-LINE-STATE [Property]

If the function that is currently running has a WHO-LINE-STATE property, the value of that property is used as the who-line state. This is used to convert functions like \TTYBACKGROUND to meaningful values like "TTY wait".

(WHO-LINE-REDISPLAY-INTERRUPT) [Function]

Updates the Who-Line. It is intended that this function be installed on an interrupt character, so that the user can easily force an update of the Who-Line. For example,

```
(ADVISE 'CONTROL-T 'BEFORE ' (WHO-LINE-REDISPLAY-INTERRUPT))
```

will cause a ^T interrupt to update the Who-Line as well as its current behavior of printing state information in the Prompt window. Alternatly, you can define a new interrupt character that will force an update of the Who-Line;

```
(INTERRUPTCHAR (CHARCODE ^U) ' (WHO-LINE-REDISPLAY-INTERRUPT) 'MOUSE)
```

will cause the Who-Line to be updated whenever the user hits a ^U.

### Other interesting things

`*WHO-LINE-DIRECTORIES*` [Global Variable]

A list of interesting directories used to generate a pop-up menu of directories to connect to when you select the DIRECTORY item in the Who-Line. The default value is a list containing just your LOGINHOST/DIR. When the Who-Line notices that you have changed your connected directory, it updates this list to contain the new directory.

(CURRENT-TTY-PACKAGE) [Function]

Returns the name of the package of the current TTY process. This function is used in the default value of `*WHO-LINE-ENTRIES*`.

(CURRENT-TTY-READTABLE-NAME) [Function]

Returns the name of the readtable of the current TTY process, or the string "Unknown" if it can't figure out the name. This function is used in the default value of `*WHO-LINE-ENTRIES*`.

(SET-PACKAGE-INTERACTIVELY)

[Function]

Pops up a menu of currently defined packages. If the user selects one of them, the current package is changed to the selected package.

(SET-READTABLE-INTERACTIVELY)

[Function]

Pops up a menu of currently known readtables. If the user selects one of them, the current readtable is changed to the selected readtable.

## WORDFNS

---

---

By: Ron Kaplan (Kaplan.pa@Xerox.com)  
Becky Burwell (Burwell.pa@Xerox.com)

Uses: SETSTRINGLENGTH

This document last edited on August 19, 1988.

### INTRODUCTION

WORDFNS is a set of functions for manipulating files of words. There are functions to do the following: sort files, manipulate sorted files, provide common i/o functions for word files, provide mapping and translation mechanisms, provide common translation functions, and provide packaged mapping utilities.

The idea behind the mapping mechanism is that you can translate a file or list of files by specifying a read function to operate on each chunk of a file (the obvious two chunks are words and lines). You can specify file specific translation functions, default functions (when file specific functions are not provided) and common translation functions for all files. The input to the first translation function is the result of applying the read function to an input stream open on a file. The output of the first translation function is passed as input to the second translation function, etc.

### USE

Note: for any file, if NIL or T is specified then the results are printed in the executive window.

### Sorting Files

(SORTWORDFILE *IFILES* *OFILE* *COMMONTRANSFNS* *DEFAULTTRANSFNS* *READFN*  
*COMMONCOMPAREFN* *KEEPDUPLICATES* *FIELDS* *SEPARATOR* *REVERSEORDERFLG*  
*FASTFLG*) [Function]

The functions sorts the words on *IFILES* and stores the result back on *OFILE*. Th duplicates are eliminated unless *KEEPDUPLICATES* is non-NIL. For a description of the function of the arguments *COMMONTRANSFNS*, *DEFAULTTRANSFNS* and *READFN* see the section entitled "Translation Mechanisms". The argument *FIELDS* is used to specify the sorting order. The separator of the fields is specified in *SEPARATOR*. If *REVERSEORDERFLG* is T the result of the sort is reversed. *FASTFLG* set T causes the sort to caches the fields by consing allowing for a quicker sort (but consumes memory).

*FIELDS* is one of: NIL, a list of field numbers or else a list of one, two or three element lists of the form: FieldNumber Type CompareFn where type is either STRING (the default) or NUMBER. The default comparefn for STRING is ALPHORDER; for NUMBER is NUMORDER [Argument]

*SEPARATOR* is one of the following: a character string, a bittable, a list of single character atoms or numbers or one of the special atoms WHITESPACE (indicating a space or tab) or the atom TAB. The default is WHITESPACE.

[Argument]

>> should I put NUMORDER and GetNthField here?<<

Note: two related functions, NUMORDER and GetNthField, are described in the miscellaneous section.

### Functions for use with sorted files

In each of the following functions:

*COMMENTFILE* contains the details of the result of the function (for example, the number of strings that were read in from each file) [Argument]

(COMMONSORTEDFILES *file1 file2 ofile COMMENTFILE*) [Function]

Computes the intersection of two sorted files, *file1* and *file2* and the results are stored on *ofile*. The files are read a line at a time. The value is the full name of *ofile*.

(COMPARESORTEDFILES *file1 file2 ofile IMINUS2 2MINUS1*

*COMMENTFILE COMMENT*) [Function]

The two sorted files, *file1* and *file2*, are compared a line at a time. The common lines are stored on *ofile*. The output is in two columns: the left column for those lines in *file1* that do not exist in *file2* and the right column for those lines in *file2* that do not exist in *file1*. The two flags *IMINUS2* and *2MINUS1* are used to determine how the comparisons will be performed. If they are not specified they are both assumed to be T thus meaning that the comparison will be performed by subtracting *file2* from *file1* and *file2* with *file1* subtracted. If only one of *IMINUS2* or *2MINUS1* is specified then only the specified one way comparison will be done. *COMMENT* is intended to be a string which, by default, is the string "Comparison". This string is inserted at the top of the file. The value is the full name of *ofile*.

(DIFFSORTEDFILES *FILE1 FILE2 OUTFILE COMMENTFILE*) [Function]

The result of subtracting *FILE1* from *FILE2* is stored on *OUTFILE*. The files are read a line at a time. The value is the full name of *ofile*.

## I/O Functions

In the two major read functions, DREADLINE and DREADWORD, the SPACE, CR, LF and ^Z in any character set are interpreted to be the corresponding character in character set zero.

(DREADLINE *stream string skipsemicolons*) [Function]

Words are read from the word-stream *stream*, smashing them into *string*, which grows as needed. Returns NIL at EOF. Skips leading and trailing separators, and if *skipsemicolons* is non-NIL then sequences from ";" to EOL are treated as a composite separator or end-marker. Unlike DREADWORD (described later in this section), segments are separated only by EOL, so compounds are not split into components. Note that *stream* must have been set up so that BIN/READCCODE returns NULL on EOF.

(DREADLINESKIPSC *stream string skipsemicolons*) [Function]

Calls DREADLINE with *skipsemicolons* bound to T.

(DREADWORD *stream string*) [Function]

Words are read from the word-stream *stream*, smashing them into *string*, which grows as needed. Returns NIL at EOF. Skips leading and trailing separators, and treats sequences from ";" to EOL as a composite separator or end-marker. Unlike DREADLINE, segments are separated by space as well as EOL, so splits compounds into components. Note that *stream* must have been set up so that BIN/READCCODE returns NULL on EOF.

(INPUTWORDSTREAM *FILE NOPRINT*) [Function]

Returns a stream that is guaranteed to be open for word-reading (e.g. using DREADLINE or DREADWORD) at the beginning of *FILE*. If *NOPRINT* is NIL then the fullname of the file will be output.

(OUTPUTWORDSTREAM *FILE*) [Function]

Returns and opens a stream for the output of words (sequential text) guaranteed closed when reset context is exited and deleted if there is an error.

## Translation Mechanisms

Translation mechanisms are supplied to allow great flexibility in translating one or more files which may be in different formats and have unique translations applied to them. To specify how a file is to be read a read function (READFN) can be specified. Two common read functions, described previously, are DREADLINE and DREADWORD.

As mentioned earlier each file can have unique or common translation functions. A translation function is a function which takes two arguments: a string (the input to be translated) and an optional scratch string which can be destructively modified. The output of the translation function is one of the following: a string, the value T or the value NIL. Readers may wish to refer to the LispUsers module SETSTRINGLENGTH. The special value T denotes that the output is the same as the input. A value of NIL means that nothing will be kept.

**>> a better name for translation set <<**

**>> what is the syntax?<<**

*IFILES* is either a single file name, a single translation set, a list of file names or a list of translation sets. Translation sets have the form: (READFN READFN TRANFN1 TRANFN2 ...). (Note the first element of the list is the actual atom READFN and the second element [Argument]

*READFN* is the read function that is used for reading the files. It is passed a stream. Unless specified otherwise, the default read function is DREADWORD. [Argument]

*DEFAULTTRANSFNS* is a single function or list of functions which is first applied to the first file. What is given to the translation function is determined by what the read function passed. Unless specified otherwise, the default read function is DREADWORD. The result of applying the first function in *DEFAULTTRANSFNS* is input to the second function in *DEFAULTTRANSFNS*. This result is then passed on for application to the functions in *COMMONTRANSFNS*. The special value T denotes that the output is the same as the input. [Argument]

*COMMONTRANSFNS* [Argument]

*DONTPRINT* is the argument which decides whether the details of the translation functions will be printed. By default it is NIL meaning that the details will be printed. [Argument]

(TRANSLATEWORDFILE *IFILES* *COMMONTRANSFNS* *DEFAULTTRANSFNS* *READFN* *DONTPRINT*) [Function]

TRANSLATEWORDFILE produces an output file by translating each word in (possibly a list of) *IFILES* through a translation function. List elements of files are paired with their own idiosyncratic translation function. Otherwise the *DEFAULTTRANSFNS* is used. *COMMONTRANSFNS* are applied to the results of the default or file-specific translations to produce the translation string. If any translation function returns NIL, that string is skipped. A translation function is assumed to be an identity if it returns T, which makes simple predicates easy.

(COLLECTWORDFILE *IFILES* COMMONTRANSFNS DEFAULTTRANSFNS READFN DONTPRINT)[Function]

Returns the list of non-NIL values of functions applied to words in *IFILES*.

(MAPWORDFILE *IFILES* COMMONTRANSFNS DEFAULTTRANSFNS MAPFN READFN DONTPRINT) [Function]

Maps mapping function over words in *IFILES*. Nothing is setup for output.

### Packaged Mapping Utilities

(LONGESTWORDS *FILES* COMMONTRANSFNS DEFAULTTRANSFNS READFN DONTPRINT)[Function]

The list of longest translated words in *FILES* is returned.

(SEXPRCOUNT *FILE* RDTBL ) [Function]

Returns the number of s-expressions in *FILE* using *RDTBL* to read.

(WORDCOUNT *IFILES* COMMONTRANSFNS DEFAULTTRANSFNS READFN DONTPRINT ) [Function]

The total number of translated words in *IFILES* is returned.

(FINDPREFIXES *IFILES* *OFIL*E PREFIXES BUTNOT READFN ) [Function]

FINDPREFIXES produces an output file *OFIL*E of those strings read by *READFN* from *IFILES* which match at least one prefix in the list of prefix strings *PREFIXES* and do not match any prefixes in the list of prefixstrings *BUTNOT*.

(FINDSUFFIXES *IFILES* *OFIL*E SUFFIXES BUTNOT NOCAPS READFN ) [Function]

FINDPREFIXES produces an output file *OFIL*E of those strings read by *READFN* from *IFILES* which match at least one suffix in the list of suffix strings *SUFFIXES* and do not match any suffixes in the list of suffix strings *BUTNOT*. If *NOCAPS* is specified then the match succeeds if the string does not have the first letter capitalized.

(FINDSUBSTRINGS *IFILES* *OFIL*E SUBSTRINGS READFN ) [Function]

FINDSUBSTRINGS produces an output file *OFIL*E of those strings read by *READFN* from *IFILES* which match at least one substring in the list of substrings *SUBSTRINGS*.

**Translation Functions**

(MIXEDCASEP *W*) [Function]

Returns *W* if it contains mixtures of uppercase and lowercase characters after the initial character.

(PROPERP *W*) [Function]

Returns *T* if the first characters of *W* is uppercase.

(NOTPROPERP *W*) [Function]

Returns *T* if the first characters of *W* is not uppercase.

(REVERSESTRING *W STR*) [Function]

Reverses *W* into *STR* and returns *STR*.

**Examples**

This example will printout all the lines that have either the prefix "re" or "no" but not the prefix "non".

```
(FINDPREFIXES '({dsk}Myfile T '("re" "no") '("non") (FUNCTION DREADLINE))
```

This example will output to file {Phylum}<Project>Suffixes all the words in the files {dsk}File1 and {dsk}File2 that end in "ion" that do not have the first letter capitalized.

```
(FINDSUFFIXES '({dsk}File1 {dsk}File2) '{Phylum}<Project>Suffixes "ion" NIL
T (FUNCTION DREADWORD))
```

**Miscellaneous Functions**

(GETNTHFIELD *STRING N SEPARATOR FIELDTYPE*) [Function]

The *N*th field in *STRING* is returned using *SEPARATOR* as the field separator and the field type is coerced to type *FIELDTYPE*.

*N* is a simple positive integer [Argument]

*SEPARATOR* is the same as that for SORTWORDFILE [Argument]

*FIELDTYPE* is either the atom NUMBER or the atom STRING and indicates how the type that the field should be coerced to. The default *FIELDTYPE* is STRING.

**Example**

```
(GETNTHFIELD "So long and thanks for all the fish" 4 'WHITESPACE 'STRING)
```

returns the string "thanks".

```
(GETNTHFIELD "Joe Smith/5551212/12 Pleasant Lane/" 2 "/" 'NUMBER)
```

returns the integer 5551212.

```
(DCOPYSTRING W STR)
```

[Function]

Copies string *W* into string *STR* and returns *STR*.

```
(NUMORDER NUMBER1 NUMBER2)
```

[Function]

Returns >>??<<

**Example**

```
(SETQ MyString (ALLOCSTRING 1))
```

```
(DCOPYSTRING "This is a much longer string" MyString)
```

## XCL-BRIDGE

By: Jan Pedersen (pedersen.PA @ Xerox.com)

XCL-BRIDGE is a module that assists in the transformation of ascii Common Lisp source files to Lisp managed files and vice versa. In the text-to-managed-file direction, user interaction is employed to repair read-in forms before establishing a resident image of a Lisp managed file. In the managed-to-text-file direction, a few simple transforms are employed to translate common filepackagecoms to equivalent Common Lisp forms.

All entry points are external to the "XCL" package.

(XCL:TEXT-TO-MANAGED-FILE *pathname filename &key (package "USER")*  
(*readtable "XCL"*) (*read-base 10*) (*combine-comments t*) [Function]

Reads an ascii lisp source file named by "pathname" and converts it to a managed file with rootname "filename". The package, readtable, and read-base employed to read the ascii file may be specified via keywords arguments, or defaulted, as shown. If the reader environment arguments are defaulted and the source file has a emacs-style "mode line", then the package and read-base will be as indicated by the "mode line". The "combine-comments" keyword controls whether adjacent comments at the same ";" level should be combined when generating sedition-style comments for the converted file.

Note that forms are only read from the `ascii.lisp` source file, not evaluated. It is assumed that the converted file should be made (via `"il:makefile"`) and compiled before any evaluation should be attempted.

Text-to-managed-file proceeds incrementally and interactively to convert the specified file. First all the forms are read, and presented to the user for editing (via Sedit). If the user accepts this primary phase, a filecoms is generated and again, presented to the user for editing. If the user accepts the generated filecoms, a file (and its contained definitions) is instantiated, completing the conversion.

```
(XCL:MANAGED-TO-TEXT-FILE filename pathname &key (package "USER")
 (readtable "XCL") (print-base 10))
```

[Function]

Prints a managed file, with rootname "filename", whose source definitions must be resident, to an ascii file "pathname" in a form suitable for reading by any Common Lisp reader. The read-print environment of the managed file may be overwritten via the keyword arguments "package", "readtable", and "print-base". Many Interlisp "filepackagecoms" are translated to their Common Lisp equivalents. For example, "il:declare:" forms are transformed to "eval-when" forms and "il:files" forms are transformed to "require" forms. As an additional convenience, defdefiners are printed as equivalent defmacros.

## Overview of the Manual

---

The *LOOPS Library Modules Manual* describes the Library Modules for Venue's Lisp Object-Oriented Programming System, LOOPS. These Library Modules, which can be loaded into Medley, provide additional functionality to LOOPS.

This manual describes the current release of the LOOPS Library Modules, which run under Medley.

---

## Organization of the Manual and How to Use It

---

This manual is divided into chapters, with each chapter focussing on a particular Library Module. A Table of Contents is included to help you find specific material.

---

## Conventions

---

This manual uses the following conventions:

- Case is significant in LOOPS and Medley. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- You need to use an Interlisp Exec to enter all exec expressions.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(*\_ self* **Selector** *Arg1 Arg2*)

- Examples are shown in the Interlisp Exec and appear in the following typeface:

89← (←LOGIN)

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form **ClassName.SelectorName**.

- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the LOOPS items (functions, methods, etc.) by using the following template:

|                  |                                                                                                                                                                                                                                                                                       |                 |             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------|
| Purpose:         | Gives a short statement of what the item does.                                                                                                                                                                                                                                        |                 |             |
| Behavior:        | Provides the details of how the item operates.                                                                                                                                                                                                                                        |                 |             |
| Arguments:       | Describes each argument in the following format:<br><br><table> <tr> <td><i>argument</i></td><td>Description</td></tr> </table>                                                                                                                                                       | <i>argument</i> | Description |
| <i>argument</i>  | Description                                                                                                                                                                                                                                                                           |                 |             |
| Returns:         | States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value. |                 |             |
| Categories:      | A way to group related methods. For example, all the methods related to Masterscope on the class <b>FileBrowser</b> have the category Masterscope, not <b>FileBrowser</b> . This item appears only for methods.                                                                       |                 |             |
| Specializes:     | The next higher class in the class hierarchy that contains a method with the same selector. For example, <b>RectangularWindow.Open</b> can specialize <b>Window.Open</b> . This appears only for methods.                                                                             |                 |             |
| Specializations: | The next lower class in the class hierarchy that contains a method with the same selector. For example, <b>Window.Open</b> is a specialization of <b>RectangularWindow.Open</b> . This appears only for methods.                                                                      |                 |             |
| Example:         | An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See the <i>LOOPS Reference Manual</i> for details.                                       |                 |             |

## Description/Introduction

---

Gauges are an important part of the LOOPS user interface for both developers and end users. Gauges assist in understanding the dynamic nature of the programs. This is in contrast to the more typical case of debugging programs using static means. In the creation of user-friendly interfaces, you can use gauges to display, in analog or digital form, various data that may be changing. Also, by employing active gauges, you can provide a convenient way to interact with a system.

One of the features of gauges is the ease with which you can use them in a system. In more traditional languages, if you want to understand how a variable is changing over the course of a computation, you must make modifications in your program wherever you want to begin or end the examination of a variable. Given the capabilities of active values used by gauges, you need only attach or detach a gauge to the data that you are interested in monitoring.

The following types of gauges are available:

- Meter; a circular instrument that wraps around any number of times.
- Dial; a bounded dial, like an automobile speedometer.
- LCD; a gauge that uses the entire window to display a value.
- Scale; a horizontal or vertical display of a gauge.
- ActiveScale; a scale that allows you to change the gauge value.

Gauges are an example of the combination of programming capabilities within LOOPS. The different types of gauges are defined within the context of an inheritance lattice. This allows the more general functionality and variables to be allocated to more general gauge classes, with specific functionality placed in more restricted classes. You can also see the use of mixins to add a small amount of functionality to several different classes of gauges.

Note: Mixins are classes that are used only in conjunction with another class to create a subclass.

The methods within gauges are built upon both function calling and message sending. Gauges are "attached" to objects through the mechanism of active values. Since gauges are built upon the mechanism of active values, gauges can only be attached to data within objects. It is not possible to use gauges to monitor any arbitrary Lisp variable.

Prerequisites

The default font for gauges is Modern 10.

Installation/Loading Instructions

Gauges are divided among several different files to allow you to load only those objects and functions that you need. The table below lists the files to load for each type of gauge. The filecoms for each file will try to load any other required gauge files from **LOOPSLIBRARYDIRECTORY**. The file GAUGES.DFASL and either GAUGEINSTRUMENTS.DFASL or GAUGEALPHANUMERICS.DFASL will always be loaded; other files may also be loaded.

| Gauge        | File to load             |
|--------------|--------------------------|
| LCD          | GAUGEALPHANUMERICS.DFASL |
| METER        | GAUGEMETERS.DFASL        |
| DIAL         | GAUGEDIALS.DFASL         |
| SCALE        | GAUGESCALES.DFASL        |
| ACTIVE SCALE | GAUGEACTIVE.DFASL        |

Additionally, the file GAUGESELFSCALEMIXIN.DFASL can be loaded to add the class **SelfScaleMixin**, and GAUGEALARMS.DFASL can be loaded to add the class **AlarmMixin**.

To load the required files, first set the value of **LOOPSDIRECTORY** to include the directory where the gauges files are stored, then type the following expression in the Executive:

(LOAD 'FILENAME)

To load all of the gauges, load the file GAUGELOADER and then enter (LOADGAUGES). GAUGELOADER also sets the variables: **GAUGEFILES** and **GaugeClasses**.

(LOADGAUGES LDFLG SOURCES?FLG) [Function]

|            |                                                                                                                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Loads all the gauges.                                                                                                                                                                                                                                                                                   |
| Behavior:  | Assumes that all of the gauge files are on the <b>LOOPSDIRECTORY</b> search path.<br><br>All the gauge files will be loaded based upon the settings of <i>LDFLG</i> and <i>SOURCES?FLG</i> . A <b>FILESLOAD</b> expression is built up and evaluated.                                                   |
| Arguments: | <i>LDFLG</i> Can be NIL, PROP, or SYSLOAD. See the <b>LDFLG</b> discussion under loading in the <i>Interlisp-D Reference Manual</i> .<br><br><i>SOURCES?FLG</i> Can be NIL or T. If NIL, this attempts to load the compiled files before trying to load the sources. If T, only the sources are loaded. |
| Returns:   | Used for side effect only.                                                                                                                                                                                                                                                                              |

**GAUGEFILES**

[Variable]

Behavior: Initialized to (GAUGEACTIVE GAUGEALARMS GAUGEALPHANUMERICS GAUGEBOUNDEDMIXIN GAUGEDIALS GAUGEDIGIMETER GAUGEDIGISCALE GAUGEINSTRUMENTS GAUGEMETERS GAUGES GAUGESCALES GAUGESELFSCALEMIXIN)

**GaugeClasses**

[Variable]

Behavior: Initialized to (GaugeAV ActiveGaugeMixin Gauge AlarmMixin BoundedMixin SelfScaleMixin)

Call (Browse **GaugeClasses**) to open a browser of all of the gauge classes.

**Application/Module Functionality**

This section describes the gauge classes and methods.

**Gauge Classes**

This section describes the available gauges shown in the following browser.

Note: The browser does not include the optional mixin classes.

Within the class description of each class, the instance variables and class variables that are specializations only because they have different default values are not listed.

| Name                         | Type          | Description                                                                                                     |
|------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------|
| <b>ActiveGaugeMixin</b>      | AbstractClass | A gauge class that allows you to set the value of the variable being monitored with the cursor, via a SET menu. |
| <b>ActiveHorizontalScale</b> | Class         | An active gauge that displays the value on a horizontal scale.                                                  |
| <b>ActiveVerticalScale</b>   | Class         | An active gauge that displays its value on a vertical scale.                                                    |
| <b>AlarmMixin</b>            | AbstractClass | A mixin that adds alarm functionality to any gauge.                                                             |
| <b>AlphaNumeric</b>          | AbstractClass | A gauge that gives an alphanumeric display of a value.                                                          |

|                          |               |                                                                                                                                               |
|--------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BarChart</b>          | Class         | A gauge that displays more than one <b>VerticalScale</b> side-by side.                                                                        |
| <b>BoundedMixin</b>      | AbstractClass | Creates a bounded scale for <b>displayVal</b> ; to be used as a mixin for instruments.                                                        |
| <b>Dial</b>              | Class         | A bounded dial, like an automobile speedometer.                                                                                               |
| <b>DigiMeter</b>         | Class         | A gauge that displays both an <b>LCD</b> and a meter.                                                                                         |
| <b>DigiScale</b>         | Class         | A gauge that displays both an <b>LCD</b> and a horizontal scale.                                                                              |
| <b>Gauge</b>             | AbstractClass | A class for objects that present a dynamic graphical image of a LOOPS value.                                                                  |
| <b>GaugeAV</b>           | Class         | An active value associated with a gauge.                                                                                                      |
| <b>HBarChart</b>         | Class         | A gauge that displays more than one <b>HorizontalScale</b> side-by side.                                                                      |
| <b>HorizontalScale</b>   | Class         | A labeled, bounded scale with a bar that fills to the right.                                                                                  |
| <b>HSGraphics</b>        | AbstractClass | Gauge that is displayed in the form of a single horizontal scale or bar.                                                                      |
| <b>Instrument</b>        | AbstractClass | A numeric gauge that is externally scaled by <b>inputLower</b> and <b>inputRange</b> and scaled internally by <b>lower</b> and <b>range</b> . |
| <b>LCD</b>               | Class         | Differs from <b>AlphaNumeric</b> in that the entire gauge window is the printing region.                                                      |
| <b>LCDMixin</b>          | AbstractClass | Computes print region differently from <b>LCD</b> .                                                                                           |
| <b>Meter</b>             | Class         | A circular instrument that wraps around any number of times.                                                                                  |
| <b>RoundScale</b>        | AbstractClass | Abstract Class for instruments with circular (arc) scales.                                                                                    |
| <b>SelfScaleMixin</b>    | AbstractClass | Provides for the gauge to rescale according to the reading.                                                                                   |
| <b>SSBarChart</b>        | Class         | A self-scaling version of <b>BarChart</b> .                                                                                                   |
| <b>SSDigiMeter</b>       | Class         | A self-scaling version of <b>DigiMeter</b> .                                                                                                  |
| <b>SSHBarChart</b>       | Class         | A self-scaling version of <b>HBarChart</b> .                                                                                                  |
| <b>SSHorizontalScale</b> | Class         | Gauge that is displayed in the form of a single scale or bar which rescales itself accordingly.                                               |
| <b>SSVerticalScale</b>   | Class         | Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.                                      |
| <b>StraightScale</b>     | AbstractClass | Abstract Class for instruments with straight scales.                                                                                          |
| <b>VSGraphics</b>        | AbstractClass | Gauge that is displayed in the form of a single vertical scale or bar.                                                                        |
| <b>VerticalScale</b>     | Class         | Gauge that is displayed in the form of a single vertical scale or bar.                                                                        |

---

**ActiveGaugeMixin**

[Class]

Description: A gauge class that allows you to set the value of the variable being monitored with the cursor, via a **SET** menu.

MetaClass: AbstractClass

|                     |                                                                              |
|---------------------|------------------------------------------------------------------------------|
| Supers:             | Object                                                                       |
| Class Variables:    | None.                                                                        |
| Instance Variables: | <b>cursor</b> The cursor to use when changing the scale; the default is NIL. |

**ActiveHorizontalScale**

[Class]

|                     |                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | An active gauge that displays the value on a horizontal scale. This gauge shows the value of the data it is connected with and allows you to change that data with the gauge.   |
| MetaClass:          | Class                                                                                                                                                                           |
| Supers:             | ActiveGaugeMixin, HorizontalScale                                                                                                                                               |
| Class Variables:    | None.                                                                                                                                                                           |
| Instance Variables: | <b>cursor</b> Cursor to use when changing the scale; its property <b>:initform</b> is set to <b>HorizontalAGCursor</b> .                                                        |
| Example:            | These gauges have an attached menu at the bottom of the gauge. When you position the cursor over this menu and press a mouse button, the cursor changes to the following shape: |

While the left button is held down, the system tracks movements of the cursor and changes the value that the gauge is monitoring.

**ActiveVerticalScale**

[Class]

|                     |                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------|
| Description:        | Similar to <b>ActiveHorizontalScale</b> , except that a vertical scale is used.                                        |
| MetaClass:          | Class                                                                                                                  |
| Supers:             | ActiveGaugeMixin, VerticalScale                                                                                        |
| Class Variables:    | None.                                                                                                                  |
| Instance Variables: | <b>cursor</b> Cursor to use when changing the scale; its <b>:initform</b> property is set to <b>VerticalAGCursor</b> . |
| Example:            | Similar to <b>ActiveHorizontalScale</b> . When setting, the cursor changes to the following shape:                     |

**AlarmMixin** [Class]

Description: A mixin that adds alarm functionality to any gauge. An alarm is defined as warning object that is set off when the value being monitored falls outside of the specified range. The gauge flashes and stays inverted when the alarm is tripped.

**CAUTION**

When a new class of gauges is created that will use the properties of **AlarmMixin**, **AlarmMixin** should be the first class on the Supers list of the new class. This guarantees that the **AlarmMixin.Set** method is invoked.

- MetaClass: AbstractClass
- Supers: Object
- Class Variables: MiddleButtonItem
- Instance Variables:
  - lowTripPoint** Alarm is triggered when reading goes below this point.
  - hiTripPoint** Alarm is triggered when reading goes above this point.
  - flashNumber** Number of times alarm will flash when it is tripped.
  - flashInterval** Interval in milliseconds between flashes.

**AlphaNumeric** [Class]

- Description: This class contains some of the methods and data for the LCD classes. These gauges can display any type of character, letters, or numbers.
- MetaClass: AbstractClass
- Supers: Gauge
- Class Variables: None.

Instance Variables: **precision** Number of characters displayed in the reading. The default value is 5.

**BarChart**

[Class]

Description: A gauge that can display more than one **VerticalScale** at once, side-by side.

MetaClass: Class

Supers: VerticalScale

Class Variables: None.

Instance Variables: **maxLabelWidth**  
Maximum width of labels on each bar. Default value is 0 which means no limit.

**scaleLeft**  
Offset within the gauge window from the left for the leftmost bar. Default value is 3.

**scaleBottom**  
Offset within the gauge window from the bottom for all the bars. Default value is 30.

Example: Here is a **BarChart** showing the size and shape of a window. It is displaying the values 15, 21, 13, and 6.

**BoundedMixin**

[Class]

Description: This mixin is a super of the scale classes and **Dial**. If a gauge that has **BoundedMixin** as a super class tries to display a new setting that is outside of the range of the gauge, the gauge will display the minimum or maximum value as appropriate and place a "???" in the window.

MetaClass: AbstractClass

Supers: Object

Class Variables: None.

Instance Variables: None.

Example: Here is a vertical scale that displays a reading greater than its maximum.

**Dial** [Class]

- Description: A bounded dial, like an automobile speedometer.
- MetaClass: Class
- Supers: BoundedMixin, RoundScale
- Class Variables: None.
- Instance Variables: This class specializes the same instance variables as **RoundScale**.
- Example: The angle of the arc changes with the shape of the window.

**DigiMeter** [Class]

- Description: A gauge that combines both a meter and an LCD.
- MetaClass: Class
- Supers: Meter, LCDMixin
- Class Variables: None.
- Instance Variables: **spaceForLCD**  
Vertical space required by LCD within the gauge. Defaults to 30.
- Example: This **DigiMeter** is displaying 55.

**DigiScale**

[Class]

Description: A gauge that combines both a horizontal scale having no ticks and an LCD.

MetaClass: Class

Supers: HorizontalScale, LCDMixin

Class Variables: None.

Example: This **DigiScale** is displaying 63 with its scale set from 0 to 100.

**Gauge**

[Class]

Description: A class for objects that present a dynamic graphical image of a LOOPS value. This class provides most of the methods for using gauges.

MetaClass: AbstractClass

Supers: Window

Class Variables: **LeftButtonItem**  
Menu options associated with the left mouse button.

**MiddleButtonItem**  
Menu options associated with the middle mouse button.

Instance Variables: **reading** External value of reading. The default value is 0.

**containedInAV**  
Active value that connects the gauge to the data it is monitoring. It should be an instance of the class **GaugeAV**.

**font** Font that is used by a gauge; default value is (Modern 10).

**width** Width of a gauge; has property **min**, which specifies the minimum width for a gauge.

**height** Height of a gauge; has property **min**, which specifies the minimum height for a gauge.

**GaugeAV**

[Class]

Description: An active value that is associated with a gauge.

MetaClass: Class

Supers: LocalStateActiveValue

|                     |                 |                                                                      |
|---------------------|-----------------|----------------------------------------------------------------------|
| Class Variables:    | None.           |                                                                      |
| Instance Variables: | <b>gauge</b>    | The gauge connected to this active value.                            |
|                     | <b>object</b>   | The object containing the variable associated with the active value. |
|                     | <b>propName</b> | The property name of the associated variable.                        |
|                     | <b>type</b>     | Data type of the associated variable.                                |
|                     | <b>varName</b>  | Name of the associated variable.                                     |

HBarChart

[Class]

|                     |                                                                                                                             |                                                                                        |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Description:        | A gauge that can display more than one <b>HorizontalScale</b> at once, side-by-side.                                        |                                                                                        |
| MetaClass:          | Class                                                                                                                       |                                                                                        |
| Supers:             | HorizontalScale                                                                                                             |                                                                                        |
| Class Variables:    | None.                                                                                                                       |                                                                                        |
| Instance Variables: | <b>maxLabelWidth</b>                                                                                                        | Maximum width of labels on each bar. Default value is 0 which means no limit.          |
|                     | <b>scaleLeft</b>                                                                                                            | Offset within the gauge window from the left for the leftmost bar. Default value is 3. |
|                     | Example: Here is an <b>HBarChart</b> showing the size and shape of a window. It is displaying the values 15, 21, 13, and 6. |                                                                                        |

HorizontalScale

[Class]

|                     |                                                                      |  |
|---------------------|----------------------------------------------------------------------|--|
| Description:        | A labeled, bounded scale with a bar that fills to the right.         |  |
| MetaClass:          | Class                                                                |  |
| Supers:             | HSGraphics                                                           |  |
| Class Variables:    | None.                                                                |  |
| Instance Variables: | None.                                                                |  |
| Example:            | This <b>HorizontalScale</b> is reading 350 on a scale from 0 to 500. |  |

HSGraphics

[Class]

|                     |                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | This class provides some of the methods for displaying the graphics of a horizontal scale.                                                                                                                                                                                                                          |
| MetaClass:          | AbstractClass                                                                                                                                                                                                                                                                                                       |
| Supers:             | StraightScale                                                                                                                                                                                                                                                                                                       |
| Class Variables:    | None.                                                                                                                                                                                                                                                                                                               |
| Instance Variables: | <b>scaleBottom</b> Bottom edge of scale in pixels. The default value is 10.<br><b>scaleLeft</b> Left edge of scale in pixels. The default value is 12.<br><b>scaleWidth</b> Width of inside of scale in pixels. The default value is 120.<br><b>scaleHeight</b> Height of scale in pixels. The default value is 15. |

**Instrument**

[Class]

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | A class that provides additional methods and data for gauges that display only numerical data. This data is externally scaled by <b>inputLower</b> and <b>inputRange</b> , and scaled internally by <b>lower</b> and <b>range</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| MetaClass:          | AbstractClass                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Supers:             | Gauge                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Class Variables:    | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Instance Variables: | <b>ticks</b> Scale marks on the instrument; value is a number or NIL; <b>smallTicks</b> property indicates the number of smaller ticks between each large tick.<br><b>displayVal</b> Internal value relative to instrument.<br><b>range</b> Range for internal <b>displayVal</b> .<br><b>inputRange</b> Range for external reading.<br><b>lower</b> Lower bound for internal <b>displayVal</b> .<br><b>inputLower</b> Lower bound for external reading.<br><b>brushWidth</b> Scale factor for width of ticks, rays, and circles in pixels.<br><b>labels</b> The labels that will be displayed on the gauge.<br><b>labelScale</b> A dotted pair representing the sign and exponent of a reading.<br><b>spaceForLabelScale</b> Extra vertical space to display scale label. |

**LCD**

[Class]

|                     |                                                                                      |
|---------------------|--------------------------------------------------------------------------------------|
| Description:        | Differs from <b>LCDMixin</b> in that the entire gauge window is the printing region. |
| MetaClass:          | Class                                                                                |
| Supers:             | AlphaNumeric                                                                         |
| Class Variables:    | None.                                                                                |
| Instance Variables: | None.                                                                                |

Example: This **LCD** is displaying the string "Mumble", and has been **Shaped**to 120 x 60.

**LCDMixin** [Class]

Description: Computes printing region differently from LCD so that an LCD may be added into another window.

MetaClass: AbstractClass

Supers: AlphaNumeric

Class Variables: None.

Instance Variables: **precision** Number of characters displayed in the reading; the default value is 3. Its property is **readingRegion**; the default value is NIL.

**readingY** Y position of bottom of reading. The default value is 7.

**Meter** [Class]

Description: A circular instrument that wraps around any number of times. It displays a sign and exponent in the lower left corner of its window.

MetaClass: Class

Supers: RoundScale

Class Variables: None.

Instance Variables: This class specializes the same instance variables as **RoundScale**.

Example: The **Meter** on the left is displaying a negative value.

**RoundScale** [Class]

Description: Abstract Class for instruments with circular (arc) scales.

MetaClass: AbstractClass

Supers: Instrument

Class Variables: None.

Instance Variables: **needleLength** Radius of needle in pixels. The default value is 15.

|               |                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------|
| <b>radius</b> | Radius of arc in pixels. The default value is 10.                                                        |
| <b>xc</b>     | x-coordinate window coordinate of center of arc. (See <b>DRAWARC</b> in the <i>Lisp Release Notes</i> .) |
| <b>yc</b>     | y-coordinate window coordinate of center of arc. (See <b>DRAWARC</b> in the <i>Lisp Release Notes</i> .) |

### **SelfScaleMixin** [Class]

|                     |                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | Provides for the gauge to rescale according to the reading.                                                                                                   |
| MetaClass:          | AbstractClass                                                                                                                                                 |
| Supers:             | Object                                                                                                                                                        |
| Class Variables:    | None.                                                                                                                                                         |
| Instance Variables: | <b>lowScaleFactor</b><br>Rescales if reading shrinks so that it will fit more than <b>lowScaleFactor</b> times in <b>inputRange</b> . The default value is 5. |

### **SSBarChart** [Class]

|                     |                                             |
|---------------------|---------------------------------------------|
| Description:        | A self-scaling version of <b>BarChart</b> . |
| MetaClass:          | Class                                       |
| Supers:             | BarChart                                    |
| Class Variables:    | None.                                       |
| Instance Variables: | None.                                       |

### **SSDigiMeter** [Class]

|                     |                                              |
|---------------------|----------------------------------------------|
| Description:        | A self-scaling version of <b>DigiMeter</b> . |
| MetaClass:          | Class                                        |
| Supers:             | DigiMeter                                    |
| Class Variables:    | None.                                        |
| Instance Variables: | None.                                        |

### **SSHBarChart** [Class]

|                     |                                              |
|---------------------|----------------------------------------------|
| Description:        | A self-scaling version of <b>HBarChart</b> . |
| MetaClass:          | Class                                        |
| Supers:             | HBarChart                                    |
| Class Variables:    | None.                                        |
| Instance Variables: | None.                                        |

### **SSHorizontalScale** [Class]

|              |                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------|
| Description: | Gauge that is displayed in the form of a single horizontal scale or bar which rescales itself accordingly. |
|--------------|------------------------------------------------------------------------------------------------------------|

MetaClass: Class  
Supers: VerticalScale  
Class Variables: None.  
Instance Variables: None.

---

**SSVerticalScale****[Class]**

Description: Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.  
MetaClass: Class  
Supers: HorizontalScale  
Class Variables: None.  
Instance Variables: None.

---

**StraightScale****[Class]**

Description: Abstract class for instruments with straight scales.  
MetaClass: AbstractClass  
Supers: BoundedMixin, Instrument  
Class Variables: None.  
Instance Variables: **shade** Shade of bar; numeric value from 0 to 65535. The default value is 65535, which is BLACKSHADE.

---

**VerticalScale****[Class]**

Description: Gauge that is displayed in the form of a single vertical scale or bar.  
MetaClass: Class  
Supers: VSGraphics  
Class Variables: None.  
Instance Variables: None.  
Example: This **VerticalScale** is displaying the value .55 and has its **Shade** set to 1258.

**VSGraphics****[Class]**

|                     |                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | Similar to <b>HSGraphics</b> but for vertical scales.                                                                                                                                                                                                                                                               |
| MetaClass:          | AbstractClass                                                                                                                                                                                                                                                                                                       |
| Supers:             | StraightScale                                                                                                                                                                                                                                                                                                       |
| Class Variables:    | None.                                                                                                                                                                                                                                                                                                               |
| Instance Variables: | <b>scaleBottom</b> Bottom edge of scale in pixels. The default value is 12.<br><b>scaleLeft</b> Left edge of scale in pixels. The default value is 15.<br><b>scaleWidth</b> Width of inside of scale in pixels. The default value is 15.<br><b>scaleHeight</b> Height of scale in pixels. The default value is 120. |

**Gauge Methods**

This section describes the available methods and functions which are used to manipulate gauges. In many cases, a particular gauge class specializes a method defined in the class **Gauge**. In this case, the specialized method definition is not explicitly defined; instead, this is noted in the Specializes/Specializations field of the description.

| Name               | Type   | Description                                                                  |
|--------------------|--------|------------------------------------------------------------------------------|
| <b>Attach</b>      | Method | Connects a gauge to an object.                                               |
| <b>Attached?</b>   | Method | Determines what the gauge is attached to.                                    |
| <b>ChangeFont</b>  | Method | Sets the gauge's instance variable <b>font</b> and updates the gauge.        |
| <b>Close</b>       | Method | Detaches the gauge and closes the window.                                    |
| <b>Destroy</b>     | Method | Destroys the gauge, detaching it first.                                      |
| <b>Detach</b>      | Method | Detaches the gauge from the variable it is attached to.                      |
| <b>Reset</b>       | Method | Resets the gauge's instance variable <b>reading</b> .                        |
| <b>SetScale</b>    | Method | Sets the scale for the gauge.                                                |
| <b>Shape</b>       | Method | Sweeps a new region.                                                         |
| <b>ShapeToHold</b> | Method | Shapes the gauge window to its smallest possible size.                       |
| <b>Update</b>      | Method | Reinitializes the gauge and its display window to reflect the current state. |

(← **self Attach** *obj varName propName type xOrPos y*) **[Method of Gauge]**

|            |                                                                                                                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Connects a gauge to an object.                                                                                                                                                                                                                                                                                     |
| Behavior:  | Displays the gauge on the screen and associates that gauge with the variable <i>varName</i> of <i>obj</i> . If <i>propName</i> is specified, the gauge will monitor the variable's property. If <i>xOrPos</i> and <i>y</i> are not specified, a small box will appear which must be positioned to place the gauge. |
| Arguments: | <i>obj</i> A pointer to the object to which the gauge is to be attached.                                                                                                                                                                                                                                           |

|                 |                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>varName</i>  | The name of the instance variable, class variable, or method to which the gauge is to be attached.                                                                                                                                                                     |
| <i>propName</i> | If non-NIL, the gauge will be attached to this property.                                                                                                                                                                                                               |
| <i>type</i>     | One of IV, CV, or METHOD, within the object being connected to the gauge. If NIL, it defaults to IV.                                                                                                                                                                   |
| <i>xOrPos</i>   | A numerical value to specify where, in screen coordinates, the gauge will be placed on the display. If NIL, you are asked to place the gauge on the screen. This can be a number to specify the x coordinate or a position. If it is a number, also specify <i>y</i> . |
| <i>y</i>        | If <i>xOrPos</i> is not a position, this specifies the y coordinate in screen coordinates for the gauge.                                                                                                                                                               |

Returns: *self*

Specializations: **StraightScale.Attach** has an additional *shade* argument so that the shade of the scale may be specified at the time the gauge is attached. The following shows the argument list for this method:

(← (\$ instance OfHorizontalScale) **Attach** *obj varName shade propName type xOrPos y*)

The **Attach** methods for **BarChart**, **HBarChart**, and their subclasses take an additional *label* argument. If no *label* argument is given, the bar is labeled with *varName*. The *label* argument comes last, as follows:

(← (\$ instance OfBarChart) **Attach** *obj varName propName propName type xOrPos y label*)

---

(← *self* **Attached?** *don'tPrintFlg*) [Method of Gauge]

Purpose: Determines what a gauge is attached to.

Behavior: If *don'tPrintFlg* is non-NIL this returns the value of the gauge instance variable **containedInAV**. If *don'tPrintFlg* is NIL, the **object** and the **varName** the gauge is attached to will be printed in an attached window.

Arguments: *don'tPrintFlg*  
Suppresses displaying what the gauge is attached to.

Returns: NIL

---

(← *self* **ChangeFont** *newFont*) [Method of Gauge]

Purpose/Behavior: Sets the gauge's instance variable **font** to *newFont* and updates the gauge. If the gauge is too small for *newFont*, it is reshaped.

Arguments: *newFont* A font in which to display the gauge's text.

Returns: Previous value of **font**.

---

(← *self* **Close**) [Method of Gauge]

Purpose/Behavior: Detaches the gauge and closes the window.

Returns: CLOSED

---

(← *self* **Destroy**) [Method of Gauge]

Purpose/Behavior: Destroys the gauge, detaching it first before closing the window.

Returns: NIL

(← *self* **Detach**)

[Method of Gauge]

Purpose/Behavior: Detaches the gauge from the variable to which it is attached. This prints in an attached window that the gauge is being detached, and deletes all of the links connecting the gauge, active value, and object being monitored. Does not close the window.

Returns: NIL

(← *self* **Reset** *newReading*)

[Method of Gauge]

Purpose/Behavior: Sets the gauge's instance variable **reading** to *newReading* and updates the gauge. If the gauge is too small for *newReading* and it is **SelfScaling**, it is reshaped.

Arguments: *newReading* Sets the instance variable **reading** to *newReading*, and updates the gauge without going through any intermediate steps.

Returns: NIL if gauge is **AlphaNumeric** or **RoundScale**; otherwise *self*.

Specializations: **Alphanumeric.Reset**, **RoundScale.Reset**

Example: The following example causes the LCD to be redisplayed with the *newReading*:

```
13← (← ($ lcd1) Reset "New Title")
```

(← *self* **SetScale** *min max*)

[Method of Gauge]

Purpose/Behavior: Sets the scale for the gauge; computes the new scale values and redisplay if necessary.

Arguments: *min* Lowest value on scale.

*max* Highest value on scale.

Returns: *self*

(← *self* **Shape** *newRegion noUpdateFlg*)

[Method of Gauge]

Purpose/Behavior: If *newRegion* is NIL, you are prompted to sweep out a region which has a minimum sized based upon a **min** property of **IV width** and **height:;min**. If *newRegion* is non-NIL, it is first checked to guarantee that it is at least as large as **width:;min** by **height:;min**.

Arguments: *newregion* List specifying the external coordinates of the window in which the gauge is displayed; list is of the form (left, bottom, width, height).

*noUpdateFlg* If NIL, reshapes the gauge.

Returns: NIL

Specializes: Window

Specializations: **LCD**, **Meter**, **DigiMeter**. **Meter.Shape** has an extra argument *ExtraSpaceFlg*. If T, this will allow you to shape a fairly arbitrary region for the gauge; if NIL, the meter is constrained to be close to a square. This latter behavior is what the user sees when trying to shape the meter from the window menu.

**BarChart**, **HBarChart**, and their subclasses can only be freely **Shaped** in the direction their bars run (i.e., **BarCharts** can be **Shaped** vertically and **HBarCharts** can be **Shaped** horizontally). Their size along the other dimension is fixed by the number of values attached to the chart.

Example: This example reshapes the gauge to a location where the lower left corner is at (10,100) a width of 50 and a height of 150.

```
14←(← ($ lcd1) Shape ' (10 100 50 150))
```

---

**(← self ShapeToHold)****[Method of Gauge]**

Purpose/Behavior: Shapes the gauge window to its smallest possible size based on **width:,min** and **height:,min** and redisplay the gauge.

Returns: NIL

Specializations: **LCD.Shape**

---

**(← self Update)****[Method of Gauge]**

Purpose/Behavior: Reinitializes the gauge and its display window to reflect the current state.

Returns: *self*

Categories: Window

---

**Examples**

The typical use pattern for a gauge is to first create it, set the scale to the appropriate value, and attach it to the desired data.

To attach a horizontal scale to a LOOPS window, **w1**, first enter

```
15←(← ($ Window) New 'w1)
#,$(& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 495))
```

```
16←(← ($ HorizontalScale) New 'hs1)
#,$(& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))
```

```
17←(← ($ hs1) SetScale 0 500)
NIL
```

Now make the connection.

```
18←(← ($ hs1) Attach ($ w1) 'width GRAYSHADE)
#,$(& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))
```

The following gauge appears and you are prompted to place it .

The title of the gauge shows the instance variable being monitored.

Gauges can be shaped larger. The graphics used to display scales do not change; extra white space is added to the top or right. You can use this space to print additional information, as follows:

```
19←(MOVETOUPPERLEFT (@ ($ hs1) window))
{WINDOW}#372,7104
```

```
20←(PRIN1 "This is an example of printing additional
information above a gauge.
```

Be aware that when the gauge is next updated, this additional text will disappear." (@ (\$ hs1) window))  
 "This is an example of printing additional information above a gauge.

Be aware that when the gauge is next updated, this additional text will disappear."

## Limitations

When a font is changed, a gauge occasionally needs to be updated to be correctly displayed.

Instruments can have only floating point numbers for labels, and cannot have integers.

---

## Description/Introduction

---

Masterscope has been modified to provide for analysis of files created under the Koto or Lyric/Medley release of LOOPS. A full explanation of Masterscope can be found in the *Lisp Library Modules Manual*. In addition to the relations explained there, LOOPS defines the relations described in this chapter.

Note: Masterscope data base files created under Buttriss Loops will not function properly in this release. Those data base files will have to be recreated.

---

## Installation/Loading Instructions

---

- Load MASTERSCOPE from your Lyric/Medley library floppies according to its loading instructions. This should load the compiled files MASTERSCOPE, MSANALYZE, and MSPARSE.
- Load LOOPSMS.DFASL from wherever you installed the LOOPS Library Modules. This should load versions of MASTERSCOPE and MSPARSE that extend Masterscope to handle LOOPS constructs.

---

## Relations

---

LOOPS defines the following relations:

| Name                | Type     | Description                                                                                                    |
|---------------------|----------|----------------------------------------------------------------------------------------------------------------|
| <b>SEND</b>         | Relation | Collects all places where the method is sent.                                                                  |
| <b>SEND SELF</b>    | Relation | Collects all places where the method is sent to <i>self</i> .                                                  |
| <b>SEND NOTSELF</b> | Relation | Collects all places where the method is sent to an object other than <i>self</i> .                             |
| <b>GET</b>          | Relation | Locates all places where the value of an instance variable is retrieved.                                       |
| <b>GET CV</b>       | Relation | Locates all places where the value of a class variable is retrieved.                                           |
| <b>PUT</b>          | Relation | Locates all places where the value of an instance variable is set.                                             |
| <b>PUT CV</b>       | Relation | Locates all places where the value of a class variable is set.                                                 |
| <b>IMPLEMENT</b>    | Relation | Locates all methods that specialize the given selector.                                                        |
| <b>SPECIALIZE</b>   | Relation | Locates all methods that specialize the given selector and use <b>←Super</b> in the body of the method.        |
| <b>OVERRIDE</b>     | Relation | Locates all methods that specialize the given selector and do not use <b>←Super</b> in the body of the method. |

|                   |          |                                                                                                                              |
|-------------------|----------|------------------------------------------------------------------------------------------------------------------------------|
| <b>USE IV</b>     | Relation | Used with an instance variable name to locate all places where the instance variable is used in a <b>GET</b> or <b>PUT</b> . |
| <b>USE CV</b>     | Relation | Used with a class variable name to locate all places where the class variable is used in a <b>GET</b> or <b>PUT</b> .        |
| <b>USE OBJECT</b> | Relation | Used with an object name to locate all places where the object is used.                                                      |

---

**SEND**[Relation]

---

Purpose/Behavior: Used between method names and selectors to collect all places where the method is sent. For example, the form

```
. WHO IS SENT BY 'Helicopter.Move
```

works, but

```
. WHO IS SENT BY Move
```

does not work.

Example: The following command allows you to edit all code that sends the message **New**.

```
. EDIT ALL WHO SEND New
```

---

**SEND SELF**[Relation]

---

Purpose/Behavior: Used between method names and selectors to collect all places where the method is sent to *self*. Places where

```
(← self methodName)
```

is found are collected, while places where

```
(← otherInstance methodName)
```

is found are not.

Example: The following command allows you to edit all code that sends the message **Clear** to *self*.

```
. WHO SENDS SELF Clear
```

---

**SEND NOTSELF**[Relation]

---

Purpose: Same as **SEND SELF**, except the only places where the message is sent to an object other than *self*.

Example: The following allows you to edit all code that sends the message **Clear** to any instance other than *self*.

```
. SHOW ALL WHO SEND NOTSELF Clear
```

---

**GET**[Relation]

---

Purpose: Used with an instance variable name to locate all places where the value of the instance variable is retrieved. This relation can be used along with the **SELF** and **NOTSELF** modifiers.

Example: This command allows you to edit all code that gets the value of the instance variable **width** from an instance other than **self** and the value of the instance variable **height** from **self**.

```
. SHOW ALL WHO GET NOTSELF width AND GET SELF height
```

**GET CV**[\[Relation\]](#)

Purpose: Same as **GET**, except that **GET CV** locates places where the value of the class variable is retrieved. This relation can be used with the **SELF** and **NOTSELF** modifiers.

Example: This command allows you to edit all code that accesses the value of the class variable **height** of **self**.

```
. SHOW ALL WHO GET CVSELF height
```

**PUT**[\[Relation\]](#)

Purpose: Used with an instance variable name to locate all places where the value of the instance variable is set. This relation can be used along with the **SELF** and **NOTSELF** modifiers.

Example: This command allows you to edit all code that sets the value of the instance variable **width**.

```
. EDIT ANY WHO PUT width
```

**PUT CV**[\[Relation\]](#)

Purpose: Same as **PUT**, except locates places where a specified class variable is set. This relation can be used along with the **SELF** and **NOTSELF** modifiers.

Example: This command list all the sections of code that set the value of the class variable **width** for an instance other than **self**.

```
. WHO PUTS CV NOTSELF width
```

**IMPLEMENT**[\[Relation\]](#)

Purpose: Used with a method name to locate all methods that specialize the given selector.

Example: This returns a list of classes where the method **Clear** is defined.

```
. WHO IMPLEMENTS Clear
```

**SPECIALIZE**[\[Relation\]](#)

Purpose: Used with a method name to locate all methods that specialize the given selector and use **←Super** in the body of the method.

Example: This command allows you to edit all the methods that are specializations of **Clear** and use the **←Super** form.

```
. EDIT ANY WHO SPECIALIZE Clear
```

**OVERRIDE**[\[Relation\]](#)

Purpose: Like **SPECIALIZE** above, except it locates all methods that specialize the given selector and **←Super** is not used in the body of the method.

Example: This command allows you to edit all the specializations of **Clear** that do not make use of the  $\leftarrow$ **Super** form.

```
. EDIT ALL WHO OVERRIDE Clear
```

---

**USE IV****[Relation]**

Purpose: Used with an instance variable name to locate all places where the instance variable is used in a **Get** or **Put**. It is equivalent to using the relation form of **GET IVName** or **PUT IVName**.

Example: This command allows you to edit all code that either sets or accesses the instance variable **width**.

```
. EDIT ANY WHO USE THE IV width.
```

---

**USE CV****[Relation]**

Purpose: Used with a class variable name to locate all places where the class variable is used in a **Get** or **Put**. It is equivalent to using the relation form: **GET CV CVName** OR **PUT CV CVName**.

Example: This command allows you to edit all code where the class variable **commonWindow** is either set or accessed.

```
. EDIT ANY WHO USE THE CV commonWindow
```

---

**USE OBJECT****[Relation]**

Purpose Uses an object name to locate all places where the object is used.

Example This command returns a list of all code where the object **Window** is used.

```
. WHO USES THE OBJECT Window??
```

---

**Limitations**

---

Masterscope has several limitations:

- Names of methods must be quoted when used with Masterscope; for example, the method name `Helicopter.Move` must be entered as `'Helicopter.Move'`.
- The following expression will not find a call to **GetValue** when in a method:

```
. WHO CALLS GetValue
```

Masterscope does not record calls to **GetValue** and **PutValue** explicitly; it records them under the **Get**- relation along with calls of the form

```
($\leftarrow$ foo Get 'bar')
```

Similarly, the following functions are recorded under relations instead of their names:

**GetClassValue**  
**PutClassValue**  
**GetClassIV**  
**PutClassIV**

Get CV  
 Put CV  
 Get IV  
 Put IV

If you want to find the explicit calls to Get/PutValue, use

```
. WHO GETS ANY AND NOT SENDS Get
```

- Masterscope currently assumes calls to **GetValue** and similar accessors are accessing instance variables; i.e.,

```
(GetValue foo 'bar)
```

records an access to the instance variable **bar**. This is not necessarily the case; **bar** could also be a class variable.

- The methods and functions that create class and instance variables populate the appropriate **PUT NOTSELF** relations. For example, a function that does

```
(←($ foo) AddCV 'bar)
```

will be found by the query

```
. WHO PUTS CV NOTSELF 'bar
```

An exception occurs with the generalized **Add** and **Delete** method. For example,

```
($ foo) Add 'IV 'bar)
```

will not be noticed as accessing the instance variable **bar**.

Also, the templates for methods and functions that accept property lists generally only notice the first property. For example,

```
((←($ foo) NewWithValues '((bar baz chain link
sausage)))
```

notices **baz** as a property, not a link.

## Description/Introduction

---

In many knowledge-based systems, it is useful to represent knowledge as interconnected sets of instances. A virtual copy mechanism allows a network of instances to be viewed as a prototype which can be copied. The copy of the prototype is virtual in that the contents of each instance is not completely copied at creation time. Instead, it inherits default values from the prototype (also called the original), thus continuing to share the parts not modified in the copy. The copied network is virtual also in the sense that only those instances needed in the processing are copied.

A virtual copy of an object in the prototype network has the following properties:

- It responds to at least the same set of messages as the prototype object and in the same way; that is, a copy has the same procedural behavior that is defined for the prototype.
- A copy inherits variables and their values from the prototype, and continues to do so until an explicit change is made in the copy. At that point, the new value is stored in the copy and it stops tracking the prototype for that variable. A fetch operation on a value that is not stored locally either finds or creates a virtual copy of the value obtained from the prototype.

---

## Installation/Loading Instructions

---

The implementation of virtual copies is contained in the file LOOPSVCOPY.LCOM. No other files are necessary.

---

## Application /Module Functionality

---

A network of instances is tied together through the values of instance variables within each of the instances. Assume an object A has an instance variable x, the value of which is the object B. A virtual copy of A will also have an instance variable named x. The value of x in the copy will point to B if B is a shared object, or x may point to a copy of B if it is to be virtual. Changing the value of x in the copy will not change the value in the original.

---

## Overview of Operation

---

By default, virtual copies share instance variables. This means that changing the value of an instance variable in the original will be tracked by the copy.

Virtual copies are implemented with two additional classes:

- **VirtualCopyMixin**

The class **VirtualCopyMixin** is a subclass of Tofu which contains two instance variables:

- % **copyMap**%
- % **copyOf**%

(These unusual names are used to avoid conflicts with any other instance variable names users may create.) This class contains several methods, most of which are required to implement virtual copies and are not used by a programmer.

Printing a virtual copy instance is a specialization of how regular instances are printed. All instances print as #,(\$& <class-name> UID). The class of a virtual copy is a dynamic mixin of the class **VirtualCopyMixin** and the class of the original object (see the *LOOPS Reference Manual* for more information on mixins). The virtual copy print function adds the name or unique identifier (UID) of the original object. For example,

#,(\$& (VirtualCopyMixin Container1) (JFW0.0X:.aF4.R>8 . 3) c1)

is a copy of the object named **c1**.

- **VirtualCopyContext**

The class **VirtualCopyContext** has no methods and only one instance variable, **copyMap**. Instances are used as an argument for calls to **MakeVirtualMixin**.

Since copies can be made of copies, you often need to determine the original object of a chain of copies with the **UltimateOriginal** function.

---

## Operands

This section describes the functions, methods, class variables, and instance variables that operate on virtual copies.

---

### VirtualIVs

[Class Variable]

Purpose/Behavior: Helps specify a class whose instances may be made into virtual copies. The value of this class variable should be either the symbol ALL, or a list of instance variables contained within instances of the class. If the value is ALL, all objects pointed to by any of the instance variables will be copied. If the value is a list of instance variables, only the instance variables on this list will have their values copied. Other instance variable values will be shared between the copy and the original.

---

### (MakeVirtualMixin x copyContextObj)

[Function]

Purpose: Creates a virtual copy of an object.

Behavior: Creates a dynamic mixin class combining the classes **VirtualCopyMixin** and the class of x. An instance of this resulting class is created and it is returned.

Arguments: *x* An object to be copied; must have the class variable **VirtualIVs** as described above.

*copyContextObj*

Usually NIL; used internally by **MakeVirtualMixin** when it calls itself. It can be an instance of **VirtualCopyContext** if you are creating an instance that is intended to be part of a currently existing network of copies starting from another entry point. See description in **Limitations** below for a further explanation of this point.

Returns: An object that is a copy of *x*.

Example: Refer to the section, "Example."

---

**% copyMap%** [Instance Variable of VirtualCopyMixin]

Purpose/Behavior: A mapping of original nodes (which are objects) in a network to the copied nodes. This map is stored in an instance of the class **VirtualCopyContext**.

---

**% copyOf%** [Instance Variable of VirtualCopyMixin]

Purpose/Behavior: Within an instance that is a copy, the value of this instance variable is a pointer to the object that was copied.

---

**(← self VirtualCopy?)** [Method of VirtualCopyMixin]

Purpose: Determines if an object is a virtual copy.

Returns: *self*

Categories: Object, VirtualCopyMixin

---

**copyMap** [Instance Variable of VirtualCopyContext]

Purpose/Behavior: The value of this instance variable is a list of dotted pairs. The CAR of each pair is the original; the CDR, the copy.

---

**(UltimateOriginal self)** [Function]

Purpose: Determines what an object is ultimately copying.

Behavior: If *self* is not a virtual copy, *self* is returned.

If *self* is a virtual copy, this recurses through the value of the instance variable **% copyOf%** until it finds the original and returns it.

Arguments: *self* A LOOPS object.

Returns: *self* or what is at the top of *self*'s copy chain.

## Example

Create a class called **test** and edit it as shown.

```
44←(←($ Class) New 'test)
#,($C test)
```

```
45←(ED 'test)
```

```
SEdit #,($C test) Package: INTERLISP
((MetaClass Class Edited%: ; Edited 11-Dec-87
 ; 16:50 by
)
 (Supers Object)
 (ClassVariables (VirtualIVs (atomCopy listCopy objCopy)))
 (InstanceVariables (atom NIL)
 (atomCopy NIL)
 (list NIL)
 (listCopy NIL)
 (obj NIL)
 (objCopy NIL))
 (MethodFns))
```

Create an instance called **t0** of this class and inspect it.

```
46←(←($ test) New 't0)
#,($& test (N↑W0.1Y%.:;h.Lh9 . 556))
```

```
47←(← ($ test)
 NewWithValues
 (BQUOTE ((atom 1)
 (atomCopy 2)
 (list (a b c))
 (listCopy (A B (\, (← ($ test) New (QUOTE t1))))
 (obj (\, (← ($ test) New (QUOTE t2))))
 (objCopy (\, (← ($ test) New (QUOTE t3)))))))
#,($& test (N↑W0.1Y%.:;h.Lh9 . 560))
```

```
48←(← IT SetName 't0)
#,($& test (N↑W0.1Y%.:;h.Lh9 . 560))
```

```
49←(INSPECT IT]
{WINDOW}#52,51234
```

```
All Values of test ($ t0).
atom 1
atomCopy 2
list (a b c)
listCopy (A B #,($ t1))
obj #,($ t2)
objCopy #,($ t3)
```

Make a copy called **t0copy** and inspect it.

```
57←(← (MakeVirtualMixin ($ t0))
 SetName
 (QUOTE t0copy))
#,($& (VirtualCopyMixin test) N↑W0.1Y%.:;h.Lh9 . 562)
```

```
58← (INSPECT IT)
{WINDOW}#53,10150
```

```
All Values of (VirtualCopyMixin test) ($ t0copy).
atom NIL
atomCopy NIL
list NIL
listCopy NIL
obj NIL
objCopy NIL
| copyOf | #,($ t0)
| copyMap | #,($& VirtualCopyContext (N+V0.1Y%.:;h.Lh9 . 563))
```

Make the following changes to **t0** and then reinspect **t0copy**.

```
60←(for iv in '(atom atomCopy list listCopy obj objCopy)
as val in (LIST 11 22 '(a b c d) '(A B C) ($ t3) ($ t1))
do (PutValue ($ t0) iv val]
NIL
```

```
61← (INSPECT IT)
{WINDOW}#53,10152
```

```
All Values of (VirtualCopyMixin test) ($ t0copy).
atom 11
atomCopy 22
list (a b c d)
listCopy (A B C)
obj #,($ t3)
objCopy #,($& (VirtualCopyMixin test) (N+V0.1Y%.:;h.Lh9 . 565) t1)
| copyOf | #,($ t0)
| copyMap | #,($& VirtualCopyContext (N+V0.1Y%.:;h.Lh9 . 566))
```

The copied instance variables have not changed since they do not track changes in the original object.

## Limitations

Some subtle issues are involved in building and using prototype structures so that the structure is preserved in the copied network. These involve how the network is typically traversed.

A general constraint is that all the links to any shared node in the prototype either all be marked as virtual variables, or none of them are. If they are all marked, then a single copy will be made and used. If none are, then the original object from the prototype will be used. Sharing with the prototype can be useful if this object is a repository for standard information that is independent of context. However, if this constraint is violated, the topology of the virtual copy will be different from that of the prototype.

In the simplest situation the network has a single entry node. In this case, a copy-map (see the section "Operands") can be created when the entry node object is first copied. After that all values are copied using this copy-map. The mechanism works well in this situation, even if there is sharing and there are cycles within the network.

At the other extreme, networks can have arbitrary connectivity, including multiple entries from outside the network, for example, from other networks or

non-objects. In this case, the following constraints are necessary to ensure correctness of the virtual copy mechanism.

The first constraint states that all access to the network must start through a copy of one of the nodes in the prototype. This condition is necessary because the criteria for copying are contained in the links from one object to another, not in the objects themselves, and a shared node could not specify a link to a node to be copied. This constraint ensures that all accesses from the outside will be copied if and only if that object would have been copied because of an internal link. Otherwise, an analogous situation would occur in which you could either reach a copy or the original node of the prototype itself depending upon which path you follow when the paths lead to the same node in the prototype.

The final constraint requires that all entries to the network should be passed the same copy-map if they are to share structure. The underlying concern in imposing these constraints is that a network be always copied the same way to maintain its topology regardless of where you start.

Suppose you want to make a virtual copy of a virtual copy, that is, to use a virtual copy of a network as a prototype itself. This is very useful if you are using a network to hold the state of a partial design and you want to try two alternative continuations of the design. Some hidden costs are associated with such multiple-level virtual copies.

Suppose further that a network N1 is used as a prototype and you make a virtual copy, N1-VC. Furthermore, N1-VC-VC is defined to be a copy of N1-VC. Values missing from N1-VC-VC are found in the corresponding object of N1-VC. If the value is missing there, the process recurs, and N1 is examined. If the value is to be a virtual copy, then this process will add a virtual copy in N1-VC, and then a second level copy in N1-VC-VC. This is necessary to preserve the semantics presented, but implies that many levels of virtual copy cannot easily do inexpensive incremental searches of a network.

## Overview of the Manual

---

The *Xerox LOOPS Library Modules Manual* describes the Library Modules for Xerox's Lisp Object-Oriented Programming System, Xerox LOOPS (TM). These Library Modules, which can be loaded into your Xerox Artificial Intelligence Environment, provide additional functionality to Xerox LOOPS.

This manual describes the Lyric/Medley Release of the Xerox LOOPS Library Modules, which run under the Lyric and Medley Releases of Xerox Lisp.

---

## Organization of the Manual and How to Use It

---

This manual is divided into chapters, with each chapter focussing on a particular Library Module. A Table of Contents is included to help you find specific material.

---

## Conventions

---

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- You need to use an Interlisp Exec to enter all exec expressions.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

```
(_ self Selector Arg1 Arg2)
```

- Examples are shown in the Interlisp Exec and appear in the following typeface:

```
89_ (_ LOGIN)
```

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form **ClassName.SelectorName**.

- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

|                  |                                                                                                                                                                                                                                                                                       |                 |             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------|
| Purpose:         | Gives a short statement of what the item does.                                                                                                                                                                                                                                        |                 |             |
| Behavior:        | Provides the details of how the item operates.                                                                                                                                                                                                                                        |                 |             |
| Arguments:       | Describes each argument in the following format:<br><br><table> <tr> <td><i>argument</i></td><td>Description</td></tr> </table>                                                                                                                                                       | <i>argument</i> | Description |
| <i>argument</i>  | Description                                                                                                                                                                                                                                                                           |                 |             |
| Returns:         | States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value. |                 |             |
| Categories:      | A way to group related methods. For example, all the methods related to Masterscope on the class <b>FileBrowser</b> have the category Masterscope, not <b>FileBrowser</b> . This item appears only for methods.                                                                       |                 |             |
| Specializes:     | The next higher class in the class hierarchy that contains a method with the same selector. For example, <b>RectangularWindow.Open</b> can specialize <b>Window.Open</b> . This appears only for methods.                                                                             |                 |             |
| Specializations: | The next lower class in the class hierarchy that contains a method with the same selector. For example, <b>Window.Open</b> is a specialization of <b>RectangularWindow.Open</b> . This appears only for methods.                                                                      |                 |             |
| Example:         | An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See the <i>Xerox LOOPS Reference Manual</i> for details.                                 |                 |             |

## References

---

The following books and manuals augment this manual.

*Xerox LOOPS Reference Manual*

*Xerox LOOPS Release Notes*

*Xerox LOOPS Users' Modules Manual*

*Interlisp-D Reference Manual*

*Common Lisp: the Language* by Guy Steele

*Xerox Common Lisp Implementation Notes, Lyric Release*

*Xerox Lisp Release Notes, Lyric and Medley Releases*

*Xerox Lisp Library Modules Manual, Lyric and Medley Releases*

# Writer's Notes -- Conventions

---

This file includes notes on conventions for *Xerox LOOPS Library Modules Manual*, Lyric Beta Release. This manual is packaged with the *Xerox LOOPS Release Notes* and *Xerox LOOPS Reference Manual* to form one binder.

Writer: Raven Kontur Brewster

Printing Date: >>DA<< >>MO<< 1988

## Directories and Files

---

The directory {ERIS}<Doc>Loops>Lyric>Beta>LibMods> contains the files for the manual. This directory has the following subdirectories:

- {ERIS}<Doc>Loops>Lyric>Beta>LibMods>Z-ReleaseInfo> contains this file on writing conventions and a file on production details.

Filenames describe the contents of the file. For example, the filename

{ERIS}<Doc>Loops>Lyric>Beta>LibMods>Gauges

contains the chapter on gauges.

Assemble the files in the following order for the manual:

```
{ERIS}<Doc>Loops>Lyric>Beta>LibMods>A1-TitlePage.tedit
{ERIS}<Doc>Loops>Lyric>Beta>LibMods>A2-TOC.tedit
{ERIS}<Doc>Loops>Lyric>Beta>LibMods>A3-Preface.tedit
{ERIS}<Doc>Loops>Lyric>Beta>LibMods>Gauges.tedit
{ERIS}<Doc>Loops>Lyric>Beta>LibMods>Masterscope.tedit
{ERIS}<Doc>Loops>Lyric>Beta>LibMods>VC.tedit
```

## Conventions

---

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(\_ self **Selector** *Arg1 Arg2*)

- Examples appear in the following typeface:

89\_(\_LOGIN)

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form **ClassName.SelectorName**.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

|                  |                                                                                                                                                                                                                                                                                       |                 |             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------|
| Purpose:         | Gives a short statement of what the item does.                                                                                                                                                                                                                                        |                 |             |
| Behavior:        | Provides the details of how the item operates.                                                                                                                                                                                                                                        |                 |             |
| Arguments:       | Describes each argument in the following format:<br><br><table><tr><td><i>argument</i></td><td>Description</td></tr></table>                                                                                                                                                          | <i>argument</i> | Description |
| <i>argument</i>  | Description                                                                                                                                                                                                                                                                           |                 |             |
| Returns:         | States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value. |                 |             |
| Categories:      | A way to group related methods. For example, all the methods related to Masterscope on the class <b>FileBrowser</b> have the category Masterscope, not <b>FileBrowser</b> . This item appears only for methods.                                                                       |                 |             |
| Specializes:     | The next higher class in the class hierarchy that contains a method with the same selector. For example, <b>RectangularWindow.Open</b> can specialize <b>Window.Open</b> . This appears only for methods.                                                                             |                 |             |
| Specializations: | The next lower class in the class hierarchy that contains a method with the same selector. For example, <b>Window.Open</b> is a specialization of <b>RectangularWindow.Open</b> . This appears only for methods.                                                                      |                 |             |
| Example:         | An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags.                                                                                          |                 |             |

## Style Sheet Addenda

---

Here are some guidelines I used when writing the LOOPS manuals. Items appear in rather random order.

- Avoid contractions.
- Avoid subscripts. Use WORD1 rather than WORD to avoid inconsistent line leading.
- Avoid wording that starts "Note that..." or "Notice that...". Either make it a note with correct format or eliminate the "Note that".
- Use semicolons rather than m-dashes.
- Each item in the template starts with an initial capital letter; e.g., "Describes..."
- The arguments are identical in the call and in the argument description.

- Parentheses appear around expressions and square brackets appear around the name of the functionality.
- The arrow in the expression is the NS character  $\leftarrow$ , not `_`. These characters appear similarly when printed, but differently on the screen. See the section, "Special Notes and Cautions," for details
- A period appears after the word None, after argument descriptions, and Returns: item.
- Items are set to or return T (instead of true).
- Menus contain options, not items or selections.
- You drag (not roll) the mouse to the right of a menu option to see its submenu.
- Use "above" and "below" when referring to things in the same section, section numbers and names when referring to things in the same chapter, and chapter numbers and names when referring to things in another chapter.
- Please study the following style sheet carefully before you start to edit. The various appearances of active value and annotated values are especially crazy making.

These things appear in **bold**:

class variables  
functions  
instance variables  
messages  
methods  
variables

**ActiveValue** - specific class/instance

active value - general information

activeValue - previous implementation of **ActiveValue**

annotatedValue - data type

**AnnotatedValue** - specific class

annotated values - general information

bitmap

data type

file package

filecoms

inspector

Lisp Library package

**localState** - instance variable

non-NIL

prettyprints

supers list

- Figures

---

## Paragraph Formatting

The text has the following format:

Bulleted lists have the following format:

The template has the following format:

The Arguments section of the template has the second line start at 18 instead of 13.

**Paragraph-Looks Menu****APPLY SHOW NEUTRAL****Left Right Centered Justified Page-Heading** type: {}

Line leading: {}pts Para Leading: {}pts Special Locn: X {}picas, Y {}picas

New Page: **Before** ~~After~~ Display mode: **Hardcopy** Keep: **Heading**Tab Type: **Left Right Centered Decimal Dotted Leader** Default Tab Size: {}**Page Layout**

Page numbering varies with the chapter.

## Bitmaps, Graphs, and Sketches

---

To do SEdit and Inspector examples for the manual, you need to reset your FONTPROFILE and scale the resulting windows to 0.8.

- In your Interlisp Executive, enter (DV FONTPROFILE)
- Edit the FONTPROFILE to be as follows. (some of this is probably overkill, but it does eliminate any suprizes)

```
SEdit FONTPROFILE Package: INTERLISP
```

```
((DEFAULTFONT 1 (GACHA 12 BRR)
 (GACHA 10)
 (TERMINAL 10))
 (ITALICFONT 1 (HELVETICA 12 MIR)
 (GACHA 10 MIR)
 (MODERN 10 MIR))
 (BOLDFONT 2 (HELVETICA 12 BRR)
 (HELVETICA 10 BRR)
 (MODERN 10 BRR))
 (LITTLEFONT 3 (HELVETICA 10)
 (HELVETICA 8 MIR)
 (MODERN 10 MIR))
 (TINYFONT 6 (GACHA 10)
 (GACHA 8)
 (TERMINAL 8))
 (BIGFONT 4 (HELVETICA 14 BRR) NIL (MODERN 12 BRR))
 (MENUFONT 5 (HELVETICA 12))
 (COMMENTFONT 6 (HELVETICA 12)
 (HELVETICA 10)
 (MODERN 10))
 (TEXTFONT 7 (TIMESROMAN 12) NIL (CLASSIC 12)))
```

-- In your Interlisp Executive, enter  
(FONTPROFILE FONTPROFILE)  
(SEdit.RESET)

-- Make bitmaps of the resulting windows, and scale these bitmaps to 0.8

To get the pop-up menus (and their drag-through submenus) into a bitmap for using as an illustration:

--Move your type-in point to the exec window.

--Bring up your pop-up menu.

--control-G

--When the menu comes up, select Mouse \*run. This will cause a break and spawn a new mouse process, so that the mouse continues to work.

--Move your type-in point to the tedit window.

--Shift-snap the menu image into the tedit window.

--Move the type-in point to the break window and type ^.

--To have your browser menus be a different font, type in your Interlisp Exec

```
(SETQ MENUFONT (FONTCREATE 'TERMNIAL 12 'BOLD))
```

--The global variable MENUFONT which is currently set to (HELVETICA 10 MRR).

--The menus that have already been created will still display this old font. Either recreate the browsers to force the menus to be recreated, or send a message to the browser

```
(_ browser ClearMenuCache)
```

to force that browser to recreate its menus.

## Special Notes and Cautions

---

Make sure you have changed the underscore to be a left arrow before loading and printing any files. To do this,

- Enter the following commands into your Executive:

```
(GETCHARBITMAP (CHARCODE _) '(MODERN 10 MRR))
(EDITBM IT)
```

- When the bitmap editor appears, delete the underscore and insert the following left arrow:

```
.....
.....
.....
.....
.....
...X....
...XX...
..XXXXXX.
...XX...
...X....
.....
.....
.....
.....
```

- Finally, enter the following commands into your Executive to store the pattern:

```
(PUTCHARBITMAP (CHARCODE _) '(MODERN 10 MRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(MODERN 10 BRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 MRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 BRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 12 BRR) IT)
```

## Description/Introduction

---

Gauges are an important part of the LOOPS user interface for both developers and end users. Gauges assist in understanding the dynamic nature of the programs. This is in contrast to the more typical case of debugging programs using static means. In the creation of user-friendly interfaces, you can use gauges to display, in analog or digital form, various data that may be changing. Also, by employing active gauges, you can provide a convenient way to interact with a system.

One of the features of gauges is the ease with which you can use them in a system. In more traditional languages, if you want to understand how a variable is changing over the course of a computation, you must make modifications in your program wherever you want to begin or end the examination of a variable. Given the capabilities of active values used by gauges, you need only attach or detach a gauge to the data that you are interested in monitoring.

The following types of gauges are available:

- Meter; a circular instrument that wraps around any number of times.
- Dial; a bounded dial, like an automobile speedometer.
- LCD; a gauge that uses the entire window to display a value.
- Scale; a horizontal or vertical display of a gauge.
- ActiveScale; a scale that allows you to change the gauge value.

Gauges are an example of the combination of programming capabilities within LOOPS. The different types of gauges are defined within the context of an inheritance lattice. This allows the more general functionality and variables to be allocated to more general gauge classes, with specific functionality placed in more restricted classes. You can also see the use of mixins to add a small amount of functionality to several different classes of gauges.

Note: Mixins are classes that are used only in conjunction with another class to create a subclass.

The methods within gauges are built upon both function calling and message sending. Gauges are "attached" to objects through the mechanism of active values. Since gauges are built upon the mechanism of active values, gauges can only be attached to data within objects. It is not possible to use gauges to monitor any arbitrary Lisp variable.

Prerequisites

The default font for gauges is Modern 10.

Installation/Loading Instructions

Gauges are divided among several different files to allow you to load only those objects and functions that you need. The table below lists the files to load for each type of gauge. The filecoms for each file will try to load any other required gauge files from **LOOPSLIBRARYDIRECTORY**. The file **GAUGES.DFASL** and either **GAUGEINSTRUMENTS.DFASL** or **GAUGEALPHANUMERICS.DFASL** will always be loaded; other files may also be loaded.

| Gauge        | File to load             |
|--------------|--------------------------|
| LCD          | GAUGEALPHANUMERICS.DFASL |
| METER        | GAUGEMETERS.DFASL        |
| DIAL         | GAUGEDIALS.DFASL         |
| SCALE        | GAUGESCALES.DFASL        |
| ACTIVE SCALE | GAUGEACTIVE.DFASL        |

Additionally, the file **GAUGESELFSCALEMIXIN.DFASL** can be loaded to add the class **SelfScaleMixin**, and **GAUGEALARMS.DFASL** can be loaded to add the class **AlarmMixin**.

To load the required files, first set the value of **LOOPSDIRECTORY** to include the directory where the gauges files are stored, then type the following expression in the Executive:

(LOAD 'FILENAME)

To load all of the gauges, load the file **GAUGELOADER** and then enter (LOADGAUGES). **GAUGELOADER** also sets the variables: **GAUGEFILES** and **GaugeClasses**.

(LOADGAUGES LDFLG SOURCES?FLG) [Function]

|            |                                                                                                                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Loads all the gauges.                                                                                                                                                                                                                                                                                   |
| Behavior:  | Assumes that all of the gauge files are on the <b>LOOPSDIRECTORY</b> search path.<br><br>All the gauge files will be loaded based upon the settings of <i>LDFLG</i> and <i>SOURCES?FLG</i> . A <b>FILESLOAD</b> expression is built up and evaluated.                                                   |
| Arguments: | <i>LDFLG</i> Can be NIL, PROP, or SYSLOAD. See the <b>LDFLG</b> discussion under loading in the <i>Interlisp-D Reference Manual</i> .<br><br><i>SOURCES?FLG</i> Can be NIL or T. If NIL, this attempts to load the compiled files before trying to load the sources. If T, only the sources are loaded. |
| Returns:   | Used for side effect only.                                                                                                                                                                                                                                                                              |

**Application/Module Functionality**

This section describes the gauge classes and methods.

**Gauge Classes**

This section describes the available gauges shown in the following browser.

Note: The browser does not include the optional mixin classes.

Within the class description of each class, the instance variables and class variables that are specializations only because they have different default values are not listed.

| Name                         | Type          | Description                                                                                                     |
|------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------|
| <b>ActiveGaugeMixin</b>      | AbstractClass | A gauge class that allows you to set the value of the variable being monitored with the cursor, via a SET menu. |
| <b>ActiveHorizontalScale</b> | Class         | An active gauge that displays the value on a horizontal scale.                                                  |
| <b>ActiveVerticalScale</b>   | Class         | An active gauge that displays its value on a vertical scale.                                                    |
| <b>AlarmMixin</b>            | AbstractClass | A mixin that adds alarm functionality to any gauge.                                                             |
| <b>AlphaNumeric</b>          | AbstractClass | A gauge that gives an alphanumeric display of a value.                                                          |

|                          |               |                                                                                                                                               |
|--------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BarChart</b>          | Class         | A gauge that displays more than one <b>VerticalScale</b> side-by side.                                                                        |
| <b>BoundedMixin</b>      | AbstractClass | Creates a bounded scale for <b>displayVal</b> ; to be used as a mixin for instruments.                                                        |
| <b>Dial</b>              | Class         | A bounded dial, like an automobile speedometer.                                                                                               |
| <b>DigiMeter</b>         | Class         | A gauge that displays both an <b>LCD</b> and a meter.                                                                                         |
| <b>DigiScale</b>         | Class         | A gauge that displays both an <b>LCD</b> and a horizontal scale.                                                                              |
| <b>Gauge</b>             | AbstractClass | A class for objects that present a dynamic graphical image of a LOOPS value.                                                                  |
| <b>GaugeAV</b>           | Class         | An active value associated with a gauge.                                                                                                      |
| <b>HBarChart</b>         | Class         | A gauge that displays more than one <b>HorizontalScale</b> side-by side.                                                                      |
| <b>HorizontalScale</b>   | Class         | A labeled, bounded scale with a bar that fills to the right.                                                                                  |
| <b>HSGraphics</b>        | AbstractClass | Gauge that is displayed in the form of a single horizontal scale or bar.                                                                      |
| <b>Instrument</b>        | AbstractClass | A numeric gauge that is externally scaled by <b>inputLower</b> and <b>inputRange</b> and scaled internally by <b>lower</b> and <b>range</b> . |
| <b>LCD</b>               | Class         | Differs from <b>AlphaNumeric</b> in that the entire gauge window is the printing region.                                                      |
| <b>LCDMixin</b>          | AbstractClass | Computes print region differently from <b>LCD</b> .                                                                                           |
| <b>Meter</b>             | Class         | A circular instrument that wraps around any number of times.                                                                                  |
| <b>RoundScale</b>        | AbstractClass | Abstract Class for instruments with circular (arc) scales.                                                                                    |
| <b>SelfScaleMixin</b>    | AbstractClass | Provides for the gauge to rescale according to the reading.                                                                                   |
| <b>SSBarChart</b>        | Class         | A self-scaling version of <b>BarChart</b> .                                                                                                   |
| <b>SSDigiMeter</b>       | Class         | A self-scaling version of <b>DigiMeter</b> .                                                                                                  |
| <b>SSHBarChart</b>       | Class         | A self-scaling version of <b>HBarChart</b> .                                                                                                  |
| <b>SSHorizontalScale</b> | Class         | Gauge that is displayed in the form of a single scale or bar which rescales itself accordingly.                                               |
| <b>SSVerticalScale</b>   | Class         | Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.                                      |
| <b>StraightScale</b>     | AbstractClass | Abstract Class for instruments with straight scales.                                                                                          |
| <b>VSGraphics</b>        | AbstractClass | Gauge that is displayed in the form of a single vertical scale or bar.                                                                        |
| <b>VerticalScale</b>     | Class         | Gauge that is displayed in the form of a single vertical scale or bar.                                                                        |

---

**ActiveGaugeMixin**

[Class]

Description: A gauge class that allows you to set the value of the variable being monitored with the cursor, via a **SET** menu.

MetaClass: AbstractClass

Supers: Object

Class Variables: None.

Instance Variables: **cursor** The cursor to use when changing the scale; the default is NIL.

**ActiveHorizontalScale**

[Class]

Description: An active gauge that displays the value on a horizontal scale. This gauge shows the value of the data it is connected with and allows you to change that data with the gauge.

MetaClass: Class

Supers: ActiveGaugeMixin, HorizontalScale

Class Variables: None.

Instance Variables: **cursor** Cursor to use when changing the scale; its property **:initform** is set to **HorizontalAGCursor**.

Example: These gauges have an attached menu at the bottom of the gauge. When you position the cursor over this menu and press a mouse button, the cursor changes to the following shape:

While the left button is held down, the system tracks movements of the cursor and changes the value that the gauge is monitoring.

**ActiveVerticalScale**

[Class]

Description: Similar to **ActiveHorizontalScale**, except that a vertical scale is used.

MetaClass: Class

Supers: ActiveGaugeMixin, VerticalScale

Class Variables: None.

Instance Variables: **cursor** Cursor to use when changing the scale; its **:initform** property is set to **VerticalAGCursor**.

Example: Similar to **ActiveHorizontalScale**. When setting, the cursor changes to the following shape:

---

**AlarmMixin** [Class]

Description: A mixin that adds alarm functionality to any gauge. An alarm is defined as warning object that is set off when the value being monitored falls outside of the specified range. The gauge flashes and stays inverted when the alarm is tripped.

---

**CAUTION**

When a new class of gauges is created that will use the properties of **AlarmMixin**, **AlarmMixin** should be the first class on the Supers list of the new class. This guarantees that the **AlarmMixin.Set** method is invoked.

---

- MetaClass: AbstractClass
- Supers: Object
- Class Variables: MiddleButtonItem
- Instance Variables:
- lowTripPoint** Alarm is triggered when reading goes below this point.
  - hiTripPoint** Alarm is triggered when reading goes above this point.
  - flashNumber** Number of times alarm will flash when it is tripped.
  - flashInterval** Interval in milliseconds between flashes.

---

**AlphaNumeric** [Class]

- Description: This class contains some of the methods and data for the LCD classes. These gauges can display any type of character, letters, or numbers.
- MetaClass: AbstractClass
- Supers: Gauge
- Class Variables: None.

Instance Variables: **precision** Number of characters displayed in the reading. The default value is 5.

**BarChart**

[Class]

Description: A gauge that can display more than one **VerticalScale** at once, side-by side.

MetaClass: Class

Supers: VerticalScale

Class Variables: None.

Instance Variables: **maxLabelWidth**  
Maximum width of labels on each bar. Default value is 0 which means no limit.

**scaleLeft**  
Offset within the gauge window from the left for the leftmost bar. Default value is 3.

**scaleBottom**  
Offset within the gauge window from the bottom for all the bars. Default value is 30.

Example: Here is a **BarChart** showing the size and shape of a window. It is displaying the values 15, 21, 13, and 6.

**BoundedMixin**

[Class]

Description: This mixin is a super of the scale classes and **Dial**. If a gauge that has **BoundedMixin** as a super class tries to display a new setting that is outside of the range of the gauge, the gauge will display the minimum or maximum value as appropriate and place a "???" in the window.

MetaClass: AbstractClass

Supers: Object

Class Variables: None.

Instance Variables: None.

Example: Here is a vertical scale that displays a reading greater than its maximum.

Dial [Class]

- Description: A bounded dial, like an automobile speedometer.
- MetaClass: Class
- Supers: BoundedMixin, RoundScale
- Class Variables: None.
- Instance Variables: This class specializes the same instance variables as **RoundScale**.
- Example: The angle of the arc changes with the shape of the window.

DigiMeter [Class]

- Description: A gauge that combines both a meter and an LCD.
- MetaClass: Class
- Supers: Meter, LCDMixin
- Class Variables: None.
- Instance Variables: **spaceForLCD**  
Vertical space required by LCD within the gauge. Defaults to 30.
- Example: This **DigiMeter** is displaying 55.

**DigiScale**

[Class]

Description: A gauge that combines both a horizontal scale having no ticks and an LCD.

MetaClass: Class

Supers: HorizontalScale, LCDMixin

Class Variables: None.

Example: This **DigiScale** is displaying 63 with its scale set from 0 to 100.

**Gauge**

[Class]

Description: A class for objects that present a dynamic graphical image of a Xerox LOOPS value. This class provides most of the methods for using gauges.

MetaClass: AbstractClass

Supers: Window

Class Variables: **LeftButtonItem**  
Menu options associated with the left mouse button.

**MiddleButtonItem**  
Menu options associated with the middle mouse button.

Instance Variables: **reading** External value of reading. The default value is 0.

**containedInAV**  
Active value that connects the gauge to the data it is monitoring. It should be an instance of the class **GaugeAV**.

**font** Font that is used by a gauge; default value is (Modern 10).

**width** Width of a gauge; has property **min**, which specifies the minimum width for a gauge.

**height** Height of a gauge; has property **min**, which specifies the minimum height for a gauge.

**GaugeAV**

[Class]

Description: An active value that is associated with a gauge.

MetaClass: Class

Supers: LocalStateActiveValue

|                     |                 |                                                                      |
|---------------------|-----------------|----------------------------------------------------------------------|
| Class Variables:    | None.           |                                                                      |
| Instance Variables: | <b>gauge</b>    | The gauge connected to this active value.                            |
|                     | <b>object</b>   | The object containing the variable associated with the active value. |
|                     | <b>propName</b> | The property name of the associated variable.                        |
|                     | <b>type</b>     | Data type of the associated variable.                                |
|                     | <b>varName</b>  | Name of the associated variable.                                     |

HBarChart

[Class]

|                     |                                                                                                                    |                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Description:        | A gauge that can display more than one <b>HorizontalScale</b> at once, side-by-side.                               |                                                                                        |
| MetaClass:          | Class                                                                                                              |                                                                                        |
| Supers:             | HorizontalScale                                                                                                    |                                                                                        |
| Class Variables:    | None.                                                                                                              |                                                                                        |
| Instance Variables: | <b>maxLabelWidth</b>                                                                                               | Maximum width of labels on each bar. Default value is 0 which means no limit.          |
|                     | <b>scaleLeft</b>                                                                                                   | Offset within the gauge window from the left for the leftmost bar. Default value is 3. |
| Example:            | Here is an <b>HBarChart</b> showing the size and shape of a window. It is displaying the values 15, 21, 13, and 6. |                                                                                        |

HorizontalScale

[Class]

|                     |                                                                      |  |
|---------------------|----------------------------------------------------------------------|--|
| Description:        | A labeled, bounded scale with a bar that fills to the right.         |  |
| MetaClass:          | Class                                                                |  |
| Supers:             | HSGraphics                                                           |  |
| Class Variables:    | None.                                                                |  |
| Instance Variables: | None.                                                                |  |
| Example:            | This <b>HorizontalScale</b> is reading 350 on a scale from 0 to 500. |  |

HSGraphics

[Class]

|                     |                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | This class provides some of the methods for displaying the graphics of a horizontal scale.                                                                                                                                                                                                                          |
| MetaClass:          | AbstractClass                                                                                                                                                                                                                                                                                                       |
| Supers:             | StraightScale                                                                                                                                                                                                                                                                                                       |
| Class Variables:    | None.                                                                                                                                                                                                                                                                                                               |
| Instance Variables: | <b>scaleBottom</b> Bottom edge of scale in pixels. The default value is 10.<br><b>scaleLeft</b> Left edge of scale in pixels. The default value is 12.<br><b>scaleWidth</b> Width of inside of scale in pixels. The default value is 120.<br><b>scaleHeight</b> Height of scale in pixels. The default value is 15. |

**Instrument**

[Class]

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | A class that provides additional methods and data for gauges that display only numerical data. This data is externally scaled by <b>inputLower</b> and <b>inputRange</b> , and scaled internally by <b>lower</b> and <b>range</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| MetaClass:          | AbstractClass                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Supers:             | Gauge                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Class Variables:    | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Instance Variables: | <b>ticks</b> Scale marks on the instrument; value is a number or NIL; <b>smallTicks</b> property indicates the number of smaller ticks between each large tick.<br><b>displayVal</b> Internal value relative to instrument.<br><b>range</b> Range for internal <b>displayVal</b> .<br><b>inputRange</b> Range for external reading.<br><b>lower</b> Lower bound for internal <b>displayVal</b> .<br><b>inputLower</b> Lower bound for external reading.<br><b>brushWidth</b> Scale factor for width of ticks, rays, and circles in pixels.<br><b>labels</b> The labels that will be displayed on the gauge.<br><b>labelScale</b> A dotted pair representing the sign and exponent of a reading.<br><b>spaceForLabelScale</b> Extra vertical space to display scale label. |

**LCD**

[Class]

|                     |                                                                                      |
|---------------------|--------------------------------------------------------------------------------------|
| Description:        | Differs from <b>LCDMixin</b> in that the entire gauge window is the printing region. |
| MetaClass:          | Class                                                                                |
| Supers:             | AlphaNumeric                                                                         |
| Class Variables:    | None.                                                                                |
| Instance Variables: | None.                                                                                |

Example: This **LCD** is displaying the string "Mumble", and has been **Shaped**to 120 x 60.

**LCDMixin** [Class]

Description: Computes printing region differently from LCD so that an LCD may be added into another window.

MetaClass: AbstractClass

Supers: AlphaNumeric

Class Variables: None.

Instance Variables: **precision** Number of characters displayed in the reading; the default value is 3. Its property is **readingRegion**; the default value is NIL.

**readingY** Y position of bottom of reading. The default value is 7.

**Meter** [Class]

Description: A circular instrument that wraps around any number of times. It displays a sign and exponent in the lower left corner of its window.

MetaClass: Class

Supers: RoundScale

Class Variables: None.

Instance Variables: This class specializes the same instance variables as **RoundScale**.

Example: The **Meter** on the left is displaying a negative value.

**RoundScale** [Class]

Description: Abstract Class for instruments with circular (arc) scales.

MetaClass: AbstractClass

Supers: Instrument

Class Variables: None.

Instance Variables: **needleLength** Radius of needle in pixels. The default value is 15.

|               |                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>radius</b> | Radius of arc in pixels. The default value is 10.                                                                             |
| <b>xc</b>     | x-coordinate window coordinate of center of arc. (See <b>DRAWARC</b> in the <i>Xerox Lisp Release Notes, Lyric Release</i> .) |
| <b>yc</b>     | y-coordinate window coordinate of center of arc. (See <b>DRAWARC</b> in the <i>Xerox Lisp Release Notes, Lyric Release</i> .) |

### **SelfScaleMixin** [Class]

|                     |                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | Provides for the gauge to rescale according to the reading.                                                                                                   |
| MetaClass:          | AbstractClass                                                                                                                                                 |
| Supers:             | Object                                                                                                                                                        |
| Class Variables:    | None.                                                                                                                                                         |
| Instance Variables: | <b>lowScaleFactor</b><br>Rescales if reading shrinks so that it will fit more than <b>lowScaleFactor</b> times in <b>inputRange</b> . The default value is 5. |

### **SSBarChart** [Class]

|                     |                                             |
|---------------------|---------------------------------------------|
| Description:        | A self-scaling version of <b>BarChart</b> . |
| MetaClass:          | Class                                       |
| Supers:             | BarChart                                    |
| Class Variables:    | None.                                       |
| Instance Variables: | None.                                       |

### **SSDigiMeter** [Class]

|                     |                                              |
|---------------------|----------------------------------------------|
| Description:        | A self-scaling version of <b>DigiMeter</b> . |
| MetaClass:          | Class                                        |
| Supers:             | DigiMeter                                    |
| Class Variables:    | None.                                        |
| Instance Variables: | None.                                        |

### **SSHBarChart** [Class]

|                     |                                              |
|---------------------|----------------------------------------------|
| Description:        | A self-scaling version of <b>HBarChart</b> . |
| MetaClass:          | Class                                        |
| Supers:             | HBarChart                                    |
| Class Variables:    | None.                                        |
| Instance Variables: | None.                                        |

### **SSHorizontalScale** [Class]

|              |                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------|
| Description: | Gauge that is displayed in the form of a single horizontal scale or bar which rescales itself accordingly. |
|--------------|------------------------------------------------------------------------------------------------------------|

MetaClass: Class  
Supers: VerticalScale  
Class Variables: None.  
Instance Variables: None.

---

**SSVerticalScale** [Class]

Description: Gauge that is displayed in the form of a single vertical scale or bar which rescales itself accordingly.  
MetaClass: Class  
Supers: HorizontalScale  
Class Variables: None.  
Instance Variables: None.

---

**StraightScale** [Class]

Description: Abstract class for instruments with straight scales.  
MetaClass: AbstractClass  
Supers: BoundedMixin, Instrument  
Class Variables: None.  
Instance Variables: **shade** Shade of bar; numeric value from 0 to 65535. The default value is 65535, which is BLACKSHADE.

---

**VerticalScale** [Class]

Description: Gauge that is displayed in the form of a single vertical scale or bar.  
MetaClass: Class  
Supers: VSGraphics  
Class Variables: None.  
Instance Variables: None.  
Example: This **VerticalScale** is displaying the value .55 and has its **Shade** set to 1258.

**VSGraphics****[Class]**

|                     |                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:        | Similar to <b>HSGraphics</b> but for vertical scales.                                                                                                                                                                                                                                                               |
| MetaClass:          | AbstractClass                                                                                                                                                                                                                                                                                                       |
| Supers:             | StraightScale                                                                                                                                                                                                                                                                                                       |
| Class Variables:    | None.                                                                                                                                                                                                                                                                                                               |
| Instance Variables: | <b>scaleBottom</b> Bottom edge of scale in pixels. The default value is 12.<br><b>scaleLeft</b> Left edge of scale in pixels. The default value is 15.<br><b>scaleWidth</b> Width of inside of scale in pixels. The default value is 15.<br><b>scaleHeight</b> Height of scale in pixels. The default value is 120. |

**Gauge Methods**

This section describes the available methods and functions which are used to manipulate gauges. In many cases, a particular gauge class specializes a method defined in the class **Gauge**. In this case, the specialized method definition is not explicitly defined; instead, this is noted in the Specializes/Specializations field of the description.

| Name               | Type   | Description                                                                  |
|--------------------|--------|------------------------------------------------------------------------------|
| <b>Attach</b>      | Method | Connects a gauge to an object.                                               |
| <b>Attached?</b>   | Method | Determines what the gauge is attached to.                                    |
| <b>ChangeFont</b>  | Method | Sets the gauge's instance variable <b>font</b> and updates the gauge.        |
| <b>Close</b>       | Method | Detaches the gauge and closes the window.                                    |
| <b>Destroy</b>     | Method | Destroys the gauge, detaching it first.                                      |
| <b>Detach</b>      | Method | Detaches the gauge from the variable it is attached to.                      |
| <b>Reset</b>       | Method | Resets the gauge's instance variable <b>reading</b> .                        |
| <b>SetScale</b>    | Method | Sets the scale for the gauge.                                                |
| <b>Shape</b>       | Method | Sweeps a new region.                                                         |
| <b>ShapeToHold</b> | Method | Shapes the gauge window to its smallest possible size.                       |
| <b>Update</b>      | Method | Reinitializes the gauge and its display window to reflect the current state. |

(← *self* **Attach** *obj varName propName type xOrPos y*)

**[Method of Gauge]**

|            |                                                                                                                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Connects a gauge to an object.                                                                                                                                                                                                                                                                                     |
| Behavior:  | Displays the gauge on the screen and associates that gauge with the variable <i>varName</i> of <i>obj</i> . If <i>propName</i> is specified, the gauge will monitor the variable's property. If <i>xOrPos</i> and <i>y</i> are not specified, a small box will appear which must be positioned to place the gauge. |
| Arguments: | <i>obj</i> A pointer to the object to which the gauge is to be attached.                                                                                                                                                                                                                                           |

|                 |                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>varName</i>  | The name of the instance variable, class variable, or method to which the gauge is to be attached.                                                                                                                                                                     |
| <i>propName</i> | If non-NIL, the gauge will be attached to this property.                                                                                                                                                                                                               |
| <i>type</i>     | One of IV, CV, or METHOD, within the object being connected to the gauge. If NIL, it defaults to IV.                                                                                                                                                                   |
| <i>xOrPos</i>   | A numerical value to specify where, in screen coordinates, the gauge will be placed on the display. If NIL, you are asked to place the gauge on the screen. This can be a number to specify the x coordinate or a position. If it is a number, also specify <i>y</i> . |
| <i>y</i>        | If <i>xOrPos</i> is not a position, this specifies the y coordinate in screen coordinates for the gauge.                                                                                                                                                               |

Returns: *self*

Specializations: **StraightScale.Attach** has an additional *shade* argument so that the shade of the scale may be specified at the time the gauge is attached. The following shows the argument list for this method:

```
(_ ($ instance OfHorizontalScale) Attach obj varName shade propName type
xOrPos y)
```

The **Attach** methods for **BarChart**, **HBarChart**, and their subclasses take an additional *label* argument. If no *label* argument is given, the bar is labeled with *varName*. The *label* argument comes last, as follows:

```
(_ ($ instance OfBarChart) Attach obj varName propName propName type
xOrPos y label)
```

---

(← *self* **Attached?** *don'tPrintFlg*) [Method of Gauge]

---

Purpose: Determines what a gauge is attached to.

Behavior: If *don'tPrintFlg* is non-NIL this returns the value of the gauge instance variable **containedInAV**. If *don'tPrintFlg* is NIL, the **object** and the **varName** the gauge is attached to will be printed in an attached window.

Arguments: *don'tPrintFlg*  
Suppresses displaying what the gauge is attached to.

Returns: NIL

---

(← *self* **ChangeFont** *newFont*) [Method of Gauge]

---

Purpose/Behavior: Sets the gauge's instance variable **font** to *newFont* and updates the gauge. If the gauge is too small for *newFont*, it is reshaped.

Arguments: *newFont* A font in which to display the gauge's text.

Returns: Previous value of **font**.

---

(← *self* **Close**) [Method of Gauge]

---

Purpose/Behavior: Detaches the gauge and closes the window.

Returns: CLOSED

---

(← *self* **Destroy**) [Method of Gauge]

---

Purpose/Behavior: Destroys the gauge, detaching it first before closing the window.

Returns: NIL

(← *self Detach*)

[Method of Gauge]

Purpose/Behavior: Detaches the gauge from the variable to which it is attached. This prints in an attached window that the gauge is being detached, and deletes all of the links connecting the gauge, active value, and object being monitored. Does not close the window.

Returns: NIL

(← *self Reset newReading*)

[Method of Gauge]

Purpose/Behavior: Sets the gauge's instance variable **reading** to *newReading* and updates the gauge. If the gauge is too small for *newReading* and it is **SelfScaling**, it is reshaped.

Arguments: *newReading* Sets the instance variable **reading** to *newReading*, and updates the gauge without going through any intermediate steps.

Returns: NIL if gauge is **AlphaNumeric** or **RoundScale**; otherwise *self*.

Specializations: **Alphanumeric.Reset**, **RoundScale.Reset**

Example: The following example causes the LCD to be redisplayed with the *newReading*:

```
13_(_ ($ lcd1) Reset "New Title")
```

(← *self SetScale min max*)

[Method of Gauge]

Purpose/Behavior: Sets the scale for the gauge; computes the new scale values and redisplayes if necessary.

Arguments: *min* Lowest value on scale.

*max* Highest value on scale.

Returns: *self*

(← *self Shape newRegion noUpdateFlg*)

[Method of Gauge]

Purpose/Behavior: If *newRegion* is NIL, you are prompted to sweep out a region which has a minimum sized based upon a **min** property of **IV width** and **height:;min**. If *newRegion* is non-NIL, it is first checked to guarantee that it is at least as large as **width:;min** by **height:;min**.

Arguments: *newregion* List specifying the external coordinates of the window in which the gauge is displayed; list is of the form (left, bottom, width, height).

*noUpdateFlg* If NIL, reshapes the gauge.

Returns: NIL

Specializes: Window

Specializations: **LCD**, **Meter**, **DigiMeter**. **Meter.Shape** has an extra argument *ExtraSpaceFlg*. If T, this will allow you to shape a fairly arbitrary region for the gauge; if NIL, the meter is constrained to be close to a square. This latter behavior is what the user sees when trying to shape the meter from the window menu.

**BarChart**, **HBarChart**, and their subclasses can only be freely **Shaped** in the direction their bars run (i.e., **BarCharts** can be **Shaped** vertically and **HBarCharts** can be **Shaped** horizontally). Their size along the other dimension is fixed by the number of values attached to the chart.

Example: This example reshapes the gauge to a location where the lower left corner is at (10,100) a width of 50 and a height of 150.

```
14_(_ ($ lcd1) Shape '(10 100 50 150))
```

---

(← *self* **ShapeToHold**)

[Method of Gauge]

Purpose/Behavior: Shapes the gauge window to its smallest possible size based on **width:;min** and **height:;min** and redisplay the gauge.

Returns: NIL

Specializations: **LCD.Shape**

---

(← *self* **Update**)

[Method of Gauge]

Purpose/Behavior: Reinitializes the gauge and its display window to reflect the current state.

Returns: *self*

Categories: Window

---

## Examples

The typical use pattern for a gauge is to first create it, set the scale to the appropriate value, and attach it to the desired data.

To attach a horizontal scale to a Xerox LOOPS window, **w1**, first enter

```
15_(_ ($ Window) New 'w1)
#,(($& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 495))
```

```
16_(_ ($ HorizontalScale) New 'hs1)
#,(($& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))
```

```
17_(_ ($ hs1) SetScale 0 500)
NIL
```

Now make the connection.

```
18_(_ ($ hs1) Attach ($ w1) 'width GRAYSHADE)
#,(($& HorizontalScale (|OZW0.1Y:.;h.Qm:| . 496))
```

The following gauge appears and you are prompted to place it .

The title of the gauge shows the instance variable being monitored.

Gauges can be shaped larger. The graphics used to display scales do not change; extra white space is added to the top or right. You can use this space to print additional information, as follows:

```
19 _ (MOVETOUPPERLEFT (@ ($ hs1) window))
 {WINDOW}#372,7104
```

```
20 (PRIN1 "This is an example of printing additional
information above a gauge.
```

Be aware that when the gauge is next updated, this additional text will disappear." (@ (\$ hs1) window))  
 "This is an example of printing additional information above a gauge.

Be aware that when the gauge is next updated, this additional text will disappear."

## Limitations

When a font is changed, a gauge occasionally needs to be updated to be correctly displayed.

Instruments can have only floating point numbers for labels, and cannot have integers.

---

## Description/Introduction

---

Masterscope has been modified to provide for analysis of files created under the Koto or Lyric/Medley release of Xerox LOOPS. A full explanation of Masterscope can be found in the *Xerox Lisp Library Modules Manual, Lyric and Medley Releases*. In addition to the relations explained there, Xerox LOOPS defines the relations described in this chapter.

Note: Masterscope data base files created under Buttress Loops will not function properly in this release. Those data base files will have to be recreated.

---

## Installation/Loading Instructions

---

- Load MASTERSCOPE from your Lyric/Medley library floppies according to its loading instructions. This should load the compiled files MASTERSCOPE, MSANALYZE, and MSPARSE.
- Load LOOPSMS.DFASL from wherever you installed the Xerox LOOPS Library Modules. This should load versions of MASTERSCOPE and MSPARSE that extend Masterscope to handle Xerox LOOPS constructs.

---

## Relations

---

Xerox LOOPS defines the following relations:

| Name                | Type     | Description                                                                                             |
|---------------------|----------|---------------------------------------------------------------------------------------------------------|
| <b>SEND</b>         | Relation | Collects all places where the method is sent.                                                           |
| <b>SEND SELF</b>    | Relation | Collects all places where the method is sent to <i>self</i> .                                           |
| <b>SEND NOTSELF</b> | Relation | Collects all places where the method is sent to an object other than <i>self</i> .                      |
| <b>GET</b>          | Relation | Locates all places where the value of an instance variable is retrieved.                                |
| <b>GET CV</b>       | Relation | Locates all places where the value of a class variable is retrieved.                                    |
| <b>PUT</b>          | Relation | Locates all places where the value of an instance variable is set.                                      |
| <b>PUT CV</b>       | Relation | Locates all places where the value of a class variable is set.                                          |
| <b>IMPLEMENT</b>    | Relation | Locates all methods that specialize the given selector.                                                 |
| <b>SPECIALIZE</b>   | Relation | Locates all methods that specialize the given selector and use <b>_Super</b> in the body of the method. |

|                   |          |                                                                                                                              |
|-------------------|----------|------------------------------------------------------------------------------------------------------------------------------|
| <b>OVERRIDE</b>   | Relation | Locates all methods that specialize the given selector and do not use <b>_Super</b> in the body of the method.               |
| <b>USE IV</b>     | Relation | Used with an instance variable name to locate all places where the instance variable is used in a <b>GET</b> or <b>PUT</b> . |
| <b>USE CV</b>     | Relation | Used with a class variable name to locate all places where the class variable is used in a <b>GET</b> or <b>PUT</b> .        |
| <b>USE OBJECT</b> | Relation | Used with an object name to locate all places where the object is used.                                                      |

---

**SEND**

[Relation]

Purpose/Behavior: Used between method names and selectors to collect all places where the method is sent. For example, the form

```
. WHO IS SENT BY 'Helicopter.Move
```

works, but

```
. WHO IS SENT BY Move
```

does not work.

Example: The following command allows you to edit all code that sends the message **New**.

```
. EDIT ALL WHO SEND New
```

---

**SEND SELF**

[Relation]

Purpose/Behavior: Used between method names and selectors to collect all places where the method is sent to *self*. Places where

```
(← self methodName)
```

is found are collected, while places where

```
(← otherInstance methodName)
```

is found are not.

Example: The following command allows you to edit all code that sends the message **Clear** to *self*.

```
. WHO SENDS SELF Clear
```

---

**SEND NOTSELF**

[Relation]

Purpose: Same as **SEND SELF**, except the only places where the message is sent to an object other than *self*.

Example: The following allows you to edit all code that sends the message **Clear** to any instance other than *self*.

```
. SHOW ALL WHO SEND NOTSELF Clear
```

---

**GET** [Relation]

Purpose: Used with an instance variable name to locate all places where the value of the instance variable is retrieved. This relation can be used along with the **SELF** and **NOTSELF** modifiers.

Example: This command allows you to edit all code that gets the value of the instance variable **width** from an instance other than self and the value of the instance variable **height** from *self*.

```
. SHOW ALL WHO GET NOTSELF width AND GET SELF height
```

---

**GET CV** [Relation]

Purpose: Same as **GET**, except that **GET CV** locates places where the value of the class variable is retrieved. This relation can be used with the **SELF** and **NOTSELF** modifiers.

Example: This command allows you to edit all code that accesses the value of the class variable **height** of *self*.

```
. SHOW ALL WHO GET CVSELF height
```

---

**PUT** [Relation]

Purpose: Used with an instance variable name to locate all places where the value of the instance variable is set. This relation can be used along with the **SELF** and **NOTSELF** modifiers.

Example: This command allows you to edit all code that sets the value of the instance variable **width**.

```
. EDIT ANY WHO PUT width
```

---

**PUT CV** [Relation]

Purpose: Same as **PUT**, except locates places where a specified class variable is set. This relation can be used along with the **SELF** and **NOTSELF** modifiers.

Example: This command list all the sections of code that set the value of the class variable **width** for an instance other than *self*.

```
. WHO PUTS CV NOTSELF width
```

---

**IMPLEMENT** [Relation]

Purpose: Used with a method name to locate all methods that specialize the given selector.

Example: This returns a list of classes where the method **Clear** is defined.

```
. WHO IMPLEMENTS Clear
```

---

**SPECIALIZE** [Relation]

Purpose: Used with a method name to locate all methods that specialize the given selector and use **\_Super** in the body of the method.

Example: This command allows you to edit all the methods that are specializations of **Clear** and use the **\_Super** form.

```
. EDIT ANY WHO SPECIALIZE Clear
```

---

**OVERRIDE****[Relation]**

Purpose: Like **SPECIALIZE** above, except it locates all methods that specialize the given selector and **\_Super** is not used in the body of the method.

Example: This command allows you to edit all the specializations of **Clear** that do not make use of the **\_Super** form.

```
. EDIT ALL WHO OVERRIDE Clear
```

---

**USE IV****[Relation]**

Purpose: Used with an instance variable name to locate all places where the instance variable is used in a **Get** or **Put**. It is equivalent to using the relation form of **GET IVName** or **PUT IVName**.

Example: This command allows you to edit all code that either sets or accesses the instance variable **width**.

```
. EDIT ANY WHO USE THE IV width.
```

---

**USE CV****[Relation]**

Purpose: Used with a class variable name to locate all places where the class variable is used in a **Get** or **Put**. It is equivalent to using the relation form: **GET CV CVName OR PUT CV CVName**.

Example: This command allows you to edit all code where the class variable **commonWindow** is either set or accessed.

```
. EDIT ANY WHO USE THE CV commonWindow
```

---

**USE OBJECT****[Relation]**

Purpose Uses an object name to locate all places where the object is used.

Example This command returns a list of all code where the object **Window** is used.

```
. WHO USES THE OBJECT Window??
```

---

**Limitations**

---

Masterscope has several limitations:

- Names of methods must be quoted when used with Masterscope; for example, the method name `Helicopter.Move` must be entered as `'Helicopter.Move'`.
- The following expression will not find a call to **GetValue** when in a method :

```
. WHO CALLS GetValue
```

Masterscope does not record calls to **GetValue** and **PutValue** explicitly; it records them under the Get- relation along with calls of the form

```
(_ foo Get 'bar)
```

Similarly, the following functions are recorded under relations instead of their names:

|                      |        |
|----------------------|--------|
| <b>GetClassValue</b> | Get CV |
| <b>PutClassValue</b> | Put CV |
| <b>GetClassIV</b>    | Get IV |
| <b>PutClassIV</b>    | Put IV |

If you want to find the explicit calls to Get/PutValue, use

```
. WHO GETS ANY AND NOT SENDS Get
```

- similar accessors are accessing instance variables; i.e.,

```
(GetValue foo 'bar)
```

records an access to the instance variable **bar**. This is not necessarily the case; **bar** could also be a class variable.

- The methods and functions that create class and instance variables populate the appropriate **PUT NOTSELF** relations. For example, a function that does

```
(_($ foo) AddCV 'bar)
```

will be found by the query

```
. WHO PUTS CV NOTSELF 'bar
```

An exception occurs with the generalized **Add** and **Delete** method. For example,

```
($ foo) Add 'IV 'bar)
```

will not be noticed as accessing the instance variable **bar**.

Also, the templates for methods and functions that accept property lists generally only notice the first property. For example,

```
((_($ foo) NewWithValues ' (bar baz chain link
sausage)))
```

notices **baz** as a property, not a link.

# Writer's Notes -- Production Details

---

This file includes notes on the production of *Xerox LOOPS Library Modules Manual*, Lyric Beta Release. This manual is packaged with the *Xerox LOOPS Release Notes* and *Xerox LOOPS Reference Manual* to form one binder.

Writer: Raven Kontur Brewster

Printing Date: >>DA<< >>MO<< 1988

## Files Needed

---

To edit or print the manual, make sure you have the following files loaded:

IMTOOLS  
SKETCH  
GRAPHER

## Fonts Used

---

{ERIS}<LISP>FONTS>

Modern font  
18-point bold  
14-point bold  
12-point bold  
10-point regular  
10-point italic  
10-point bold

Terminal font  
10-point regular

## Printing Information

---

The manual was printed under a Lyric sysout on the Tsunami printer.

## Artwork

---

- The cover page for the binder is in the file {ERIS}<Doc>Loops>Lyric>Beta>BinderCover.tedit.

## Special Notes and Cautions

---

If you bring the file into a TEdit window to print it, you must first make sure your underscore character is redefined as a left arrow. See the file on conventions for details. This restriction does not apply if you use the Hardcopy option from the File Browser.

---

## Description/Introduction

---

In many knowledge-based systems, it is useful to represent knowledge as interconnected sets of instances. A virtual copy mechanism allows a network of instances to be viewed as a prototype which can be copied. The copy of the prototype is virtual in that the contents of each instance is not completely copied at creation time. Instead, it inherits default values from the prototype (also called the original), thus continuing to share the parts not modified in the copy. The copied network is virtual also in the sense that only those instances needed in the processing are copied.

A virtual copy of an object in the prototype network has the following properties:

- It responds to at least the same set of messages as the prototype object and in the same way; that is, a copy has the same procedural behavior that is defined for the prototype.
- A copy inherits variables and their values from the prototype, and continues to do so until an explicit change is made in the copy. At that point, the new value is stored in the copy and it stops tracking the prototype for that variable. A fetch operation on a value that is not stored locally either finds or creates a virtual copy of the value obtained from the prototype.

---

## Installation/Loading Instructions

---

The implementation of virtual copies is contained in the file `LOOPSCOPY.LCOM`. No other files are necessary.

---

## Application /Module Functionality

---

A network of instances is tied together through the values of instance variables within each of the instances. Assume an object A has an instance variable x, the value of which is the object B. A virtual copy of A will also have an instance variable named x. The value of x in the copy will point to B if B is a shared object, or x may point to a copy of B if it is to be virtual. Changing the value of x in the copy will not change the value in the original.

---

## Overview of Operation

---

By default, virtual copies share instance variables. This means that changing the value of an instance variable in the original will be tracked by the copy.

Virtual copies are implemented with two additional classes:

- **VirtualCopyMixin**

The class **VirtualCopyMixin** is a subclass of Tofu which contains two instance variables:

- % **copyMap**%
- % **copyOf**%

(These unusual names are used to avoid conflicts with any other instance variable names users may create.) This class contains several methods, most of which are required to implement virtual copies and are not used by a programmer.

Printing a virtual copy instance is a specialization of how regular instances are printed. All instances print as #,(\$& <class-name> UID). The class of a virtual copy is a dynamic mixin of the class **VirtualCopyMixin** and the class of the original object (see the *Xerox LOOPS Reference Manual* for more information on mixins). The virtual copy print function adds the name or unique identifier (UID) of the original object. For example,

```
#,($& (VirtualCopyMixin Container1) (JFW0.0X:.aF4.R>8 . 3) c1)
```

is a copy of the object named **c1**.

- **VirtualCopyContext**

The class **VirtualCopyContext** has no methods and only one instance variable, **copyMap**. Instances are used as an argument for calls to **MakeVirtualMixin**.

Since copies can be made of copies, you often need to determine the original object of a chain of copies with the **UltimateOriginal** function.

---

## Operands

This section describes the functions, methods, class variables, and instance variables that operate on virtual copies.

---

### VirtualIVs

[Class Variable]

**Purpose/Behavior:** Helps specify a class whose instances may be made into virtual copies. The value of this class variable should be either the symbol **ALL**, or a list of instance variables contained within instances of the class. If the value is **ALL**, all objects pointed to by any of the instance variables will be copied. If the value is a list of instance variables, only the instance variables on this list will have their values copied. Other instance variable values will be shared between the copy and the original.

---

### (**MakeVirtualMixin** *x copyContextObj*)

[Function]

**Purpose:** Creates a virtual copy of an object.

**Behavior:** Creates a dynamic mixin class combining the classes **VirtualCopyMixin** and the class of *x*. An instance of this resulting class is created and it is returned.

**Arguments:** *x*                      An object to be copied; must have the class variable **VirtualIVs** as described above.

*copyContextObj*

Usually **NIL**; used internally by **MakeVirtualMixin** when it calls itself. It can be an instance of **VirtualCopyContext** if you are creating an instance that is intended to be part of a currently existing network of copies starting from another entry point. See description in **Limitations** below for a further explanation of this point.

**Returns:** An object that is a copy of *x*.

Example: Refer to the section, "Example."

**% copyMap%** [Instance Variable of VirtualCopyMixin]

Purpose/Behavior: A mapping of original nodes (which are objects) in a network to the copied nodes. This map is stored in an instance of the class **VirtualCopyContext**.

**% copyOf%** [Instance Variable of VirtualCopyMixin]

Purpose/Behavior: Within an instance that is a copy, the value of this instance variable is a pointer to the object that was copied.

**(← self VirtualCopy?)** [Method of VirtualCopyMixin]

Purpose: Determines if an object is a virtual copy.

Returns: *self*

Categories: Object, VirtualCopyMixin

**copyMap** [Instance Variable of VirtualCopyContext]

Purpose/Behavior: The value of this instance variable is a list of dotted pairs. The CAR of each pair is the original; the CDR, the copy.

**(UltimateOriginal self)** [Function]

Purpose: Determines what an object is ultimately copying.

Behavior: If *self* is not a virtual copy, *self* is returned.

If *self* is a virtual copy, this recurses through the value of the instance variable **% copyOf%** until it finds the original and returns it.

Arguments: *self* A Xerox LOOPS object.

Returns: *self* or what is at the top of *self*'s copy chain.

## Example

Create a class called **test** and edit it as shown.

```
44_(_ ($ Class) New 'test)
#,($C test)

45_(ED 'test)
```

```
SEdit #,($C test) Package: INTERLISP
((MetaClass Class Edited%: ; Edited 11-Dec-87
 ; 16:50 by
)
 (Supers Object)
 (ClassVariables (VirtualIVs (atomCopy listCopy objCopy)))
 (InstanceVariables (atom NIL)
 (atomCopy NIL)
 (list NIL)
 (listCopy NIL)
 (obj NIL)
 (objCopy NIL))
 (MethodFns))
```

Create an instance called **t0** of this class and inspect it.

```
46_(_ ($ test) New 't0)
#,($& test (N↑W0.1Y%.:;h.Lh9 . 556))

47_(_ ($ test)
 NewWithValues
 (BQUOTE ((atom 1)
 (atomCopy 2)
 (list (a b c))
 (listCopy (A B (\, (_ ($ test) New (QUOTE t1))))))
 (obj (\, (_ ($ test) New (QUOTE t2))))
 (objCopy (\, (_ ($ test) New (QUOTE t3))))))
#,($& test (N↑W0.1Y%.:;h.Lh9 . 560))

48_(_ IT SetName 't0)
#,($& test (N↑W0.1Y%.:;h.Lh9 . 560))

49_(INSPECT IT)
{WINDOW}#52,51234
```

```
All Values of test ($ t0).
atom 1
atomCopy 2
list (a b c)
listCopy (A B #,($ t1))
obj #,($ t2)
objCopy #,($ t3)
```

Make a copy called **t0copy** and inspect it.

```
57_(_ (MakeVirtualMixin ($ t0))
 SetName
 (QUOTE t0copy))
#,($& (VirtualCopyMixin test) N↑W0.1Y%.:;h.Lh9 . 562)
```

```
58_ (INSPECT IT)
{WINDOW}#53,10150
```

```
All Values of (VirtualCopyMixin test) ($ t0copy).
atom NIL
atomCopy NIL
list NIL
listCopy NIL
obj NIL
objCopy NIL
| copyOf | #,($ t0)
| copyMap | #,($& VirtualCopyContext (N+V0.1Y%.:;h.Lh9 . 563))
```

Make the following changes to **t0** and then reinspect **t0copy**.

```
60_ (for iv in '(atom atomCopy list listCopy obj objCopy)
as val in (LIST 11 22 '(a b c d) '(A B C) ($ t3) ($ t1))
do (PutValue ($ t0) iv val]
NIL
```

```
61_ (INSPECT IT)
{WINDOW}#53,10152
```

```
All Values of (VirtualCopyMixin test) ($ t0copy).
atom 11
atomCopy 22
list (a b c d)
listCopy (A B C)
obj #,($ t3)
objCopy #,($& (VirtualCopyMixin test) (N+V0.1Y%.:;h.Lh9 . 565) t1)
| copyOf | #,($ t0)
| copyMap | #,($& VirtualCopyContext (N+V0.1Y%.:;h.Lh9 . 566))
```

The copied instance variables have not changed since they do not track changes in the original object.

## Limitations

Some subtle issues are involved in building and using prototype structures so that the structure is preserved in the copied network. These involve how the network is typically traversed.

A general constraint is that all the links to any shared node in the prototype either all be marked as virtual variables, or none of them are. If they are all marked, then a single copy will be made and used. If none are, then the original object from the prototype will be used. Sharing with the prototype can be useful if this object is a repository for standard information that is independent of context. However, if this constraint is violated, the topology of the virtual copy will be different from that of the prototype.

In the simplest situation the network has a single entry node. In this case, a copy-map (see the section "Operands") can be created when the entry node object is first copied. After that all values are copied using this copy-map. The mechanism works well in this situation, even if there is sharing and there are cycles within the network.

At the other extreme, networks can have arbitrary connectivity, including multiple entries from outside the network, for example, from other networks or

non-objects. In this case, the following constraints are necessary to ensure correctness of the virtual copy mechanism.

The first constraint states that all access to the network must start through a copy of one of the nodes in the prototype. This condition is necessary because the criteria for copying are contained in the links from one object to another, not in the objects themselves, and a shared node could not specify a link to a node to be copied. This constraint ensures that all accesses from the outside will be copied if and only if that object would have been copied because of an internal link. Otherwise, an analogous situation would occur in which you could either reach a copy or the original node of the prototype itself depending upon which path you follow when the paths lead to the same node in the prototype.

The final constraint requires that all entries to the network should be passed the same copy-map if they are to share structure. The underlying concern in imposing these constraints is that a network be always copied the same way to maintain its topology regardless of where you start.

Suppose you want to make a virtual copy of a virtual copy, that is, to use a virtual copy of a network as a prototype itself. This is very useful if you are using a network to hold the state of a partial design and you want to try two alternative continuations of the design. Some hidden costs are associated with such multiple-level virtual copies.

Suppose further that a network N1 is used as a prototype and you make a virtual copy, N1-VC. Furthermore, N1-VC-VC is defined to be a copy of N1-VC. Values missing from N1-VC-VC are found in the corresponding object of N1-VC. If the value is missing there, the process recurs, and N1 is examined. If the value is to be a virtual copy, then this process will add a virtual copy in N1-VC, and then a second level copy in N1-VC-VC. This is necessary to preserve the semantics presented, but implies that many levels of virtual copy cannot easily do inexpensive incremental searches of a network.

---

## References

This directory contains all the documentation for Xerox Loops in all its various incarnations.  
Directories are as follows:

{ERIS}<Doc>LOOPS> - most general information  
{ERIS}<Doc>loops>ProductionSpecs> - specs for all versions of Koto LOOPS

{ERIS}<Doc>Loops>Koto>Final - Product Release for Koto LOOPS (Oct 87)  
{ERIS}<Doc>Loops>Lyric>Alpha - Alpha Lyric LOOPS (Jan 88)

Most directories have the following subdirectories:

Ref> - Reference Manual  
RelNote> - Release Notes  
LibMod> - Library Modules Manual (Lyric Release)  
LibPkg> - Library Packages Manual (Koto Release)  
UserMod> - Users' Modules Manual (Lyric Release)  
UserPkg> - Users' Packages Manual (Koto Release)

And even further in the diectory maze,  
X-Index> - has IMPTR files and resulting index  
Z-ReleaseInfo> - holds more details on conventions and production details.

Enjoy,  
Raven Brewster

This appendix describes how to install the LOOPS System files, Library Modules files, and Users' Modules files on the Sun Workstation.

---

## Overview of the Distribution Kit

---

The distribution kit for LOOPS on the Sun consists of a single ¼-inch tape cartridge. It contains the complete release in "tar" format and creates appropriate directories when its contents are extracted.

---

## Preparation

---

Preparing to install LOOPS requires that the Medley release of Lisp is already installed and that adequate file space is available.

Before installing LOOPS, remember that

- the Medley 1.0, 1.1 or 1.2 release of Lisp must already be installed on your Sun Workstation;
- the complete LOOPS distribution requires about 1.2 MBytes of file space.

---

## Installation

---

The software installation procedure shows the steps required for installing the Medley LOOPS software on a Sun Workstation with Medley already installed. Examples are given where appropriate. Only those users who are system administrators and have **root** privileges can install the LOOPS, Medley release.

Before starting software installation, remember that the LOOPS software requires about 1.2 MBytes of file space.

1. Log in under your username.

```
login yourname
```

```
prompt%
```

where **yourname** is replaced by your username.

2. Check for available space with the **df** command:

```
prompt% df
```

| Filesystem | kbytes | used | avail  | capacity | Mounted on |
|------------|--------|------|--------|----------|------------|
| /dev/xy0a  | 7437   | 5470 | 1223   | 82%      | /          |
| /dev/xy0h  | 148455 | 4900 | 128709 | 96%      | /usr/misc  |

3. Determine if you need to run **su** to make a directory for the distribution. If so, type in **su**:

```
prompt% su
```

4. Make a directory for the distribution. This directory should be named **/usr/local/lde/loops**. If you have enough space on the file system containing **/usr/local/lde**, then

```
prompt# mkdir /usr/local/lde/loops/
```

If you don't have enough space on **/usr/local/lde**, go to step 6.

5. Make yourself owner of this directory:

```
prompt# /etc/chown yourname /usr/local/lde/loops/
```

where **yourname** is your username.

6. If you don't have space on the file system which contains **/usr/local/lde**, but do have space somewhere else, for instance on **/usr1**, then make the directory there and link **/usr/local/lde/loops** to it:

```
prompt# mkdir /usr1/loops
```

```
prompt# /etc/chown yourname /usr/usr1/loops
```

```
prompt# ln -s /usr1/loops /usr/local/lde/loops
```

7. If you ran **su**, leave the privileged shell by typing:

```
prompt% exit
```

8. Insert the ¼-inch cartridge tape, containing the LOOPS software, in the drive.

9. Connect to **/usr/local/lde/loops**:

```
prompt# cd /usr/local/lde/loops
```

10. Load the Medley software from tape. Indicate the appropriate device abbreviation for your tape by replacing **xx** in the example below with

**ar** for the Archive drive,

**st** for a SCSI tape drive.

This example shows the command entry sequence:

```
prompt# tar xvpf /dev/rxx0
```

As the software is loaded (a process that takes some time) the system prints a series of lines in the following form:

```
x ./system/LOOPS., 28552 bytes, 56 tape blocks
```

The x at the beginning of the line indicates that the file is being extracted from the tape.

This creates directories named:

/usr/local/lde/loops/system/

/usr/local/lde/loops/library/

/usr/local/lde/loops/users/

This is a good time to set the protection of the extracted directories and files so that the work group using LOOPS has at least read access to them.

11. Boot Medley Lisp.
12. Open an Interlisp Executive Window.
13. Make certain the time is set correctly.
14. Set the **DIRECTORIES** and **DISPLAYFONTDIRECTORIES** variables appropriately so the sysout can find your Lyric/Medley library and font files.
15. Make the LOOPS System directory your connected directory:

```
CONN {DSK}/usr/local/lde/loops/system/
```

16. Enter the following into your Exec:

```
LOAD (LOOPS)
```

A menu appears that looks like this:

```

Loops system
Install from distribution
Load into sysout

```

17. Select the menu option **Install from distribution**.

The following menu appears:

| Loops directories       | Click here when           |
|-------------------------|---------------------------|
| LOOPSDIRECTORY          | {DSK}<LISPFILES>LOOPS>    |
| LOOPSLIBRARYDIRECTORY   | {DSK}<LISPFILES>LOOPS>LIB |
| LOOPUSERSDIRECTORY      | {DSK}<LISPFILES>LOOPS>USE |
| LOOPUSERSRULESDIRECTORY | {DSK}<LISPFILES>LOOPS>RUL |

This menu shows the current (or default, if unset) values of the variables LOOPS examines when it loads things.

If you have installed LOOPS under /usr/local/lde/loops/ click the mouse on the menu items to set these directories to point where the tape was unloaded:

```

LOOPSDIRECTORY {dsk}/usr/local/lde/loops/system/
LOOPSLIBRARYDIRECTORY {dsk}/usr/local/lde/loops/library/
LOOPUSERSDIRECTORY {dsk}/usr/local/lde/loops/users/
LOOPUSERSRULESDIRECTORY {dsk}/usr/local/lde/loops/users/

```

As the last installation step, the installation tool automatically modifies the file LOOPSSITE, writes it out to the value of the variable **LOOPSDIRECTORY**, and compiles it.

When this step is finished, the first menu reappears:

```
Loops system
Install from distribution
Load into sysout
```

18. Select the menu option **Load into sysout** to load LOOPS into your system. The following menu appears:

```
Load Which?
Loops
Loops Masterscope
Gauges
LoopsBackwards
VirtualCopy
```

19. Select **LOOPS** from the menu to load LOOPS from the location where you installed it.

Once LOOPS is loaded the LOOPS System menu reappears. To load one of the other LOOPS library or Users' modules, select the appropriate name in the Load Which? menu.

20. Position your mouse cursor anywhere on the screen except for the Load Which? menu, then press the left mouse button to exit the installation procedure.

Medley LOOPS is now installed on your Sun Workstation.

---

## Loading After Installation

---

This section describes how to reload LOOPS into a newly started Lisp sysout after LOOPS has been previously installed.

1. Start up Medley on your Sun Workstation.
2. Open an INTERLISP Exec window.
3. Make sure **DIRECTORIES** points to a directory containing **GRAPHER.LCOM**, and **DISPLAYFONTDIRECTORIES** points to a directory containing the Helvetica display font files from your Lisp distribution kit.

4. Connect to the directory containing the LOOPS system files:

```
(CNDIR ' {DSK} /USR/LOCAL/LDE/LOOPS/SYSTEM/)
```

5. Load LOOPS loader program:

```
(FILESLOAD LOADLOOPS)
```

6. Run the LOOPS loader program:

```
(LOADLOOPS)
```

This procedure loads only the LOOPS system files. Please see the manuals describing the LOOPS Library and Users' Modules for their loading procedures.

---

**CAUTION**

LOOPS uses the new compiler and its macrolet facilities. When LOOPS is loaded, it sets your **\*DEFAULT-CLEANUP-COMPILER\*** to **'CL:COMPILE-FILE**. More information on this cleanup flag and the new compiler is available in the *Lisp Release Notes*, in your Medley Lisp kit.

## ***Annotated Values and Active Values***

In the previous chapters, IVs, CVs, and their properties have been treated as passive entities without structure. ***Annotated values*** are a way of associating behavior and annotations with variables. In keeping with the object oriented programming style of LOOPS, these annotations are objects. Annotation objects are called ***active values***. When a variable containing an annotated value is accessed, a message is sent to the active value. This mechanism is dual to the notion of messages: messages are a way of telling objects to perform operations, which can change their variables as a side effect; active values are a way of accessing variables, which can send messages as a side effect.

This chapter first describes the structure and implementation of annotated values. Functions for explicitly dealing with annotated values are documented. Then the class `ActiveValue` is introduced and the standard protocol for active values is described. Next, the standard subclasses of `ActiveValue` are explained.

### **5.1. Annotated Values**

LOOPS defines a new INTERLISP data type called `annotatedValue`. Each `annotatedValue` contains a single field. This field contains an object, the annotated value's active value. The standard variable access functions described in previous chapters (`GetValue`, `PutValue`, `GetClassValue`, `PutClassValue`) treat values that are annotated values specially. `GetValue` and `GetClassValue` do not return the annotated value. Instead, they send the contained active value a message, and return the result of that message. Similarly, if the current value of a variable is an annotated value, `PutValue` and `PutClassValue` operate by sending the contained active value a message.

`type? annotatedValue value` [Macro]

Returns true if *value* is an annotated value, false otherwise. This is the standard way to test to see if a value is an annotated value.

`create annotatedValue annotatedValue ← object` [Macro]

Creates a new annotated value with active value *object*. No checking of *object* is performed.

`fetch annotatedValue of value` [Macro]

Returns the active value contained in the annotated value *value*. If *value* is not an annotated value, generates an error.

`replace annotatedValue of value with object` [Macro]

Replaces the active value contained in the annotated value *value* with *object*. If *value* is not an annotated value, generates an error. No checking of *object* is performed.

`←AV av selector . args` [Macro]

←AV is a message sending form that can be used with annotated values. (←AV *av selector . args*)  
→ (← (fetch annotatedValue of *av*) *selector . args*) .

AnnotatedValue [Class]

Sometimes people forget to extract the active value from an annotated value, and they end up trying to use an annotated value as an object. Using the `LispDataType` feature, LOOPS takes care of this for you. Annotated values are considered to belong to the LOOPS class `AnnotatedValue`. If you send a message to an annotated value, the behavior is found in the class `AnnotatedValue`. There, the method for `MessageNotUnderstood` forwards the message off to the contained active value. Similarly, if you attempt to get an IV from an annotated value, the get ends up happening to the wrapped active value.

## 5.2. The Abstract Class ActiveValue

Active values follow a standard protocol that allow them to be used inside of annotated values.

In the description of methods for active values, the arguments *containingObj*, *varName*, *propName*, and *type* are used to describe the variable containing the active value. *type* is one of IV, CV, or NIL : a *type* of IV or NIL indicates that the variable is an instance variable or an instance variable property of *containingObj*; a *type* of CV indicates a class variable or class variable property of *containingObj*. If *propName* is NIL, the variable is either an IV or a CV, otherwise it is an IV or CV property with name *propName*. *containingObj* is the instance or class that contains the variable.

ActiveValue [Abstract class]

The class `ActiveValue` captures the protocol followed by all active value objects. `ActiveValue` is an abstract class, so you cannot make instances of `ActiveValue`. Specializations of `ActiveValue` need to specialize the `GetWrappedValueOnly` and `PutWrappedValueOnly` methods. Methods that you want to specialize include `AVPrintSource`, `GetWrappedValue`, `PutWrappedValue`, `WrappingPrecedence`, and `CopyActiveValue`.

### 5.2.1 Displaying Annotated Values

← *self* AVPrintSource [ActiveValue method]

An annotated value determines how it will print out by sending the AVPrintSource message to the its active value. This message returns a form suitable for use by the INTERLISP function DEFPRINT. The result should be a pair of the form (*item1* . *item2*). *item1* will be printed using PRIN1, and then *item2* will be printed by PRIN2 (see the IRM description of DEFPRINT for more details).

The default method in ActiveValue returns the list

```
("#." $AV className avNames (ivName value propName value ...) (ivName ...)...)
```

which will cause the annotated value to print out as

```
#.($AV className avNames (ivName value propName value ...) (ivName ...)...) .
```

*className* is the name of the class of the active value. *avNames* is a list of names of *self*; the last element of *avNames* is the uid of *self*. The lists (*ivName value propName value ...*) describe the state of the IVs of the active value. Note that the uid of the active value is included in the printed form, so the identity of the active value object can be recovered. In this way, different annotated values can share the same active value, and have this sharing maintained across a dump/load-up.

\$AV *className avNames* . *ivForms* [Special Form]

\$AV is used to reconstruct a dumped annotated value. It returns a new annotated value whose active value is reconstructed from the *avNames* and *ivForms*.

### 5.2.2 Fetching and Replacing Wrapped Values

← *self* GetWrappedValue *containingObj varName propName type* [ActiveValue method]

The GetWrappedValue message provides a way to perform arbitrary actions when a variable is read. When GetValue (or GetClassValue) finds an annotated value in an instance, it does not return the annotated value. Instead, it sends the contained active value the GetWrappedValue message and returns the result of this message.

The default method in ActiveValue sends the message GetWrappedValueOnly to *self*. If this value is an annotated value, it is triggered by sending it the GetWrappedValue message, and the result is returned; otherwise the value is returned with no further processing.

← *self* GetWrappedValueOnly [ActiveValue method]

Returns the immediate "local state" of the variable that is wrapped by the active value *self*. If this local state is a nested active value, it is not triggered. The default implementation causes an error by calling SubclassResponsibility.

```
← self PutWrappedValue containingObj varName
 newValue propName type [ActiveValue method]
```

The PutWrappedValue message provides a way to perform arbitrary actions when a variable is set. When PutValue (or PutClassValue) attempts to replace an annotated value, it instead sends the contained active value the PutWrappedValue message.

The default method in ActiveValue checks to see if the current value is a nested active value by sending the GetWrappedValueOnly message to *self*. If the result is an annotated value, PutWrappedValue forwards the message on the the nested active value; otherwise it sends the message PutWrappedValueOnly to *self* and returns the result.

```
← self PutWrappedValueOnly newValue [ActiveValue method]
```

Replaces the immediate "local state" of the variable that is wrapped by the active value *self*. The current local state is replaced. If the current value is a nested active value, it is not triggered. The default implementation causes an error by calling SubclassResponsibility.

### 5.2.3 Inheriting Active Values

Typical implementations of PutWrappedValue store the new value in the active value. However, if the active value is shared among different instances all these instances would see this change. In particular, if the active value is inherited from the class of the instance, all other instances of the class would see this change. This behavior is usually not desired. The GetWrappedValue method of active values is also free to alter the internal state of the active value, causing the same problem. To get around this problem, the annotated value is first copied, and this copy is stored in the instance. The CopyActiveValue method implements this copying. When GetValue or PutValue finds no local value, it first checks to see if the current value is an annotated value inherited from the class. If it is, it sends CopyActiveValue to the active value, and stores the result in the instance. The put or get then proceeds.

```
← self CopyActiveValue annotatedValue [ActiveValue method]
```

*annotatedValue* is an annotated value that surrounds *self*. CopyActiveValue should return a copy of *annotatedValue*, containing a copy of *self*. It is possible, and in some cases desirable, for an implementation of CopyActiveValue to return *annotatedValue*.

The default behavior returns a new annotated value wrapped around a copy of *self*. IV values of *self* are not copied, the values are shared with the copy, except that IVs of *self* that contain annotated values are copied using the CopyActiveValue message.

### 5.2.4 Adding and Deleting Annotations

```
← self AddActiveValue containingObj varName
 propName type annotatedValue [ActiveValue method]
```

Adds the annotated value *annotatedValue* to the variable specified by *containingObj*, *varName*, *propName*, and *type*. If *annotatedValue* is not specified or is NIL, *annotatedValue* defaults to a newly created annotated value containing the active value *self*. If the variable is already an annotated value, the AddActiveValue method uses the WrappingPrecedence message (below) to

## Annotated Values and Active Values

determine if *annotatedValue* should be nested in the current annotated value or wrapped around it. The method returns *annotatedValue*.

← *self* WrappingPrecedence [ActiveValue method]

Specifies where an annotated value containing *self* should be added to an existing annotated value. T means that this active value must go on the outside of any other annotated values. NIL means it must go on the inside. A number specifies a precedence: active values with larger WrappingPrecedence values go outside ones with smaller WrappingPrecedence values. If two active values have the same (numeric) WrappingPrecedence, the order is not determined. The default implementation of WrappingPrecedence returns 100.

← *self* DeleteActiveValue containingObj varName propName type [ActiveValue method]

Finds the first annotated value on the variable specified by *containingObj*, *varName*, *propName*, and *type* that has *self* as its active value and deletes it from that variable. Returns that annotated value if one was found, NIL otherwise.

← *self* ReplaceActiveValue newVal containingObj  
varName propName type [ActiveValue method]

It is sometimes desirable to replace an annotated value in a variable with some new value. (← *self* ReplaceActiveValue newVal containingObj varName propName type) replaces the annotated value containing *self* in the variable described by *containingObj*, *varName*, *propName*, and *type* with the new value *newVal*.

### 5.2.4 Manipulating Active Values

Some programs need to explicitly test and trigger active values. The following functions can be used to access IVs and CVs without triggering active values.

GetValueOnly object varName propName [Function]

GetValueOnly is the same as GetValue, except that GetValueOnly does not trigger any active values. GetValueOnly returns the immediate value of the variable. If this is not an annotated value, GetValueOnly returns the same value as GetValue. If there is no local value, the inherited value is returned. See also the function GetIVHere.

GetClassValueOnly object varName propName [Function]

GetClassValueOnly is the same as GetClassValue, except that GetClassValueOnly does not trigger any active values. GetClassValueOnly returns the immediate value of the variable. If this is not an annotated value, GetClassValueOnly returns the same value as GetClassValue. *object* can be either an instance or a class.

ObjRealValue object varName value propName type [Macro]

If *value* is not an annotated value returns *value*, otherwise returns the value of (←AV GetWrappedValue object varName propName type). This macro is used by GetValue and

GetClassValue to trigger active values, and can be used by programs that explicitly test for active values.

PutValueOnly *object varName newValue propName* [Function]

PutValueOnly is the same as PutValue, except that PutValueOnly does not trigger any active values. PutValueOnly replaces the immediate value of the variable with *newValue*, even if the old value is an annotated value.

PutClassValueOnly *object varName newValue propName* [Function]

PutClassValueOnly is the same as PutClassValue, except that PutClassValueOnly does not trigger any active values. PutClassValueOnly replaces the immediate value of the variable with *newValue*, even if the old value is an annotated value. *object* can be either an instance or a class.

← *self* HasAV? *av* [ActiveValue method]

Returns true if the active value (or annotated value) *av* is nested inside in the active value *self*.

### 5.3. Specializations of ActiveValue

---

**The ActiveValue Class Hierarchy**

---

#### 5.3.1 NotSetValue and Variable Inheritance

NotSetValue [Variable]

LOOPS uses annotated values to trigger IV inheritance. When an instance is created, its IVs are initialized to contain (the value of) NotSetValue. NotSetValue is an annotated value whose active value is the prototype instance of the class NotSetValue. The class NotSetValue specializes the

## Annotated Values and Active Values

default `ActiveValue` protocol to trigger IV inheritance. In this way `GetValue` does not need to do any special check to see if a value needs to be inherited — all it needs to do is see if the value is an annotated value. Note that `GetValueOnly` does need to do a special check for `NotSetValue`, but see the function `GetIVHere`.

`NotSetValue form`

[Macro]

Returns true if *form* evaluates to `NotSetValue`, otherwise false.  $(\text{NotSetValue } form) \rightarrow (\text{EQ } form \text{ 'NotSetValue})$ . This is the approved way of testing a value to see if it is `NotSetValue`.

$\leftarrow self \text{ AVPrintSource}$

[NotSetValue method]

Returns the pair  $(\text{"#."} \text{ . NotSetValue})$ . This causes (the value of) `NotSetValue` to print out as `#.NotSetValue`. This will be read in as the value of the variable `NotSetValue`.

$\leftarrow self \text{ GetWrappedValue containingObj varName propName type}$

[NotSetValue method]

If *type* is `NIL` or `IV`, this evaluates  $(\leftarrow containingObj \text{ IVValueMissing varName propName 'GetValue})$  and returns the result; if *type* is `CV`, evaluates  $(\leftarrow class \text{ CVValueMissing varName propName 'GetValue})$  (where *class* is the class of *containingObj* if *containingObj* is an instance, else *containingObj* if it is a class) and returns the result; otherwise an error is generated. See the methods `IVValueMissing` and `CVValueMissing` on the class `Object`.

$\leftarrow self \text{ PutWrappedValue containingObj varName}$

*newValue propName type*

[NotSetValue method]

If *type* is `NIL` or `IV`, this evaluates  $(\leftarrow containingObj \text{ IVValueMissing varName propName 'PutValue newValue})$  and returns the result; if *type* is `CV`, evaluates  $(\leftarrow class \text{ CVValueMissing varName propName 'PutValue newValue})$  (where *class* is the class of *containingObj* if *containingObj* is an instance, else *containingObj* if it is a class) and returns the result; otherwise an error is generated. See the methods `IVValueMissing` and `CVValueMissing` on the class `Object`.

$\leftarrow self \text{ CopyActiveValue annotatedValue}$

[NotSetValue method]

Returns `#.NotSetValue`. There is only one `NotSetValue`.

$\leftarrow self \text{ WrappingPrecedence}$

[NotSetValue method]

Returns `NIL`. `#.NotSetValue` must always be on the inside of any sequence of nested active values.

`GetIVHere object varName propName`

[Function]

If *propName* is `NIL` and there is a local value for the IV *varName* in the instance *object*, that value is returned. If *propName* is not `NIL` and there is a local value for the IV property *propName* of the IV *varName* in the instance *object*, that value is returned. Otherwise, if *propName* is `NIL` `GetIVHere` returns `#.NotSetValue`, and if *propName* is not `NIL` `GetIVHere` returns (the value of) `NoValueFound`.

---

## LOOPS8

GetCVHere *object varName propName* [Function]

*object* must be a class. Returns the value of the class variable that is found in the class *object*. If none is found, then returns `#.NotSetValue`.

GetClassIV *class varName propName* [Function]

Returns the default value or property value of the instance variable *varName* in the class *class*.

PutClassIV *class varName newValue propName* [Function]

Stores *newValue* as the default value or property value of the instance variable *varName* in the class *class*. If *varName* is not already local to the class, this will cause an error. Returns *newValue*.

### 5.3.2. Indirect Variables

In some applications it is important to be able to access values indirectly from other instances. For example, Steele [Steele80] has recommended this as an approach for implementing equality constraints.

IndirectVariable [Class]

Mumble.

### 5.3.3. ReplaceMeAV

The active value mixin `ReplaceMeAV` can be used when an active value should be replaced when a variable is first set.

ReplaceMeAV [Abstract class]

Mumble.

### 5.3.4. LocalStateActiveValue

Many kinds of active values explicitly store the "real" value of the variable in an IV of the active value.

LocalStateActiveValue [Abstract class]

Mumble.

### 5.3.5. InheritingAV

Some kinds of active values want to compute a value based on what would have been inherited if the active value had not been present. For example, it might be desired to append items onto an inherited value (see the class `AppendSuperValue`).

InheritingAV [Abstract class]

Mumble.

---

## Annotated Values and Active Values

### 5.3.6. FirstFetchAV

Mumble.

FirstFetchAV [Class]

Mumble.

### 5.3.7. Breaking and Tracing Variable Access

Mumble.

BreakOnPut [Class]

Mumble.

BreakOnPutOrGet [Class]

Mumble.

TraceOnPut [Class]

Mumble.

TraceOnPutOrGet [Class]

Mumble.

UnBreakIt *self varName propName type* [Class]

Mumble.

### 5.3.8. NoUpdatePermittedAV

The active value class NoUpdatePermittedAV can be used to prevent a value from being updated.

NoUpdatePermittedAV [Class]

Mumble.

### 5.3.9. AppendSuperValue

The active value class AppendSuperValue can be used to append data to inherited values.

AppendSuperValue [Class]

Mumble.

### 5.3.10. ExplicitFnActiveValue

ExplicitFnActiveValue

[Class]

ExplicitFnActiveValue explicitly store functions that will be triggered when the variable is fetched or replaced. They have three IVs: *localState*, *getFn*, and *putFn*. The *localState* is the "real" value of the variable (possibly a nested active value), the *getFn* and *putFn* are names of functions that are applied with standard arguments by the *GetWrappedValue* and *PutWrappedValue* methods. The *getFn* and *putFn* are called with arguments *containingObj*, *varName*, *oldOrNewValue*, *propName*, *activeValue*, and *type*. ExplicitFnActiveValue active values print out as #. (\$A *localState* *getFn* *putFn*), where the *localState*, *getFn*, and *putFn* are the values of the corresponding IVs of the active value.

## 5.4. Compatibility with older versions

The following existed in older versions of LOOPS, which had a different implementation of active values. They are provided for compatibility purposes only. New programs should not use them. They are not fully supported, and will not exist in future releases. The current implementations of these use the new active values. They are fully compatible with the older versions except where noted.

### 5.4.1. Old Style Active Values

LOOPS used to combine the notion of annotated value and active value. Variable annotations were instances of the INTERLISP datatype *activeValue*.

*activeValue*

[Record]

In this version of LOOPS, the record *activeValue* is an access record that converts the three fields of the old active values to appropriate functions for accessing annotated values. Forms like (*type?* *activeValue* *form*) and (*fetch* *localState* *of* *activeValue*) will do the right thing. Reading in old style active values automatically converts them to annotated values wrapping an instance of the class *ExplicitFnActiveValue*.

*GetLocalState* *av self varName propName type*

[Function]

Works just like in the old LOOPS.

*PutLocalState* *av newValue self varName propName type*

[Function]

Works just like in the old LOOPS.

*GetLocalStateOnly* *av*

[Function]

Works just like in the old LOOPS.

---

### Annotated Values and Active Values

`PutLocalStateOnly av newValue` [Function]

Works just like in the old LOOPS.

`ReplaceActiveValue av newVal self varName propName type` [Function]

Works just like in the old LOOPS.

`MakeActiveValue self varOrSelector newGetFn newPutFn  
newLocalSt propName type` [Function]

Works just like in the old LOOPS, except that the interpretation of *newLocalSt* is different. `MakeActiveValue` ignores the value of *newLocalSt*, and always creates a new active value. This is the behavior that the old `MakeActiveValue` produced when *newLocalSt* was `Embed`.

### 5.4.2. GetFns and PutFns

`DefAVP fnName putFlg` [Function]

Works just like in the old LOOPS.

`NoUpdatePermitted self varname oldOrNewValue propName activeValue type` [Function]

Works just like in the old LOOPS.

`FirstFetch self varname oldOrNewValue propName activeValue type` [Function]

Works just like in the old LOOPS.

`GetIndirect self varname oldOrNewValue propName activeValue type` [Function]

Works just like in the old LOOPS.

`PutIndirect self varname oldOrNewValue propName activeValue type` [Function]

Works just like in the old LOOPS.

`ReplaceMe self varname oldOrNewValue propName activeValue type` [Function]

Works just like in the old LOOPS.

`AtCreation self varname oldOrNewValue propName activeValue type` [Function]

No longer works. Instead, you can use either the `FirstFetch` function, or the `:initForm` property of IVs.

## 5.5. Summary of Variable Access Functions

The following tables summarizes the available functions for variable access.

|                       | Inherit/Trigger                | Inherit/Don't Trigger                  | Don't Inherit/Don't Trigger  |
|-----------------------|--------------------------------|----------------------------------------|------------------------------|
| <i>from instances</i> |                                |                                        |                              |
| IV                    | GetValue<br>PutValue           | GetValueOnly<br>PutValueOnly           | GetIVHere                    |
| CV                    | GetClassValue<br>PutClassValue | GetClassValueOnly<br>PutClassValueOnly | <n.a.><br><n.a.>             |
| <i>from classes</i>   |                                |                                        |                              |
| IV                    | <n.a.><br><n.a.>               | GetClassIV<br>PutCIVHere               | GetClassIVHere<br>PutClassIV |
| CV                    | GetClassValue<br>PutClassValue | GetClassValueOnly<br>PutClassValueOnly | GetCVHere<br>PutCVHere       |

## Tailoring MasterScope

### Extending analysis of functions

MasterScope maintains a number of tables describing how (analyzed) functions relate to other objects. The template keywords **TEST**, **PROP**, **FUNCTION**, etc. correspond to some of these tables. For a number of applications, the user would like to be able to define new template words and the database tables that go along with them.

**(ADDTEMPLATEWORD WORD)** [Function]

defines a new table to hold a new MasterScope relation. The name of the table will be **WORD**, and **WORD** can be used in function templates. This is a new function.

Functions are also provided to allow the user to access these new tables inside of a MasterScope command.

**(MSADDRELATION RELATION TABLES)** [Function]

defines a new relation for MasterScopes parser and command interpreter. For example, **(MSADDRELATION ' (FETCH FETCHES FETCHING FETCHED) )** could have been used to define the **FETCH** relation.

**RELATION** is a list of **ROOT PRESENT PARTICIPLE** and **PAST** conjugations of the new relation. **TABLES** is a list of MasterScope database tables that will be **UNIONed** to compute the new relation. (If **TABLES** is an atom it will be coerced to a list containing that atom. If the tables do not already exist, they will automatically be created by **ADDTEMPLATEWORD**). **TABLES** defaults to the **ROOT** of the relation.

**(MSADDMODIFIER RELATION MODIFIERS TABLES)** [Function]

defines a new modifier for the given relation. For example, the phrase **SET FREE** could have been defined by **(MSADDMODIFIER 'SET 'FREE ' (SETFREE) )**.

**RELATION** is a known MasterScope relation (either built-in or defined by **MSADDRELATION** above). **MODIFIERS** is a list of equivalent modifiers. **TABLES** is a list of MasterScope database tables that should be **UNIONed** to compute the new, modified relation. (If any of the tables do not exist, they will be created by **ADDTEMPLATEWORD**). This is a new function.

**(MSADDTYPE TYPE TABLES HOWUSED SYNONYMS)** [Function]

tells MasterScope what it means to use an object of a given type. The phrase **USE THE FIELD** could be defined by **(MSADDDTYPE 'FIELD' (FETCH REPLACE) ' (USE FETCH REPLACE) )**.

**TYPE** is the type of the object being described. The word **TYPE** can then be used in MasterScope commands. **TABLES** indicates how the relation **USE THE <TYPE> . . .** is defined. **HOWUSED** is a list of verb describing how the type can be used. The above example not only lets you use the phrase **USE THE FIELD**, but also the phrases **FETCH THE FIELD** and **REPLACEUSE THE FIELD**. The default value of **HOWUSED** is **(USE)**. Finally, **SYNONYMS** is a list of synonyms for **TYPE**.

In addition to these new functions there are a number of other ways to tailor MasterScope.

Some MasterScope templates, for example **(IF expression template template )** can compute the template to be used. These expressions can access the current form via the free variable **EXPR**. The free variable **PARENT** can be used to access the expression that contains the current expression. This has existed all along, but has not been documented.

#### **ANALYZEUSERFNS**

[Variable]

is a list each of whose elements is a function that will be **APPLY\***ed to the name, definition, and the results of the MasterScope analysis of a function whenever it is analyzed. The result of each application becomes the new result of the MasterScope analysis.

The results of the MasterScope analysis is an ALIST associating relations (**BIND**, **CALL**, etc) with the corresponding data for the function. This can be used to compute relations that are determined by some global context. This has existed all along, but has not been documented.

#### **(SETSYNONYM PHRASE MEANING -)**

[Function]

defines a new synonym for MasterScope's parser. Both **MEANING** and **PHRASE** are lists of words; anywhre **PHRASE** is seen in a command, **MEANING** will be substituted. For example, **(SETSYNONYM 'GLOBALS' (VARS IN GLOBALVARS OR @(GETPROP X 'GLOBALVAR)))** would allow the user to refer with the single word **GLOBALS** to the set of variables which are either in **GLOBALVARS** or have a **GLOBALVAR** property.

**SETSYNONYM** includes a small pattern match ability. A **&** in **PHRASE** will match any word; the word will be substituted for **N** in **MEANING** where **N** is the number of **&**'s which have been matched. For example, **(SETSYNONYM ' (FOO & &) ' (IN 1 OR ON 2))** will take **FOO FIE FUM** into **IN FIE OR ON FUM**.

This is an old function, but the documentation (IRM p 13.20) was incomplete—specifically the pattern match stuff was not mentioned.

## **Extending MasterScope commands**

**DESCRIBELST**

[Variable]

is a list each of whose elements is a list containing a descriptive string and a form. The form is evaluated (it can refer to the name of the function being described by the free variable **FN**); if it returns a non-**NIL** value, the description string is printed followed by the value. If the value is a list, its elements are printed with commas between them. For example, the entry ("**types:** " **(GETRELATION FN ' (USE TYPE) T)** would include a listing of the types used by each function. From the IRM, p 13.7.

**MSCHECKFNS**

[Variable]

is a list of functions that will be used to extend the **CHECK** MasterScope command. The **CHECK** command will **APPLY\*** each function on **MSCHECKFNS** to the list of files being checked. This is new.

**Analyzing new types of objects**

*This doesn't work yet.*

**(MSADDANALYZE PLURAL SINGULAR ANALYZEFN RELATIONS)**

[Function]

defines a new type for MasterScope analysis. For example, **(MSADDANALYZE 'CLASSES 'CLASS 'AnalyzeClass ??)** will let you execute MasterScope commands like **. ANALYZE ANY CLASS ON 'MYFILE** and **. WHAT CLASS DEFINES THE IV foo**. The function **ANALYZEFN** should be a function of two arguments, the item name and the flag **REANALYZE?**, and should return an **ALIST** associating relation names to corresponding data for the object. This is a new function.

**Need to do**

**(DUMPDATABASE)** needs to store out all the new words, relation, etc.

Analyzing new types of things needs to store the info someplace, and **ERASE** needs to be able to find it.

Need a **FILEPKGTYPE** for the MasterScope words.

Proposal for Loops manual contents.

This ordering is based on the Interlisp Reference manual. Numbers in `[[...]]`'s indicate the corresponding parts in the (new) IRM. Other comments are enclosed in `{}`'s. I envision a manual in a single binder, with large tabs marking the IRM volume separation, and smaller tabs for each chapter.

*[[Release Notes]]*

### Installation

Variables `LOOPSDIRECTORY`, `OptionalLispuserFiles`, and `LoadLoopsForms`.

Maybe even `LOOPUSERSDIRECTORIES`?

The function `LOADLOOPS`

The file `LOOPSSITE`

Just load the file `LOOPS`

Initial screen setup

### Customer Support

### Differences from old Loops

KnowledgeBases no longer a part of Loops

Functions `ReadLeafObj`, `AllGlobalNames`, `RememberName`, and `GlobalName` no longer exist

Variables `WritingSummaryFlg`, `WritingLayerFlg`, `LeafInstanceFlg`, `FirstEnvFlg`, `OpenKBFiles`, `DefaultKBName`, `CurrentEnvironment`, `CurrentNameTable`, and `CurrentUIDTable` no longer exist

Macro `Modified` no longer exists

Rules no longer a part of Loops

Rules are not distributed. If they are needed, they can be loaded by first recompiling them and then loading the file `LOOPSRULES-ROOT`. This replaces a few functions and methods in the standard system and then load the rules files.

Code cleaned up

Variables `VarNameIndexes`, `PrintStatusWindow`, and `TTY` no longer exist

Functions `DC`, `DE`, `UE`, `EM`, `EI`, `EC`, and `FILE` no longer exist

Macro `@@` no longer exists. Change `(@@ foo)` to `(@ ::foo)`, or even `(@ foo)`

Usermacros `PU`, `UE`, and `EU` no longer exist

The argument that controls updating in the window methods

`SetOuterRegion`, `SetRegion`, `Shape`, and `Shape1` have all been changed to `noUpdateFlg`. They used to be a mixture of `updateFlg` and `dontUpdateFlg`.

The interpretation of the `left`, `bottom`, `width`, and `height` IVs in the class `Window` is now the same as Lisp windows: `left` and `bottom` refer to the lower left corner of the outside of the window, `width` and `height` refer to the outside dimensions of the window (including title).

The file `LoopsMixin` has been deleted. The classes `DatedObject`, `IndirectObj`, `Node`, `Perspective`, `NamedObject`, `GlobalNamedObject`, `TextItem`, `VarLength`, `StrucMeta`, `ListMetaClass`, `TempClass`, and `Template` no longer exist.

Old messages `List` and `List!` are now called `ListAttribute` and `ListAttribute!`. This change was required for future migration to `CommonLoops`. The old methods for `List` and `List!` are still available in the `LOOPSBACKWARDS` file.

The functions `DebugLoops`, `LOOPSDIR`, `i/d`, and `TESTLOOPS` have been removed from the system.

The functions `CheckDestroyedObjects` and `RemoveClassDef` have been removed from the system.

## I/O

Support for reading in old style read macro (like `$(localState getFn putFn)` or `#mMumble`) is available in the file `LOOPSBACKWARDS`.

UIDs are no longer strings. They are CONSES of session-id's and uid numbers.

## Active Values

Most of the old functions for active values have been moved to `LOOPSBACKWARDS`. The functions `GetLocalState`, `PutLocalState`, `GetLocalStateOnly`, `PutLocalStateOnly`, `ReplaceActiveValue`, `MakeActiveValue`, and `DefAVP` are still around, and seem to work. The exception is `MakeActiveValue` — it now always `EMBEDS`.

Functions `GetActiveValueGetFn`, `GetActiveValuePutFn`, `GetActiveValueLocalState`, `PtcieauGtn`, `alueGetFn`, etc no longer exist. Replacements are available in the file `LOOPSBACKWARDS`.

`NotSetValue` is no longer ?—it is now an active value. This may require changes to any code that directly referred to ?.

## Virtual Copies

The messages `MakeCopy99`, `MakeCopyActiveValue99`, `MakeCopyList99`, and `MakeCopyObject99` in `VirtualCopies` have been renamed `\Internal/MakeCopy`, `\Internal/MakeCopyActiveValue`, etc

Method properties no longer exist

Function `PushNewValue` no longer defined. Instead, use `CHANGETRAN`.

Can't load new Loops files into old Loops.

## Conversion of old Loops code to new Loops

Old code will need to be recompiled.

File `LOOPSBACKWARDS`

Function `ConvertLoopsFiles`

## Future Directions

Proposal for Loops manual contents.

This ordering is based on the Interlisp Reference manual. Numbers in [[]]'s indicate the corresponding sections in the (new) IRM.

# ERRATA FOR THE LYRIC / MEDLEY RELEASE OF XEROX LOOPS

---

Please note the following corrections to the Lyric/Medley release of the manual and software. These descriptions and workarounds supplement the Lyric/Medley *Xerox LOOPS Release Notes*.

---

## Notes and Cautions

---

### Documentation comments in examples

---

Documentation props are now strings, as mentioned in the Lyric/Medley version of the *Xerox LOOPS Release Notes*. However, many of the manual's examples incorrectly show comments being used for documentation on methods, and instance and class variables.

### Conversion of instance files

---

We have encountered a case where instance files from Koto LOOPS failed to load after conversion under Lyric/Medley LOOPS. This occurs when instances refer to each other (their IVs contain one another).

This type of instance file must be written out in the INTERLISP readtable, since only that readtable handles the "hash dot" reader macro used to write out a reference to an instance. After conversion of such files, place a MAKEFILE-ENVIRONMENT property on the file that will cause it to be written and read in the INTERLISP readtable.

### GetIt for missing IV props

---

There is an inconsistency in **GetIt**'s behavior when retrieval of missing instance variable properties is attempted. If the object being retrieved from is an *instance*, this returns the value of **NoValueFound**, and triggers any active values. However, if the object being retrieved from is a *class*, **GetIt** returns the value of **NotSetValue**, and does not trigger active values. A workaround would be to check for both **NoValueFound** and **NotSetValue** as return values from **GetIt**.

## LOOPS Rules

---

The User's Module "Rules" has changed to track differences between Koto and Lyric/Medley LOOPS. In Koto LOOPS, one could create RuleSets that were not methods; this is no longer possible. RuleSets can no longer reside "bare" in a FNS definition.

Several things follow from this change:

- **RunRS** no longer works.
- **DefRSM** is now the only way to create new RuleSets. The documented **New** method for the class **RuleSet** is used internally by **DefRSM**; software should no longer specialize or depend on it.
- The RuleSet method **CopyRules** no longer works. RuleSets can be copied using **CopyMethod**.

## Converting Koto RuleSets

---

Converting older RuleSets to run in the Lyric/Medley release of Xerox LOOPS is a two-step process. The first step takes place in the Koto release of LOOPS; the second step occurs in the Lyric/Medley release of LOOPS.

While still running the Koto release of LOOPS, you must first pass preKoto RuleSets through the converter in the LOOPSBACKWARDS User's Module. This will upgrade the RuleSets to run in Koto LOOPS. RuleSets which reside in FNS must also be moved into methods at this time. A final ready-to-convert version of the RuleSet files should then be made.

After starting up the Lyric/Medley release of Xerox LOOPS any previously prepared Koto RuleSets can be passed through the converter in the CONVERSION-AIDS User's Module. Some types of Koto converted Buttriss RuleSets will print out a message during conversion; these must then be rule-compiled, i.e. translated from RuleSet to executable code by sending the RuleSet the **RE** message and exiting the rule editor with **OK&LispCompile**.

After these steps all RuleSet formats will be correctly updated and the fully converted files can be made.

# A. ACTIVE VALUES IN BUTTRESS LOOPS

---

In the Buttress version of LOOPS, the concept of active values was implemented differently. The current **ExplicitFnActiveValue** acts very much like the old active values, and is used to provide compatibility with existing Xerox LOOPS code. Most of the functions described in this chapter are found only in the LOOPSBACKWARDS user package, work as they did in the Buttress version of LOOPS, and should be used only to bring existing code into the current system.

Descriptions of the functionality in this appendix are written in terms of the new **ActiveValues** wherever possible.

The active value/annotated value system discussed in Chapter 8, Active Values, is a new implementation. Programs developed using the Buttress activeValue system automatically convert into the new system when loaded, using the **ExplicitFnActiveValue** capability described in Chapter 8, Active Values, and in this appendix.

Note: The following functions and records are maintained for compatibility purposes only; they are not fully supported and may not exist in future Xerox LOOPS releases. Programs that use these records and functions should be changed. The LOOPSBACKWARDS user package must be loaded for these functions to work.

---

## A.1 Buttress System of ActiveValues

---

The Buttress LOOPS implementation combined the notions of annotated value and active value. To annotate a variable, the value was replaced with an instance of an Interlisp-D data type called activeValue, but there were no LOOPS classes with similar names and functions as there are now.

| activeValue  |                                                                                                                                                                                                                                       | [Record]                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Purpose:     | Buttress implementation of the active values concept. Specifically, the Lisp data type equivalent to the present annotatedValue.                                                                                                      |                                                                                                                          |
| Behavior:    | An activeValue placed as the value of a variable invoked evaluation of code on access attempts rather than just returning a stored value.                                                                                             |                                                                                                                          |
| Field Names: | <b>localState</b>                                                                                                                                                                                                                     | A place for data storage.                                                                                                |
|              | <b>getFn</b>                                                                                                                                                                                                                          | The name of a function applied when the program retrieves the value of a variable that contained an activeValue.         |
|              | <b>putFn</b>                                                                                                                                                                                                                          | The name of a function that was applied when the program replaces the value of a variable that contained an activeValue. |
|              | If either the <b>getFn</b> or <b>putFn</b> fields is NIL, default actions returned or replaced the <b>localState</b> , respectively. Nesting was accomplished by the <b>localState</b> of an activeValue being itself an activeValue. |                                                                                                                          |

**ExplicitFnActiveValue**

[Class]

- Purpose: Mimics the behavior of the Buttress-style active values and allows simple changes to the user code triggered by the **ActiveValue** mechanism.
- Behavior: **Get** accesses to the wrapped variable cause the **getFn** to be called, and **Put** accesses cause **putFn** to be called. Enables the old style activeValues to look like the new style without changing any functionality.
- Instance Variables:
- localState** A place for data storage.
  - getFn** The name of a function applied when the active variable is read.
  - putFn** The name of a function applied when the active variable is changed.

**(MakeActiveValue self varOrSelector newGetFn newPutFn newLocalState propName type)**

[Function]

- Purpose: Makes the value of some variable an active value.
- Behavior: Creates a new activeValue record and installs it according to the arguments.
- Arguments:
- self* Object whose variable is changed to an active value.
  - varOrSelector* Variable name or method selector where the data type activeValue is placed.
  - newGetFn* and *newPutFn* If NIL, the old values of **getFn** and **putFn** are not overwritten. If T, the values of **getFn** and **putFn** are changed to NIL. Any other values are placed in the **getFn** and **putFn** fields of the activeValue.
  - newLocalState* The value of this argument is ignored. A new **ActiveValue** instance is always created. The contents of **localState** is changed to the previous value of the variable or property being made active.
  - propName* Name of the property, if the active value is to be placed on a property list. This is NIL if the active value is associated with a variable or method.
  - type* Indicates the type of the variable *varNameOrSelector*. Must be one of IV (or NIL) for instance variable, CV for class variable, CLASS for a class property, or METHOD for a method property.

**(DefAVP fnName putFlg)**

[Function]

- Purpose: Creates a template for defining an active value function.
- Behavior: Creates a template and leaves you in the Interlisp-D function editor.
- Arguments:
- fnName* Name of the function.
  - putFlg* T indicates function is a **putFn**; NIL indicates a **getFn**.
- Returns: The function name on exit from the editor.

**(GetLocalState activeValue self varName propName type)**

[Function]

Purpose: Retrieves data from **localState**.

Behavior: Retrieves the value stored in the **localState** of *activeValue*. Nested active values will be triggered.

Arguments: *activeValue* An **ActiveValue**.

*self* The object containing the **ActiveValue**.

*varName* The name of the variable were the **ActiveValue** is stored.

*propName* The name of an instance or class variable property. This is NIL if the **ActiveValue** is associated with the value of the variable itself.

*type* Specifies where the **ActiveValue** was stored. NIL means an instance variable, CV means class variable, CLASS means a class property, METHOD means a method property.

Returns: Contents of the **localState** field of *activeValue*.

---

**(PutLocalState *activeValue newValue self varName propName type*)** [Function]

---

Purpose: Data replacement.

Behavior: Stores *newValue* in the **localState** field of *activeValue*. Nested active values will be triggered.

Arguments: *activeValue* An **ActiveValue**.

*newValue* A new value to be stored in **localState**.

*self* The object containing the **ActiveValue**.

*varName* The name of the variable were the **ActiveValue** is stored.

*propName* The name of an instance or class variable property. This is NIL if the **ActiveValue** is associated with the value of the variable itself.

*type* Specifies where the **ActiveValue** was stored. NIL means an instance variable, CV means class variable, CLASS means a class property, METHOD means a method property.

Returns: The value of *newValue*.

---

**(GetLocalStateOnly *activeValue*)** [Function]

---

Purpose: Gets a value from **localState** without triggering any nested **ActiveValue**.

Behavior: Retrieves the value stored in the **localState** field of the **ActiveValue** without triggering any nested **ActiveValue**.

Arguments: *activeValue* The **ActiveValue** in which the **getFn** and **putFn** is found.

Returns: The contents of **localState**.

---

**(PutLocalStateOnly** *activeValue newValue*)

[Function]

- Purpose: Puts a value into a **localState** without triggering any nested **ActiveValues**.
- Behavior: Replaces the value stored in the **localState** of *activeValue* without triggering any nested **ActiveValue**.
- Arguments: *activeValue* An **ActiveValue**.  
*newValue* Value used for the replacement.
- Returns: The value of *newValue*.

---

**(ReplaceActiveValue** *activeValue newVal self varName propName type*)

[Function]

- Purpose: In an object's variable which has an **ActiveValue** installed, overwrites *activeVal* with *newVal*, providing a way of removing an **ActiveValue**.
- Behavior: Searches arbitrarily deep nesting to replace the occurrence of *activeVal* with *newVal*. If no match is found in the list that is the value of the variable described by the arguments, an error is invoked.
- Arguments: *activeValue* The **ActiveValue** to be replaced.  
*newVal* A new value to be stored in the object's variable.  
*self* The object containing the **ActiveValue**.  
*varName* The name of the variable where the **ActiveValue** is stored.  
*propName* The name of an instance or class variable property. This is NIL if the **ActiveValue** is associated with the value of the variable itself.  
*type* Specifies where the **ActiveValue** was stored. NIL means an instance variable, CV means class variable, CLASS means a class property, METHOD means a method property.  
*newValue* Value used for the replacement.
- Returns: Value of *newVal*.

A.2 GETFNS AND PUTFNS

---

A.2 GETFNS AND PUTFNS

---

---

## A.2 getFns and putFns

---

In the Buttress version of LOOPS, where the only kind of active value was equivalent to **ExplicitFnActiveValue**, specialization of active values was done not the way it is in Xerox LOOPS, but by the equivalent of putting special purpose functions into the **getFn** and **putFn** instance variables. The following functions emulate the behaviors they had in the Buttress version, using the current **ActiveValue** mechanisms.

In all cases, the functions are installed in the **getFn** or **putFn** instance variable of an **ActiveValue**, and are called when an attempt is made to get or put the variable where the **ActiveValue** is stored. The arguments and values returned are irrelevant to the use of these functions.

**(NoUpdatePermitted** *self varName oldOrNewValue propName activeValue type*) [Function]

---

Purpose: **putFn** for preventing the updating of a variable.

Behavior: LOOPS-defined **putFn** that causes a break if an attempt is made to replace the value of the variable containing the **ActiveValue**.

**(FirstFetch** *self varName oldOrNewValue PropName activeValue type*) [Function]

---

Purpose: **getFn** for dynamic variable initialization.

Behavior: LOOPS-defined **getFn** that expects the **localState** of *activeValue* to be an Interlisp-D expression to be evaluated. On the first fetch, the expression is evaluated and the variable or property is set to the value of the expression.

**(GetIndirect** *self varName oldOrNewValue PropName activeValue type*) [Function]

---

Purpose: LOOPS-defined **getFn** that functions as a pointer to another variable.

Behavior: **GetIndirect** and **PutIndirect** together set up an **ActiveValue** whose **localState** contains a pointer to where the actual value is stored. This is used when the value of a variable should always be the same as another.

**(PutIndirect** *self varName oldOrNewValue PropName activeValue type*) [Function]

---

Purpose: LOOPS-defined **putFn** that functions as a pointer to another variable.

Behavior: See **GetIndirect**.

**(ReplaceMe** *self varName oldOrNewValue PropName activeValue type*) [Function]

---

Purpose: LOOPS-defined **putFn** which removes both itself and any **getFn**.

Behavior: In some cases, you may want to compute a default value if given, but replace the active value by the value given if you set the value of a variable. For this, you can employ **ReplaceMe**. Any replacement attempt at the variable containing an **ActiveValue** with this as its **putFn** results in the value of the variable being replaced, and the **ActiveValue** disappearing.

**(AtCreation** *self varName oldOrNewValue PropName activeValue type*) [Function]

---

Purpose: LOOPS-defined **getFn** used to replace the active value with a dynamically computed value at instance creation.

Behavior: This function no longer works.

To achieve the closest functionality, use the **FirstFetchAV** specialization of the class **ActiveValue** (see Chapter 8, Active Values) or the **FirstFetch** function described above.

# Sun 3 & 4 LOOPS — 1/4" tar Tape

## Manufacturing Instructions

(Envos Internal Use Only)

1. Go to Tree (or any available Sun 3 with a tape drive on it), and log in.
2. Insert a blank 1/4-inch cartridge in the tape drive. You must use a 600-foot tape.
3. Type the following commands (the text in bold):

```
tree%: cd /python/loops
tree%: makereleasetape
```

The system will type something like this:

You should have a tape in the cartridge drive already, and should be connected to the correct directory. Please verify that you are connected to the right place.

You are connected to:

/python/loops (or something ending in /python/pcl)

Type ^C to Abort

Type ^D to continue

4. Type control-D. The tape will now get written, followed by a message telling you that it is finished.
5. When the tape has finished moving (it rewinds automatically), remove it from the drive, and turn the write-protect tab to the "Safe" setting.
6. Label the cartridge and its container (green LOOPS labels). If those were the last 2 labels, make another 10 (Chuck's PC has the files).
7. Don't forget to log out.

# Sun 3 & 4 LOOPS — 1/2" 9-Track 1600 bpi

## Manufacturing Instructions

(Envos Internal Use Only)

1. Go to python and load a 1/2-inch tape into its tape drive. Hit the "Density" button until the light next to "1600" is lit. You'll need to use a small reel of tape for this.
2. At python's console, log in as yourself.
3. Type the following commands (the text in bold):

```
python%: cd /python/loops
python%: maketape1600
```

The system will type something like this:

You should have a tape mounted on python's mag tape drive, and should be connected to the correct directory. Please verify that you are connected to the right place.

You are connected to:

/python/loops (or something ending in /python/pcl)

Type ^C to Abort

Type ^D to continue

4. Type control-D. The tape will now get written, followed by a message telling you that it is finished.
5. When the tape has finished moving (it rewinds automatically), remove it from the drive, and remove the write-protect ring.
6. Label the tape (green Loops label). If that was the last label, make another 10 (Chuck's PC has the files).
7. Hit the "density" button on the tape drive until the light next to "Host" is lit.
8. Don't forget to log out.

LOOPS integrates several programming paradigms to facilitate the design of artificial intelligence applications.

- Object-oriented programming, in which information is organized in terms of objects. Every object belongs to a class, and the classes are arranged in an inheritance lattice which allows complex objects to be described simply. Objects communicate with each other by sending messages. When an object receives a message, it performs some action, which can include sending messages to other objects.
- Procedure-oriented programming, in which smaller subroutines build larger procedures and in which data and instructions are kept separate.
- Access-oriented programming, in which accessing a value triggers an action. This paradigm is useful to monitor certain values.
- Rule-oriented programming, in which programs are organized around recursively composable sets of pattern-action rules. These rules provide a convenient way to describe flexible responses to a wide range of events. This part of LOOPS is included in the users' modules.

As a new user of LOOPS, you first must become familiar with its terminology and with the fundamental concepts described by that terminology. This chapter presents the terminology and related concepts.

---

## **1.1 Introduction to Objects**

---

This section shows the LOOPS hierarchy, called a lattice, in Figure 1-1, and describes the key terms in separate subsections. Terms appear in order of increasing complexity, with simpler terms described first and subsequent terms building on these simpler terms.

Figure 1-1. LOOPS Lattice

1.1.1 Object

As shown in Figure 1-2, an object is a structure consisting of data and a pointer to functionality that can manipulate the data. In procedure-oriented programming, data and functionality are considered as separate entities.

Figure 1-2. An Object

### 1.1.2 Message

Sending messages to objects provides an alternative to invoking procedures or calling functions. An object responds to a message by computing a value to be returned to the sender of the message, as shown in Figure 1-3. As a side effect, the data within an object may change during the computation. Messages contain a selector for the desired functionality. Messages may also contain arguments, as do procedures.

Figure 1-3. An Object Responding to a Message

### 1.1.3 Method

When an object receives a message, it determines what functionality it must apply to the arguments of the message. This functionality is called a method and is very similar to a procedure. A key concept that distinguishes methods from procedures is that in procedure-oriented programming, the calling routine determines which procedure to apply. In object-oriented programming, you determine the message to send and the object receiving the message determines the method to apply.

### 1.1.4 Selector

A message that is sent to an object contains a selector. The object uses the selector to determine which method is appropriate to apply to the message arguments. As shown in Figure 1-4, when an object receives a message with a specific selector, the object searches a lookup table containing selectors and methods to find the method associated with that particular selector.

Figure 1-4. A Message Containing a Selector

### 1.1.5 Class

---

A class describes objects that are similar; that is, objects containing the same type of data fields and responding to the same messages, as shown in Figure 1-5. Think of the class that describes an object as being a template

for the functionality of its objects. When an object is sent a message, the class that describes that object handles the message, not the object itself. Different objects of the same class can respond to messages in the same way; that is, they apply the same method in response to receiving the same message.

To create new objects, send a message to a class requesting that a new object be created. Classes respond to messages because they are also objects.

Figure 1-5. Class with Several Objects

### 1.1.6 Instance

An instance is an object described by a particular class. Every object within LOOPS is an instance of exactly one class.

## 1.2 Storage of Data in Objects

The data associated with an object is called an object's variables. Methods can change the values of these variables.

### 1.2 STORAGE OF DATA IN OBJECTS

#### 1.2 STORAGE OF DATA IN OBJECTS

### 1.2.1 Class Variables and Instance Variables

LOOPS supports two kinds of variables:

- Instance variables, often abbreviated IVs.

Instance variables contain the information specific to an instance.

- Class variables, often abbreviated CVs.

Class variables contain information shared by all instances of the class. A class variable is typically used for information about a class taken as a whole.

Both kinds of variables have names, values, and other properties. For example, the class for **Point** could specify two instance variables, **x** and **y**, and a class variable, **lastPoint**, used by methods associated with all points.

For any particular instance, you can access the values for the instance variables specific to that instance. You can also access the values for the class variables that are available to all instances of the same class.

Determining the value of a class variable requires a similar lookup procedure to that occurring when searching for a method to execute. Instance variable values are stored within the instances, and class variable values are stored within the class.

A class describes the structure of its instances by specifying the names and default values of instance variables, as shown in Figure 1-6. In this way, when a message is sent to a class to create a new instance, LOOPS can determine from the class description the number of instance variables for which it must allocate space the the initial values for those variables.

Figure 1-6. Class Variables and Instance Variables

---

## 1.2.2 Properties

LOOPS provides extensible property lists for classes, their variables, and their methods. Property lists provide places for storing documentation and additional kinds of information. For example, in a knowledge engineering

application, a property list for an instance variable could be used to store the following information:

- Support (reasons for believing a value)
- Certainty factor (numeric assessments of degree of belief) • Containments on values
- Dependencies (relationships to other variables)
- Histories (previous values)

## 1.3 METACLASSES

## 1.3 METACLASSES

## 1.3 Metaclasses

Classes themselves are instances of some class. Metaclasses are classes whose instances are classes. When a class is sent a message, its metaclass determines the response. For example, instances of a class are created by sending the class the message **New**. This message is handled by the class that describes the class receiving the message. For most classes, this method is provided by the standard metaclass for classes **Class**.

To create a new class, send a message to the class **Class**. The class that handles this message is **MetaClass**. Instances of **MetaClass** are classes that describe objects which are classes. Instances of **Class** are classes whose instances are not classes. Figure 1-7 shows an instance of **MetaClass**, which is a class named **Class**, and instances of **Class**, which are named **Window** and **Point**.

Another class available in the system is **AbstractClass**. This is useful when creating classes that implement general functionality, which must then be specialized into instantiable classes. Instances of this class are classes that are impossible to instantiate. An example of an **AbstractClass** is **ActiveValue**, which is described in Chapter 5, Active Values.

Figure 1-7. A Metaclass and its Instances

---

## 1.4 Introduction to Inheritance

---

Inheritance allows you to organize information in objects. With a few incremental changes, you can use inheritance to create objects that are almost like other objects. Inheritance allows you to avoid specifying redundant information and simplifies updating, since information that is common to several objects need be changed in only one place.

LOOPS objects exist in an inheritance network of classes. Figure 1-8 shows an example in which a class **3DPoint** is a subclass of another class **Point**. Instances of **3DPoint** contain instance variables that are defined in

1.4 INTRODUCTION TO INHERITANCE

---

### 1.4 INTRODUCTION TO INHERITANCE

---

**Point** as well as **3DPoint**. **Point** is referred to as a superclass of **3DPoint**. When an instance of **3DPoint** is created, the instance variables it contains and the messages to which it responds are not limited to those instance variables or methods as defined in the class **3DPoint**. For example, the object **pt2** contains three instance variables; two of them are inherited from the class **Point** and the other defined in the class **3DPoint**. This instance can also respond to three different messages containing one of the three different selectors: **selector1**, **selector2**, or **selector3**.

All descriptions in a class are inherited by a subclass unless overridden in the subclass. For methods and class variables, this is implemented by a runtime search for the information, looking first in the class, and then at the superclasses specified by its supers list. For instance variables, no search is made at run time. Default values are cached in the class, and are updated if any superclass is changed, thus maintaining the same semantics as the search. Each class can specify inheritance of structure and behavior from any number of superclasses.

Figure 1-8. A Sample Inheritance Network

### 1.4.1 Single Superclasses

In the simplest case, each class specifies only one superclass. If the class **A** has the supers list (**B**), which is a one-element list containing **B**, then all of the instance variables specified local to **A** are added to those specified for **B**, recursively. That is, **A** gets all those instance variables described in **B** and all of **B**'s supers. For example, in Figure 1-9, **A** has instance variables **x**, **z**, and **B1**.

Any conflict of variable names is resolved by using the description closer to **A** in traversing up the hierarchy to its top at the class **Object**. Method lookup uses the same conflict resolution. The method to respond to a message is obtained by first searching in **A**, and then searching recursively in **A**'s supers list. For example, in Figure 1-9, the method **selector2** uses **methodA2** instead of **methodB2**.

Figure 1-9. A Class with a Single Superclass

## 1.4.2 Multiple Superclasses

---

Classes in LOOPS can have more than one class specified on their supers list. Multiple superclasses permit a modular programming style where the following conditions hold:

- Methods and associated variables for implementing a particular feature are placed in a single class.
- Objects requiring combinations of independent features inherit them from multiple supers.

As in Figure 1-10, if **A** has the supers list (**B C**), first the description from **A** is used, then the description from **B** and its supers is inherited, and finally the description from **C** and its supers. In the simplest usage, the different features have unique variable names and selectors in each super. In case of a name conflict, LOOPS uses a depth first left-to-right precedence.

For example, if any super of **B** had a method for **selector3**, then it would be used instead of the method **methodC3** from **C**. In every case, inheritance from **Object** is only considered after all other classes on the recursively defined supers list. The general rule is left-to-right, depth first, up to where the separate branches of the hierarchy join together; that is, up to any class that is repeated. Alternatively, consider the list as generated by listing all the

superclasses in a depth first left-to-right order, eliminating all but the last occurrence of a class in the list.

Figure 1-10. A Class with Multiple Superclasses

## 1.5 Introduction to Access-Oriented Programming: Using Active Values

In access-oriented programming, you can specify a particular procedure to invoke for read or write access of any variable of an object. LOOPS checks every object variable access to determine whether the value is marked as an active value. An active value is a LOOPS object. If a variable is marked as an active value, then aa message is sent to the active value object whenever the variable is read or set. This mechanism is dual to the notion of sending messages. Messages are a way of telling objects to perform operations, which can change their variables as a side effect. Active values are a way of accessing variables, which can send messages as a side effect.

The messages sent to the active value object will depend on the type of access. If you try to read a variable, the message **GettingWrapped Value** is sent to the active value object. If you try to set a variable, the message **Putting Wrapped Value** is sent. The object receiving the message may or may not trigger side effects as the result of receiving these messages. In this way, you have control over the side effects that may occur as a result of accessing data.

Active values enable one process to monitor another one. For example, LOOPS has debugging tools that use active values to trace and trap references to object variables. A graphics module updates views of particular objects on a display when their variables are changed. In both cases, the monitoring process is invisible to, and isolated from, the monitored process. No changes to the code of the monitored object are necessary to enable monitoring.

Active values can also be used to maintain constraints among data in a system. As one piece of data changes, the active value associated with that data can contain functionality that updates other data within the system. Examples of this are spreadsheets or electric circuit modeling.

A powerful feature of active values is that they can be nested to yield a natural composition of the access functions.

---

## 1.6 Introduction to the LOOPS User Interface

---

A key feature of LOOPS is its smooth integration with the Venue Medley environment. Many of the tools within Medley have been extended to provide the necessary functionality for manipulating objects. Among these tools are the following:

- SEdit
- The inspector
- Masterscope
- The File Manager
- The Library Module Grapher

This section describes how LOOPS interfaces with each of these Medley tools.

Another aspect of LOOPS is that objects have a name space that is separate from the Lisp name space. LOOPS names are Interlisp symbols. Applying a LOOPS function **\$** to a Medley symbol extracts a pointer to a LOOPS object. Objects can also be pointed to as a Lisp value.

---

### 1.6.1 SEdit

---

Class structures are Lisp data types. To change a class structure, LOOPS creates a list structure source for the class definition. This list can then be edited easily by SEdit. Upon exiting SEdit, the list structure is converted back to a data type. This process of converting to and from a list is hidden from view.

---

### 1.6.2 Inspector

---

Inspector macros have been defined within LOOPS that allow you to view the necessary class and instance data while hiding implementation details. Inspectors opened on classes or instances also provide functionality for changing the way one views an object. As an example, you can inspect a class and see or not see information inherited from its superclasses.

### **1.6.3 Masterscope**

---

The Library Module Masterscope has been extended to a LOOPS Library Module so that message sending and the use of instance and class variables are understood. The functionality of CHECK has been extended to allow consistency checking of LOOPS methods.

### **1.6.4 File Manager**

---

Additional File Manager commands have been added to allow you to save classes, instances, and methods on files.

### **1.6.5 Grapher Module**

---

An important part of the LOOPS interface is its ability to show relationships between objects and to enable the programmer to easily manipulate those objects. Browsers of various kinds are in the system to allow you to understand the relationships between classes and how those classes are related to files. The browsers are built upon the Library module Grapher. You can easily extend the built-in browsers to create views onto any object relationship. An example of this is a decision tree where each node was an object representing a particular state of a system.

|             |         |
|-------------|---------|
| INDEX ..... | INDEX-1 |
|-------------|---------|

|                |            |
|----------------|------------|
| GLOSSARY ..... | GLOSSARY-1 |
|----------------|------------|

Every object within the LOOPS system is an instance of some class. In this manual, however, the word instance generally refers to objects that are not themselves classes. Instances are a data type that contain local storage for instance variables, a pointer to the class that describes the instance, the Unique Identifier (UID), and other information.

This chapter describes naming and creating instances, accessing data stored within instances or pointed to by instances, and other related topics.

## 2.1 Instance Naming Conventions

A separate name space for LOOPS objects is maintained by the LOOPS system within a separate object name table. Since Lisp structures and LOOPS objects are stored in separate name tables, you can use the same symbol to refer to both a Lisp structure and a LOOPS object.

Note: The separate name space is not implemented by using the Common Lisp Package System.

Instances are not created with names; therefore, it may be necessary to keep pointers to them. Two ways are available to create pointers:

- Use Lisp variables, as in:

```
(SETQ window1 (← ($ Window) New))
```

This creates an instance of the class **Window** that can be referenced by the Lisp variable **window1**.

- Use a LOOPS name. This can be done in two ways:

- Assign a name at the same time the instance is created. This can be done by using

```
(← ($ Window) New 'window2)
```

as described above. This creates an instance of the class **Window** that can be referenced by the LOOPS expression `($ window2)`.

- Use the message **SetName** if you have a pointer to an object and want to assign a LOOPS name to that object.

The following table shows the items that manipulate LOOPS names.

| Name | Type              | Description                                                                                                              |
|------|-------------------|--------------------------------------------------------------------------------------------------------------------------|
| \$   | NLambda and Macro | Distinguishes between the Lisp value of a symbol and the LOOPS value of the same symbol; does not evaluate its argument. |

## 2.1 INSTANCE NAMING CONVENTIONS

---

|                            |          |                                                                                                                  |
|----------------------------|----------|------------------------------------------------------------------------------------------------------------------|
| <b>\$!</b>                 | Function | Distinguishes between the Lisp value of a symbol and the LOOPS value of the same symbol; evaluates its argument. |
| <b>SetName</b>             | Method   | Assigns a LOOPS name to an object.                                                                               |
| <b>UnSetName</b>           | Method   | Removes a name pointer to an object.                                                                             |
| <b>Rename</b>              | Method   | Changes the name of an object.                                                                                   |
| <b>GetObjectNames</b>      | Function | Returns the names of an object, including its UID.                                                               |
| <b>ErrorOnNameConflict</b> | Variable | Causes a break to occur when an attempting to name an object that already has a LOOPS name.                      |

---

**(\$ name)** [NLambda and Macro]

---

Purpose/Behavior: Returns a pointer to a LOOPS object specified by the LOOPS name *name*. If no object exists for *name*, NIL is returned.

Arguments: *name* A LOOPS name.

Returns: Pointer to a LOOPS object or NIL; see Behavior.

Example: Given that

```
24←(← ($ Window) New 'window2)
#, ($& Window (NEW0.1Y%:.;h.eN6 . 495))
```

then

```
25←($ window2)
#, ($& Window (NEW0.1Y%:.;h.eN6 . 495))
```

The returned value is a pointer to the new window instance. For a further explanation, see Chapter 18, Reading and Printing.

---

**(\$! name)** [Function]

---

Purpose/Behavior: Returns a pointer to an object specified by the value of the variable *name*, given that the value is a LOOPS name. If no object exists for *name*, NIL is returned.

Arguments: *name* Evaluates to a valid LOOPS name.

Returns: Pointer to a LOOPS object or NIL; see Behavior.

Example: Given that

```
26←(SETQ foo 'Window)
Window
```

and **Window** is a LOOPS object, then

```
27←($! foo)
#, ($C Window)
```

---

**(← self SetName name)** [Method of Object]

---

Purpose: Assigns a LOOPS name to an object.

Behavior: If *name* is NIL, then a break occurs. If *name* is not a symbol, a break occurs. If *name* is already in use as a LOOPS name, and if the variable

*ErrorOnNameConflict* is non-NIL, then a break occurs, giving you the chance to OK "rebinding" *name*.

Note: If an object has multiple names, (*← self* **SetName** *NewName*) results in both the old name and new name appearing when (FILES?) is executed. The instance is also printed twice on the file if both names are specified to be saved.

Arguments: *self* An object.  
*name* The LOOPS name to be given to the object; must be a symbol.  
 Returns: *self*  
 Categories: Object  
 Specializations: Class

Example: Given the commands

```
28←(SETQ window1 (← ($ Window) New))
#,$& Window (NEW0.1Y%.:;h.eN6 . 496))
```

```
29←(← window1 SetName 'window3)
#,$& Window (NEW0.1Y%.:;h.eN6 . 496))
```

the Lisp variable **window1** and the LOOPS expression

```
($ window3)
```

now point to the same object.

---

(*← self* **UnSetName** *name*) [Method of Object]

---

Purpose: Removes a LOOPS name pointer to an object.  
 Behavior: Removes the reference of *name* to *self* from the object name table maintained by the LOOPS system. If *name* is NIL, all names pointing to *self* in the object name table are removed from the files on **FILELST**. If *name* is non-NIL and the instance is associated with any files on **FILELST**, the instance is removed from those files. If *name* is not a valid LOOPS name for the object in question, an error occurs.  
 Arguments: *self* An object.  
*name* A LOOPS name.  
 Returns: Used for side effect only.  
 Categories: Object

---

(*← self* **Rename** *newName* *oldNames*) [Method of Object]

---

Purpose: Changes the name of an object.  
 Behavior: If *oldNames* is NIL, removes all old names when *newName* is installed as the name for *self*; otherwise replaces only names specified in *oldNames* by *newName*. If *oldNames* is not a valid LOOPS name for the object in question, an error occurs.  
 Arguments: *self* Evaluates to a LOOPS name.  
*newName* The LOOPS name to be given to the object; must be a symbol.

## 2.1 INSTANCE NAMING CONVENTIONS

---

|                  |                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | <i>oldNames</i>                                                                                                                                                                                                                                                                                                                       | List of symbols whose names are to be removed; if NIL, all old names are removed when <i>newName</i> is installed as the name for <i>self</i> . |
| Returns:         | <i>self</i>                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                 |
| Categories:      | Object                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                 |
| Specializations: | Class                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                 |
| Example:         | Examine the following expressions to see the effects of <b>Rename</b> .<br><br>30←(\$ window2)<br>#,\$(& Window (NEW0.1Y%:.H53.G2A . 496))<br><br>31←(← (\$ window2) Rename 'MyWindow')<br>#,\$(& Window (NEW0.1Y%:.H53.G2A . 496))<br><br>32←(\$ window2)<br>NIL<br><br>33←(\$ MyWindow)<br>#,\$(& Window (NEW0.1Y%:.H53.G2A . 496)) |                                                                                                                                                 |

| (GetObjectNames <i>object</i> ) |                                                                                                                                                                                | [Function]      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Purpose/Behavior:               | Returns the names of <i>object</i> , including its UID.                                                                                                                        |                 |
| Arguments:                      | <i>object</i>                                                                                                                                                                  | A LOOPS object. |
| Returns:                        | The names of <i>object</i> , including its UID.                                                                                                                                |                 |
| Example:                        | The command<br><br>(PROGN<br>(← (\$ Window) New 'w1)<br>(← (\$ w1) SetName 'wlagain)<br>(GetObjectNames (\$ w1)))<br><br>returns<br><br>(wlagain w1 (NEW0.1Y%:.H53.G2A . 497)) |                 |

| ErrorOnNameConflict | [Variable]                                                                                                                                                                                                                                                                                                                          |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose/Behavior:   | Behavior depends on the value. <ul style="list-style-type: none"><li>• If NIL, the existing object is replaced by a new object.</li><li>• If non-NIL, a break occurs when an attempt is made to give an object a name that is already in use as a LOOPS name.</li></ul> Initially, the value for <b>ErrorOnNameConflict</b> is NIL. |

---

## 2.2 CREATING INSTANCES

---

| 2.2 Creating Instances                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When an instance is created by sending the <b>New</b> message to a class, the default behavior for <b>Class.New</b> is to send the message <b>NewInstance</b> to the |

newly created object. If you require that special or additional operations occur at instance creation time, specialize the method **NewInstance**. Specializations of the **NewInstance** method should return *self*. You also have the capability to pass arguments to the **NewInstance** method when the **New** message is sent to create the instance. For example, the following defines a class **NamedClass** which adds the instance variable **name** and specializes **New** to set that instance variable to the name of the instance when created.

```
(DefineClass 'NamedClass)
(← ($ NamedClass) AddIV 'name)
(DefineMethod ($ NamedClass) 'New ' (self name)
' (←@ (←self NewInstance name) name name))
```

You can also indicate whether instances are to be saved on files using the File Manager, which is described in Chapter 14, File Manager.

The following table shows the methods in this section.

| Name                 | Type   | Description                                                   |
|----------------------|--------|---------------------------------------------------------------|
| <b>New</b>           | Method | Creates a new object of a particular class.                   |
| <b>←New</b>          | Macro  | Creates an object and sends a message to it.                  |
| <b>NewInstance</b>   | Method | Allows initialization of newly created instances by class.    |
| <b>NewWithValues</b> | Method | Creates an object with instance variables of assigned values. |

(← class **New** name arg1 arg2 ...) [Method of Class]

Purpose: Creates a new object, which is an instance of the class *class*.

Behavior: Creates a new instance *name* and then sends the message (← "the new instance" **NewInstance** *name* arg1arg2 ...)

In the default case, the **New** method uses the default values for the instance variable values in the newly created instance. These default values are given in the instance variable descriptions of the given class. When that process is finished, the instance can be altered in various ways by sending it messages. Specializations of the **New** method should return the new instance, and can take more arguments after *name*.

The internal data structure of an instance contains a pointer to the class of which it is an instance.

Arguments: *class* Pointer to a class.

*name* Name assigned to the instance; if NIL, object does not have a LOOPS name.

*arg1arg2...* Arguments passed to the **NewInstance** method.

Returns: Newly created instance of the class.

Categories: Class

Specializations: AbstractClass, MetaClass

Example: The following command creates a new instance named **window1** of class **Window**.

```
20← (← ($ Window) New 'window1)
#, ($& Window (NEW0.1Y%.:.;h.eN6 . 515))
```

The command

```
21← (INSPECT (← ($ Window) New))
```

results in the following inspector window:

```
All Values of Window ($ window1).
left NIL
bottom NIL
width 12
height 12
window #, ($AV LispWindowAV ((YI
title NIL
menus T
```

Some of the values assigned to the various instance variables are default values. These values are defined in the class **Window**.

---

**(←New class selector args)**

[Macro]

Purpose: Creates an instance and sends a message to it within one form.

←**New** is pronounced "send new."

Behavior: Is equivalent to the form

```
(← (← class New) selector args)
```

Arguments: *class* Evaluates to a class.

*selector* Name of the message to be sent to the new instance.

*args* Arguments to be sent to the function invoked by the message.

Returns: The new instance.

Example: The command

```
23← (←New ($ Window) Open)
```

creates a new instance of the class **Window** and then sends the message **Open** to the newly created object.

---

**(← self NewInstance name arg1 arg2 arg3 arg4 arg5)**

[Method of Object]

Purpose: Allows initialization of newly created instances by the class of the instance, as opposed to the metaclass. Subclasses of **Object** that specialize this method should have a ←**Super** form within the method to allow the execution of the default behavior.

Behavior: Not normally called directly, but is sent by method **New**. The default behavior is as follows.

If *name* is non-NIL, the message **SetName** is sent to *self*.

Within *self*, instance variables that are bound to the value of **NotSetValue** and have an **:initForm** property in the class description are filled. This allows you to override the **:initForm** behavior by setting values for instance variables before executing the ←**Super** form. See the discussion of **:initForm** in Section 2.3, "Data Storage in Instances at Creation Time."

Sends the message **SaveInstance** to *self* with the argument *name*.

Note: Specializations of the **NewInstance** method should return *self*.

|                  |                                   |                                                                    |
|------------------|-----------------------------------|--------------------------------------------------------------------|
| Arguments:       | <i>self</i>                       | Evaluates to a class.                                              |
|                  | <i>name</i>                       | LOOPS name given to a new instance.                                |
|                  | <i>arg1...arg5</i>                | Optional arguments referenced by user-written specialization code. |
| Returns:         | LOOPS name of new object created. |                                                                    |
| Categories:      | Object                            |                                                                    |
| Specializations: | IndexedObject                     |                                                                    |

(← *class* **NewWithValues** *valDescriptionList*)

[Method of Class]

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:         | Creates a new object and initializes the instance variables specified in <i>valDescriptionList</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                   |
| Behavior:        | Creates the object with no other initialization, directly installs the values and property lists specified in <i>valDescriptionList</i> , and returns the created object. Variables that have no description in <i>valDescriptionList</i> are given no value in the instance and thus inherit the default value from the class.<br><br><b>NewWithValues</b> does not invoke the <b>NewInstance</b> method or the <b>:initForm</b> properties (see Section 2.3, "Data Storage in Instances at Creation Time"). This means that the instance is not recognized by the File Manager; to be recognized, the instance must be named. |                                                                                                                                                                                                                                                                   |
| Arguments:       | <i>class</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Pointer to a class.                                                                                                                                                                                                                                               |
|                  | <i>valDescriptionList</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Evaluates to a list of value descriptions, each of which is a list of variableNames and properties, for example,<br><br>$((\text{VarName1 value1 prop1a propVal1a prop1b propVal1b ...})$ $(\text{VarName2 value2 prop2a propVal2a prop2b propVal2b ...}) \dots)$ |
| Returns:         | The created object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                   |
| Categories:      | Class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                   |
| Specializations: | MetaClass                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                   |
| Example:         | The command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                   |

```
22←(INSPECT (← ($ Window) NewWithValues '((width 300)(height 200))))
```

results in the following inspector window:

```
All Values of Window ($ (MWX0.;F5.o28.Z;
left NIL
bottom NIL
width 300
height 200
window #,($AV LispWindowAV ((YI
title NIL
menus T
```

Contrast the values for the instance variables width and height with the inspector window for **New**, above.

## 2.3 DATA STORAGE IN INSTANCES AT CREATION TIME

### 2.3 DATA STORAGE IN INSTANCES AT CREATION TIME

## 2.3 Data Storage in Instances at Creation Time

When an instance is first created, the value of the variable **NotSetValue** is assigned to its instance variables. **NotSetValue** is initialized to be an active value of the class **NotSetValue** and should not be changed by the user. Trying to access an instance variable triggers this active value which in turn triggers the method **IVValueMissing**.

Data is stored in instances on all Puts and on **GetValues** when the default value is an active value but not **NotSetValue**. Be aware that in reading the value of an instance variable that is not stored in the instance, changes in the default value of the instance variable in the class description are seen in accesses of the instance.

One exception to this method of data storage at creation time is if an instance variable has the property **:initForm** in the class description. In this case, data is stored in the instance at the time of creation.

Testing for whether data is stored locally in the instance can be done in two ways:

- Through the user interface, you can inspect an instance in the local mode. (See Chapter 18, User Input/Output Modules, for more information.) Values not locally stored appear as #,NotSetValue.
- Programmatically, through the function **GetIVHere** with the macro **NotSetValue**.

The following table describes the items in this section.

| Name                  | Type        | Description                                                                                                          |
|-----------------------|-------------|----------------------------------------------------------------------------------------------------------------------|
| <b>IVValueMissing</b> | Method      | Handles cases when an attempt is made to access the value of an instance variable that is not stored in an instance. |
| <b>NotSetValue</b>    | Macro       | Determines if its argument is equivalent to the value of <b>NotSetValue</b> .                                        |
| <b>:initForm</b>      | IV Property | Signals a property value that can be evaluated.                                                                      |

(← *self* **IVValueMissing** *varName propName typeFlg newValue*) [Method of Object]

**Purpose:** Invoked by the system to handle the cases when you try to access the value of an instance variable that is not stored in an instance. This is the mechanism the system uses to access default values.

**Behavior:** Varies according to the functionality that invoked it.

- **GetValueOnly** accesses return the default value of the instance variable stored in the class.
- **GetValue** accesses return the default value of the instance variable stored in the class if it is not an active value. If the default value is an active value, a copy of the active value is made, stored in the instance, and sent the **GetWrappedValue** message.
- **PutValueOnly** accesses store the new value in the instance.
- **PutValue** accesses store the new value in the instance unless the default value of the instance variable stored in the class is an active value. If this is the case, a copy of the active value is made, stored in the instance, and sent the **PutWrappedValue** message.

**Arguments:** *varName* Instance variable name.

*propName* Property name for instance variable *varName*.

*typeFlg* Used internally to indicate the type of access.

*newValue* If called by **PutValueOnly** or **PutValue**, this is the value to be placed into the instance variable or property name.

Returns: Value depends on the functionality that invoked this method; see Behavior.

Categories: Object

**(NotSetValue arg)**

[Macro]

Purpose: Determines if *arg* is **EQ** to the value of **NotSetValue**.

Arguments: *arg* Any value.

Returns: NIL or T.

Example: Given that

```
51←(← ($ Window) New 'w)
#,($& Window (NEW0.1Y%.:;h.eN6 . 515))

then

52←(NotSetValue (GetIVHere ($ w) 'title))
T
```

**:initForm**

[IV property]

Purpose: This allows instance variables to be initialized at the time of the creation of an instance. The **:initForm** property and its value are in the class definition. Its value is a form that is evaluated when an instance is created. The result of the evaluation is stored as the value of the instance variable containing this property in the newly created instance.

This behavior does not hold if the value of the instance variable is not **NotSetValue**. Refer to the method **Object.NewInstance** in Section 2.2, "Creating Instances," for more information.

Example: Given the commands

```
53←(DefineClass 'testclass)
#,($C testclass)

54←(AddCIV ($ testclass) 'date NIL '(:initForm| (DATE)))
date

then

55←(INSPECT (← ($ testclass) New))
```

returns the following inspector window:

```
All Values of testclass ($ (MWX0.:F
date "30-Mar-88 13:53:37")
```

## 2.4 CHANGING THE NUMBER OF INSTANCE VARIABLES IN AN INSTANCE

### 2.4 CHANGING THE NUMBER OF INSTANCE VARIABLES IN AN INSTANCE

## 2.4 Changing the Number of Instance Variables in an Instance

An instance can contain more instance variables than are defined in the class that describes it. It is not possible to remove an instance variable from an instance if the instance variable is defined in the class.

When you try to access the value of an instance variable that is not defined as an instance variable in the instance, the **IVMissing** method is invoked.

The following table shows the functions and methods in this section.

| Name                  | Type     | Description                                                                                                                |
|-----------------------|----------|----------------------------------------------------------------------------------------------------------------------------|
| <b>AddIV</b>          | Function | Adds an instance variable to an instance.                                                                                  |
| <b>AddIV</b>          | Method   | Adds an instance variable to <i>self</i> .                                                                                 |
| <b>DeleteIV</b>       | Function | Removes an instance variable or property from an instance.                                                                 |
| <b>DeleteIV</b>       | Method   | Removes an instance variable or property from <i>self</i> .                                                                |
| <b>ConformToClass</b> | Method   | Makes <i>self</i> contain only those instance variables that are defined or inherited by the class of <i>self</i> .        |
| <b>IVMissing</b>      | Method   | Is sent by the system when an attempt is made to access an instance variable that does not exist. It is used for recovery. |

**(AddIV self name value propName)** [Function]

Purpose: Adds an instance variable to an instance.

Behavior: Varies according to the arguments.

- If *propName* is non-NIL and if *name* already exists, it is added as a property to the instance variable *name* with the value *value*.
- If *name* already exists, and if *propName* is NIL, the value of the instance variable *name* is changed to *value*.
- If *name* does not exist and if *propName* is non-NIL, the instance variable *name* is added to the instance and given the value of the variable **NotSetValue**. It is given the property *propName* with the value *value*.
- If *name* and *propName* already exist, the value of the property *prop* is changed to *value*.

Arguments:

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| <i>self</i>     | A pointer to the instance.                            |
| <i>name</i>     | The name of the instance variable to be added.        |
| <i>value</i>    | The value the new instance variable will be assigned. |
| <i>propName</i> | Property name of instance variable name; may be NIL.  |

Returns: Used for side effect only.

Example: Given that

```
55←(← ($ Window) New 'w)
```

the command

```
56←(AddIV ($ w) 'left 1234)
```

changes the value of the instance variable **left** to 1234. The command

```
57← (AddIV ($ w) 'foo 1234)
```

adds the instance variable **foo** to (\$ w) and gives it the value 1234.

(← *self* **AddIV** *name* *value* *propName*)

[Method of Object]

Purpose: Adds an instance variable to *self*.

Behavior: Method form of the function **AddIV**.

Arguments: See the function **AddIV**.

Returns: NIL

Categories: Object

Specializations: Class

Example: Given that

```
58← (← ($ Window) New 'w)
```

the command

```
59← (← ($ w) AddIV 'left 1234)
```

changes the value of the instance variable **left** to 1234. The command

```
60← (← ($ w) AddIV 'foo 1234)
```

adds the instance variable **foo** to (\$ w) and gives it the value 1234.

(**DeleteIV** *self* *varName* *propName*)

[Function]

Purpose: Removes an instance variable or property from an instance.

Behavior: Varies according to the arguments.

- If *self* does not have *varName*, an error occurs.
- If *varName* is defined in the class or a super class of *self*, an error occurs.
- If the instance *self* has *varName*, and *propName* is NIL, the instance variable is deleted.
- If *propName* is non-NIL, it is deleted only if it is a locally stored property, that is, not defined in a class. If *propName* is not a property of *varName* or is defined in a class, no error occurs.

Arguments: *self* A pointer to the instance from which the instance variable is to be deleted.

*varName* The name of the instance variable to be deleted.

*propName* If non-NIL, specifies that a property, not an instance variable, is to be deleted.

Returns: If no errors occur, this returns *self*.

Example: The following command deletes the instance variable **foo** from (\$ w):

```
62← (DeleteIV ($ w) 'foo)
```

---

(← *self* **DeleteIV** *varName propName*)

[Method of Object]

Purpose: Deletes an instance variable or property from *self*.

Behavior: Method version of the function **DeleteIV**.

Arguments: See the function **DeleteIV**.

Returns: If no errors occur, this returns *self*.

Categories: Object

---

(← *self* **ConformToClass**)

[Method of Object]

Purpose/Behavior: Makes *self* contain only those instance variables that are defined in or inherited by the class of *self*.

Returns: NIL

Categories: Object

Example: This example adds an instance variable to an instance and shows how **ConformToClass** removes it.

```
63←(← ($ Window) New 'w1)
(#, ($& Window (|MXWO.:F5.G18.Z:?.18))

64←(← ($ w1) AddIV 'NewIV 1234)
1234

65←(INSPECT ($ w1))
```

This produces the following inspector window:

```
All Values of Window ($ w1).
left NIL
bottom NIL
width 12
height 12
window #, ($AV LispWindowAV ((YI
title NIL
menus T
NewIV 1234
```

```
66←(← ($ w1) ConformToClass)
NIL

67←(INSPECT ($ w1))
```

This produces the following inspector window:

```
All Values of Window ($ w1).
left NIL
bottom NIL
width 12
height 12
window #, ($AV LispWindowAV ((YI
title NIL
menus T
```

---

(← *self* **IVMissing** *varName propName typeFlg newValue*)

[Method of Object]

Purpose: This message is sent by the system when an attempt is made to access an instance variable that does not exist. It is used for recovery.

Behavior: Varies according to the arguments.

- If the instance variable *varName* is now defined in the class, copy it to *self*. This can happen if the class was changed after the instance was created.
- If there is a class variable with the name *varName*, use it. The method of use is determined by the **:allocation** class variable property:

- `dynamicCached`

Copy the class variable to *self* on puts or gets.

- `dynamic`

Copy the class variable to *self* on puts. If the access is by **GetValue** or **GetValueOnly**, then get the value from the class. The value retrieved from the class is dependent on the value of *propName* and the class variable property **:initform**. If *propName* is NIL and there is a class variable property **:initform**, then retrieve the value returned from evaluating **:initform**. Otherwise, retrieve the value of the class variable *varName* if *propName* is NIL or the value of the property *propName* if it is non-NIL.

- `class` (the default if there is no **:allocation** property)

Do not copy the class variable *varName* to *self*. On puts, store the value in the class. With gets, do the same as the case when the **:allocation** property is dynamic. Essentially, this allows you to access class variables with the same syntax as instance variables.

An attempt is made to correct the spelling of *varName* and try the above steps again before breaking.

Arguments: *self* A pointer to the instance.

*varName* Instance variable name for *self*.

*propName* Property name of instance variable *varName*.

*typeFlg* One of **PutValue**, **PutValueOnly**, **GetValue**, **GetValueOnly**.

*newValue* Value to be stored in *varName*.

Returns: If doing a put, this returns *NewValue*; else this returns the value of the instance variable name.

Categories: Object

Example: If **w1** is a **Window**, then the following command breaks under **Object.IVMissing** because windows do not have an instance variable named **mumble**.

```
(← ($ w1) Get 'mumble)
```

## 2.5 MOVING VARIABLES

## 2.5 MOVING VARIABLES

## 2.5 Moving Variables

These functions allow you to move variables between classes.

| Name                  | Type     | Description                         |
|-----------------------|----------|-------------------------------------|
| <b>RenameVariable</b> | Function | Changes a variable name in a class. |

|                          |          |                                                       |
|--------------------------|----------|-------------------------------------------------------|
| <b>MoveVariable</b>      | Function | Moves an instance variable from one class to another. |
| <b>MoveClassVariable</b> | Function | Moves an class variable from one class to another.    |

---

**(RenameVariable** *className oldVarName newVarName classVarFlg*) [Function]

|            |                                                                                                                                                                                                                                 |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Changes <i>oldVarName</i> to <i>newVarName</i> in class <i>className</i> .                                                                                                                                                      |
| Behavior:  | Can cause inconsistency without warning; does not test for references to the variable in methods of <i>className</i> .                                                                                                          |
| Arguments: | <i>className</i> Class in which function is defined.<br><i>oldVarName</i> Old name of variable.<br><i>newVarName</i> New name of variable.<br><i>classVarFlg</i> If not NIL, then <i>oldVarName</i> refers to a class variable. |
| Returns:   | If successful, returns <i>newVarName</i> ; else NIL.                                                                                                                                                                            |
| Example:   | The following command renames the class variable <b>OldVar</b> to <b>NewVar</b> .<br><pre>27← (RenameVariable (\$ MyClass) 'OldVar 'NewVar T)</pre>                                                                             |

---

**(MoveVariable** *oldClassName newClassName varName*) [Function]

|            |                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Moves an instance variable from <i>oldClassName</i> to <i>newClassName</i> .                                                                   |
| Behavior:  | Moves both the <i>varName</i> instance variable and its description to <i>newClassName</i> . Deletes <i>varName</i> from <i>oldClassName</i> . |
| Arguments: | <i>oldClassName</i> Source class.<br><i>newClassName</i> Destination class.<br><i>varName</i> Variable to be moved.                            |
| Returns:   | Used for side effect only.                                                                                                                     |

---

**(MoveClassVariable** *oldClassName newClassName varName*) [Function]

|            |                                                                                                                                           |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Moves a class variable from <i>oldClassName</i> to <i>newClassName</i> .                                                                  |
| Behavior:  | Moves the class variable <i>varName</i> and its properties to <i>newClassName</i> . Deletes <i>varName</i> from the <i>oldClassName</i> . |
| Arguments: | <i>oldClassName</i> Source class.<br><i>newClassName</i> Destination class.<br><i>varName</i> Class variable to be moved.                 |
| Returns:   | Used for side effect only.                                                                                                                |

## 2.6 DESTROYING INSTANCES

---

## 2.6 Destroying Instances

---

A protocol allows you to customize the behavior of the system at instance destruction time. The naming convention is somewhat asymmetrical to that of creation time. To programmatically influence instance creation, specialize the method **NewInstance**. To programmatically influence instance destruction, specialize the method **Destroy**. Include a (**←Super**) in specializations of **Destroy** to guarantee normal system behavior.

The following table describes the methods in this section.

| Name                   | Type   | Description                                                                                        |
|------------------------|--------|----------------------------------------------------------------------------------------------------|
| <b>Destroy</b>         | Method | Removes an object from the environment.                                                            |
| <b>Destroy!</b>        | Method | Removes an object from the environment. If the object is a class, it also destroys all subclasses. |
| <b>DestroyInstance</b> | Method | Modifies the data structure of an instance as described above.                                     |

---

(**← self Destroy**) [Method of Object]

---

Purpose: Removes an object from the environment.

Behavior: Sends the **DestroyInstance** message with *self* as an argument to the class of *self*. **UnmarkedAsChanged** is called to remove the instance from the notice of the File Manager.

Arguments: *self*          A pointer to the instance.

Returns: Used for side effect only.

Categories: Object

Specializations: Class, DestroyedClass, IndexedObject, Window

Example: The following command destroys an instance named **window1**.

```
70← (← ($ window1) Destroy)
```

---

(**← self Destroy!**) [Method of Object]

---

Purpose/Behavior: Removes an object from the environment. If the object is a class, it also destroys all subclasses.

Arguments: *self*          A pointer to the instance.

Returns: Used for side effect only.

Categories: Object

Specializations: Class, DestroyedClass, DestroyedObject

---

(**← class DestroyInstance instance**) [Method of Class]

---

Purpose/Behavior: Destroys *instance* by overwriting its contents. When an instance is destroyed, several things occur:

- The instance is removed from any files on **FILELST**. See the *Interlisp-D Reference Manual*.
- The instance is deleted from system hash tables used for maintaining object identities.
- The class of the instance is changed to **DestroyedObject**.
- Other fields of the internal instance data structure are set to NIL.

If an instance is only pointed to by a LOOPS name, its data structure is freed for garbage collection.

Arguments: *class*        Class of *instance*.  
*instance*      The instance being destroyed.

Returns: Used for side effect only.

Categories: Class

Specializations: MetaClass, DestroyedClass

---

## 2.7 METHODS CONCERNING THE CLASS OF AN OBJECT

---

### 2.7 METHODS CONCERNING THE CLASS OF AN OBJECT

---

---

## 2.7 Methods Concerning the Class of an Object

---

Given an instance, you often need to manipulate the class of an instance. This section describes how to perform this manipulation.

| Name               | Type     | Description                                                                   |
|--------------------|----------|-------------------------------------------------------------------------------|
| <b>ChangeClass</b> | Method   | Changes the class of an instance.                                             |
| <b>Class</b>       | Macro    | Determines the class of an object.                                            |
| <b>Class</b>       | Method   | Determines the class of an object.                                            |
| <b>ClassName</b>   | Function | Returns the class name of an object.                                          |
| <b>ClassName</b>   | Method   | Returns the class name of an object.                                          |
| <b>InstOf</b>      | Method   | Determines if <i>self</i> is an instance of a class.                          |
| <b>InstOf!</b>     | Method   | Determines if <i>self</i> is an instance of a class or any of its subclasses. |

You can also compute a class corresponding to a Lisp data type for Lisp objects by using **GetLispClass**, described in Chapter 4, Metaclasses.

---

(← *self* **ChangeClass** *newClass*) [Method of Object]

---

Purpose: Changes the class of an instance.

Behavior: Creates a blank instance of the *newClass*. Any instance variables that are locally stored within *self* are added to the new instance.

---

If *newClass* is not the name of a class or a pointer to the class, an error occurs.

Arguments: *self* A pointer to an instance.  
*newClass* Either the name of a class or a pointer to the class.

Returns: *self*

Categories: Object

Specializations: IndexedObject

Example: Create an instance of class **Window** and assign a local value to the instance variable **width** - all other instance variables of (\$ w) lack local values. Then, when the class of (\$ w) is changed to **IndirectVariable**, (\$ w) will have all of the instance variables of its new class, plus the one instance variable of its old class which had a local value, **width**.

```
71←(← ($ Window) New 'w)
#,$& Window (NEW0.1Y%.:;h.eN6 . 501))

72←(←@ ($ w) width 123)
123

73←(← ($ w) ChangeClass 'IndirectVariable)
#,$& IndirectVariable (NEW0.1Y%.:;h.eN6 . 502))

74←(← ($ w) Inspect)
```

This produces the following inspector window:

| All Values of Indi |     |
|--------------------|-----|
| object             | NIL |
| varName            | NIL |
| propName           | NIL |
| type               | NIL |
| width              | 123 |

---

(Class *self*)

[Macro]

Purpose: Determines the class of an object.

Behavior: If *self* is a LOOPS object, return its class.  
If *self* is not a LOOPS object, evaluate (**GetLispClass** *self*)

Arguments: *self* A pointer to a LOOPS or Lisp object.

Returns: Value depends on the arguments; see Behavior.

Example: Given that

```
75←(← ($ Window) New 'window1)
#,$& Window (NEW0.1Y%.:;h.eN6 . 503))

then

76←(Class ($ window1))
#,$C Window)
```

Note: If *self* is an annotated value, the method **Class** and the macro **Class** return different values. See Chapter 8, Active Values, for more information on annotated values.

---

(← *self* **Class**)

[Method of Object]

Purpose/Behavior: Method version of the macro **Class**.

Arguments: *self* A pointer to a LOOPS object or a Lisp data structure.

Returns: Value depends on the arguments; see Behavior of the macro **Class**.

Categories: Object

Example: Given that

```
77←(← ($ Window) New 'window1)
#,$& Window (NEW0.1Y%.:;h.eN6 . 504))

then

78←(← ($ window1) Class)
#,$C Window
```

---

(**ClassName** *self*)

[Function]

Purpose: Returns the class name of the class of the object.

Behavior: Varies according to the argument.

- If *self* is a class, this returns the name of that class.
- If *self* is an instance, this returns the name of the class that describes that instance.
- If *self* is neither of these, an attempt is made to get the class of *self* by applying the function **GetLispClass** to *self*. If this returns NIL, the function **LoopsHelp** is called with the arguments *self* and "has no class name."

Arguments: *self* Can have multiple values; see Behavior.

Returns: Value depends on the argument; see Behavior.

Example: The command

```
80←(ClassName ($ Window))

returns

Window
```

---

(← *self* **ClassName**)

[Method of Object]

Purpose/Behavior: Method version of the function **ClassName**.

Arguments: See the function **ClassName**.

Returns: Value depends on the arguments; see Behavior of the function **ClassName**.

Categories: Object

---

(← *self* **InstOf** *class*)

[Method of Object]

Purpose/Behavior: Determines if *self* is an instance of *class*.

Arguments: *self* A pointer to an instance.

*class* A symbol name of a class or a pointer to a class.

Returns: T or NIL

Categories: Object

Example: Given that

```

83←(← ($ Window) New 'w1)
#, ($& Window (NEW0.1Y%:.;h.eN6 . 505))

then

84←(← ($ w1) InstOf 'Window)
T

85←(← ($ w1) InstOf ($ Window))
T

```

(← *self* **InstOf!** *class*) [Method of Object]

Purpose: Determines if *self* is an instance of *class* or any of *class*'s subclasses.

Behavior: Tests if class of *self* is a subclass of *class*.

Arguments: *self* A pointer to an instance.  
*class* A symbol name of a class or a pointer to a class.

Returns: Object

Categories: Object

2.8 COPYING INSTANCES

## 2.8 COPYING INSTANCES

## 2.8 Copying Instances

This section describes the methods for copying instances.

| Name               | Type   | Description                                                                                                                                                    |
|--------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CopyDeep</b>    | Method | Copies all nested objects, annotated values, and lists.                                                                                                        |
| <b>CopyShallow</b> | Method | Creates a new instance of the same class as <i>oldInstance</i> . Fills the instance variables of the new instance with the data contained in the old instance. |

(← *oldInstance* **CopyDeep** *newObjAList*) [Method of Object]

Purpose: Copies all nested objects, annotated values, and lists. All other values are shared, not copied. This method is similar to the Interlisp function **COPYALL**.

Behavior: Creates a new instance of the same class as *oldInstance*. Fills the instance variables of the new instance with copies of lists, active values, and instances pointed to by *oldInstance*.

Arguments: *oldInstance* A pointer to an instance.  
*newObjAList*

An association list of old copied objects with their associated copies; used to allow copying of circular structures. Users typically let this argument default to NIL.

Returns: The value of the new instance.

Categories: Object

Example: Create the class **CopyTest** with the following structure:

```
SEdit CopyTest Package: INTERLISP
((MetaClass Class Edited%: ; Edited 22-Mar-88
 ; 11:07 by jrb:
)
 (Supers Object) (ClassVariables)
 (InstanceVariables (var NIL)
 (list NIL)
 (instance NIL))
 (MethodFns))
```

Create the instance **CopyTest1** and initialize it as shown in the following inspector:

```
All Values of CopyTest ($ CopyTest1).
var 123
list (ABC)
instance #,($ CopyTest2)
```

Now create a copy and inspect it.

```
(INSPECT (SETQ DeepCopy (← ($ CopyTest1) CopyDeep)))
```

```
All Values of CopyTest ($ (MUX0.:F5.G18.?7C . 517)).
var 123
list (ABC)
instance #,($ CopyTest (MUX0.?:F5.G18.?7C . 518))
```

The value of the instance variable **instance** is different. Also,

```
(EQ (@ ($ CopyTest1) list) (@ DeepCopy list))
```

returns NIL.

(← *oldInstance* **CopyShallow**)

[Method of Object]

Purpose/Behavior: Creates a new instance of the same class as *oldInstance*. Fills the instance variables of the new instance with the data contained in the old instance.

Arguments: *oldInstance*  
A pointer to an instance.

Returns: A copy filled with the values shared by the instances.

Categories: Object

Example: Compare this example to the **CopyDeep** example above. Use the same **CopyTest1** instance as above.

```
(INSPECT (SETQ ShallowCopy (← ($ CopyTest1) CopyShallow)))
```

```

All Values of CopyTest ($ CopyTest1).
var 123
list (ABC)
instance #, ($ CopyTest2)

```

The value of the instance variable **instance** is the same. Also,

```
(EQ (@ ($ CopyTest1) list) (@ ShallowCopy list))
```

returns T.

## 2.9 QUERYING STRUCTURE OF INSTANCES

## 2.9 QUERYING STRUCTURE OF INSTANCES

## 2.9 Querying Structure of Instances

At run time, user-written code may need to determine the structure of some object which has been passed into it. This section describes the methods to do this.

| Name                  | Type   | Description                                                                                            |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------|
| <b>HasCV</b>          | Method | Determines if a class variable can be accessed via <i>self</i> .                                       |
| <b>HasIV</b>          | Method | Determines if an instance variable can be accessed via <i>self</i> .                                   |
| <b>Inspect</b>        | Method | Inspects <i>self</i> as a class or instance.                                                           |
| <b>ListAttribute</b>  | Method | Determines instance variable or instance variable property names contained in an instance.             |
| <b>ListAttribute!</b> | Method | Recursively determines instance variable or instance variable property names contained in an instance. |
| <b>WhereIs</b>        | Method | Searches the supers hierarchy to find a class where a specified name is defined.                       |

(← *self* **HasCV** *cvName* *propName*) [Method of Object]

Purpose: Returns T if the class variable *cvName* (or its property *propName* if it is non-NIL) can be accessed via *self*; otherwise NIL.

Behavior: Sends the message **HasCV** to the class of *self* passing the arguments *cvName* and *propName*.

Arguments: *self*            A pointer to an instance or a class.  
*cvName*            Class variable name  
*propName*        Property name for class variable *cvName*.

Returns: T or NIL; see Behavior.

Categories: Object

Specializations: Class

Example: The following command checks if an instance **window1** has the class variable **RightButtonItem**:

```
87← (← ($ window1) HasCV 'RightButtonItem)
T
```

---

(← *self* **HasIV** *ivName* *propName*)

[Method of Object]

Purpose/Behavior: Returns T if the instance variable *ivName* (or its property *propName* if it is non-NIL) can be accessed via *self*; otherwise NIL.

Arguments: *self* A pointer to an instance or a class.  
*ivName* Instance variable name.  
*propName* Property name for instance variable *ivName*.

Returns: T or NIL; see Behavior.

Categories: Object

Specializations: Class

---

(← *self* **Inspect** *INSPECTLOC*)

[Method of Object]

Purpose/Behavior: Inspects *self* as a class or an instance. Uses *INSPECTLOC* as the region for the inspector window if it is given.

Arguments: *self* A pointer to an instance.  
*INSPECTLOC* The region for the inspector window. If NIL, the system prompts you to place the window.

Returns: The Lisp window used by the inspector.

Categories: Object

Example: The following command inspects an instance (\$ window1)

```
88← (← ($ window1) Inspect)
```

This results in the following inspector window:

The image shows a terminal window titled "All Values of Window (\$ window1)". It displays a list of instance variables and their values: left is NIL, bottom is NIL, width is 12, height is 12, window is #, (\$AV LispWindowAV ((YI, title is NIL, and menus is T.

```
All Values of Window ($ window1).
left NIL
bottom NIL
width 12
height 12
window #, ($AV LispWindowAV ((YI
title NIL
menus T
```

---

(← *self* **ListAttribute** *type* *name*)

[Method of Object]

Purpose: Determines instance variable or instance variable property names contained in an instance.

Behavior: Converts *type* into uppercase on entry. The remaining behavior varies according to the arguments.

- If *type* is one of IV, IVPROPS, or NIL, and *name* is the name of an instance variable of *self*, this returns a list of property names of *name* that have property values locally stored in the instance.

- If *type* is IVS, this returns a list of the instance variable names of *self*, whether or not the values for the instance variables are locally stored.
- If *type* is none of the above, this evaluates (`← (Class self) ListAttribute type name`).

Note: Using a *type* of **SUPERS** or **SUPERCLASSES** returns a list of the names of the super classes.

Arguments: *self* A pointer to an instance.  
*type* See Behavior.  
*name* If *type* is one of IV, IVPROPS, or NIL, then *name* is an instance variable of *self*; else it is NIL.

Returns: Value depends on the arguments; see Behavior.

Categories: Object

Specializations: Class

Example: Given that

```
90←(← ($ Window) New 'w1)
#,($& Window (NEW0.1Y%.:;h.eN6 . 515))
```

then

```
91←(← ($ w1) ListAttribute 'IVS)
(left bottom width height title menus)
```

```
92←(← ($ w1) ListAttribute 'IV 'menus)
NIL
```

After opening (`$ w1`), positioning the cursor anywhere on the window, and pressing the left and right mouse buttons to create some menus, then

```
93←(← ($ w1) ListAttribute 'IV 'menus)
(LeftButtonItem RightButtonItem)
```

(`← self ListAttribute! type name verboseFlg`)

[Method of Object]

Purpose: Provides a recursive form of **ListAttribute**. Omits inheritance from the classes **Object** and **Tofu** unless *verboseFlg* is T.

Behavior: Converts *type* into uppercase on entry. The remaining behavior varies according to the arguments.

- If *type* is IVS, this is the same as **ListAttribute**.
- If *type* is one of IV, IVPROPS, or NIL, and *name* is the name of an instance variable of *self*, this returns a list of property names of *name*.
- If *type* is none of the above, this evaluates (`← (Class self) ListAttribute! type name`).

Note: Using a *type* of **SUPERS** or **SUPERCLASSES** returns a list of the names of the super classes.

Arguments: *self* A pointer to an instance.  
*type* See Behavior.  
*name* If *type* is one of IV, PROPS, or NIL, then *name* is an instance variable of *self*; else it is NIL.

*verboseFlag* T or NIL; if T, inheritance from object and **Tofu** are included. If NIL, they are omitted.

Returns: Value depends on the arguments; see Behavior.

Categories: Object

Specializations: Class

Example: Given that

```
95←(← ($ Window) New 'w1)
#,$& Window (NEW0.1Y%:.;h.eN6 . 515))
```

then

```
96←(← ($ w1) ListAttribute! 'IV 'menus)
(RightButtonItem doc TitleItems ...)
```

Purpose: Searches supers hierarchy to find class where *name* is defined.

Behavior: Performs the method **Class.ListAttribute** for *self* and for each super class of *self*, checking to see if *name* (or *propName* as appropriate) is a member of the list returned. The value returned is the class where *name* (or *propName*) is first found.

The *type* argument is changed to uppercase and then coerced to a valued type argument for **ListAttribute**.

- If *type* is one of METHOD, METHODS, NIL, or T, it becomes METHODS. **WhereIs** then looks for a method with the name *name*.
- If *type* is one of IVPROP or IVPROPS, it becomes IVPROPS. **WhereIs** then looks for an instance variable property with the name *name*.
- If *type* is one of IV or IVS, it becomes IVS. **WhereIs** then looks for an instance variable with the name *name*.
- If *type* is one of CV or CVS, it becomes CVS. **WhereIs** then looks for a class variable with the name *name*.

Arguments: *self* A pointer to an instance.  
*type* See Behavior.  
*name* The name of an object attribute being searched for.  
*propName* Property name for instance variable *name*.

Returns: The class where *name* or *propName* is first found.

Categories: Object

Example: The command

```
97←(← (← ($ LatticeBrowser) New) WhereIs 'left 'IV)
returns
#, ($C Window)
```

2.10 OTHER INSTANCE ITEMS

---

2.10 OTHER INSTANCE ITEMS

---

---

## 2.10 Other Instance Items

---

This section describes other items involved with instances.

---

### NoValueFound

---

[Variable]

Purpose/Behavior: Returned as a result of various accesses; initially set to NIL. When developing code, rebind this to the symbol **NoValueFound** to assist in debugging.

---

### (NoValueFound *arg*)

---

[Macro]

Purpose/Behavior: Returns value of (EQ **NoValueFound** *arg*).

Arguments: *arg* Any value.

Returns: T or NIL.

**(ValueFound *arg*)**

[Macro]

Purpose/Behavior: Returns value of (NEQ **NoValueFound** *arg*).

Arguments: *arg* Any value.

Returns: T or NIL.

[This page intentionally left blank]

Classes provide a description of instances within the object domain. The following information is contained within a class:

- The metaclass for this class. See Chapter 4, Metaclasses, for a discussion of metaclasses.
- Class Properties. Examples of class properties are an edit stamp and documentation.
- The supers list for this class. Classes exist in a hierarchy and the supers list places the class within that hierarchy. Instances of the class contain data and respond to messages that are described within the class and superclasses of the class.
- Class variables, their values, and their properties and values.
- Instance variables, their default values, and their properties and values.

This chapter covers creating and destroying classes, editing, accessing data stored in classes, inheritance, and related topics. Other chapters that contain information relevant to this chapter are Chapter 4, Metaclasses, since a metaclass is a class of classes, and Chapter 10, Browsers, since the primary user interface for manipulating classes is the browser.

---

## 3.1 Creating Classes

---

Several ways are available to create a class:

- Use the browser interface.
- Use function calling or message sending.
- Use dynamic mixins to dynamically create classes.

The rules for naming classes are the same as those for naming instances. Simply stated, a class name must be a litatom. One exception to this rule is the naming of dynamic mixin classes, which is discussed later in this chapter.

A class is generally referred to with this form: (\$ className). See Chapter 2, Instances, for more details regarding LOOPS names.

As discussed in Chapter 2, Instances, the protocol that is followed when instances are created is for the LOOPS system to send the **NewInstance** message to the newly created instance. The **NewInstance** message can be specialized to incorporate behavior specific to the creation time of an instance. Similarly, the system follows a protocol when creating a class using the **New** message. After the class is created, it is sent the **NewClass** message.

3.1.1 Function Calling and Message Sending

The following table shows the items in this section.

| Name               | Type     | Description                                                       |
|--------------------|----------|-------------------------------------------------------------------|
| <b>DefineClass</b> | Function | Creates a new class.                                              |
| <b>New</b>         | Method   | Creates a new class.                                              |
| <b>CreateClass</b> | Method   | Creates a new class.                                              |
| <b>NewClass</b>    | Method   | Provides a placeholder for modifying the class creation protocol. |

**(DefineClass** *name supers self*) [Function]

Purpose: Creates a new class.

Behavior: If *name* is not a litatom, a break occurs.

- If *supers* is non-NIL, it should be a list of classes or names of classes to be the supers for the newly created class. If the list contains multiple classes, this results in a class that has multiple super classes (see Section 3.3, "Inheritance"). The order of classes in the list specifies the order in which lookup will proceed. If one of the these classes is not a valid class, a break occurs.
- If *supers* is NIL and if *self* is (\$ MetaClass), then the supers list is (Class).
- If both *supers* is NIL and *self* is NIL, the supers list is (Object).

If *self* is non-NIL, it is installed as the metaclass for the newly created class. See Chapter 4, Metaclasses.

A class is then built with an **Edited:** property containing the date and time and the value of variable **INITIALS**. (See the *Interlisp-D Reference Manual*.)

The newly created class has no class variables, instance variables, or methods.

The variable **LASTWORD** is set to *name*, which is added to **USERWORDS** for spelling escape completion. (See the *Interlisp-D Reference Manual* for information on **LASTWORD** and **USERWORDS**.)

Arguments: *name* A LOOPS name to be given to the class.

*supers* A list of classes.

*self* A metaclass.

Returns: The class object.

Examples: The following command defines a subclass of the class **Object**.

```
(DefineClass 'ExampleClass)
```

The following command defines a subclass of the class **Window**.

```
(DefineClass 'MyClass '(Window))
```

The following command defines a class with multiple supers: **ExampleClass** and **Window**.

```
(DefineClass 'AnotherClass '(ExampleClass Window))
```

The following command defines a subclass of the class **Window** that has **AbstractClass** as its metaclass.

```
(DefineClass 'DontMakeMe ' (Window) ($ AbstractClass))
```

---

(← *class* **New** *name* *supers* *init1* *init2* *init3*) [Method of Metaclass]

---

Purpose: Creates a new class.

Behavior: Sends the message **CreateClass** to *class*, passing the arguments *name* and *supers*. This returns a new class which is then sent the message **NewClass** passing the arguments *init1*, *init2*, and *init3*.

Arguments: *class* A pointer to a class.  
*name* A LOOPS name to be given to the class.  
*supers* A list of classes.  
*init1, init2, inti3*  
See Behavior.

Returns: The new class.

Categories: Object

Specializes: Class

Specializations: AbstractClass

Example: The following command creates the class, **AClass**, which is a subclass of the class **Window**. The metaclass of **AClass** is **Class**.

```
(← ($ Class) New 'AClass ' (Window))
```

After **AClass** is created, the system sends the following message:

```
(← ($ AClass) NewClass)
```

---

(← *self* **CreateClass** *name* *supers*) [Method of Metaclass]

---

Purpose: Creates a new class.

Behavior: Method version of **DefineClass**.

Arguments: *self* A metaclass.  
*name* The name of the newly created class.  
*supers* A list of classes.

Returns: The class object.

Categories: MetaClass

---

(← *class* **NewClass** *init1* *init2* *init3*) [Method of Class]

---

Purpose: Provides a hook into class initialization. If you want special actions to occur when creating a class, specialize this method.

Arguments: *class* A pointer to a class.  
*init1, init2, init3*  
Dependent on user-defined functionality.

Returns: `class`

Categories: `Class`

Example: Create a subclass of **Class** called **MyClass**:

```
(DefineClass 'MyClass ' (Class))
```

Give it a method **NewClass**:

```
(DefineMethod ($ MyClass) 'NewClass ' (init1 init2 init3)
' (PROGN (PutClass self init1 'prop1) self))
```

This looks like the following display editor window:

```
SEdit MyClass.NewClass Package: INTERLISP
(Method ((MyClass NewClass) self init1 init2 init3)
;; This demonstrates the NewClass protocol
(PutClass self init1 'prop1) self)
```

Now send the class **MyClass** the following command:

```
(← ($ MyClass) New 'testclass NIL "this is a test")
```

This results in the creation of the class shown in the following display editor window:

```
SEdit #,($C testclass) Package: INTERLISP
((MetaClass MyClass Edited%: ; Edited 2-Dec-87
; 15:24 by
; Martin.pasa
prop1 "this is a test")
(Supers Object) (ClassVariables)
(InstanceVariables) (MethodFns))
```

To display the class, enter

```
(← ($ testclass) Edit)
```

---

### 3.1.2 Dynamic Mixins

In some programming situations, you may develop sets of mixins that are designed to be used together. (Mixins are classes that are used only in conjunction with another class to create a subclass, or provide some functionality useful in more than one class.) For example, the class **NamedClass** adds one instance variable **name** and specializes the **New** message to ensure that the instance variable **name** contains the name of the object.

```
(DefineClass 'NamedClass)
(← ($ NamedClass) AddIV 'name)
(DefineMethod ($ NamedClass) 'New ' (self name)
' (←@ (←self NewInstance name) name name))
```

Other classes that want the names of their objects in an instance variable **name** can use **NamedClass** as a mixin.

As another example, assume that you have one set consisting of **A1**, **A2**, **A3**, and **A4** and another set containing **B1**, **B2**, and **B3**. Formerly, to allow creation of an instance taking properties from arbitrary combinations of an element from each set, you had to create in advance all 12 combinations of classes with a super from **A** and a super from **B**. This was even more cumbersome if the **As** and **Bs** can also combine with any of a set of 5 **Cs**.

What is desired is the ability to create combinations of these classes on the fly, without having to invent a name for each combination and without having each present in the system when only a few may be needed in any given application. To meet this need, LOOPS now provides the dynamic mixin class. The name of such a class is a list, in order, of the classes which are to be the supers of the class. Such a class is automatically created the first time it is referred to. Thus, the following sequence

```
(DefineClass 'A)
(DefineClass 'B)
(← ($ (A B)) New)
```

creates the class whose supers are **A** and **B** (if it did not already exist), and builds an instance of that class.

Dynamic mixins appear in browsers as shown in this sample window.

All of the browser operations still function on dynamic mixin classes.

These classes print as

```
#, ($C (A B))
```

## 3.2 DESTROYING CLASSES

### 3.2 DESTROYING CLASSES

## 3.2 Destroying Classes

The following messages have been provided to destroy a class that has been created. Destroyed classes, if not being pointed to in some fashion, are eventually collected by the garbage collector.

The following table shows the methods in this section.

| Name                | Type   | Description                                |
|---------------------|--------|--------------------------------------------|
| <b>Destroy</b>      | Method | Removes a class from the LOOPS system.     |
| <b>Destroy!</b>     | Method | Destroys a class and its subclasses.       |
| <b>DestroyClass</b> | Method | Destroys a class by deleting its contents. |

(← class **Destroy**)

[Method of Class]

Purpose: Removes a class from the LOOPS system.

Behavior: If *self* has any subclasses, a break occurs and you are prompted to determine if you want to use **Destroy!**.

Sends the message **DestroyClass** to the metaclass of *self*.

Specializations of this method may be necessary to undo any actions that might have been performed by user specializations of the **NewClass** method. If you specialize **Destroy**, be sure to include a ←**Super** to guarantee that the functionality of the **Destroy** method is performed.

### 3.1 CREATING CLASSES

---

Arguments: *class*      Must be a class.

Returns: NIL

Categories: Object

Specializes: Object

Specializations: DestroyedClass

Example: The following command destroys the class **Datum**:

(← (\$ Datum) Destroy)

---

(← *class* **Destroy!**)

[Method of Class]

Purpose: Destroys a class and its subclasses.

Behavior: Recursively sends the **Destroy** message to *self* and its subclasses.

Arguments: *class*      Must be a class.

Returns: NIL

Categories: Object

Specializes: Object

Specializations: DestroyedClass

---

(← *class* **DestroyClass** *classToDestroy*)

[Method of Class]

Purpose: Destroys *classToDestroy* by deleting its contents. This method is invoked by the LOOPS system and should generally not be called directly by user code. However, it can be specialized to change the way classes are destroyed.

Behavior: Performs the following actions:

- Removes *classToDestroy* from any files on **FILELST**.
- Sends the **Destroy!** message to all methods locally associated with *classToDestroy*.
- Removes *classToDestroy* from any subclass data contained in the supers of *classToDestroy*.
- Changes the class name of *classToDestroy* to **\*aDestroyedClass\***.
- Changes the supers list of *classToDestroy* to **DestroyedObject** and **Object**.
- Changes the metaclass of *classToDestroy* to **DestroyedClass**.
- Sets other fields of the internal class data structure to NIL.

Arguments: *class*      Metaclass of *classToDestroy*.

*classToDestroy*  
Class to destroy.

Returns: NIL

Categories: Class

Specializations: DestroyedClass

---

## 3.3 Inheritance

---

Classes exist in an ordered lattice or hierarchy. Information contained within a class - the supers list - defines where that class is located within the lattice. The supers list specifies the classes immediately above a given class. When an instance of a class is created, it contains not only the instance variables of the defining class, but also the instance variables of all of the classes above the defining class in the class hierarchy. When you try to determine the value of a class variable associated with an instance, all classes above the defining class may be searched. When you send a message to an instance, all classes above the defining class may be searched for the appropriate method.

There are two types of inheritance:

- Simple, in which a class has only one superclass.
- Multiple, in which a class has two or more classes on its supers list.

When an instance is created, it may contain an instance variable that is defined in more than one class. The default value for that instance variable depends on its inheritance. In the case of simple inheritance, the instance variable gets the value from the class that is lowest in the hierarchy. In multiple inheritance, the instance variable gets the value from the class that is lowest in an inheritance list. To create this list,

1. Put the first class that describes the instance.
2. Begin with the first class on its supers list and move up from it, making a list of classes which assume simple inheritance.
3. Build one of these lists for all successive super classes.
4. Append these lists together.
5. Remove all occurrences of any classes that appear in the list a multiplicity of times except for the last entry.

Another way to think about this, which creates the same inheritance list, is the following:

1. Begin with the first super class and walk up the hierarchy until you reach a class where the inheritance paths merge.
2. Walk up each path leading from each successive super class to where paths merge.
3. Take the class where the paths merge and walk up from there.

As an example of simple inheritance, examine Figure 3-1 which shows some of the class variables and instance variables defined within each class.

Figure 3-1. Simple Inheritance Lattice

An instance of the class **ClassBrowser** has this as an inheritance list:

ClassBrowser  
 LatticeBrowser  
 Window  
 Object  
 Tofu

The instance variable values of this instance are as follows:

| IV            | Value           | From Class            |
|---------------|-----------------|-----------------------|
| <b>title</b>  | "Class browser" | <b>ClassBrowser</b>   |
| <b>width</b>  | 64              | <b>LatticeBrowser</b> |
| <b>height</b> | 32              | <b>LatticeBrowser</b> |
| <b>menus</b>  | T               | <b>Window</b>         |

Accessing the value of the class variable **LeftButtonItems** causes this value to come from the class **ClassBrowser**.

Figure 3-2 shows an example of multiple inheritance.

Figure 3-2. Multiple Inheritance Lattice

If the order of the supers for **Class5** is **Class3** and then **Class4** (that is, its supers list is (Class3 Class4 )), then the inheritance list for an instance of **Class5** is as follows:

**Class5**  
**Class3**  
**Class4**  
**Class2**  
**Class1**

The instance variable and class variable values this instance are as follows:

| IV  | Value | From Class    | CV  | Value | From Class    |
|-----|-------|---------------|-----|-------|---------------|
| iv1 | 11    | <b>Class1</b> | cv1 | A4    | <b>Class4</b> |
| iv2 | 22    | <b>Class2</b> | cv2 | B     | <b>Class1</b> |
| iv3 | 33    | <b>Class3</b> | cv3 | C     | <b>Class3</b> |
| iv4 | 45    | <b>Class5</b> | cv4 | D4    | <b>Class4</b> |

3.4 EDITING CLASSES

## 3.4 EDITING CLASSES

---

## 3.4 Editing Classes

---

Changing the contents of a class typically involves using the display editor, although programmatical ways to make these changes are available. To edit a class structure, the LOOPS system first changes the structure to a list and then passes that list to the display editor. Upon exit from the display editor, the system translates the modified list back into the class structure.

The editor is most often called from the browser interface. (See Chapter 10, Browsers.) The following method provides a programmatical way to invoke the editor.

---

(← *class* **Edit** *commands*)

[Method of Class]

Purpose: Edits a class definition.

Behavior: Calls **EDITE** (see the *Interlisp-D Reference Manual*) with the translated class structure passed as the **EXPR** argument and *commands* passed as the **COMS** argument.

This method binds the variable **LASTCLASS** to the class name of *self*.

Arguments: *class*        Pointer to a class.  
*commands*    Commands passed to **EDITE**.

Returns: Name of the class.

Categories: Object

Specializes: Object

Example: The following command causes a display editor window to appear.

```
(← ($ LoopsIcon) Edit)
```

Calling the editor causes a structure to appear in a display editor window. At this time, you can change the structure of the class by using any of the following techniques:

- Changing the value of the class's metaclass. This is done by changing the class name after the word **MetaClass**.
- Changing the superclasses for the class. The form for this is :

```
(Supers class1 class2 ...)
```

At least one class must be in the supers list. The order of this list determines the order of inheritance; the first class after the word **Supers** on this list is the first class to search for inherited data and methods.

- Adding or removing class properties. Class properties occur within the same list as **MetaClass**, after the metaclass class name. The form for this is

```
(MetaClass metaclassName classProp1 propVal1 classProp2
propVal2 ...)
```

- Adding or removing class variables or associated properties. The form for class variables is:

```
(ClassVariables
(cvName1 cvVal1 prop1a propVal1a prop1b propVal1b ...)
(cvName2 cvVal2 prop2a propVal2a prop2b propVal2b ...)
...)
```

It is not necessary to have any properties for a class variable. If the length of each class variable list is not an even number, a break occurs under the editor. The message in the break window describes an odd length list the first time you try to exit from the editor.

- Adding or removing instance variables or associated properties. These have the same form as class variables with the distinction that the value listed for each instance variable is not its value, but only its default value for the purposes of instantiation.

For example, examine the display editor window in Figure 3-3.

```
SEdit #,($C IndirectVariable) Package: INTERLISP
((MetaClass Class doc
 (* Active Value for redirecting references to another
 variable)
 Edited%: (* smL " 9-May-86 09:52"))
 (Supers ActiveValue) (ClassVariables)
 (InstanceVariables
 (object NIL doc (* The object with the "real" variable))
 (varName NIL doc (* The name of the "real" variable))
 (propName NIL doc (* The prop name of the "real" variable))
 (type NIL doc (* The type of the "real" variable)))
 (MethodFns IndirectVariable.GetWrappedValueOnly
 IndirectVariable.PutWrappedValueOnly
 IndirectVariable.WrappingPrecedence))
```

Figure 3-3. Sample Display Editor Window

This figure shows the following information:

- The title bar of the display editor window indicates the class being edited.
- The metaclass of the class **IndirectVariable** in this example is the class **Class**. **IndirectVariable** has two class properties. The first is a **doc** property. The second is an **Edited:** property.
- This class has one super class: **ActiveValue**.
- This class has no class variables. It has four instance variables: **object**, **varName**, **propName**, and **type**. Each has a **doc** property.
- The **MethodFns** are listed in this structure as a convenience. It is not possible to add or delete elements of this list from the editor and have any changes actually occur. Selecting one of the method function names and then selecting Edit (Meta-O in SEdit) allows you to edit that method either as its method code (METHOD-FNS), its method object (METHODS), or its Interlisp code (FNS).

### 3.5 MODIFYING CLASSES

### 3.5 MODIFYING CLASSES

## 3.5 Modifying Classes

In addition to the editing technique for changing a class, you can use programmatic means to modify the structure of a class. This section describes the functions and methods for modifying classes.

| Name          | Type   | Description                       |
|---------------|--------|-----------------------------------|
| <b>Add</b>    | Method | Adds a component to a class.      |
| <b>Delete</b> | Method | Deletes a component from a class. |

|                        |          |                                                                           |
|------------------------|----------|---------------------------------------------------------------------------|
| <b>DeleteClassProp</b> | Function | Removes a class property from a class.                                    |
| <b>AddCV</b>           | Function | Adds a class variable to a class.                                         |
| <b>AddCV</b>           | Method   | Adds a class variable to a class.                                         |
| <b>DeleteCV</b>        | Function | Deletes a class variable or one of its properties from a class.           |
| <b>AddCIV</b>          | Function | Adds an instance variable to a class; can also add properties to a class. |
| <b>AddIV</b>           | Method   | Adds an instance variable to a class.                                     |
| <b>DeleteCIV</b>       | Function | Removes an instance variable or property from a class.                    |
| <b>ReplaceSupers</b>   | Method   | Changes the super classes of a class.                                     |

---

(← *class* **Add** *type name value prop*) [Method of Class]

---

Purpose/Behavior: Adds a component to a class.

Arguments:

|              |                                                                    |
|--------------|--------------------------------------------------------------------|
| <i>class</i> | Pointer to a class.                                                |
| <i>type</i>  | One of IV, IVPROP, CV, CVPROP, METAClass, or METHOD.               |
| <i>name</i>  | The name of the item to be added.                                  |
| <i>value</i> | The value, or default value if <i>type</i> is one of IV or IVPROP. |
| <i>prop</i>  | The name of the property, if a property is to be added.            |

Returns: NIL

Categories: Class

Example: The following command adds a new instance variable **color** to class **Datum**:

```
(← ($ Datum) Add 'IV 'color)
```

---

(← *class* **Delete** *type name prop*) [Method of Class]

---

Purpose: Deletes a component from a class.

Behavior: Varies according to the arguments.

- If *type* is one of IV, IVPROP, or NIL, this calls (**DeleteCIV** *class name prop*).
- If *type* is one of CV or CVPROP, this calls (**DeleteCV** *class name prop*).
- If *type* is META, METAClass, or CLASS, and if *prop* is NIL, then the metaclass of *self* is changed to the class **Class**.
- If *type* is META, METAClass, or CLASS, and if *prop* is non-NIL, then this calls (**DeleteClassProp** *class prop*).
- If *type* is METHOD or SELECTOR, this calls (**DeleteMethod** *class name prop*).

Arguments:

|              |                           |
|--------------|---------------------------|
| <i>class</i> | A pointer to a class.     |
| <i>type</i>  | See Behavior.             |
| <i>name</i>  | IV, CV, or selector name. |

*prop*            A property name.

Returns:    NIL

Categories:    Class

Example:    The following command deletes the instance variable **color** from the class **Datum**:

```
(← ($ Datum) Delete 'IV 'color)
```

---

**(DeleteClassProp classRec propName)** [Function]

Purpose:    Removes a class property from a class.

Behavior:    Marks *classRec* as changed.

Arguments:    *classRec*    Pointer to a class.

*propName*    Property to be deleted.

Returns:    NIL if *propName* is not found; otherwise *propName*.

---

**(AddCV class varName newValue)** [Function]

Purpose:    Adds a class variable to a class.

Behavior:    Varies according to the arguments.

- If *varName* is NIL, you are prompted to enter a name.
- If *varName* is already a class variable, its value is changed to *newValue*. NIL is returned.
- If *varName* is not a class variable of *class*, it is added to *class* with the value *newValue*. Also, a **doc** property is added with the following value:

```
`(* CV added by , (USERNAME NIL T))
```

*varName* is returned in this case.

Arguments:    *class*            A pointer to a class.

*varName*        Name of the new variable.

*newValue*        The new value.

Returns:    Value depends on the arguments; see Behavior.

---

**(← class AddCV varName newValue)** [Method of Class]

Purpose:    Adds a class variable to a class.

Behavior:    Provides a method version of the function **AddCV**.

Arguments:    See the function **AddCV**.

Returns:    NIL

Categories:    Class

---

**(DeleteCV class varName prop)** [Function]

Purpose: Deletes a class variable or one of its properties from a class.

Behavior: Marks *class* as changed.

Arguments: *class* Pointer to a class.  
*varName* Class variable name to be deleted.  
*prop* Property to be deleted.

Returns: NIL, if *varName* is not found, else *varName*.

---

(**AddCIV** *class varName defaultValue otherProps*) [Function]

---

Purpose: Adds an instance variable, and perhaps properties, to a class.

Behavior: If the length of *otherProps* is odd, an error occurs.

The remaining behavior varies according to the arguments.

- If *varName* is NIL, you are prompted to enter a name.
- If *varName* is already an instance variable of *class*, then change its default value to *defaultValue*. Properties on *otherProps* are added or changed as necessary. NIL is returned.
- If *varName* is not an instance variable of *class*, it is added to *class* and its default value is *defaultValue*. Properties on *otherProps* are also added. If there is no **doc** property, it is added and given the following value:  

```
`(* IV added by , (USERNAME NIL T))
```

*varName* is returned in this case.

Arguments: *class* Must be a pointer to a class.  
*varName* New instance variable name.  
*defaultValue* New default value.  
*otherProps* NIL or a list in property list format.

Returns: Value depends on the arguments; see Behavior.

---

(**← class AddIV** *varName defaultValue otherProps*) [Method of Class]

---

Purpose: Adds an instance variable to a class.

Behavior: Provides a method version of the function **AddCIV**.

Arguments: See the function **AddCIV**.

Returns: NIL

Categories: Object

Specializes: Object

Example: Define a new class **TestClass**, add an instance variable **testIV** with two properties **testProp1** and **testProp2**, all with initial values, and then prettyprint the class's variables.

```
64← (DefineClass 'TestClass)
#, ($C TestClass)
```

```

65←(← ($ TestClass) AddIV 'testIV 1234
'(testProp1 1 testProp2 2))
testIV

66←(← ($ TestClass) PPV! T)
#,$ TestClass)
MetaClass and its Properties
Class Edited: (* edited: 24-Sep-87 08:41 by mcgill)
Supers
(Object Tofu)
Instance Variable Descriptions
testIV 1234 doc (* IV added by MCGILL)
testProp2 2 testProp1 1
Class Variables

```

**(DeleteCIV class varName prop)**

[Function]

- Purpose:** Removes an instance variable or property from a class.
- Behavior:** If *class* does not have *varName*, a break occurs.  
Marks *class* as changed.
- Arguments:** *class*            Pointer to a class.  
*varName*       Instance variable to be deleted.  
*prop*           If non-NIL, property to be deleted.
- Returns:** Value depends on the arguments.
- NIL for removing an instance variable if successful.
  - *prop* for removing a property if successful.
  - NIL if *prop* is not a property.

**(← class ReplaceSupers supers)**

[Method of Class]

- Purpose:** Changes the super classes of a class.
- Behavior:** Checks that no circular lists can be made in the inheritance lattice.
- If the super class of *class* is Tofu, no change occurs.
  - If *supers* is different from the current *supers*, the *supers* list of *class* is changed and *class* is marked as changed.
- Arguments:** *class*            Pointer to a class.  
*supers*           A list of class names or classes.
- Returns:** NIL
- Categories:** Class

## 3.6 METHODS FOR MANIPULATING CLASS NAMES

## 3.6 METHODS FOR MANIPULATING CLASS NAMES

## 3.6 Methods for Manipulating Class Names

LOOPS classes must have one and only one LOOPS name. The following functions and methods allow you to change and rename class names.

| Name             | Type     | Description                                                                                |
|------------------|----------|--------------------------------------------------------------------------------------------|
| <b>Rename</b>    | Method   | Changes the name of a class. Prompts for name if not provided, then calls <b>SetName</b> . |
| <b>SetName</b>   | Method   | Changes the name of a class.                                                               |
| <b>UnSetName</b> | Method   | Unnames a class.                                                                           |
| <b>ClassName</b> | Function | Finds the class name of an object.                                                         |

(← *class* **Rename** *newName*) [Method of Class]

Purpose: Changes the name of a class. Prompts for name if not provided, then calls **SetName**.

Behavior: Varies according to the argument.

- If *newName* is NIL, this causes a break and prompts you for a name. **Rename** then sends the message **SetName** passing this name as an argument
- If *newName* is non-NIL, **Rename** sends the message **SetName** passing *newName* as an argument.

Arguments: *class*      Pointer to a class.  
*newName*      A litatom.

Returns: NIL

Categories: Object

Specializes: Object

Example: The following command renames class **Datum** to **Thing**:

```
(← ($ Datum) Rename 'Thing)
```

(← *class* **SetName** *newClassName*) [Method of Class]

Purpose: Changes the name of a class.

Behavior: Removes the old name of *self* from **ObjNameTable**.

**SetName** uses the Interlisp-D function **EDITCALLERS** to rename references to the class name or any file that contains the class. If **EDITCALLERS** cannot succeed, for example, when a file is not RANDACCESSP, a message is printed that the class cannot be renamed on that file. For complete information on **EDITCALLERS**, see the *Interlisp-D Reference Manual*.

The names of the method functions of *class* are changed to use *newClassName*.

Arguments: *class*      Pointer to a class.  
*newClassName*  
                     A litatom.

Returns: NIL  
 Categories: Object  
 Specializes: Object

(← *class* **UnSetName**)

[Method of Class]

Purpose: Unnames a class, but does not destroy it. Has limited usefulness for keeping a class name from being typed in.

Behavior: Removes *class* from the LOOPS name hash table and from any files on **FILELST**. This method is intended to be used internally only; it is not recommended to create an unnamed class.

Arguments: *class*      Pointer to a class.

Returns: NIL

Categories: Object

Specializes: Object

(**ClassName** *self*)

[Function]

Purpose: Finds the class name of an object.

Behavior: Varies according to the arguments.

- If *self* is a class, this returns the name of that class.
- If *self* is an instance, this returns the name of the class that describes that instance.
- If *self* is neither a class or an instance, this returns **Tofu**.

Arguments: *self*      See Behavior.

Returns: Value depends on the arguments; see Behavior.

Example: Given that

```
(← ($ Window) New 'w1)
```

the commands

```
(ClassName ($ w1))
(ClassName ($ Window))
```

both return **Window**.

### 3.7 QUERYING THE STRUCTURE OF A CLASS

#### 3.7 QUERYING THE STRUCTURE OF A CLASS

## 3.7 Querying the Structure of a Class

The following functions and methods allow you to query what is contained in a class.

| Name | Type | Description |
|------|------|-------------|
|------|------|-------------|

|                       |          |                                                                                     |
|-----------------------|----------|-------------------------------------------------------------------------------------|
| <b>GetClassProp</b>   | Method   | Obtains a class's metaclass or properties.                                          |
| <b>HasAttribute</b>   | Method   | Determines whether <i>self</i> has an attribute name.                               |
| <b>HasAttribute!</b>  | Method   | Recursive form of <b>HasAttribute</b> , but works only on classes.                  |
| <b>HasCV</b>          | Method   | Determines if a class has a class variable with a specified property.               |
| <b>HasItem</b>        | Method   | Determines if a class has an item of a given type.                                  |
| <b>HasIV</b>          | Method   | Determines if a class has an instance variable with a specified property.           |
| <b>HasIV!</b>         | Method   | Same as <b>HasIV</b> , except that <b>HasIV!</b> also searches up the supers chain. |
| <b>ListAttribute</b>  | Method   | Lists the elements of a class that are local to the class.                          |
| <b>ListAttribute!</b> | Method   | Lists all the items associated with a class.                                        |
| <b>WhoHas</b>         | Function | Determines what classes contains a specified item.                                  |

---

(← *class* **GetClassProp** *propname*) [Method of Class]

---

Purpose: Obtains a class's metaclass or properties by following metaclass links.

Behavior: Varies according to the arguments.

- If *propname* is NIL, this returns the *class*'s metaclass.
- If *propname* is non-NIL, this looks first in *class* for that property. If it cannot find it there, it looks through *class*'s metaclass links.
- If no property is found, the value of the variable **NotSetValue** is returned.

Arguments: *class* A pointer to a class.  
*prop* Property name.

Returns: Value depends on the arguments; see Behavior.

Categories: Class

Example: The following commands show the variety of responses.

```
51←(← ($ Window) GetClassProp)
#, ($C Class)

52←(← ($ Window) GetClassProp 'doc)
"A LOOPS object which represents a window"

53←(← ($ IconWindow) GetClassProp 'doc)
"An icon window that appears as an irregular shaped image
on the screen -- See the ICONW Library utility"
```

---

(← *self* **HasAttribute** *type name propname*) [Method of Class]

---

Purpose: Determines whether *self* has an attribute name, with a property *propname* if supplied.

Behavior: *self* can be an instance or a class. Remaining behavior depends on *type*, which is converted to uppercase on entry:

- If *type* is IV, IVPROP, or NIL, this returns T if *self* has an instance variable of *name*, with a property called *propname* (if *propname* is non-NIL), otherwise it returns NIL.
- If *type* is CV or CVPROP, this returns T if *self* has a CV called *name*, with a property of *propname* (if *propname* is non-NIL), otherwise it returns NIL.
- If *type* is METHOD or SELECTOR, this returns NIL or the name of the method implementing *name*.

**HasAttribute** applied to an instance reports on the actual state of the instance; it sees all instance variables and class variables whether local, inherited, or specially added to the instance. If only local attributes are required, use ( $\leftarrow$  (Class instance) HasAttribute ...).

Arguments: *self* Can be an instance or a class.  
*type* See Behavior.  
*name* A symbol which is looked up as the variable or method name.  
*propname* A symbol which is looked up as the property name.

Returns: See Behavior.

Categories: Object

Specializations: Class

Example: The command

```
($\leftarrow$ ($ LoopsIcon) HasAttribute 'IV 'icon)
```

returns T.

( $\leftarrow$  class **HasAttribute!** *type name propname*)

[Method of Class]

Purpose: Recursive form of **HasAttribute**; only works on classes

Behavior: Similar to **HasAttribute**, but will also search through *class* 's supers.

Arguments: *class* A class.  
*type* See Behavior under **HasAttribute**.  
*name* A symbol which is looked up as the variable or method name.  
*propname* A symbol which is looked up as the property name.

Returns: See Behavior.

Categories: Object

Specializations: Class

Example: The command

```
($\leftarrow$ ($ LoopsIcon) HasAttribute 'IV 'left)
```

returns NIL, but

```
($\leftarrow$ ($ LoopsIcon) HasAttribute! 'IV 'left)
```

returns T.

---

(← *class* **HasCV** *cvName prop*)

[Method of Class]

Purpose: Determines if a class has a class variable *cvName* with a property *prop*.

Note: The preferred form of this method is **HasAttribute** or **HasAttribute!**.

Behavior: Varies according to the arguments.

- If *prop* is NIL, this returns T if *class* contains a class variable called *cvName*, else NIL.
- If *prop* is non-NIL, this returns T if *class* contains a class variable called *cvName* with the property *prop*, else NIL.

Note: **HasCV** does not distinguish between locally defined class variables and inherited class variables. If you need to test a class to see if it has a class variable defined locally, you can use the **HasAttribute** method. For example, the form (←MyClass HasAttribute 'CV 'ABC) will return a non-NIL value if and only if the class **MyClass** has a local definition of the class variable ABC.

Arguments: *class*            A pointer to a class.  
*cvName*            A class variable name.  
*prop*            Property name.

Returns: NIL or T; see Behavior.

Categories: Object

Specializes: Object

Example: The command

```
(← ($ Window) HasCV 'TitleItems)
```

returns T.

---

(← *class* **HasItem** *itemName prop itemType*)

[Method of Class]

Purpose: Determines if a class has an item of a given type.

Note: The preferred form of this method is **HasAttribute** or **HasAttribute!**.

Behavior: Varies according to the arguments.

- If *itemType* is IV or IVS, this sends the message (← *class* **HasIV** *itemName prop*).
- If *itemType* is CV or CVS, this sends the message (← *class* **HasCV** *itemName prop*).
- If *itemType* is SELECTOR, METHOD, SELECTORS, or METHODS, this finds the corresponding local method of *class*.
- If *itemType* is not one of the above, this returns NIL.

Arguments: *class*            Pointer to a class.  
*prop*            Property name.  
*itemType*       See Behavior.

Returns: Value depends on the arguments; see Behavior.

Categories: Class

(← class **HasIV** *IVName prop*) [Method of Class]

Purpose: Determines if a class has an instance variable *IVName* with a property *prop*.

Note: The preferred form of this method is **HasAttribute** or **HasAttribute!**.

Behavior: *class* should point to a class.

- If *prop* is NIL, this returns T if *IVName* is contained in *class*.
- If *prop* is non-NIL, this returns T if *IVName* is contained in *class*, and *prop* is a property of *IVName* in *class* or one of its supers.

Arguments: *class* Pointer to a class.

*IVName* Instance variable name.

*prop* Property name.

Returns: Value depends on the arguments; see Behavior.

Categories: Object

Specializes: Object

(← class **HasIV!** *IVName prop*) [Method of Class]

Purpose/Behavior: Same as **HasIV**, except that **HasIV!** also searches up the supers chain.

Note: The preferred form of this method is **HasAttribute** or **HasAttribute!**.

Arguments: See the method **HasIV**.

Returns: Value depends on the arguments; see Behavior.

Categories: Class

(← class **ListAttribute** *type name*) [Method of Class]

Purpose: Lists the elements of a class that are local to the class.

Behavior: *type* is converted to uppercase on entry. The remaining behavior varies according to the arguments.

- If *type* is IVS, this returns the instance variable names (not values) local to *class*. *name* is ignored.
- If *type* is IV, IVPROPS, or NIL, *name* should be bound to an instance variable of *class*. This returns the property names (not values) of the instance variable *name*. If *name* is not an instance variable of *class*, this returns NIL.
- If *type* is CVS, this returns the class variables local to *class*. *name* is ignored.
- If *type* is CV or CVPROPS, *name* should be bound to a class variable of *class*. This returns the property names of the class variable *name*. If *name* is not a class variable of *class*, this returns NIL.

- If *type* is METHODS or SELECTORS, this returns the selectors for the class. *name* is ignored.

Arguments:    *class*            Pointer to a class.  
              *type*            See Behavior.  
              *name*            See Behavior.

Returns:      Value depends on the arguments; see Behavior.

Categories:   Object

Specializes:   Object

Example:      The following commands show the variety of responses.

```
55←(← ($ SupersBrowser) ListAttribute 'IVs')
(title)
```

```
56←(← ($ Window) ListAttribute 'iv 'menus)
(DontSave Title LeftButtonItem MiddleButtonItem TitleItems doc)
```

```
57←(← ($ IconWindow) ListAttribute 'METHODS')
(GetMenuItems)
```

---

(← *class* **ListAttribute!** *type name verboseFlg*)

[Method of Class]

Purpose:       Lists all items associated with a class.

Behavior:     Provides a recursive version of **ListAttribute**.

If *verboseFlg* is NIL, items that are inherited from Tofu, Object, or Class are omitted, unless *class* is one of Tofu, Object, or Class.

*type* is converted to uppercase on entry.

- If *type* is META or METAClass, this returns the same as **ListAttribute**.
- If *type* is IVS or NIL, this returns the instance variables an instance of *class* would have.
- If *type* is SUPERS or SUPERCLASSES, this returns the ordered list of super classes of *class*.
- If *type* is SUBS or SUBCLASSES, this returns all of the subclasses of *class*.
- If *type* is any other option that can be passed to **ListAttribute**, this returns all local and inherited values.

Arguments:    *class*            Pointer to a class.  
              *type*            See Behavior.  
              *name*            A litatom.  
              *verboseFlg*    See Behavior.

Returns:      Value depends on the arguments; see Behavior.

(WhoHas *name type files editFlg*)

[Function]

|            |                                                                                                                                                                                       |                                                                                    |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Purpose:   | Determines what classes contain a specified item.                                                                                                                                     |                                                                                    |
| Behavior:  | Returns a list of classes on <i>files</i> that contain <i>name</i> . If <i>editFlg</i> is non-NIL, then edit the methods (if <i>type</i> is METHOD), or the classes before returning. |                                                                                    |
| Arguments: | <i>name</i>                                                                                                                                                                           | The item specified.                                                                |
|            | <i>type</i>                                                                                                                                                                           | One of IV, CV, METHOD, or Method. If <i>type</i> is NIL, it defaults to METHOD.    |
|            | <i>files</i>                                                                                                                                                                          | A file or a list of files. If <i>files</i> is NIL, it defaults to <b>FILELST</b> . |
|            | <i>editFlg</i>                                                                                                                                                                        | T or NIL.                                                                          |
| Returns:   | A list of classes on <i>files</i> that contain <i>name</i> .                                                                                                                          |                                                                                    |

## 3.8 COPYING CLASSES AND THEIR CONTENTS

## 3.8 COPYING CLASSES AND THEIR CONTENTS

## 3.8 Copying Classes and Their Contents

Inheritance lets classes be described in terms of other classes in a hierarchical manner. When it is preferable to duplicate a class description in different parts of a lattice these methods provide the capability.

The following table shows the methods in this section.

| Name          | Type   | Description                                   |
|---------------|--------|-----------------------------------------------|
| <b>Copy</b>   | Method | Copies a class.                               |
| <b>CopyCV</b> | Method | Copies a class variable to another class.     |
| <b>CopyIV</b> | Method | Copies an instance variable to another class. |

(← class **Copy** *name*)

[Method of Class]

|             |                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| Purpose:    | Makes a copy of a class.                                                                                                      |
| Behavior:   | If <i>name</i> is NIL, you are prompted to supply a name for the new class. This copies variables and properties and methods. |
| Arguments:  | <i>class</i> The class being copied.                                                                                          |
|             | <i>name</i> The name of the copy.                                                                                             |
| Returns:    | The new class.                                                                                                                |
| Categories: | Class                                                                                                                         |
| Example:    | Given that                                                                                                                    |

```
(DefineClass 'Datum)
(← ($ Datum) AddIV 'something)
```

the following command makes a copy of class **Datum** and names it **Thing**:

```
(← ($ Datum) Copy 'Thing)
```

(← class **CopyCV** *cvName toClass*)

[Method of Class]

|                   |                                                                                                                |                                         |
|-------------------|----------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| Purpose/Behavior: | Copies a class variable to another class. This also copies the properties of <i>cvName</i> to <i>toClass</i> . |                                         |
| Arguments:        | <i>class</i>                                                                                                   | The source class.                       |
|                   | <i>cvName</i>                                                                                                  | The name of the class variable to copy. |
|                   | <i>toClass</i>                                                                                                 | The destination class.                  |
| Returns:          | NIL                                                                                                            |                                         |
| Categories:       | Class                                                                                                          |                                         |

---

(← *class* **CopyIV** *ivName toClass*)

[Method of Class]

|                   |                                                                                                                    |                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| Purpose/Behavior: | Copies an instance variable to another class. This also copies the properties of <i>ivName</i> to <i>toClass</i> . |                                            |
| Arguments:        | <i>class</i>                                                                                                       | The source class.                          |
|                   | <i>ivName</i>                                                                                                      | The name of the instance variable to copy. |
|                   | <i>toClass</i>                                                                                                     | The destination class.                     |
| Returns:          | NIL                                                                                                                |                                            |
| Categories:       | Class                                                                                                              |                                            |

3.9 ENUMERATING INSTANCES OF CLASSES

---

3.9 ENUMERATING INSTANCES OF CLASSES

---

---

## 3.9 Enumerating Instances of Classes

---

New instances may be created without names, or without being tracked. These methods allow you to produce a list of instances according to their classes. **Prototype** instances are a convenience used where the methods defined for a class must be used, but there is no logical instance for the class.

The following table shows the items in this section.

| Name                 | Type   | Description                                                                                    |
|----------------------|--------|------------------------------------------------------------------------------------------------|
| <b>AllInstances</b>  | Method | Finds all instances of a class.                                                                |
| <b>AllInstances!</b> | Method | Finds all instances of a class or its subclasses.                                              |
| <b>IndexedObject</b> | Class  | Keeps track of instances so that <b>AllInstances</b> searches can proceed more rapidly.        |
| <b>PrintOn</b>       | Method | Modifies how instances of <b>IndexedObject</b> that do not have LOOPS names will be printed.   |
| <b>Prototype</b>     | Method | Returns an instance of a class that is stored on the class's class variable <b>Prototype</b> . |

---

(← *class* **AllInstances**)

[Method of Class]

|          |                                 |
|----------|---------------------------------|
| Purpose: | Finds all instances of a class. |
|----------|---------------------------------|

|             |                                                                                                                                                                                                                                                                          |          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| Behavior:   | Checks if <i>class</i> is a subclass of <b>IndexedObject</b> . If so, a faster search is used to find all of the instances of <i>class</i> . If not, this checks if each object is an instance of <i>class</i> . Instances that do not yet have a UID will not be found. |          |
| Arguments:  | <i>class</i>                                                                                                                                                                                                                                                             | A class. |
| Returns:    | A list of the instances found.                                                                                                                                                                                                                                           |          |
| Categories: | Class                                                                                                                                                                                                                                                                    |          |
| Example:    | The following command produces a list of all the LOOPS window instances:<br><br>61← (← (\$ Window) AllInstances)                                                                                                                                                         |          |

(← *class* **AllInstances!**)

[Method of Class]

|             |                                                                                                                                                                                                                                                                                         |                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Purpose:    | Finds all instances of a class or its subclasses.                                                                                                                                                                                                                                       |                       |
| Behavior:   | Returns a list of instances that are instances of <i>class</i> or any of its subclasses. Instances that do not have the class <b>IndexedObject</b> as a super class, or that do not yet have a UID are not found. (See Chapter 18, Reading and Printing, for more information on UIDs.) |                       |
| Arguments:  | <i>class</i>                                                                                                                                                                                                                                                                            | A pointer to a class. |
| Returns:    | A list of the instances found.                                                                                                                                                                                                                                                          |                       |
| Categories: | Class                                                                                                                                                                                                                                                                                   |                       |

**IndexedObject**

[Class]

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:         | Keeps track of instances so that <b>AllInstances</b> searches can proceed more rapidly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                |
| Behavior:        | This class is to be used as a <b>Mixin</b> (an addition superclass), and should be the first class on a supers list for a class.<br><br><b>IndexedObject</b> provides <b>NewInstance</b> and <b>Destroy</b> protocols that cause instances to be added to or removed from a global list when they are created or destroyed. This global list allows the <b>AllInstances</b> protocols to search more quickly.<br><br><b>IndexedObject</b> also provides a <b>PrintOn</b> protocol that modifies how instances will be printed if they have no LOOPS name. |                                                                                                                                                                                                                                                                                |
| MetaClass:       | Class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                |
| Supers:          | Object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                |
| Class Variables: | <b>IdentifierVar</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | The name of an instance variable which will contain a string which could provide some identification to the user. Used in <b>PrintOn</b> if variable is in object and filled. <b>shortName</b> , the value of this class variable, is the default variable name which is used. |

(← *self* **PrintOn**)

[Method of IndexedObject]

|           |                                                                                                                                                                                             |  |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Purpose:  | Modifies how instances of <b>IndexedObject</b> that do not have LOOPS names will be printed.                                                                                                |  |
| Behavior: | If <i>self</i> has a LOOPS name, or if <i>self</i> does not have an instance variable with a name equal to (@ <i>self</i> ::IdentifierVar), then do a (← <b>Super</b> ). Otherwise, build a |  |

form that incorporates the value of the instance variable *IV* referenced by (*@self ::IdentifierVar*).

Arguments: *self*            An instance.

Returns:    A list ; see example

Categories:    Object

Specializes:    Object

Example:    Create a class, **IndexedObjectTest**, that has this structure.

```
62← (DefineClass 'IndexedObjectTest ' (IndexedObject))
#, ($C IndexedObjectTest)

63← (← ($ IndexedObjectTest) AddIV 'shortName 'ioTest)
shortName
```

Create an instance.

```
64← (SETQ test (← ($ IndexedObjectTest) New))
#, ($& IndexedObjectTest (YMW0.0X%:>T4.n18 . 36))

65← (←@ test shortName 'changeName)
changeName

66← (← test PrintOn)
("#, " $& IndexedObjectTest (changeName (YMW0.0X%:>T4.n18 . 36)))
```

---

(← *class* **Prototype** *newProtoFlg*)

[Method of Class]

Purpose:    Returns a prototype instance of a class.

Behavior:    Varies according to the arguments.

- If *class* has a class variable **Prototype** and the variable's value is an instance of *class*, return the value (assuming *newProtoFlg* is NIL).
- If there is no class variable **Prototype**, or if there is a class variable **Prototype** but its value is not an instance of *class*, or if *newProtoFlg* is non-NIL, then create a new instance of *class*, store the instance on the class variable **Prototype**, and return the instance.

See **Proto** in Chapter 7, Message Sending Forms, for more information.

Arguments: *class*            A class.

*newProtoFlg*  
If non-NIL, create a new prototype instance.

Returns:    The prototype.

Categories:    Class

Example:    LOOPS defines an icon to make it easy to bring up class browsers and file browsers. The icon is the **Prototype** instance of the class **LoopsIcon**.

To move the icon to the center of the bottom of the screen, enter

```
71← (←Proto ($ LoopsIcon) Move (QUOTIENT SCREENWIDTH 2) 0)
(576 . 0)
```

This places the left edge of the icon at the center of the screen. To move the icon to the center of the screen, enter

```

72←(LET ((icon (← ($ LoopsIcon) Prototype)))
 (← icon Move (QUOTIENT (DIFFERENCE SCREENWIDTH
 (@ icon width))
 2)
 0))
(544 . 0)

```

## 3.10 DEALING WITH INHERITANCE

## 3.10 DEALING WITH INHERITANCE

## 3.10 Dealing with Inheritance

The inheritance lattice for classes shows how methods and variables are shared (see Chapter 10, Browsers, for details on how to graph the lattice on the screen). To programmatically inspect and add to this lattice via **Specialize**, use the following functions and methods:

| Name                 | Type     | Description                                           |
|----------------------|----------|-------------------------------------------------------|
| <b>Fringe</b>        | Method   | Finds the leaves of a branch of an inheritance tree.  |
| <b>Specialize</b>    | Method   | Creates a subclass of a class.                        |
| <b>SubClasses</b>    | Method   | Returns a list of subclasses.                         |
| <b>Subclass</b>      | Method   | Determines if a class is a subclass of another class. |
| <b>AllSubClasses</b> | Function | Computes the subclasses of a class.                   |
| <b>SubsTree</b>      | Function | Computes all the names of the subclasses of a class.  |

(← *class* **Fringe**) [Method of Class]

**Purpose:** Finds the leaves of a branch of an inheritance tree.

**Behavior:** Returns a list of subclasses of *class*, whether close or distant, that have no subclasses.

**Arguments:** *class*      A class, the root of the tree to explore.

**Returns:** Names of subclasses of *class* that have no subclasses.

**Categories:** Class

**Example:** The following commands show the variety of responses.

```

73←(← ($ Window) Fringe)
(InstanceBrowser MetaBrowser SupersBrowser FileBrowser
LoopsIcon IconWindow)

```

```

74←(← ($ ClassBrowser) Fringe)
(MetaBrowser SupersBrowser FileBrowser)

```

(← *class* **Specialize** *newName*) [Method of Class]

**Purpose:** Creates a subclass of a class.

**Behavior:** Creates a class with *class* as its only super.

- If *newName* is non-NIL, this is the name of the new class.

- If *newName* is NIL, this creates a name consisting of the name of *class* followed by an integer.

Arguments: *class*            Pointer to a class.  
*newName*    Name of the new subclass.

Returns:    The new class.

Categories: Class

Example:    Given that

```
(DefineClass 'Datum)
```

the following command creates a specialization of the class **Datum** called **DatumX**:

```
(← ($ Datum) Specialize 'DatumX)
```

---

(← *class* **SubClasses**)

[Method of Class]

Purpose:     Returns a list of subclasses.

Behavior:   The classes returned by this are the immediate subclasses of *class*.

Arguments: *class*            A pointer to a class.

Returns:    A list of subclasses.

Categories: Class

Specializations: DestroyedClass

Example:    The following command gets a list of the subclasses of the class **Window**:

```
(← ($ Window) SubClasses)
```

---

(← *class* **Subclass** *super*)

[Method of Class]

Purpose:     Determines if a class is a subclass of another class.

Behavior:   If *class* is a subclass of *super*, *super* is returned, else NIL.

Arguments: *class*            Pointer to a class.

*super*        Either the LOOPS name of a class or a pointer to a class.

Returns:    Value depends on the arguments; see Behavior.

Categories: Class

Example:    The command

```
(← ($ DestroyedClass) Subclass 'Class)
```

returns

```
#, ($C Class)
```

---

(**AllSubClasses** *class* *currentSubs*)

[Function]

Purpose:     Computes the subclasses of a class.

Behavior: This is a recursive function that computes (without duplicates) all of the subclasses of *class*.

Arguments: *class* Must be a pointer to a class, for example, (\$ Window).  
*currentSubs* Used by LOOPS; NIL when called by the user.

Returns: A list of classes.

Example: The command  
 (AllSubClasses (\$ LatticeBrowser))  
 returns  
 (#, (\$C FileBrowser) #, (\$C SupersBrowser)  
 #, (\$C MetaBrowser) #, (\$C ClassBrowser)  
 #, (\$C InstanceBrowser))

**(SubsTree class currentList)**

[Function]

Purpose: Computes the names of the subclasses of a class.

Behavior: Provides a recursive function that computes (without duplicates) all of the names of the subclasses of *class*.

Arguments: *class* Can be a class name or a pointer to a class  
*currentList* Used internally by **SubsTree**; it should be NIL when called by the user.

Returns: A list of class names.

Example: The command  
 (SubsTree 'LatticeBrowser)  
 returns  
 (InstanceBrowser ClassBrowser MetaBrowser SupersBrowser  
 FileBrowser)

## Overview of the Manual

---

The *LOOPS Reference Manual* provides a detailed description of all the methods, functions, classes, and other items available in the Lisp Object-Oriented Programming System, LOOPS. This manual describes the Medley Release of LOOPS, which runs under Medley.

This manual is for people who are familiar with LOOPS programming principles, and is not intended to teach you LOOPS or how to use it. Please contact your LOOPS distributor for information about classes and training material.

---

## Organization of the Manual and How to Use It

---

This manual is divided into chapters, with most chapters focusing on a particular aspect of LOOPS. The organization of this manual is similar to the *Interlisp-D Reference Manual*.

A Table of Contents is included at the beginning of the manual to help you find specific material. At the end of the manual, a Glossary is included to define terms within the context of LOOPS.

All readers should review Chapter 1, Introduction, before referring to specific material.

---

## Conventions

---

This manual uses the following conventions:

- Case is significant in LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type. Optional arguments are indicated by a dash (-).
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a message sending form appears as follows:

(← self **Selector** *Arg1 Arg2* -)

- Examples appear in the following typeface:

89← (←LOGIN)

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Method names often appear in the form **ClassName.SelectorName**.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the LOOPS items (functions, methods, etc.) by using the following template:

|                  |                                                                                                                                                                                                                                                                                                                                                                     |                 |             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------|
| Purpose:         | Gives a short statement of what the item does.                                                                                                                                                                                                                                                                                                                      |                 |             |
| Behavior:        | Provides the details of how the item operates.                                                                                                                                                                                                                                                                                                                      |                 |             |
| Arguments:       | Describes each argument in the following format:<br><br><table> <tr> <td><i>argument</i></td><td>Description</td></tr> </table>                                                                                                                                                                                                                                     | <i>argument</i> | Description |
| <i>argument</i>  | Description                                                                                                                                                                                                                                                                                                                                                         |                 |             |
| Returns:         | States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.                                                                               |                 |             |
| Categories:      | A way to group related methods. For example, all the methods related to Masterscope on the class <b>FileBrowser</b> have the category Masterscope, not <b>FileBrowser</b> . This item appears only for methods.                                                                                                                                                     |                 |             |
| Specializes:     | The next higher class in the class hierarchy that contains a method with the same selector; only appear for methods. For example, <b>the manual entry for RectangularWindow.Open</b> would say that it specializes <b>Window.Open</b> , since <b>Window</b> is the first superclass of <b>RectangularWindow</b> that implements a method for <b>Open</b> .          |                 |             |
| Specializations: | The next lower class(es) in the class hierarchy that contains method(s) with the same selector; only appears for methods. For example, the manual entry for <b>Window.Open</b> would say that it has a specialization of <b>RectangularWindow.Open</b> since <b>RectangularWindow</b> is a subclass of <b>Window</b> and has its own version of <b>Open</b> method. |                 |             |
| Example:         | An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See Chapter 18, Reading and Printing, for details.                                                                                                                     |                 |             |

In object-oriented programming, every object is described by a class. Instances are described by classes and classes are, in turn, described by metaclasses. The methods that an instance inherits are defined in the class definition of that instance and the methods that the class inherits are defined in the metaclass definition of that class's metaclass. Sending a message to an instance invokes method in class. Similarly, sending a message to class invokes method in metaclass.

The two classes **Class** and **MetaClass** are metaclasses of other classes. If **Class** or **MetaClass** refers to the metaclass, it appears in a bold typeface.

One method defined by a class's metaclass is **New**, which returns a new instance of a class. Different classes can initialize their instances in different ways. For example, one class may need to have certain values assigned to instance variables at creation, while another does not. The different forms of **New** are defined in separate metaclasses.

A class's metaclass is assigned when the class is created. A new class is created by sending a metaclass the message **New** or by specializing an already existing class. In the latter case, the metaclass defaults to the metaclass of the class's super class. The class's metaclass can be changed by directly editing the class definition.

This chapter discusses the metaclasses provided with LOOPS, describes pseudoclasses, explains how to define new metaclasses, and discusses the root class **Tofu**.

## 4.1 Specific Metaclasses

This section describes the metaclasses provided by LOOPS: **Class**, **MetaClass**, **AbstractClass**, and **DestroyedClass**. These metaclasses are shown in Figure 4-1.

Figure 4-1. Class Browser Showing Metaclasses

### 4.1.1 Metaclass Class

**Class** is the default metaclass for LOOPS classes. When a class whose metaclass is **Class** receives the message **New**, it creates a new instance of itself and returns that instance. If this message is sent at the top level, the definition of the created instance is printed in the Executive window.

### 4.1.2 Metaclass MetaClass

---

**MetaClass** is the metaclass for all metaclasses and provides the message **New** to all metaclasses. For metaclasses, the result of sending the message **New** is the definition of a new metaclass. This is discussed in detail in Section 4.3, "Defining New Metaclasses."

### 4.1.3 Metaclass AbstractClass

---

If a class's metaclass is **AbstractClass**, then it cannot be instantiated. If an abstract class is sent the message **New**, the following message is printed to the TTY window.

```
#, ($C className) Abstract Class cannot be instantiated
```

To make a class an **AbstractClass**, either send the metaclass **AbstractClass** the message **New** or change the metaclass of the class definition directly using the editor.

Use an abstract class to define a class which should not have any instances. For example, consider mixin classes. Mixins are always used in conjunction with another class to create a subclass. Instances are created from the new subclass that has the mixin as one of its parents. Because mixins never have instances, they have **AbstractClass** as their metaclass.

As an example, consider a circuit simulation module that contains various classes such as **Resistors**, **Inductors**, **Batteries**, and **Wires**. A possibility is to define a super class for these classes called **AnalogDevice** to contain all the information common to all such classes: current, impedance, voltage drop, etc. This super class also holds all the methods common to the classes, such as **ApplyOhmsLaw**. Since **AnalogDevice** is not itself intended to be instantiated (only its subclasses are), its metaclass can be **AbstractClass** so that an error occurs if it is accidentally instantiated.

Note: Whenever **AnalogDevice** is specialized to create a new subclass, be sure to change its metaclass.

### 4.1.4 Metaclass DestroyedClass

---

**DestroyedClass** is the metaclass for classes that have been sent the message **Destroy** or **Destroy!** Trying to instantiate a **DestroyedClass** causes an error. Attempts to destroy a **DestroyedClass** have no effect.

4.2 PSEUDOCASSES

## 4.2 PSEUDOCASSES

---

## 4.2 Pseudoclasses

---

Pseudoclasses provide an object interface to Lisp data types, which are also known as Lisp objects. Pseudoclasses associate a class with the type name of a Lisp object. When messages are sent to Lisp objects of the named type, the messages are actually sent to the pseudoclass. Lisp objects which have pseudoclasses are considered pseudoinstances.

Pseudoclasses provide two special cases in the message-sending mechanism: for lists whose first element is a class, or for ordinary Lisp data types.

In the first case, the list's first element is used as the class to look up the method to be used.

In the second case, the class of the data type is found by using the **GetLispClass** function, which looks in an internal table based on the type name of the data type. If none is found, it is assumed to be **Tofu**. If found, the data type is considered a pseudoclass and instances of it pseudoinstances.

Pseudoclasses also provide special cases in the behavior of **GetValue** and **PutValue**, to allow simulation of variable or property access, as described below.

---

**(GetValue pseudoinstance varName propName)** [Function]

---

**Purpose:** A variation on the behavior of **GetValue** to simulate retrieving variable or property values on pseudoinstances.

**Behavior:** If **GetValue** is called with *self* bound to a pseudoinstance, then the method associated with the selector **GetValue** in the pseudoclass is called with the arguments:

*pseudoinstance varName propName*

**Arguments:**

*pseudoinstance* A Lisp object which has a pseudoclass.

*varName* The simulated variable name.

*propName* The simulated property name, or NIL.

**Returns:** The result of the call to the **GetValue** method in the pseudoclass.

---

**(PutValue pseudoinstance varName propName newValue)** [Function]

---

**Purpose:** A variation on the behavior of **PutValue** to simulate setting of variable or property values on pseudoinstances.

**Behavior:** If **PutValue** is called with *self* bound to a pseudoinstance, then the method associated with the selector **PutValue** in the pseudoclass is called with the arguments:

*instance varName newValue propName*

**Arguments:**

*pseudoinstance* A Lisp object which has a pseudoclass.

*varName* The simulated variable name.

*propName* The simulated property name, or NIL.

*newValue* The new value to be placed in the simulated slot.

**Returns:** The result of the call to the **PutValue** method in the pseudoclass.

---

**(GetLispClass obj)** [Function]

---

**Purpose:** Used by the system to compute a class corresponding to a Lisp data type.

**Behavior:** Gets the hash value for the key (**TYPENAME** *obj*) from an internal hash array.

- If this hash value is NIL, (\$ Tofu) is returned.
- If the hash value is not NIL and it is a class, it is returned.

- In all other cases, the hash value, which should be a function, is applied to *obj* and the result is returned.

Arguments: *obj*            A Lisp object.

Returns: Value depends on the hash value; see Behavior.

Example: The command

```
79← (GetLispClass (create annotatedValue))
```

returns

```
#, ($C AnnotatedValue)
```

---

**LispClassTable**

[Global Variable]

Purpose: Used by **GetLispClass** to map type names of Lisp objects to pseudoclasses.

Format: This hash table has EQ hashing. It contains pairs of symbol keys (a type name) and either classes, NIL, or a function object to be applied (see **GetLispClass**).

---

**4.2.1 Example**

This example creates a pseudoclass from the Lisp data type STRINGP.

1. Define a class **String** that receives its messages:

```
37← (DefineClass 'String)
#, ($C String)
```

2. Place an entry in the LispClass hash table to link the Lisp data type STRING to the **String** class.

```
38← (PUTHASH 'STRINGP ($ String) LispClassTable)
#, ($C String)
```

3. Add methods to **String** which will operate on Lisp STRINGPs, for example:

```
39← (DefineMethod ($ String) 'UpCase ' (self)
 ' (U-CASE self))
String.Upcase
```

This allows messages like the following:

```
40← (← "abc" UpCase)
"ABC"
```

4. Specialize **GetValue** and **PutValue** to allow element access in strings, for example:

```
41← (DefineMethod ($ String) 'GetValue ' (index)
 ' (NTHCHAR self index))
String.GetValue
```

```
42← (DefineMethod ($ String) 'PutValue ' (index value)
 ' (RPLSTRING self index value))
String.PutValue
```

This allows messages to access characters in strings, for example:

```
43← (← "abc" GetValue 2)
b

44← (← "abc" PutValue 2 'p)
"apc"
```

## 4.3 DEFINING NEW METACLASSES

## 4.3 DEFINING NEW METACLASSES

## 4.3 Defining New Metaclasses

A new metaclass must be defined if you want to create several classes for which a class message, such as **Destroy**, needs to be specialized. To create a new metaclass, an object of the class **MetaClass** must be instantiated. This is done by sending **MetaClass** the message **New**.

(← (\$ **MetaClass**) **New** *metaClassName* *supers*) [Method of Metaclass]

- Purpose:** Instantiates a new metaclass with **MetaClass** as its metaclass, *metaClassName* as its name, and *supers* as a list of its super classes.
- Behavior:** Evaluates *metaClassName*, which must evaluate to a symbol. The default for *supers* is (**Class**). If used, *supers* must evaluate to a list of classes. The message returns the new metaclass.
- Arguments:** *metaClassName*  
Name of the new metaclass; must evaluate to a symbol.  
*supers* List of classes.
- Categories:** **MetaClass**
- Specializes:** Class.New
- Specializations:** AbstractClass.New
- Example:** Assume the following **MetaClass** definition:

```
42← (← ($ MetaClass) New 'ListMetaClass' (Class))
#, ($C ListMetaClass)
```

The message **New** can then be defined for the metaclass, **ListMetaClass**. In this example, it saves all the instances created of a class with the metaclass **ListMetaClass**. The instances are stored as the value of the class property **AllInstances**. Define the message **New** using **DefineMethod** as follows:

```
DefineMethod ($ ListMetaClass) 'New' (name arg1 arg2 arg3
arg4 arg5)
' ((* * Create an instance and add it to
list in class)
(LET ((newObj (←Super)))

(* * newObj is the instance returned by
sending the New message provided by
the class CLASS.)

(PutClass
self
(CONS newObj (LISTP (GetClassHere
```

```
self 'AllInstances)))
'AllInstances)

(* * LISTP returns list or
 NIL if not a list)
(* * GetClassHere returns the value
 of a property of a class.)

newObj]
```

Now a new class can be defined by sending #,(\$C ListMetaClass) the message **New**. The result is a new class with **ListMetaClass** as the metaclass.

```
43←(←($ ListMetaClass) New 'Book)
#, ($C Book) [New class called Book]

44←(←($ Book) New 'Book1)
#, ($C Book1)

45←(←($ Book) New 'Book2)
#, ($C Book2)

46←(GetClass ($ Book) 'AllInstances)
#, ($C Book2) #, ($C Book1) [List of all instances created so far]
```

4.4 TOFU

4.4 TOFU

4.4 Tofu

The highest class in the LOOPS hierarchy is **Tofu**, which is an acronym for Top of the Universe. It is the simplest class, having no instance variables and only three defined messages:

- **MessageNotUnderstood**
- **MethodNotFound**
- **SuperMethodNotFound**

Figure 4-2 shows specializations of **Tofu**. The most familiar specialization of **Tofu** is the class **Object**, which is the root of the most of the other classes. Another specialization of **Tofu** is **AnnotatedValue**. **AnnotatedValue** is used with active values (see Chapter 8, Active Values).

Figure 4-2. Specializations of Tofu

If another evaluation protocol or scheme for catching error conditions is needed, specialize **Tofu** and define all the methods required for handling data, usually some subset of the methods of **Object**. Specializing Tofu should only be necessary on very rare occasions.

The following table shows the methods in this section.

| Functionality | Type | Description |
|---------------|------|-------------|
|---------------|------|-------------|

|                             |        |                                                                                                                    |
|-----------------------------|--------|--------------------------------------------------------------------------------------------------------------------|
| <b>MessageNotUnderstood</b> | Method | Provides the error handling mechanism for when a message is sent to an object that cannot respond to that message. |
| <b>MethodNotFound</b>       | Method | Provides some intermediate checking before sending the message <b>MessageNotUnderstood</b> .                       |
| <b>SuperMethodNotFound</b>  | Method | Provides some intermediate checking before sending the message <b>MessageNotUnderstood</b> .                       |

(← *self* **MessageNotUnderstood** *selector messageArguments superFlg*) [Method of Tofu]

|                   |                                                                                                                                                                                                                               |                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| Purpose/Behavior: | Provides the error handling mechanism for when a message is sent to an object that cannot respond to that message.<br><br>Calls <b>ERROR</b> with a list which includes <i>self</i> , <i>selector</i> , and "not understood." |                                                                   |
| Arguments:        | <i>self</i>                                                                                                                                                                                                                   | An object receiving a message with the selector <i>selector</i> . |
|                   | <i>selector</i>                                                                                                                                                                                                               | A selector.                                                       |
|                   | <i>messageArguments</i>                                                                                                                                                                                                       | A list of the arguments to the message.                           |
|                   | <i>superFlg</i>                                                                                                                                                                                                               | Used internally.                                                  |
| Returns:          | See Behavior.                                                                                                                                                                                                                 |                                                                   |
| Categories:       | Tofu                                                                                                                                                                                                                          |                                                                   |

This chapter discusses the various ways to access data:

- Generalized Get and Put functions
- Accessing data in instances
- Accessing data in classes

## 5.1 Generalized Get and Put Functions

These functions support generalized instance variable and property access for LOOPS objects. They can be very useful for implementing methods that support new types of conditional accessing; they have been used to simplify code in the active values system, for example.

This section deals with the following functions:

| Name             | Type     | Description                                                                                                                                                 |
|------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GetIt</b>     | Function | Retrieves values from instance variables and properties.                                                                                                    |
| <b>GetItOnly</b> | Function | Like <b>GetIt</b> , but returns active values on a variable/property without triggering them.                                                               |
| <b>GetItHere</b> | Function | Like <b>GetIt</b> , but returns active values on a variable/property without triggering them; does not observe <b>NotSetValue</b> as <b>GetItOnly</b> does. |
| <b>PutIt</b>     | Function | Stores values into instance variables and properties.                                                                                                       |
| <b>PutItOnly</b> | Function | Like <b>PutIt</b> , but stores by smashing active values on a variable/property without triggering them.                                                    |

(GetIt self varOrSelector propName type)

[Function]

Purpose: Retrieves values from instance variables and properties.

Behavior: Varies according to the arguments.

- If *type* is 'IV or NIL
  - If *self* is an instance, this is equivalent to **(GetValue self varOrSelector propName)**
  - If *self* is a class, this is equivalent to **(GetClassIV self varOrSelector propName)**
- If *type* is 'CV, this is equivalent to **(GetClassValue self varOrSelector propName)**

- If *type* is 'CLASS, this is equivalent to (**GetClass** *self* (**OR** *varOrSelector* *propName*))
- If *type* is 'METHOD, this is equivalent to (**GetMethod** *self* *varOrSelector* *propName*)

Arguments: *self* A class or an instance.  
*varOrSelector* An instance variable name or the name of a method.  
*propName* Property name.  
*type* Specifies the type of the object *self*.

Returns: Value depends on the arguments; see Behavior.

Example: The command

```
(GetIt ($ Window) 'doc NIL 'CLASS)
```

returns

```
"A Loops object that represents a window"
```

---

**(GetItOnly** *self* *varOrSelector* *propName* *type*)

[Function]

Purpose: Retrieves values from instance variables and properties without triggering active values.

Behavior: Varies according to the arguments.

- If *type* is 'IV or NIL
  - If *self* is an instance, this is equivalent to (**GetValueOnly** *self* *varOrSelector* *propName*)
  - If *self* is a class, this is equivalent to (**GetClassIV** *self* *varOrSelector* *propName*)
- If *type* is 'CV, this is equivalent to (**GetClassValueOnly** *self* *varOrSelector* *propName*)
- If *type* is 'CLASS, this is equivalent to (**GetClassOnly** *self* (**OR** *varOrSelector* *propName*))
- If *type* is 'METHOD, this is equivalent to (**GetMethodOnly** *self* *varOrSelector* *propName*)

Arguments: *self* A class or an instance.  
*varOrSelector* An instance variable name or the name of a method.  
*propName* Property name.  
*type* Specifies the type of the object *self*.

Returns: Value depends on the arguments; see Behavior.

Example: The command

```
(GetItOnly (GetClassValue ($ LoopsIcon) 'Prototype) 'window)
```

returns the LoopsWindowAV that holds the image of the LOOPS icon. Calling **GetIt** with similar arguments returns the Lisp window object held by that LoopsWindowAV.

**(GetItHere self varOrSelector propName type)**

[Function]

**Purpose:** Retrieves values from instance variables and properties without triggering active values; does not observe **NotSetValue** like **GetItOnly**.

**Behavior:** Varies according to the arguments.

- If *type* is 'IV or NIL
- If *self* is an instance, this is equivalent to **(GetIVHere self varOrSelector propName)**
- If *self* is a class, this is equivalent to **(GetClassIVHere self varOrSelector propName)**
- If *type* is 'CV, this is equivalent to **(GetCVHere self varOrSelector propName)**
- If *type* is 'CLASS, this is equivalent to **(GetClassHere self (OR varOrSelector propName))**
- If *type* is 'METHOD, this is equivalent to **(GetMethodHere self varOrSelector propName)**

**Arguments:** *self* A class or an instance.  
*varOrSelector* An instance variable name or the name of a method.  
*propName* Property name.  
*type* Specifies the type of the object *self*.

**Returns:** Value depends on the arguments; see Behavior.

**Example:** The command

```
(GetItHere (GetClassValue ($ LoopsIcon) 'Prototype) 'title)
```

returns the value of **NotSetValue**. Calling **GetIt** with similar arguments returns the default value for this instance variable, NIL.

**(PutIt self varOrSelector newValue propName type)**

[Function]

**Purpose:** Stores values into instance variables and properties.

**Behavior:** Varies according to the arguments.

- If *type* is 'IV or NIL
- If *self* is an instance, this is equivalent to **(PutValue self varName newValue propName)**
- If *self* is a class, this is equivalent to **(PutClassIV self varName newValue propName)**
- If *type* is 'CV, this is equivalent to **(PutClassValue self varName newValue propName)**
- If *type* is 'CLASS, this is equivalent to **(PutClass self newValue (OR varName propName))**

**Arguments:** *self* A class or an instance.

*varName*      An instance variable name.

*propName*    Property name.

*type*          Specifies the type of the object *self*.

Returns:      Value depends on the arguments; see Behavior.

Example:      The command

```
(PutIt (GetClassValue ($ LoopsIcon) 'Prototype) 'title "foo")
```

sets the instance variable **title** of the LOOPS icon prototype to "foo". This can be verified by inspecting (GetClassValue (\$ LoopsIcon) 'Prototype) and examining the title slot.

**(PutItOnly self varOrSelector newValue propName type)** [Function]

---

Purpose:        Stores values into instance variables and properties and smashes any active values it finds in its way without triggering them.

Behavior:     Varies according to the arguments.

- If *type* is 'IV or NIL
- If *self* is an instance, this is equivalent to  
  **(PutValueOnly self varName newValue propName)**
- If *self* is a class, this is equivalent to  
  **(PutClassIV self varName newValue propName)**
- If *type* is 'CV, this is equivalent to  
  **(PutClassValueOnly self varName newValue propName)**
- If *type* is 'CLASS, this is equivalent to  
  **(PutClassOnly self newValue (OR varName propName))**

Arguments:    *self*            A class or an instance.

*varName*      An instance variable name.

*propName*    Property name.

*type*          Specifies the type of the object *self*.

Returns:      Value depends on the arguments; see Behavior.

Example:      If the inspector from the **PutIt** example is used to set a break on the the instance variable **title** of the LOOPS icon prototype, then doing

```
(PutItOnly (GetClassValue ($ LoopsIcon) 'Prototype) 'title "mumble")
```

will set the instance variable **title** to "mumble" while smashing the trace active value.

## 5.2 ACCESSING DATA IN INSTANCES

## 5.2 ACCESSING DATA IN INSTANCES

---

## 5.2 Accessing Data in Instances

Two kinds of variables are associated with an instance:

- Its local instance variables, also referred to as IVs.
- The class variables, also referred to as CVs, that it shares with all instances of the class.

The data contained within instances are the values of instance variables and associated properties as well as a pointer to the class that describes the instance. Details of the LOOPS implementation determine exactly when the values of instance variables are stored within an instance. In some cases, the system must look to the class to find the values of instance variables. In general, you do not need to be concerned with this distinction; however, the details of it are covered in Chapter 2, Instances.

The types of data that an instance may contain is not limited. The values for an instance variable or a class variable can be any Lisp or LOOPS data structure.

The active value is a special case of data. When you try to access a variable with an active value as its value, the active value may be returned, depending upon the type of access. Normally, however, data computed by the active value is returned, not the active value. The details of how this computation is performed is described in Chapter 8, Active Values.

Instance variable names and class variable names are symbols and are not necessarily unique to each class. Although it is possible to use the same symbol for both a class variable name and an instance variable name, it is advisable not to do this since some of the LOOPS functionality examines both the instance variables and class variables in the search for data. See the method **IVMissing** in the class **Object**.

This section deals with the following functions and methods. See the *LOOPS Library Modules Manual* for information on how these interact with Masterscope.

| Name                     | Type     | Description                                                                                                                                                                           |
|--------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GetValue</b>          | Function | Finds the value of an instance variable.                                                                                                                                              |
| <b>Get</b>               | Method   | Finds the value of an instance variable.                                                                                                                                              |
| <b>PutValue</b>          | Function | Writes the value of an instance variable.                                                                                                                                             |
| <b>Put</b>               | Method   | Writes the value of an instance variable.                                                                                                                                             |
| <b>GetValueOnly</b>      | Function | Finds the value of an instance variable without triggering active values.                                                                                                             |
| <b>PutValueOnly</b>      | Function | Writes the value of an instance variable without triggering active values.                                                                                                            |
| <b>GetClassValue</b>     | Function | Returns the value of a class variable.                                                                                                                                                |
| <b>PutClassValue</b>     | Function | Changes the value of a class variable. The change occurs within the class and therefore causes all instances to access the new value of the variable.                                 |
| <b>GetClassValueOnly</b> | Function | Returns the value of a class variable; does not trigger active values.                                                                                                                |
| <b>PutClassValueOnly</b> | Function | Changes the value of a class variable. The change occurs within the class and therefore causes all instances to access the new value of the variable. Does not trigger active values. |

**GetIVHere**

Function

Gets the value stored in an instance variable without invoking active values.

---

**(GetValue self varName propName)**

[Function]

Purpose: Finds the value of an instance variable when *varName* and *propName* are to be computed.

Behavior: Varies according to the arguments.

- If *self* is an instance and *propName* is NIL, this returns the value of the instance variable *varName*. If there is no instance variable of the name *varName* and there is a class variable of that name, this returns the value of the class variable. See the **IVMissing** message for a complete discussion of this behavior. If there is neither an instance variable or class variable of that name, a break occurs.
- If *self* is an instance and *propName* is non-NIL, this returns the value of the property *propName* of the instance variable or class variable *varName*. If there is no property of the name, *propName*, this returns the value of the variable **NoValueFound**.
- If the value of *varName* (or *propName* if it is non-NIL) is an active value, the active value is activated.
- If *self* is not an instance, this calls **(GetIt self varName propName 'IV)**

See the *LOOPS Library Modules Manual* about interaction with Masterscope.

Arguments: *self*            A class or an instance.  
*varName*        Instance or class variable name.  
*propName*      Property name.

Returns: Value depends on the arguments; see Behavior.

Example: Given that

```
32←(← ($ window1) Shape '(100 200 300 400))
(100 200 300 400)
```

then

```
33←(GetValue ($ window1) 'width)
300
```

```
34←(GetValue ($ window1) 'LeftButtonItem)
((Update ...))
```

---

**(← self Get varName propName)**

[Method of Object]

Purpose/Behavior: Method version of **GetValue**.

Arguments: See **GetValue**.

Categories: Object

---

**(PutValue self varName newValue propName)**

[Function]

Purpose: Writes the value of an instance variable when *varName* and *propName* are to be computed.

Behavior: Varies according to the arguments.

- If *self* is an instance and *propName* is NIL, this changes the value of the instance variable *varName* to *newValue*. This returns *newValue*. If *varName* is not an instance variable of *self*, this causes a break.
- If *self* is an instance and *propName* is non-NIL, this changes the value of the property *propName* of the instance variable *varName* to *newValue*. If *propName* is not already a property of *varName*, it is added. This returns *newValue*.
- If the value of *varName* (or *propName* if it is non-NIL) is an active value, the active value is activated.
- If *self* is a class, this calls  
(**PutIt** *self varName newValue propName* 'IV)

See the *LOOPS Library Modules Manual* about interaction with Masterscope.

Arguments: *self* A class or an instance.  
*varName* Instance name or class name.  
*newValue* The new value for *varName* or *propName*.  
*propName* Property name.

Returns: Value depends on the arguments; see Behavior.

Example: (PutValue (\$ window1) 'width 120)

---

(← *self* **Put** *varName newValue propName*) [Method of Object]

---

Purpose/Behavior: Method version of the function **PutValue**.

Arguments: See **PutValue**.

Categories: Object

Specializations: Class

---

(**GetValueOnly** *self varName propName*) [Function]

---

Purpose: Similar to **GetValue**, except that it overrides the active value mechanism.

Behavior: See **GetValue**. If the value found is an active value, it is returned without triggering its side effects.

Arguments: See **GetValue**.

Returns: See Behavior.

Example: The following expressions compare **GetValue** and **GetValueOnly**

```
35←(GetValue ($ window1) 'window)
{WINDOW}#nn, mmmm

36←(GetValueOnly ($ window1) 'window)
#,$AV LispWindowAV ...)
```

---

(**PutValueOnly** *self varName newValue propName*) [Function]

---

Purpose: Similar to **PutValue**, except that it overrides the active value mechanism.

|            |                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------|
| Behavior:  | See <b>PutValue</b> . The argument <i>newValue</i> overwrites any active value on the slot without triggering it. |
| Arguments: | See <b>PutValue</b> .                                                                                             |
| Returns:   | Used for side effect only.                                                                                        |

---

**(GetClassValue** *self varName propName*) [Function]

---

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Returns the value of a class variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Behavior:  | <p>Varies according to the arguments.</p> <ul style="list-style-type: none"><li>• If <i>propName</i> is NIL, this returns the value of the class variable <i>varName</i>. If <i>varName</i> is not a class variable, a break occurs.</li><li>• If <i>propName</i> is non-NIL, this returns the value of the property, <i>prop</i>, of the class variable <i>varName</i>. If <i>varName</i> has no property of that name, the value of the variable <b>NoValueFound</b> is returned.</li></ul> <p>See the <i>LOOPS Library Modules Manual</i> about interaction with Masterscope.</p> |
| Arguments: | <p><i>self</i>            An instance or a class.</p> <p><i>varName</i>        Class variable name of <i>self</i>.</p> <p><i>propName</i>       Property name for class variable <i>varName</i>; may be NIL.</p>                                                                                                                                                                                                                                                                                                                                                                     |
| Returns:   | Value depends on the arguments; see Behavior.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Example:   | <p>The following commands show a variety of returned values.</p> <pre>37←(GetClassValue (\$ window1) 'window)</pre> <p>This breaks, since window is not a class variable of <b>Window</b>.</p> <pre>38←(GetClassValue (\$ window1) 'LeftButtonItem) ((Update ...))</pre> <pre>39←(GetClassValue (\$ window1) 'LeftButtonItem 'qwerty) NIL</pre>                                                                                                                                                                                                                                      |

---

**(PutClassValue** *self varName newValue propName*) [Function]

---

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Changes the value of a class variable. The change occurs within a class and therefore causes a class variable lookup by other instances to find the new value.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Behavior:  | <p>Varies according to the arguments.</p> <ul style="list-style-type: none"><li>• If <i>propName</i> is NIL, this changes the value of the class variable <i>varName</i> to <i>newValue</i>. If <i>varName</i> is not a class variable, this breaks.</li><li>• If <i>propName</i> is non-NIL, this changes the value of the property, <i>propName</i>, of the class variable <i>varName</i> to <i>newValue</i>. If <i>varName</i> has no property of that name, the property is added.</li></ul> <p>See the <i>LOOPS Library Modules Manual</i> about interaction with Masterscope.</p> |
| Arguments: | <p><i>self</i>            An instance or a class.</p> <p><i>varName</i>        Class variable name of <i>self</i>.</p> <p><i>newValue</i>       Value to be assigned to class variable or property name.</p>                                                                                                                                                                                                                                                                                                                                                                            |

*propName* Property name for class variable *varName*; may be NIL.

Returns: *newValue*

Example: The following command breaks since **left** is not a class variable name of **Window**.

```
40←(PutClassValue ($ window1) 'left 1234)
```

The command

```
41←(PutClassValue ($ window1) 'TitleItems 1234)
```

changes the value of **TitleItems**. The command

```
42←(PutClassValue ($ window1) 'TitleItems 123 'asdf)
```

adds the property **asdf** with the value 123 to **TitleItems**.

**(GetClassValueOnly self varName propName)**

[Function]

Purpose: Gets the value of a class variable without triggering active values.

Behavior: Varies according to the arguments.

- If *propName* is NIL, this returns the value of the class variable *varName* without triggering active values. If *varName* is not a class variable, this breaks.
- If *propName* is non-NIL, this returns the value of the property, *propName*, of the class variable *varName* without triggering active values. If *varName* has no property of that name, the value of the variable **NotSetValue** is returned.

See the *LOOPS Library Modules Manual* about interaction with Masterscope.

Arguments: *self* An instance or a class.

*varName* Class variable name for *self*.

*propName* Property name of class variable *varName*; may be NIL.

Returns: Value depends on the arguments; see Behavior.

Example: The following command returns the value of the variable **NotSetValue** since **LeftButtonItem** has no property of the name **qwerty**.

```
43←(GetClassValueOnly ($ window1) 'LeftButtonItem 'qwerty)
#,NotSetValue
```

**(PutClassValueOnly self varName newValue propName)**

[Function]

Purpose: Changes the value of a class variable without triggering active values. The change occurs within a class and therefore causes a class variable lookup by other instances to find the new value.

Behavior: The behavior is the same as **PutClassValue** except that the value stored does not trigger an active value, but overwrites it instead.

Arguments: *self* An instance or a class.

*varName* Class variable name of *self*.

*newValue* Value to be assigned to class variable or property name.

*propName*    Property name for class variable *varName*; may be NIL.

Returns:    *newValue*

---

**(GetIVHere self *varName propName*)** [Function]

---

Purpose:    Gets the value stored in an instance without invoking active values.

Behavior:    Returns the value of *varName* (or the property, *propName*, if it is non-NIL) without triggering active values. If the value of *varName* (or *propName*) is not yet stored in *self*, the value of the variable **NotSetValue** is returned.

See the *LOOPS Library Modules Manual* about interaction with Masterscope.

Arguments:    *self*            Must be an instance.

*varName*       Instance variable of *self*.

*propName*      Property name for variable *varName*; may be NIL.

Returns:    Value depends on the arguments; see Behavior.

Example:    Given that

```
44←(← ($ Window) New 'w2)
#,$(& Window (NEW0.1Y%.:;h.eN6 . 496))
```

then

```
45←(GetIVHere ($ w2) 'left)
,NotSetValue
```

After entering the command

```
46←(PutValue ($ w2) 'left 123)
123
```

then

```
47←(GetIVHere ($ w2) 'left)
123
```

---

### 5.2.1 Compact Accessing Forms

---

When you write methods for classes that you have defined, there are a number of accesses to the data contained in the object bound to the method argument *self*. The following forms have been created to allow a more concise notation for these accesses.

| Name | Type  | Description                                                                              |
|------|-------|------------------------------------------------------------------------------------------|
| @    | Macro | Provides compact <b>GetValue</b> and <b>GetClassValue</b> forms.                         |
| @*   | Macro | Provides compact <b>GetValue</b> forms.                                                  |
| ←@   | Macro | Provides compact <b>PutValue</b> and <b>PutClassValue</b> forms and assigns a new value. |

---

**(@ *accessPath*)** [Macro]

---

Purpose:    Provides compact **GetValue** or **GetClassValue** forms.

Behavior: The *accessPath* can be one, two, or three arguments.

- If the *accessPath* is one argument, *self* is assumed to be the object and the argument points to an instance variable. This is the most common usage in methods in which you need to get the value of an instance variable contained in *self*. For example,

```
(@ iv1)
```

translates to

```
(GetValue self 'iv1).
```

- If the *accessPath* is two arguments, the first argument is an object and the second argument is an instance variable. For example,

```
(@ ($ w) left)
```

translates to

```
(GetValue ($ w) 'left).
```

- If the *accessPath* is three arguments, the first argument is an object, the second argument is an instance variable, and the third argument is a property. For example,

```
(@ ($ w) menus DontSave)
```

translates to

```
(GetValue ($ w) 'menus 'DontSave).
```

When programming using objects, one object often points to another object. For example, the value of an instance variable is another object. Using different *accessPath* forms allows you to write accesses into objects that are nested inside of other objects. As an example, assume an object (\$ pipe) has an instance variable named *output* with a value (\$ tank), which has an instance variable named *level*. The command

```
(@ ($ pipe) output:level)
```

which is equivalent to

```
(@ (@ ($ pipe) output) level)
```

gets the value of the instance variable *level* of (\$ tank).

The ":" is a delimiter that indicates instance variable access. The following table shows all the delimiters.

| Delimiter | Description                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| :         | Indicates instance variable access.                                                                                      |
| ::        | Accesses the value of a class variable whose name follows the double colon.                                              |
| :,        | Accesses the value of a property whose name follows the colon-comma.                                                     |
| .         | Sends a message to the object with the selector following the period.                                                    |
| !         | Evaluates the next expression.                                                                                           |
| \         | States that the next symbol refers to a Lisp symbol. This is often used in conjunction with the exclamation mark, above. |

**\$** States that the next expression is a LOOPS object.

You can test forms using these delimiters by evaluating  
(Parse@ (LIST accessPath) 'IV) .

Arguments: *accessPath* One, two, or three arguments; refer to Behavior.

Returns: See Behavior.

Example: The following examples show the (@ accessPath) form, the Parse@ test, and the translation.

1. (@ foo)  
(Parse@ (LIST 'foo) 'IV)  
(GetValue self 'foo)
2. (@ ::fie:foe)  
(Parse@ (LIST '::(GetValue (GetClassValue self 'fie) 'foe)

The following three examples are rarely seen in code, but they are additional examples of the expressions that can be interpreted by the system.

3. (@ foo::!::fum)  
(Parse@ (LIST 'foo::!::fum) 'IV)  
(GetClassValue (GetValue self 'foo) (GetClassValue self 'fum))
4. (@ (\$ w) fie:,foe.fum)  
(Parse@ (LIST '(\$ w) 'fie:,foe.fum) 'IV)  
(← (GetValue (\$ w) 'fie 'foe) fum)
5. (@ \$fie.foe:!\fum.!foo)  
(Parse@ (LIST '\$fie.foe:!\fum.!foo) 'IV)  
(←! (GetValue (← (GetObjectRec 'fie) foe) fum) (GetValue self 'foo))

---

**(@\* accessPath)**

[Macro]

Purpose/Behavior: Provides a concise form for writing embedded **GetValue** forms.

Arguments: *accessPath* An object followed by an arbitrary number of instance variable names.

Returns: The value of a nested instance variable.

Example: The command

```
(@* ($ foo) a b c)
```

translates to

```
(GetValue (GetValue (GetValue ($ foo) 'a) 'b) 'c)
```

---

**(←@ accessPath newValue)**

[Macro]

Purpose/Behavior: Similar to the @ macro, but used to assign a new value instead of reading a value. Evaluates *newValue*.

Arguments: *accessPath* See Behavior in the @ macro.

*newValue* Value to be assigned to variable indicated by *accessPath*.

Returns: *newValue*

Example: The following examples show the ( $\leftarrow$ @ accessPath) form, the Parse@ test, and the translation.

1. ( $\leftarrow$ @ foo 1234)  
 (ParsePut@ (LIST 'foo 1234) 'IV)  
 (PutValue self 'foo 1234)
2. ( $\leftarrow$ @ (\$ w) ::left 1234)  
 (ParsePut@ (LIST (\$ w) ' ::left 1234) 'IV)  
 (PutClassValue #.(\$ w) 'left 1234)
3. ( $\leftarrow$ @ (\$ w) menus DontSave 'Any)  
 (ParsePut@ (LIST (\$ w) 'menus 'DontSave '(QUOTE Any)) 'IV)  
 (PutValue #.(\$ w) 'menus 'Any 'DontSave)

## 5.2.2 Support for Changetran

Interlisp uses Changetran to provide an extensive set of facilities for expressing changes to structures, such as push, pushnew, pop, add, change, by using access expressions. You can use any LOOPS access expression in a Changetran context, so that you can now write expressions such as:

```
(push (@ v1) newTop)
(change (@ x) newValue)
(pushnew (@ colors:,truck) 'red)
(pop (@ ::cv17))
(add (@ x:y:z) 37)
```

The first two are equivalent to:

```
(PushValue self 'v1 (CONS newTop(@ V1)))
(_@ x newValue)
```

This uniform interface allows simpler expressions for changes, and arbitrary extensions through Changetran. See the *Interlisp-D Reference Manual* for more information on Changetran.

## 5.3 ACCESSING DATA IN CLASSES

### 5.3 ACCESSING DATA IN CLASSES

## 5.3 Accessing Data in Classes

A number of functions and methods are available for reading and storing data within classes. Some of these change existing data, and others change the structure of the class by adding variables or properties.

When reading or storing data, some of these functions trigger any active values that are associated with that data. See Chapter 8, Active Values, for a discussion of their behavior.

### 5.3.1 Metaclass and Property Access

Associated with a class are a metaclass and properties. This section describes the following functions to manipulate their values.

| Name            | Type     | Description                                |
|-----------------|----------|--------------------------------------------|
| <b>GetClass</b> | Function | Obtains a class's metaclass or properties. |

|                     |          |                                                                                        |
|---------------------|----------|----------------------------------------------------------------------------------------|
| <b>PutClass</b>     | Function | Changes the metaclass or class properties of a class.                                  |
| <b>GetClassOnly</b> | Function | Obtains a class's metaclasses or properties without triggering active values.          |
| <b>PutClassOnly</b> | Function | Changes the metaclass or class properties of a class without triggering active values. |
| <b>GetClassHere</b> | Function | Obtains a property local to the class.                                                 |

---

**(GetClass *classRec* *propName*)** [Function]

---

Purpose: Obtains a class's metaclass or properties by following metaclass links.

Behavior: Sends the message **GetClassProp** to *classRec* and passes *propName* as an argument.

Varies according to the arguments.

- If *propName* is NIL, this returns the *class*'s metaclass.
- If *propName* is non-NIL, this looks first in *class* for that property. If it cannot find it there, it looks through *class*'s metaclass links.
- If no property is found, the value of the variable **NotSetValue** is returned.

Arguments: *classRec*    Pointer to a class.  
*propName*    Property name.

Returns: See Behavior.

Example: The following commands show the variety of returned values.

```
31←(GetClass ($ Window))
#,$C Class)

32←(GetClass ($ Window) 'doc)
" A LOOPS object which represents a window"

33←(GetClass ($ IconWindow) 'doc)
"An icon window that appears as an irregular shaped image
on the screen -- See the ICONW Library utility"
```

---

**(PutClass *classRec* *newValue* *propName*)** [Function]

---

Purpose: Changes the metaclass or class properties of a class.

Behavior: Varies according to the arguments.

- If *propName* is NIL, this changes the metaclass of *classRec* to *newValue*. If *newValue* is not a class or the name of a class, this causes a break.
- If *propName* is non-NIL and *classRec* already has this property, this triggers an active value on *propName* if it exists and changes the value of *propName* to *newValue*.
- If *propName* is non-NIL and *classRec* does not have this property, the property is added with the value *newValue*.

Marks the class *classRec* as changed.

Arguments: *classRec*    Pointer to a class.

*newValue* See Behavior.

*propName* Property name.

Returns: Newly created class object.

Example: The following command changes the **doc** property of class **Datum**:

```
66←(DefineClass 'Datum)
#,($C Datum)
```

```
67←(PutClass ($ Datum) '(* this is the updated doc for class Datum) 'doc)
(* this is the updated doc for class Datum)
```

**(GetClassOnly** *classRec propName*)

[Function]

Purpose: Obtains a class's metaclass or properties by following superclass links, without triggering active values.

Behavior: Varies according to the arguments.

- If *propName* is NIL, this returns the *classRec*'s metaclass.
- If *propName* is non-NIL, this looks first in *classRec* for that property. If it cannot find it there, it looks through *classRec*'s supers links. This returns the value of the property found without triggering active values.
- If no property is found, the value of the variable **NotSetValue** is returned.

Arguments: *classRec* Pointer to a class.

*propName* Property name.

Returns: Value depends on the arguments; see Behavior.

Example: The command

```
(GetClassOnly ($ IconWindow) 'doc)
```

returns

```
"An icon window that appears as an irregular shaped image
on the screen -- See the ICONW Library utility"
```

**(PutClassOnly** *classRec newValue propName*)

[Function]

Purpose: Changes the metaclass or class properties without triggering active values.

Behavior: Varies according to the arguments:

- If *propName* is NIL, this changes the metaclass of *classRec* to *newValue*. If *newValue* is not a class or the name of a class this causes a break.
- If *propName* is non-NIL and *classRec* already has this property, this changes the value of *propName* to *newValue*. Any active values are replaced.
- If *propName* is non-NIL and *classRec* does not have this property, the property is added with the value *newValue*.

The class *classRec* is marked as changed.

Arguments: *classRec* Pointer to a class.

*newValue*    A class or the name of a class.

*propName*    NIL or the name of a class property.

Returns:    *newValue*

---

**(GetClassHere classRec propName)** [Function]

---

Purpose:    Obtains property local to class.

Behavior:    Gets the class property without triggering active values or inheritance. If there is no local property the value of **NotSetValue** is returned.

Arguments:    *classRec*    Pointer to a class.

*propName*    NIL or the name of a class property.

Returns:    *newValue*

Example:    The command

```
(GetClassHere ($ ActiveValue) 'doc)
```

returns

```
#,NotSetValue
```

---

### 5.3.2 Class Variable Access

---

A class variable can be thought of as being shared by all instances of that class and by all instances of any of its subclasses. This section describes how to access class variables with the functions shown in the following table.

| Name                     | Type     | Description                                                                                       |
|--------------------------|----------|---------------------------------------------------------------------------------------------------|
| <b>GetClassValue</b>     | Function | Returns the value of a class variable or property.                                                |
| <b>PutClassValue</b>     | Function | Stores a value in a class variable or property.                                                   |
| <b>GetClassValueOnly</b> | Function | Returns the value of a class variable or property, without triggering active values.              |
| <b>PutClassValueOnly</b> | Function | Stores a value in a class variable or property, without triggering active values.                 |
| <b>GetCVHere</b>         | Function | Returns the value of a class variable in a particular class without looking for inherited values. |
| <b>PutCVHere</b>         | Function | Stores a class variable locally with a value if it is not local.                                  |

---

**(GetClassValue self varName prop)** [Function]

---

Purpose:    Returns the value of a class variable or property.

Behavior:    Varies according to the arguments.

If *self* is an instance, the lookup begins at the class of the instance, since instances do not have class variables stored locally. If *self* is a class, the lookup is in that class.

- If *prop* is NIL, **GetClassValue** returns the value of the class variable *varName*. If *varName* is not found, this breaks.
- If *prop* is non-NIL, **GetClassValue** returns the value of the property *prop*, associated with the class variable *varName*. If the value is an active value, it is activated. If *varName* has no property *prop*, this returns the value of the variable **NoValueFound**.

If the class does not have a class variable *varName*, **GetClassValue** searches through the super classes of the class until it finds *varName*. Since this is rare, class variables are stored only in the class in which they are defined, and the runtime search is necessary.

Arguments: *self*            An instance or a class.  
               *varName*        A class variable name.  
               *prop*            Property name.

Returns: Value depends on the arguments; see Behavior.

Example: Given that

```
(← ($ Window) New 'window1)
```

then the command

```
(GetClassValue ($ window1) 'LeftButtonItem)
```

returns the same value as the command

```
(GetClassValue ($ Window) 'LeftButtonItem)
```

The command

```
(GetClassValue ($ Window) 'abcde)
```

breaks. The command

```
(GetClassValue ($ Window) 'LeftButtonItem 'wxyz)
```

returns the value of **NoValueFound**.

**(PutClassValue self varName newValue propName)**

[Function]

Purpose: Stores a value in a class variable or property.

Behavior: Varies according to the arguments.

If *self* is an instance, the lookup begins at the class of the instance, since instances do not have class variables stored locally. If *self* is a class, the lookup is in that class.

- If *prop* is NIL, **PutClassValue** changes the value of the class variable *varName*.
- If *prop* is non-NIL, **PutClassValue** stores *newValue* as the value of the property, *prop*. If an active value is the current value, it is triggered.

If *varName* is not local to the class, the value is put in the first class in the inheritance list in which *varName* is found. If *varName* is not found, a break occurs.

Arguments: *self*            An instance or a class.  
               *varName*        A class variable name.

*newValue*    A new value.

*propName*    Property name.

Returns: *newValue*

Example: Given that

```
(← ($ Window) New 'window1)
```

then the command

```
(PutClassValue ($ window1) 'LeftButtonItem 2 'number)
```

adds the property number with the value 2 to the class variable **LeftButtonItem** of the class **Window**. The following command performs the same action.

```
(PutClassValue ($ Window) 'LeftButtonItem 2 'number)
```

---

**(GetClassValueOnly** *classRec varName prop*) [Function]

---

Purpose: Returns the value of a class variable or property, without triggering active values.

Behavior: Similar to **GetClassValue**, with the following exceptions:

- If **GetClassValueOnly** finds that the value is an active value, the active value is returned without being triggered.
- If *prop* is non-NIL and is not found, **GetClassValueOnly** returns the value of the variable **NotSetValue**.

Arguments: See **GetClassValue**.

Returns: Value depends on the arguments; see Behavior.

Example: The command

```
(GetClassValueOnly ($ Window) 'abcde)
```

breaks. The command

```
(GetClassValueOnly ($ Window) 'LeftButtonItem 'wxyz)
```

returns the value of **NotSetValue**.

---

**(PutClassValueOnly** *self varName newValue propName*) [Function]

---

Purpose: Stores the value of a class variable or property, without triggering active values.

Behavior: Similar to **PutClassValue**, except that **PutClassValueOnly** does not trigger an active value, but replaces it with *newValue*.

Arguments: See **PutClassValue**.

Returns: Used for side effect only.

---

**(GetCVHere** *classRec varName propName*) [Function]

---

Purpose: Returns the value of a class variable in a particular class without looking for inherited values.

**Behavior:** Returns the value of the class variable *varName*, or the *propName* property if *propName* is non-NIL.

If the value is an active value, it is returned without being triggered.

If there is no *varName* (or *propName*), this returns the value of the variable **NotSetValue**.

**Arguments:** *classRec* Must be a class.  
*varName* A class variable name.  
*propName* Property name.

**Returns:** Value depends on the arguments; see Behavior.

**Example:** The command

```
(GetCVHere ($ NonRectangularWindow) 'LeftButtonItem)
```

returns

```
#,NotSetValue
```

The command

```
(GetCVHere ($ Window) 'LeftButtonItem)
```

returns

```
((Update (QUOTE Update)...))
```

**(PutCVHere self varName value)**

[Function]

**Purpose:** Puts a class variable locally with a value if it is not local.

**Behavior:** Calls **(AddCV self varName value)**.

**Arguments:** *self* An instance or a class.  
*varName* A class variable name.  
*value* Value for the class variable.

**Returns:** *value*

### 5.3.3 Instance Variable Access

An instance variable can be thought of as being local to each instance of a class. The class defines what instance variables and their default values will be in an instance. This section describes the functions that manipulate the default values in the class.

See the *LOOPS Library Modules Manual* for interaction with Masterscope.

| Name                  | Type     | Description                                                                                                       |
|-----------------------|----------|-------------------------------------------------------------------------------------------------------------------|
| <b>GetClassIV</b>     | Function | Gets the default value of an instance variable or associated property as defined in a class or one of its supers. |
| <b>GetClassIVHere</b> | Function | Gets the default value of an instance variable or associated property as defined in a class.                      |

|                   |          |                                                                |
|-------------------|----------|----------------------------------------------------------------|
| <b>PutClassIV</b> | Function | Changes the default value for an instance variable in a class. |
|-------------------|----------|----------------------------------------------------------------|

---

|                                              |            |
|----------------------------------------------|------------|
| <b>(GetClassIV <i>self varName prop</i>)</b> | [Function] |
|----------------------------------------------|------------|

---

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                     |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| Purpose:   | Gets the default value of an instance variable or associated property as defined in a class or one of its supers.                                                                                                                                                                                                                                                                                                                    |                                                     |
| Behavior:  | If <i>self</i> is not bound to a class, an error occurs.<br><br>Searches through the supers of <i>self</i> to find <i>varName</i> or <i>prop</i> . <ul style="list-style-type: none"><li>• If <i>prop</i> is NIL, this returns the default value for <i>varName</i>.</li><li>• If <i>prop</i> is non-NIL, this returns its default value.</li></ul> If the default value is an active value, it is returned without being triggered. |                                                     |
| Arguments: | <i>self</i>                                                                                                                                                                                                                                                                                                                                                                                                                          | Must be bound to a class.                           |
|            | <i>varName</i>                                                                                                                                                                                                                                                                                                                                                                                                                       | The name of an instance variable.                   |
|            | <i>prop</i>                                                                                                                                                                                                                                                                                                                                                                                                                          | Name of a property associated with <i>varName</i> . |
| Returns:   | Value depends on the arguments; see Behavior.                                                                                                                                                                                                                                                                                                                                                                                        |                                                     |
| Example:   | The commands<br><br><pre>(GetClassIV (\$ Window) 'window) (GetClassIV (\$ NonRectangularWindow) 'window)</pre><br>both return<br><br><pre>#, (\$AV LispWindowAV ...)</pre>                                                                                                                                                                                                                                                           |                                                     |

---

|                                                  |            |
|--------------------------------------------------|------------|
| <b>(GetClassIVHere <i>self varName prop</i>)</b> | [Function] |
|--------------------------------------------------|------------|

---

|            |                                                                                                                                                                                                                           |                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| Purpose:   | Gets the default value of an instance variable or associated property as defined in a class.                                                                                                                              |                                                     |
| Behavior:  | Similar to <b>GetClassIV</b> . This does not search the super classes of <i>self</i> for <i>varName</i> . If <i>varName</i> or <i>prop</i> is not local to <i>self</i> , this returns the value of <b>NotSetValue</b> .   |                                                     |
| Arguments: | <i>self</i>                                                                                                                                                                                                               | Pointer to a class.                                 |
|            | <i>varName</i>                                                                                                                                                                                                            | Name of an instance variable.                       |
|            | <i>prop</i>                                                                                                                                                                                                               | Name of a property associated with <i>varName</i> . |
| Returns:   | The default value of <i>varName</i> or <i>prop</i> or <b>NotSetValue</b> .                                                                                                                                                |                                                     |
| Example:   | The command<br><br><pre>(GetClassIVHere (\$ Window) 'window)</pre><br>returns<br><br><pre>#, (\$AV LispWindowAV ...)</pre><br>the command<br><br><pre>(GetClassIVHere (\$ NonRectangularWindow) 'window)</pre><br>returns |                                                     |

#,NotSetValue

**(PutClassIV** *self varName newValue propName*)

[Function]

Purpose: Changes the default value for an IV in a class.

Behavior: If *self* is not a class that contains the instance variable *varName*, an error occurs.

- If *propName* is NIL, the default value for the instance variable *varName* is changed to *newValue*.
- If *propName* is non-NIL, the default value for it is changed to *newValue*.

Arguments: *self* Must be a class that contains the instance variable *varName*.

*varName* An instance variable name.

*newValue* The new default value.

*propName* Property name.

Returns: *newValue* (used for side effect only).

Example: After the commands

```
68←(DefineClass 'Datum)
#,($C Datum)
```

```
69←(← ($ Datum) AddIV 'id# NIL)
id#
```

the following command changes the default value of the instance variable **id#** to '(7) for all new instances of the class **Datum**:

```
70←(PutClassIV ($ Datum) 'id# '(7))
(7)
```

|                        |                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| abstract class         | A class which cannot be instantiated, for example, <b>ActiveValue</b> .                                                                                                                                                      |
| active value           | The mechanism that carries out access-oriented programming for variables in LOOPS. Active values send messages as a side effect of having an object's variable referenced.                                                   |
| activeValue            | The previous implementation of the active value concept.                                                                                                                                                                     |
| <b>ActiveValue</b>     | An abstract class that defines the general protocol followed by all active value objects.                                                                                                                                    |
| annotatedValue         | A special Interlisp-D data type that wraps each <b>ActiveValue</b> instance.                                                                                                                                                 |
| <b>AnnotatedValue</b>  | An abstract class that allows an annotatedValue to be treated as an object.                                                                                                                                                  |
| browser                | A window that allows you to examine and change items in a data structure.                                                                                                                                                    |
| class                  | A description of one or more similar objects; that is, objects containing the same types of data fields and responding to the same messages.                                                                                 |
| class inheritance      | The means by which a class inherits variables, values, and methods from its super class(es).                                                                                                                                 |
| class lattice          | A network showing the inheritance relationship among classes.                                                                                                                                                                |
| class variable (CV)    | A variable that contains information shared by all instances of the class. A class variable is typically used for information about a class taken as a whole.                                                                |
| inheritance            | The means by which you can organize information in objects, create objects that are similar to other objects, and update objects in a simplified way.                                                                        |
| Inspector              | A Lisp display program that has been modified to allow you to view classes, objects, and active values.                                                                                                                      |
| instance               | An object described by a particular class. Every object within LOOPS is an instance of exactly one class.                                                                                                                    |
| instance variable (IV) | A variable that contains information specific to an instance.                                                                                                                                                                |
| instantiate            | To make a new instance of a class.                                                                                                                                                                                           |
| lattice                | An arrangement of nodes in a hierarchical network, which allows for multiple parents of each node.                                                                                                                           |
| Masterscope            | A Lisp Library Module program analysis tool that has been modified to allow analysis of LOOPS files.                                                                                                                         |
| message                | A command sent to an object that activates a method defined in the object's class. The object responds by computing a value that is returned to the sender of the message.                                                   |
| metaclass              | Classes whose instances are classes or abstract classes.                                                                                                                                                                     |
| method                 | What an object applies to the arguments of a message it receives. This is similar to a procedure in procedure-oriented programming, except that here, you determine the message to send and the object receiving the message |

|                         |                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | determines the method to apply, instead of the calling routine determining which procedure to apply.                                                                                            |
| mixin                   | A class that is used in conjunction with another class to create a subclass. Mixins never have instances, and hence have <b>AbstractClass</b> as their metaclass.                               |
| object                  | A data structure that contains data and a pointer to functionality that can manipulate the data.                                                                                                |
| property list           | A place for storing additional information on classes, their variables, and their methods.                                                                                                      |
| selector                | Part of a message that is sent to an object. The object uses the selector to determine which method is appropriate to apply to the message arguments.                                           |
| self                    | A method argument that represents the receiver of the message.                                                                                                                                  |
| specialization          | The process of creating a subclass from a class, or the result of that process.                                                                                                                 |
| subclass                | A class that is a specialization of another class.                                                                                                                                              |
| super class             | A class from which a given class inherits variables, values, and methods.                                                                                                                       |
| Tofu                    | An acronym for Top of the universe, which is the highest class in the LOOPS hierarchy.                                                                                                          |
| Unique Identifier (UID) | An alphanumeric identifier that LOOPS uses to store and retrieve objects. Objects do not have UIDs unless they are named, are instances of indexed objects, or are instances printed to a file. |
| wrap                    | Objects have fields that can contain data. Some <b>ActiveValue</b> can be added so this data is stored within it. When this occurs, the <b>ActiveValue</b> wraps the data.                      |

Methods are the expressions that evaluate when a message is sent to an instance or a class. Methods are analogous to Interlisp-D functions, except that they are defined by a LOOPS class and invoked by sending a message to an instance of that class.

This chapter presents the basic constructs used to create and implement methods. Also included are important methods and functions relevant to the definition and maintenance of methods.

---

## 6.1 Categories

---

LOOPS methods can be divided into categories. This section contains a brief description of each method category. These categories serve as additional documentation only; they do not imply differences in implementation.

Any symbol can be used as a category. Categories can be used as a tool for the organization of methods. Methods may belong to more than one category.

---

### **Class** [Category]

---

Messages associated with a class method can only be sent to an object of type class. Methods associated with the class **Class** have this category. See Chapter 3, Classes, for more information on classes.

---

### **Object** [Category]

---

The message associated with an object method can only be sent to an object of type object. Methods associated with the class **Object** have this category.

---

### **Internal** [Category]

---

Internal methods are low-level system methods, and should not be specialized by users.

---

### **Public** [Category]

---

Public methods are defined by the user or the system. These methods can be specialized by users.

---

### **Any** [Category]

---

Methods that have not been categorized belong to this category by default.

---

### **Masterscope** [Category]

---

Masterscope is an interactive program analysis tool. Methods that are predefined for Masterscope are local only to Masterscope and can be used only when Masterscope has been invoked. Refer to the *Lisp Library Modules Manual* for more information on Masterscope.

---

(← *self* **AllMethodCategories**) [Method of Class]

---

Purpose/Behavior: Extracts and lists the categories of all methods defined by the class *self*.

Arguments: *self*            Pointer to a class.

Returns: The categories of the methods defined by the class of *self*.

Categories: Class

Example: Line 98 shows the categories of all methods defined in the class *self*.

```
98←(← ($ Class) AllMethodCategories)
(Class Object Masterscope)
```

---

(← *self* **CategorizeMethods** *categorization*) [Method of Class]

---

Purpose: Allows you to change how methods are categorized.

Behavior: Varies according to the arguments.

- If *categorization* is NIL, this opens a display editor window with a form that represents the current categorizations. After you have exited from the editor, these new categorizations are installed.

- If *categorization* is non-NIL, it must be of the following form:

*(category1 (selector1 ... selectorN)) (category2 (selector ...)).*

A categorization specified by **CategorizeMethods** deletes any previous categorization; i.e., if method Print for class Thing was in categories Internal and I/O, after doing

```
(← ($ Thing) CategorizeMethods ' ((Output
(Print)) (Printing (Print))))
```

Print will be only in categories Output and Printing.

Arguments: *self*            Pointer to a class.

*categorization*

A list in the form as described in Behavior, or NIL.

Categories: Class

Example: This example shows how to use **CategorizeMethods** with categorization NIL.

```
1←(← ($ MetaClass) CategorizeMethods)
```

The following display editor window appears:

```
SEdit Package; INTERLISP
((Any (CreateClass DestroyInstance New NewWithValues))
 (Public (CreateClass DestroyInstance New NewWithValues))
 (Internal NIL)
 (MetaClass (CreateClass))
 (Class (DestroyInstance New NewWithValues)))
```

(← *self* **ChangeMethodCategory** *selector newCategory*) [Method of Class]

Purpose: Changes the category of a selected method.

Behavior: Varies according to the arguments.

- If *selector* is NIL, a menu appears showing the selectors for the class of *self*. This is done using the message **PickSelector** to determine the *selector* that is to have its category changed.
- If *selector* is supplied, but not associated with *self*, this message returns NIL.
- If *newCategory* is an atom, adds *selector* to the category. If *newCategory* is a list of atoms, removes *selector* from all its current categories, then adds it to the categories in the list. If *newCategory* is NIL, pops up a menu showing all of the known categories and an additional item, **\*other\***. If **\*other\*** is selected, you are prompted to enter a new category name.

Arguments: *self* Pointer to a class.

*selector* Method selector for class of *self* or NIL.

*newCategory*  
An atom, a list of atoms, or NIL.

Returns: The new category if there was a change made; else NIL.

Categories: Class

Example: The following command changes the categories of the method associated with **Shape1**.

```
2←(← ($ Window) ChangeMethodCategory
 'Shape1 ' (Window Internal))
(Window Internal)
```

## 6.2 STRUCTURE OF METHOD FUNCTIONS

### 6.2 STRUCTURE OF METHOD FUNCTIONS

## 6.2 Structure of Method Functions

This section discusses the structure of a LOOPS method.

(**Method** :FUNCTION-TYPE *type* ((*class selector*) *self args ...*) *body...*) [Definer]

Purpose: Similar to **DefineMethod**, but gives more control over the argument list and body syntax. Allows use of Common Lisp lambda argument lists, and Common Lisp syntax in the body of the method. This is the form you will see when editing methods.

**Behavior:** Defines a method whose argument list is either Interlisp (default) or Common Lisp style. The body of the method may likewise contain either Common Lisp or Interlisp syntax. Common Lisp syntax is distinguished by lexical scoping, etc. (see the *Common Lisp Implementation Notes* for more information).

**Arguments:**

|                 |                                                                                                                                                                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>     | The :FUNCTION-TYPE type clause is optional and defaults to :IL.<br><br>:IL - The body of the method uses Interlisp syntax, allows CLISP expressions, etc.<br><br>:CL - The body of the method uses Common Lisp syntax (is lexically scoped). |
| <i>class</i>    | The class to which the method will be attached.                                                                                                                                                                                              |
| <i>selector</i> | The new method's selector.                                                                                                                                                                                                                   |
| <i>self</i>     | This argument must be present and first.                                                                                                                                                                                                     |
| <i>args</i>     | If type was given as :CL this argument list may contain Common Lisp keys like &OPTIONAL, &KEY and &REST.                                                                                                                                     |
| <i>body</i>     | The body of the method. If the type was given as :CL it will be treated as the body of a Common Lisp lambda is, e.g. scoping will be lexical.                                                                                                |

**Returns:** The name of the method function.

**Example:**

```
12← (Method :FUNCTION-TYPE :CL ((Window Foo) self bar
&OPTIONAL baz &REST glorp)
 (CL:FORMAT T "Bar ~s baz ~s glorp ~s~%" bar baz
glorp))
13← (← ($ Window) New 'Flarb)
14← (← ($ Flarb) Foo 1 2 3 4)
Bar 1 baz 2 glorp (3 4)
```

---

## 6.3 CREATING, EDITING, AND DESTROYING METHODS

---

### 6.3 CREATING, EDITING, AND DESTROYING METHODS

---

---

## 6.3 Creating, Editing, and Destroying Methods

---

This section describes the methods and functions which are used to create, rename, delete, and edit LOOPS methods.

| Name                          | Type     | Description                                           |
|-------------------------------|----------|-------------------------------------------------------|
| <b>DefineMethod</b>           | Function | Defines a new method on a class.                      |
| <b>DeleteMethod</b>           | Function | Deletes a method from a class.                        |
| <b>EditMethod</b>             | Method   | Invokes the editor on a method of a class.            |
| <b>SubclassResponsibility</b> | Macro    | Appears in the template when you create a new method. |

**(DefineMethod class selector args expr file - )**

[Function]

Purpose: Defines a new method on a class.

Behavior: Varies according to the arguments.

- If *args* is a non-NIL symbol and *expr* is NIL, its function definition is installed as the method for (class selector). This definition must accept an appropriate number of arguments and otherwise work as a LOOPS method. Also, *args* must be a symbol of the form **Name1.Name2** for many of the LOOPS internal routines to handle it properly.
- If *args* is a list of arguments and *expr* is a function, its body will be installed as the definition of **class.selector**.

Arguments: *class* Class in which method is defined.

*selector* Method selector (message).

*args* List of arguments.

*expr* Function definition or NIL.

*file* Place where method is stored.

Example: The following expression shows how to add a method called **Increment** to a class called **Documentation**.

```
(DefineMethod ($ Documentation) 'Increment ' (Number) ' (PLUS number 1)
```

**(DeleteMethod class selector prop )**

[Function]

Purpose: Deletes a method from a class.

Behavior: Varies according to the arguments.

- If *prop* is NIL or T, the method is deleted from the class.
- If *prop* is T, the function definition is also deleted.

Note: You may also delete methods by using the **ClassInheritance Browser**. Position the mouse on the appropriate class, press the middle mouse button, and select **DeleteMethod** from the resulting menu.

Arguments: *class* Class in which method is defined.

*selector* Method selector (message).

*prop* T or NIL; determines whether the function definition is deleted.

Example: The following command deletes the method associated with **'MyOpen** from **LatticeBrowser**.

```
(DeleteMethod ($ LatticeBrowser) 'MyOpen)
```

**(← self EditMethod selector commands okCategories)**

[Method of Class]

Purpose: Invokes the display editor on a method of a class.

Behavior: Varies according to the arguments.

- If *selector* is NIL, a menu of selectors is presented using the message **PickSelector** in *okCategories*. This can be a list or a symbol.

- If *selector* is non-NIL, and if it corresponds to a method that is in not *self*'s class, you are asked whether the method should be created.
- If *selector* cannot be found, the spelling corrector is invoked to find a correct local selector. If it can be corrected, the local method is used, or an inherited method that is made local is used. When the method is finally determined, **EDITF** (refer to the *Lisp Release Notes* and the *Interlisp-D Reference Manual*) is invoked with *commands* passed as the second argument.

Note: You may also edit methods by using the **ClassInheritance Browser**. Position the mouse on the appropriate class, press the middle mouse button, and select **EditMethod** from the resulting menu.

|             |                     |                                           |
|-------------|---------------------|-------------------------------------------|
| Arguments:  | <i>self</i>         | Class name.                               |
|             | <i>selector</i>     | Refers to the method.                     |
|             | <i>commands</i>     | List of <b>EDITF</b> commands.            |
|             | <i>okCategories</i> | Atom or list specifying valid categories. |
| Categories: | Class               |                                           |

(SubclassResponsibility) [Macro]

Purpose/Behavior: Appears in the template when you create a new method. It is used to make sure you specialize a method.

6.4 ESCAPING FROM MESSAGE SYNTAX

6.4 ESCAPING FROM MESSAGE SYNTAX

---

---

## 6.4 Escaping from Message Syntax

---

The methods described in the previous section manipulate methods in a specific order. Sometimes it may be necessary to invoke multiple inherited methods in some other order. The more general functions in this section have been provided to do this.

---

**CAUTION**

These functions do not conform to the conventions of method inheritance and should be used as a last resort and with extreme caution.

---

The following table shows the items in this section.

| Name               | Type     | Description                                                                                                         |
|--------------------|----------|---------------------------------------------------------------------------------------------------------------------|
| <b>DoMethod</b>    | Function | Computes the action which should be a method associated with a class and applies it to an object and arguments.     |
| <b>ApplyMethod</b> | Function | Computes the action which should be a method associated with a class and applies it to an object and argument list. |

|                       |          |                                                                                            |
|-----------------------|----------|--------------------------------------------------------------------------------------------|
| <b>DoFringeMethod</b> | Function | Invokes a method in the class of an object or in each of the super classes for that class. |
|-----------------------|----------|--------------------------------------------------------------------------------------------|

---

**(DoMethod** *object selector class arg1 ... argn*) [Function]

---

|            |                                                                                                                                                                                                            |                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| Purpose:   | Computes the action which should be a method associated with <i>class</i> and applies it to <i>object</i> .                                                                                                |                                            |
| Behavior:  | All of the arguments are evaluated. If <i>class</i> is NIL, <b>DoMethod</b> uses the class of <i>object</i> . If no method from <i>class</i> can be computed from <i>selector</i> , an error is generated. |                                            |
| Arguments: | <i>object</i>                                                                                                                                                                                              | Instance to which action is applied.       |
|            | <i>selector</i>                                                                                                                                                                                            | Evaluates to a method selector.            |
|            | <i>class</i>                                                                                                                                                                                               | NIL or class in which method name resides. |
|            | <i>arg1...argn</i>                                                                                                                                                                                         | The arguments for the method.              |

---

**(ApplyMethod** *object selector argList class*) [Function]

---

|            |                                                                                                                                     |                                      |
|------------|-------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Purpose:   | Same as <b>DoMethod</b> .                                                                                                           |                                      |
| Behavior:  | Applies the selected method to the already evaluated arguments in <i>argList</i> ; otherwise, this is the same as <b>DoMethod</b> . |                                      |
| Arguments: | <i>object</i>                                                                                                                       | Instance to which action is applied. |
|            | <i>selector</i>                                                                                                                     | Evaluates to a method name.          |
|            | <i>arglist</i>                                                                                                                      | The arguments for the method.        |
|            | <i>class</i>                                                                                                                        | Class in which method name resides.  |

Example: This example illustrates the MessageNotUnderstood protocol, the function **ApplyMethod**, and the macro **\_Super**. This is a specialization of the default **MessageNotUnderstood** message that tries to correct the spelling of the selector. (See Chapter 11, Errors and Breaks, for more information on **MessageNotUnderstood**.)

```
(Method ((DwimObject MessageNotUnderstood)
 self selector messageArguments superFlg)
 (LET ((correctSelector (FixSelectorSpelling selector)))
 (COND ((correctSelector (ApplyMethod correctSelector messageArguments))
 (T (_Super))))))
```

Note: *self* is included in the list of **messageArguments**.

---

**(DoFringeMethods** *object selector arg1 ... argn*) [Function]

---

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Purpose:   | Invokes method for <i>selector</i> in the class of <i>object</i> or in each of the super classes for that class.                                                                                                                                                                                                                                                                                                                                             |                  |
| Behavior:  | Evaluates all of the arguments. If the method for <i>selector</i> in the class of <i>object</i> is defined in that class (not through inheritance), <b>DoFringeMethods</b> invokes the local method. If there is no local method, <b>DoFringeMethods</b> goes down the class of <i>object</i> , and for each super invokes its method for selector if one exists. If the supers share supers this can result in the same method being called more than once. |                  |
| Arguments: | <i>object</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                | Class instance.  |
|            | <i>selector</i>                                                                                                                                                                                                                                                                                                                                                                                                                                              | Method selector. |

*arg1...argn* Arguments to *selector*.

Returns: NIL

6.5 MOVEMENT BETWEEN CLASSES

6.5 Movement between Classes

This section describes functions and methods that are used in moving methods between classes, as well as stack method macros.

6.5.1 Movement of Methods

The following functions and methods are used to move methods, instance variables, and class variables between classes.

| Name                    | Type     | Description                                                                            |
|-------------------------|----------|----------------------------------------------------------------------------------------|
| <b>RenameMethod</b>     | Function | Renames a function used as a method.                                                   |
| <b>MoveMethod</b>       | Function | Moves a method from one class to another.                                              |
| <b>MoveMethod</b>       | Method   | Moves a method from one class to another.                                              |
| <b>MoveMethodToFile</b> | Function | Moves a method to this file if it has the same name as a function on a specified file. |
| <b>CalledFns</b>        | Function | Finds names of all functions called from a set of classes.                             |

**(RenameMethod** *classOrName oldSelector newSelector*) [Function]

Purpose: Renames a function used as a method in *classOrName*.

Behavior: This changes the selector for a method. If no method is associated with *oldSelector* or *newSelector*, this generates an error. Explicit references to *oldSelector* such as

`(←Super self oldSelector)`

will not be fixed by **RenameMethod**.

Arguments: *classOrName* Class in which function is defined.

*oldSelector* Old name of method; invokes method before this function is called.

*newSelector* New name of method; invokes method after this function is called.

Returns: If successful, returns *newSelector* in the form **ClassName.Selector**.

Example: The following command renames a method named **Foo** to **Fie** in the class **MyClass**.

```
24←(RenameMethod ($ MyClass) 'Foo 'Fie)
```

**(MoveMethod** *oldClassName newClassName selector newSelector files*) [Function]

Purpose: Moves a method from *oldClassName* to *newClassName*. The method is deleted from *oldClassName*.

Behavior: If *newSelector* is a different name than *selector*, **MoveMethod** renames the method. Explicit references to *oldSelector* such as

```
(←Super self oldSelector))
```

will not be fixed by **RenameMethod**.

Note: You may also move methods by using the **ClassInheritance Browser**. Position the mouse on the appropriate class, press the middle mouse button, and select **MoveMethod** from the resulting menu.

Arguments: *oldClassName*  
Source class.

*newClassName*  
Destination class.

*selector* Method selector to be moved.

*newSelector*  
New name; if NIL, the existing *selector* is preserved.

*files* Files in which the change is to occur.

Example: The following command moves the method **Buy** from class **Car** to class **Boat** and renames the method to **Purchase**.

```
25←(MoveMethod ($ Car) ($ Boat) 'Buy 'Purchase)
Boat.Purchase
```

**(← self MoveMethod** *newClassName selector*) [Method of Class]

Purpose: Moves a method from the class associated with *self* to *newClassName*.

Behavior: Same as the function **MoveMethod**, except that you cannot rename *selector*.

Arguments: *self* Pointer to a class from which the method is taken.

*newClassName*  
Destination class; must be a class, not a class name.

*selector* Method selector to be moved.

Returns: **NewsClass.Selector**

**(MoveMethodsToFile** *file*) [Function]

Purpose/Behavior: Moves a method to this file if it has the same name as a function on *file*.

Arguments: *file* Name of a file to which methods are moved.

Returns: Normally T; NIL if a method does not have the same name as a function on *file*.

**(CalledFns classes definedFlg )** [Function]

Purpose: Finds names of all functions called from a set of *classes*.

Behavior: Varies according to the arguments.

- If *definedFlg* is NIL, all the functions associated with *classes* are returned.
- If *definedFlg* is T, the defined functions are returned.
- If *definedFlg* is 1, the undefined functions are returned.

Arguments: *classes*      List of classes to search.  
*definedFlg*    NIL, 1, or T.

Returns: NIL or the list of functions.

Example: The following command finds all functions called from the class **Method**.

`(CalledFns ' (Method) )`

## 6.5.2 Stack Method Macros

---

This section describes macros that access methods on the stack.

**(ClassNameOfMethodOwner)** [Macro]

Purpose: Uses the stack to perform a help check. Returns the name of the class to which the method on top of the stack belongs.

**(SelectorOfMethodBeingCompiled)** [Macro]

Purpose: Uses the stack to perform a help check. Returns the name of the method being compiled.

**(ArgsOfMethodBeingCompiled)** [Macro]

Purpose: Uses the stack to perform a help check. Returns all arguments associated with the method being compiled.

## 7. MESSAGE SENDING FORMS

Objects in LOOPS communicate with each other by sending messages. This chapter describes the standard message sending forms used in LOOPS.

The following table shows the macros in this section.

| Name                      | Type                   | Description                                                                                                                                      |
|---------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>←</code>            | Macro and Function     | Sends a message to an object.                                                                                                                    |
| <b>SEND</b>               | Macro and Function     | Sends a message to an object.                                                                                                                    |
| <code>←!</code>           | Macro and Function     | Evaluates the selector and sends a message to an object.                                                                                         |
| <code>←IV</code>          | Macro                  | Invokes the function stored in an instance variable of the object.                                                                               |
| <code>←Try</code>         | Macro                  | Sends a message to an object only if it has a corresponding method.                                                                              |
| <code>←Proto</code>       | Macro                  | Sends a message to the prototype instance of a class.                                                                                            |
| <code>←Super</code>       | Macro and Function     | Combines an inherited method with local code; must appear in the body of a method.                                                               |
| <code>←Super?</code>      | Macro                  | Combines an inherited method with local code; must appear in the body of a method. This does not cause an error if there is no inherited method. |
| <code>←SuperFringe</code> | Macro and Function     | Invokes general methods for objects with more than one super class from which to inherit methods; must appear in the body of a method.           |
| <code>←New</code>         | NLambda NoSpread Macro | Creates an instance of a class and then sends a message to that instance.                                                                        |
| <b>FetchMethod</b>        | Macro                  | Finds the function name which implements the method invoked by a selector.                                                                       |

In addition, Chapter 8, Active Values, contains a description of `←AV`, and Chapter 15, Performance Issues, contains a description of `←Process` and `←Process!`.

`(← self sel arg1 ... argn )` [Macro and Function]

Purpose: Sends the message with the selector *sel* to an object *self*. This is the standard way to send a message.

Behavior: Evaluates all arguments except *sel*.

When an object receives a message, it tries to match the selector *sel* with the names of its methods. If the object or the message does not recognize the message, a **Not Understood** error occurs.

The function version does more error checking than the macro and also attempts to convert unbound symbols into names for classes and instances.

Arguments: *self*            Pointer to an object.  
*sel*            Selector; not evaluated.  
*arg1...argn*   Arguments associated with *sel*.

Returns:    The value returned by the method associated with *sel*.

Example:    In this example, the message **New** is sent to the class **Window**. This returns the newly created instance.

```
76←(← ($ Window) New 'Window1)
#,$(& Window (|OZW0.1Y:.;h.Qm:| . 495))
```

---

**(SEND *self sel arg1 ... argn*)** [Macro and Function]

---

Purpose:    Same as ←, above.

Example:    The expression

```
(SEND ($ Window) 'New 'Window1)
```

is equivalent to

```
(← ($ Window) New 'Window1)
```

---

**(←! *self sel arg1 ... argn*)** [Macro and Function]

---

Purpose/Behavior:    Sends a message with the selector *sel* to an object *self*. It differs from ← in that it evaluates all of its arguments, including *sel*.

Arguments:    *self*            Pointer to an object.  
*sel*            Selector, which is evaluated.  
*arg1...argn*   Arguments associated with *sel*.

Example:    This example illustrates the fact that ←! evaluates the *sel* argument.

The code

```
(for sel in '(Shape Invert)
 do (←! ($ Window1 sel))
```

is equivalent to

```
(←Window1 Shape) (←Window1 Invert)
```

---

**(←IV *self IVName arg1...argn*)** [Macro]

---

Purpose:    Invokes the function stored in the instance variable *IVName* of the object *self*.

Behavior:    Gets a function from *IVName* of *self* and applies the function to *self* with the arguments *args*. Returns the value of the function or breaks.

            ←IV does not evaluate *IVName*.

Arguments:    *self*            Pointer to an object.  
*IVName*       Instance variable name, which is not evaluated.

*arg1...argn* Arguments associated with *sel*; bound to arguments specified in the call.

**(←Try self sel arg1 ... argn)** [Macro]

**Purpose:** Sends the message with the selector *sel* to *self*, but only if there is a corresponding method.

**Behavior:** If *sel* is in fact a selector of *self*, the method is applied and the appropriate value is returned. If the method is not a selector of *self*, the symbol **NotSent** is returned.

**Arguments:** *self* Pointer to an object.  
*sel* Selector; not evaluated.  
*arg1...argn* Arguments associated with *sel*.

**Example:** The expression (←(\$ Window1) abcd) normally causes a break.

```
79←(←Try ($ Window1) Update)
NIL

80←(←Try ($ Window1) abcd)
NotSent
```

**(←Proto class sel arg1 ... argn)** [Macro]

**Purpose:** Sends a message to the prototype instance of a class.

**Behavior:** Creates an instance of a class, if necessary, and puts that instance on the class variable **Prototype** of *class*, marking the class as changed. This instance is referred to as the prototype instance. **Proto** then sends the message *sel* to that instance.

**Arguments:** *class* Pointer to a class.  
*sel* Selector; not evaluated.  
*arg1...argn* Arguments associated with *sel*.

**Example:** Usually only one instance of **LoopsIcon** is needed at a time, so the class **LoopsIcon** keeps one in its class variable **Prototype**.

```
81←(←Proto ($ LoopsIcon) Open)
```

**(←Super self sel arg1 ... argn)** [Macro and Function]

**Purpose:** Can invoke an inherited method within a method. ←**Super** must appear in the body of a method; it cannot be invoked directly.

**Behavior:** Searches up the class hierarchy and invokes the next more general method of the same name, even if a specialized method is inherited over a distance. It returns the value from that super method. You can use the form (←**Super**) when the arguments are not changed. If no arguments are provided, ←**Super** uses the arguments of the method from which it was called.

←**Super** and the other similar functions are now lexically scoped; that is, it is illegal to call ←**Super** anywhere but within a method body, and any selector given must be the same as the selector for that method.

**Arguments:** *self* Pointer to an object.  
*sel* Selector; not evaluated. Must be the same as the selector of the method in which the ←**Super** appears.

*arg1...argn* Arguments associated with *sel*.

Example: Two examples of **←Super** are included:

- One example shows where the arguments are not changed.
- One example shows where the arguments are changed.

*Example 1:* A use of **←Super** where the arguments are not changed.

Define a subclass of **Window** that will call **RINGBELLS** before a window is shaped.

```
(DefineClass 'RingingWindow ' (Window))
```

Through the browser interface, specialize the method **Shape**, to create the following method.

```
(RingingWindow.Shape
 (Method ((RingingWindow Shape)
 self newRegion noUpdateFlg)
 COMMENT **COMMENT**
 (RINGBELLS)
 (←Super)))
```

Executing the following command calls **RINGBELLS** before the new window is shaped.

```
(←New ($ RingingWindow) Shape)
```

In the method above, if the positions of **RINGBELLS** and **(←Super)** were reversed, **RINGBELLS** would be called after the window was shaped.

*Example 2:* A use of **←Super** where the arguments are changed.

Define a subclass of **Window** that will be square.

```
(DefineClass 'SquareWindow ' (Window))
```

Through the browser interface, specialize the method **Shape**, to create the following method.

```
(SquareWindow.Shape
 (Method ((SquareWindow Shape)
 self newRegion noUpdateFlg)
 COMMENT **COMMENT**
 (←Super self Shape
 (create REGION
 using
 (SETQ newRegion
 (OR newRegion
 (GETREGION)))
 HEIGHT ← (fetch WIDTH
 of
 newRegion)
 noUpdateFlg)))
```

Executing the following command creates a square window:

```
(←New ($ SquareWindow) Shape)
```

---

(←**Super?** *self sel arg1 ... argn*) [Macro]

---

- Purpose: Invokes the single next most general method; must appear in the body of a method. This does not cause an error if no inherited method matches.
- Behavior: Analogous to ←**Super**. The difference between ←**Super?** and ←**Super** is that ←**Super?** does not break if the *sel* does not have a more general method, whereas ←**Super** generates a break if there is not a more general method.
- Arguments: *self* Pointer to an object.
- sel* Selector; not evaluated. Must be the same as the selector of the method in which the ←**Super?** appears.
- arg1...argn* Arguments associated with *sel*.

---

(←**SuperFringe** *self sel arg1 ... argn*) [Macro and Function]

---

- Purpose: Invokes general methods for objects with more than one super class from which you wish to inherit methods; must appear in the body of a method.
- Behavior: It invokes and executes the next more general method of the same name from each of the classes on the super's list *object's* class. Calling ←**SuperFringe** is analogous to sending ←**Super** up through each item on the super's list. If no arguments are provided ←**SuperFringe** uses the arguments of the method from which it was called.
- Arguments: *self* Pointer to an object.
- sel* Selector; not evaluated. Must be the same as the selector of the method in which the ←**SuperFringe** appears.
- arg1...argn* Arguments associated with *sel*.

---

(←**New** *class selector arg1 ... argn*) [NLambda NoSpread Macro]

---

- Purpose: Creates an instance of class and then sends *sel* and arguments to that instance.
- Behavior: Creates a new instance of a class and sends a message to that instance. It returns the instance as a value and discards any value that may be returned by invoking the method specified by selector. ←**New** is equivalent to (← (← *ClassName New*) *selector arg1 ... argn*).
- Arguments: *class* Pointer to a class.
- sel* Selector; not evaluated.
- arg1...argn* Arguments associated with *sel*.
- Returns: The new instance.
- Example: This example shows an example of ←**New** that creates a new instance of the class **Window** and asks you to shape it.

```
99← (←New ($ Window) Shape)
#, ($& Window (|OZW0.1Y:.;h.Qm:| . 497))
```

---

(← *class* **FetchMethod** *sel*) [Method of Class]

---

- Purpose: Finds the function name which implements the method invoked by sending a message with the selector *sel* to an instance of *class*. The function can be found in either *class* or its supers.

Behavior: Calls the function **FetchMethod**.

Arguments: *class*            Pointer to a class.  
*sel*                    Selector; evaluated.

Returns: The function for *sel* or NIL.

Example: Line 100 shows that the class **Window** implements the method **Update**.

```
100←(← ($ Window) FetchMethod 'Update)
Window.Update
```

Line 1 shows that neither the class **Window** nor any of its supers implements the method **abcd**.

```
1←(← ($ Window) FetchMethod 'abcd)
NIL
```

Line 2 shows that the class **Object** implements the method **PP** which will be triggered when instances of the class **Window** receive the **PP** message.

```
2←(← ($ Window) FetchMethod 'PP)
Object.PP
```

[This page intentionally left blank]

Active values are used in LOOPS to transpose the access of data within an object to a message being sent to a different object. Typical uses include:

- Causing side effects to occur when data is accessed
- Debugging
- Initializing variables
- Maintaining constraints between variables

An **ActiveValue** is an instance of a subclass of the LOOPS class **ActiveValue**. When an **ActiveValue** instance is installed in the value of a variable, further references to that variable cause messages to be sent to the instance.

LOOPS provides several kinds of active values which are described in this chapter. You can obtain new behavior by specializing one of the existing LOOPS **ActiveValue** subclasses.

When **GetValue** notices that an **ActiveValue** is installed on the variable, it sends the **GetWrappedValue** message to the **ActiveValue**. Similarly, when **PutValue** notices that an **ActiveValue** is installed on the variable, it sends the **PutWrappedValue** message to the **ActiveValue**. The value returned from the get or put is the value returned from the message send. Each specialization of **ActiveValue** either inherits these methods from its superclasses or specializes them to call user code. The messages are received and processed by the **ActiveValue** instances.

For example, assume that you are modeling a simulation that requires the value of an instance variable called `windSpeed` to be a random value. You can make the value of `windSpeed` into an active value called (`$ RandomWindSpeedAV1`). Now, if you try to determine the value of `windSpeed` by entering

```
(@ ($ SomeAirport) windSpeed)
```

the value returned from this expression is the value returned from

```
(← ($ RandomWindSpeedAV1) GetWrappedValue . otherArgs)
```

This returns the required random value.

The variable containing the **ActiveValue** may still have a current value. Most system **ActiveValue** subclasses are specializations of **LocalStateActiveValue**, which uses an instance variable `localState` in the **ActiveValue** to hold the value.

For efficient implementation, LOOPS uses a special Interlisp data type, the `annotatedValue` data type, to "wrap" each **ActiveValue** instance when it is installed as a value within an object; the `annotatedValue` contains the **ActiveValue** instance. That is, if the value of an instance variable is said to be an active value, in actuality, the value of the instance variable is an `annotatedValue` which contains the active value. This allows every **GetValue** or **PutValue** to use Interlisp's microcoded type checking mechanism to see if it should be processed normally or via the **ActiveValue** mechanism. This extra layer is largely invisible in application programs. LOOPS also contains a class

**AnnotatedValue** to handle the occasional accident when a user forgets about the distinction between **annotatedValue** and **ActiveValue**, and attempts to treat an **annotatedValue** as a **LOOPS** object.

The class **ActiveValue** defines the general protocol followed by all active value objects. Methods setting up the basic functionality of **ActiveValues** are defined in this class and inherited by all its specializations. Methods defined in this class include **AVPrintSource** to specify how **annotatedValues** print, **AddActiveValue** to install an **ActiveValues**, and **DeleteActiveValue** to delete an installed **ActiveValue**.

The class **ActiveValue** itself is an abstract class; that is, it is a placeholder in the class hierarchy that is not intended to be instantiated. When this documentation refers to an active value object, it is referring to an instantiation of a specialization of the class **ActiveValue**.

Note: The current **ActiveValue** is different from the **activeValue** implementation in the Buttruss version of **LOOPS**. See Appendix A, Active Values in Buttruss **LOOPS**, for more information.

---

## 8.1 Using Active Values

---

A general template is available when using active values. As with all templates, you should not blindly follow it. A good understanding of the active value mechanism is necessary to avoid errors in more complicated situations.

- Determine the functionality that you want the active value to provide. For example, will it cause a side effect to occur on access of data? Will it maintain constraints between two pieces of data? The required functionality will give an indication of which active value class you should use.
- Specialize one of the active value classes to satisfy your specific requirements, if necessary.
- Create an instance of the active value class that you have chosen or created.
- Initialize the contents of that instance, if necessary.
- Install that active value instance on the data that you want to become active. This is accomplished by using the **AddActiveValue** message.

In a number of situations, you may want to install an active value on an instance variable for every instance of a class. One technique for doing this is discussed in Section 8.5, "Active Values in Class Structures."

### 8.2 SPECIALIZATIONS OF THE CLASS ACTIVEVALUE

---

## 8.2 SPECIALIZATIONS OF THE CLASS ACTIVEVALUE

---

---

## 8.2 Specializations of the Class ActiveValue

---

The class **ActiveValue** is an abstract class, and therefore cannot be instantiated. This class contains a number of methods, described in Section 8.3, "ActiveValue Methods," that are necessary for the active value mechanism to function. As a user, you will be making active values which are instances of some subclass of **ActiveValue**, either one of those already provided or one that you created. Figure 8-1 shows the class **ActiveValue** and its specializations. This section describes the subclasses of **ActiveValue**

in order of their appearance in this figure. Also included is information on specializing active values.

Figure 8-1. The Class **ActiveValue** and its Specializations

### 8.2.1 IndirectVariable

This specialization sets up the functionality of an **ActiveValue** to return the value of another variable as its value. It is analogous to the concept of indirect addressing in other computer languages.

Note: Indirect variables must be the innermost of nested active values. Wrapping precedence (see Section 8.3, "Active Value Methods") insures this.

#### IndirectVariable [Class]

**Purpose:** Enables variable values to be accessed indirectly from other variables. This simulates two variables sharing the same memory location. This is a useful technique for implementing simulations and enforcing constraints.

**Behavior:** When a Fetch is made on the variable containing the **IndirectVariable** instance, this active value retrieves and returns the value of the tracked variable. If a Store is made with the variable containing the **IndirectVariable** instance, this active value stores the new value in the tracked variable. Essentially, this forces the two variables to share the same data.

**Instance Variables:**

- object** Object instance containing the tracked value.
- varName** The name of the variable being tracked.
- propName** If non-NIL, the name of the variable property being tracked.
- type** Type of variable being tracked. Value can be CV, IV or NIL, which defaults to IV.

**Examples:** Several examples are included to show the use of **IndirectVariable**.

**Example 1:** Consider a chemical reactor simulation where you have a tank draining into a pipe. The output pressure of the tank needs to equal the input pressure of the pipe. The following demonstrates this.

First, build the appropriate pipe and tank classes and make instances of them.

```

78← (DefineClass 'Tank)
 #, ($C Tank)

79← (DefineClass 'Pipe)
 #, ($C Pipe)

```

```
80← (← ($ Tank) AddIV 'outputPressure)
outputPressure
```

```
81← (← ($ Pipe) AddIV 'inputPressure)
inputPressure
```

```
82← (← ($ Tank) New 'tank1)
#,$& Tank (NYW0.0X%:.aF4.6R8 . 5))
```

```
83← (← ($ Pipe) New 'pipe1)
#,$& Pipe (NYW0.0X%:.aF4.6R8 . 6))
```

Create an instance of **IndirectVariable** and initialize its contents to point to the tank's output pressure.

```
84← (← ($ IndirectVariable) New 'indVar1)
#,$& IndirectVariable (NYW0.0X%:.aF4.6R8 . 7))
```

```
85← (←@ ($ indVar1) object ($ tank1))
#,$& Tank (NYW0.0X%:.aF4.6R8 . 5))
```

```
86← (←@ ($ indVar1) varName 'outputPressure)
outputPressure
```

Install the active value instance as the value of the pipe's input pressure.

```
87← (← ($ indVar1) AddActiveValue ($ pipe1) 'inputPressure)
#,$AV IndirectVariable (indVar1 (NYW0.0X%:.aF4.6R8 . 7)) (object
#,$& Tank (NYW0.0X%:.aF4.6R8 . 5))) (varName outputPressure))
```

Accesses to either the pipe's input pressure or the tank's output pressure produce the same result.

```
90← (@ ($ pipe1) inputPressure)
NIL
```

```
92← (←@ ($ pipe1) inputPressure 100)
100
```

```
94← (@ ($ tank1) outputPressure)
100
```

```
95← (←@ ($ tank1) outputPressure 200)
200
```

```
96← (@ ($ pipe1) inputPressure)
200
```

An inspector window of (\$ pipe1) appears as follows:

```
All Values of Pipe ($ pipe1).
inputPressure #,$AV IndirectVariable (indVar1 (
```

**Example 2:** Consider a conveyor that must be three feet above a bin. Assume both have an instance variable named height.

First, create the classes and instances.

```
53← (DefineClass 'Bin)
#,$C Bin)
```

```
54← (DefineClass 'Conveyor)
#,$C Conveyor)
```

```
55← (← ($ Bin) AddIV 'height 0)
height
```

```

56← (← ($ Conveyor) AddIV 'height 0)
height

57← (← ($ Bin) New 'bin1)
#,$& Bin (|DAW0.1Y:.H53.]99| . 506))

58← (← ($ Conveyor) New 'conveyor1)
#,$& Conveyor (|DAW0.1Y:.H53.]99| . 507))

```

Create a specialization of **IndirectVariable** and specialize the methods **GetWrappedValue** and **PutWrappedValue**. You need to specialize **IndirectVariable** because you do not want to maintain equality between the two variables, but instead want to maintain a different mathematical relationship. The **\_Supers** are used to use the default behavior of **IndirectVariable** which takes care of retrieving or storing the data into the tracked variable.

```

59← (DefineClass '3FeetAbove
' (IndirectVariable))
#,$C 3FeetAbove)

```

```

SEdit 3FeetAbove.GetWrappedValue Package: INTERLISP
(Method ((3FeetAbove GetWrappedValue) self
 containingObj varName propName type)
 ;; Compute value of indirect variable and add 3 to it
 (PLUS 3
 (←Super self GetWrappedValue
 containingObj varName propName
 type))))

```

```

SEdit 3FeetAbove.PutWrappedValue Package: INTERLISP
(Method ((3FeetAbove PutWrappedValue) self
 containingObj varName newValue propName type)
 ;; Instead of placing newValue here, subtract 3
 ;; from it and put it in the indirect variable
 (←Super self PutWrappedValue containingObj
 varName (DIFFERENCE newValue 3)
 propName type)
 ;; return newValue
 newValue)

```

Create an instance of **3FeetAbove** and initialize its contents to point to the bin's height.

```

65← (← ($ 3FeetAbove) New '3fa1)
#,$& 3FeetAbove (|DAW0.1Y:.H53.]99| . 505))

66← (←@ ($ 3fa1) object ($ bin1))
#,$& Bin (|DAW0.1Y:.H53.]99| . 506))

67← (←@ ($ 3fa1) varName 'height)
height

```

Install this instance of **3FeetAbove** as the value of the conveyor's height.

```

68← (← ($ 3fa1) AddActiveValue ($ conveyor1) 'height)
#,$AV 3FeetAbove (3fa1 (|DAW0.1Y:.H53.]99| . 505))
 (object #,$& Bin (|DAW0.1Y:.H53.]99| . 506))
 (varName height))

```

The height of **bin1** defaults to 0, what is the height of **conveyor1**?

```

69← (@ ($ bin1) height)
0

```

```
70← (@ ($ conveyor1) height)
3
```

Set either **bin1's** height or **conveyor1's** height and notice how they track each other.

```
71← (←@ ($ bin1) height 15)
15
```

```
72← (@ ($ conveyor1) height)
18
```

```
73← (←@ ($ conveyor1) height 21)
21
```

```
74← (@ ($ bin1) height)
18
```

---

## 8.2.2 LocalStateActiveValue

---

This specialization sets up a class of **ActiveValue** that contains the instance variable **localState**, which is used primarily for storing the value of the referenced variable.

If you need an active value that will produce your own specific side-effect, you will most likely use your own specialization of **LocalStateActiveValue**. The data that would have been accessed, had an active value not been installed, is stored in the **localState** instance variable.

---

### LocalStateActiveValue

[Class]

**Purpose:** Creates a subclass of **ActiveValue** with an instance variable to hold the current value of the referenced variable.

**Behavior:** Holds the data that normally is stored in the variable where it is installed. At installation time, the current variable value is placed in the **localState** instance variable of the **ActiveValue**. Subclasses of **LocalStateActiveValues** are the most common **ActiveValue** instances.

The class **LocalStateActiveValue** is commonly specialized. In particular, it is usually desirable to specialize the methods **GetWrappedValue** and **PutWrappedValue** associated with new subclasses of **LocalStateActiveValue**. These methods implement the active value messages sent when the variable is accessed.

**Instance Variable:** **localState** Stores the value of the referenced variable.

**Examples:** Several examples are included to show the use of **LocalStateActiveValue**.

**Example 1:** In this example, an active value will print a message if an attempt is made to store an out-of-range value in an instance variable.

Define a subclass of **LocalStateActiveValue** and give it two instance variables that will store the values of the limits.

```
99← (DefineClass 'WarningAV' (LocalStateActiveValue))
#, ($C WarningAV)

100← (← ($ WarningAV) AddIV 'lowTrigger 0)
lowTrigger

101← (← ($ WarningAV) AddIV 'highTrigger 100)
highTrigger
```

Specialize **LocalStateActiveValue**'s **PutWrappedValue** method to create one for **WarningAV**.

```
SEdit WarningAV.PutWrappedValue Package: INTERLISP
(Method ((WarningAV PutWrappedValue) self containingObj
 varName newValue propName type)
 ;; If newValue is greater than highTrigger or lower
 ;; than lowTrigger, then print a message, but store
 ;; the data anyway
 (if (OR (< newValue (@ lowTrigger))
 (> newValue (@ highTrigger)))
 then (PRINTOUT T "The value " newValue
 " is out of range." T))
 (<Super self PutWrappedValue containingObj
 varName newValue propName type))
```

Create an instance of a Bin and attach an instance of a **WarningAV** to its height.

```
4← (← ($ Bin) New 'bin3)
#, ($& Bin (|DAW0.1Y:.H53.]99| . 513))

5← (←New ($ WarningAV) AddActiveValue ($ bin3) 'height)
#, ($& WarningAV (|DAW0.1Y:.H53.]99| . 514))
```

Attempt to store various values into the bin's height.

```
7← (←@ ($ bin3) height 10)
10

8← (←@ ($ bin3) height -10)
The value -10 is out of range.
-10

9← (←@ ($ bin3) height 110)
The value 110 is out of range.
110

10← (@ ($ bin3) height)
110
```

**Example 2:** In this example, an active value will return a random number when it is read from. Puts to it will change the range of the random value returned on gets. This will use **localState** for something other than storing the data for active values that provide only pure side-effect behavior.

```
99← (DefineClass 'RandomAV '(LocalStateActiveValue))
#, ($C RandomAV)

100← (← ($ RandomAV) AddIV 'localState '(0 100))
localState
```

Specialize **LocalStateActiveValue**'s **PutWrappedValue** and **GetWrappedValue** methods to create them for **RandomAV**.

```
SEdit RandomAV.GetWrappedValue Package: INTERLISP
(Method ((RandomAV GetWrappedValue) self containingObj
 varName propName type)
 ;; Get the value of the localState.
 ;; We'll assume for this example that the value returned
 ;; is a list of two numbers. If it is not, we get an error.
 (APPLY #'RAND (@ localState)))
```

```
SEdit RandomAV.PutWrappedValue Package: INTERLISP
(Method ((RandomAV PutWrappedValue) self containingObj
 varName newValue propName type)
 ;; We'll assume that the new value is a list of two
 ;; numbers.
 (←@ localState newValue))
```

Now, try to test this.

```
36← (DefineClass 'RandomTest)
#,$C RandomTest)

39← (← IT AddIV 'randomIV)
randomIV

40← (← ($ RandomTest) New 'rt1)
#,$& RandomTest (DCW0.0X%:.aF4.5S; . 518))

41← (←New ($ RandomAV) AddActiveValue ($ rt1) 'randomIV)
#,$& RandomAV (DCW0.0X%:.aF4.5S; . 519))

42← (@ ($ rt1) randomIV)
24

43← redo
32

44← redo
9

45← redo
49

46← (←@ ($ rt1) randomIV '(4.0 5.0))
(4.0 5.0)

47← (@ ($ rt1) randomIV)
4.190201

48← REDO
4.1129

49← REDO
4.380234

50← REDO
4.397278
```

---

### 8.2.2.1 ExplicitFnActiveValue

**ExplicitFnActiveValue** emulates the activeValue implementation from the Buttress version of LOOPS. Users are discouraged from using this particular form of active values within new projects.

See the *LOOPS Users' Modules* for details on *LOOPSBACKWARDS*, which describes **ExplicitFnActiveValue**. See Appendix A, Active Values in Buttriss *LOOPS*, for details on the compatibility of **ActiveValue** with *activeValue*.

### 8.2.2.2 NoUpdatePermittedAV

This specialization sets up a class of **ActiveValue** that prevents the value of a variable from being replaced.

#### NoUpdatePermittedAV

[Class]

- Purpose:** Prevents the value of a variable from being replaced using the **PutValue** method.
- Behavior:** Stores the current value of the variable in **localState**, then prevents it from being updated. **GetWrappedValue** requests return the value found in **localState**, but **PutWrappedValue** requests cause a break with the break message **NoUpdatePermitted!**, or a message if sent from the Exec.
- Example:** Suppose an identification number for a piece of data should never be changed. Installing a **NoUpdatePermittedAV** in the data's ID number will cause a break if a replacement attempt is made.

Start with a user-defined class named **Datum**. Make a **Datum** instance named **Datum1**. Set the instance variable named **idNumber** to the value 999. Look at the instance. Make a new instance of **NoUpdatePermittedAV**, and name it **NumberGuard**. Install the **ActiveValue** in the instance variable **idNumber** of the instance **Datum1**. Look at the **ActiveValue** instance; the **localState** instance variable contains the previous value of **idNumber**. To test this **ActiveValue**, attempt to replace the **idNumber** of **Datum1** with a new value.

```
67← (DefineClass 'Datum)
#, ($C Datum)

68← (← ($ Datum) AddIV 'idNumber 0)
idNumber

69← (← ($ Datum) New 'Datum1)
#, ($& Datum (|DAW0.1Y:.H53.]99| . 524))

70← (←@ ($ Datum1) idNumber 999)
999

71← (← ($ Datum1) PP)
(DEFINST Datum (Datum1 (|DAW0.1Y:.H53.]99| . 524)) (idNumber 999))
#, ($& Datum (|DAW0.1Y:.H53.]99| . 524))

74← (← ($ NoUpdatePermittedAV) New 'NumberGuard)
#, ($& NoUpdatePermittedAV (|DAW0.1Y:.H53.]99| . 525))

75← (← ($ NumberGuard) AddActiveValue ($ Datum1) 'idNumber)
#, ($AV NoUpdatePermittedAV (NumberGuard (|DAW0.1Y:.H53.]99| . 525))
(localState 999))

76← (← ($ Datum1) PP)
(DEFINST Datum (Datum1 (|DAW0.1Y:.H53.]99| . 524))
(idNumber #, ($AV NoUpdatePermittedAV (NumberGuard
(|DAW0.1Y:.H53.]99| . 525)) (localState 999))))
#, ($& Datum (|DAW0.1Y:.H53.]99| . 524))

77← (←@ ($ Datum1) idNumber 888)
No update permitted!
NIL
```

### 8.2.2.3 LispWindowAV

---

This specialization sets up a class of **ActiveValue** used by the system to guarantee that the **window** instance variable within a LOOPS **Window** instance contains an Interlisp window. This class provides functionality required by the LOOPS system, and should not generally be used by LOOPS users.

---

|                     |         |
|---------------------|---------|
| <b>LispWindowAV</b> | [Class] |
|---------------------|---------|

---

- |           |                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:  | Guarantees that a variable contains a window which has been made into a LOOPS window.                                                                                                                                                                                                                                                            |
| Behavior: | Meant to be installed only in the instance variable <b>window</b> of instances of class <b>Window</b> . A specialization of <b>LocalStateActiveValue</b> . Checks to see if its <b>localState</b> is a window, and assures that other instance variables of the window instance are set correctly. See Chapter 19, Windows, for further details. |

### 8.2.2.4 Breaking and Tracing Active Values

---

The following active values are all specializations of **LocalStateActiveValue** and are used for debugging, as described in Chapter 12, Breaking and Tracing. This chapter also describes **UnbreakIt**, which unbreaks or untraces a method of a class. These classes provide functionality required by the LOOPS system, and are not generally used by LOOPS users.

Note: All breaks and traces occur before the variable is read or modified.

---

|                   |         |
|-------------------|---------|
| <b>BreakOnPut</b> | [Class] |
|-------------------|---------|

---

- |           |                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:  | Breaks when a replacement attempt is made.                                                                                                                  |
| Behavior: | Breaks when a replacement attempt is made. Local variables bound at the time of the break are <b>containingObj</b> , <b>varName</b> , and <b>propName</b> . |

---

|                        |         |
|------------------------|---------|
| <b>BreakOnPutOrGet</b> | [Class] |
|------------------------|---------|

---

- |           |                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:  | Breaks when a retrieval or replacement of a variable is made. This is a specialization of <b>BreakOnPut</b> .                                                                          |
| Behavior: | Break occurs before any access to the variable where it is installed. Local variables bound at the time of the break are <b>containingObj</b> , <b>varName</b> , and <b>propName</b> . |

---

|                   |         |
|-------------------|---------|
| <b>TraceOnPut</b> | [Class] |
|-------------------|---------|

---

- |           |                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:  | Traces replacements of a variable.                                                                                                                                                                                          |
| Behavior: | Has a specialized <b>PutWrappedValue</b> method that causes the values of the arguments <b>containingObj</b> , <b>varName</b> , and <b>propName</b> to print in the trace window when the variable is about to be modified. |

---

|                        |         |
|------------------------|---------|
| <b>TraceOnPutOrGet</b> | [Class] |
|------------------------|---------|

---

- |          |                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------|
| Purpose: | Traces retrievals and replacements of a variable. This is a specialization of <b>TraceOnPut</b> . |
|----------|---------------------------------------------------------------------------------------------------|

Behavior: The **GetWrappedValue** method is also specialized so that the variable is traced before any access of the variable where it is installed.

### 8.2.2.5 AppendSuperValue

This specialization allows the value of a variable to reside only partially in the local instance or class. This is a specialization of the **ReplaceMeAV**, **InheritingAV**, and **LocalStateActiveValue** classes.

#### AppendSuperValue [Class]

Purpose: Allows the value of a variable to be defined by both a local value and an inherited value.

Behavior: When an instance of **AppendSuperValue** is installed in a variable, Get-references return its **localState** appended to the end of the inherited value the variable would have if it had no local value. Any **PutValue** to the variable replaces the active value, not just the **localState**; **InheritingAV** and its specializations are designed for use more in class variables where replacement is infrequent.

Examples: Several examples are included to show the use of **AppendSuperValue**.

**Example 1:** Append the **localState** of the instance variable **idNumber** to the default value specified in the class description.

```
23← (DefineClass 'Datum)
#, ($C Datum)

24← (← ($ Datum) AddIV 'idNumber '(5))
idNumber

25← (← ($ Datum) New 'Datum1)
#, ($ Datum1)

26← (@ ($ Datum1) idNumber)
(5)

27← (←@ ($ Datum1) idNumber '(9))
(9)

28← (@ ($ Datum1) idNumber)
(9)

29← (←New ($ AppendSuperValue) AddActiveValue ($ Datum1) 'idNumber)
#, ($& AppendSuperValue (45 . 54648))

30← (@ ($ Datum1) idNumber)
(5 9)
```

**Example 2:** In this example, there are two classes of cars; the **Two-tone-Car** class is a subclass of the class **Car**. Each **Car** class has the instance variable **color**. The default value for **color** in the class **Car** is (white).

```
89← (DefineClass 'Car)
#, ($C Car)

90← (DefineClass 'Two-tone-Car '(Car))
#, ($C Two-tone-Car)

91← (← ($ Car) AddIV 'color '(white))
color
```

```
92← (← ($ Two-tone-Car) AddIV 'color)
color
```

The default value for color in the class **Two-tone-Car** is an instance of **AppendSuperValue** with its **localState** set to (blue). The technique for adding active values as default values in a class is discussed in Section 8.3.1, "Adding and Deleting Active Values."

```
100← (← ($ AppendSuperValue) New 'asv1)

1← (←@ ($ asv1) localState '(blue))

2← (PutClassIV ($ Two-tone-Car) 'color
 (create annotatedValue
 annotatedValue ← ($ asv1)))
#, ($AV AppendSuperValue (asv1 (|DAW0.1Y:.H53.]99| . 528))
 (localState (blue)))

9← (← ($ Car) New 'car1)
#, ($& Car (|DAW0.1Y:.H53.]99| . 531))

10← (← ($ Two-tone-Car) New 'ttcar1)
#, ($& Two-tone-Car (|DAW0.1Y:.H53.]99| . 532))

11← (@ ($ car1) color)
(white)
```

When an instance of a **Two-tone-Car** is created the default value for its instance variable **color** is the combination of the values in both the classes **Car** and **Two-tone-Car**. The first inspector shows the existence of the active value that provides this behavior. As soon as one puts a value for color in this instance, the **AppendSuperValue** active value is replaced by the new value as shown in the second inspector.

```
12← (@ ($ ttcar1) color)
(white blue)
```

```
13← (INSPECT ($ ttcar1))
{WINDOW}#50,5000
```

```
All Values of Two-tone-Car ($ ttcar1).
color #,($AV AppendSuperValue (asv1 (|
```

```
14← (←@ ($ ttcar1) color '(tan brown))
(tan brown)
```

```
All Values of Two-tone-Car ($ ttcar1).
color (tan brown)
```

For another example, see the **TitleItems** class variable of the class **ClassBrowser**, where **AppendSuperValue** is used to add menu items to an inherited menu.

---

### 8.2.2.6 FirstFetchAV

This specialization has instances that have an expression as the value of the instance variable **localState**. These active values allow a form to be evaluated the first time that they are read.

---

#### FirstFetchAV

[Class]

Purpose: This is a specialization of the **ReplaceMeAV** mixin and **LocalStateActiveValue**. Instances of this class have an expression as the value of the instance variable **localState**.

**Behavior:** On the first get access, the expression in **localState** is evaluated. The resulting value replaces the **FirstFetchAV** so the variable is no longer an active value. On the first put access, the put value replaces the **FirstFetchAV** so the variable is no longer an active value. A **FirstFetchAV** is often used as the default value for a variable. This class also specializes the method **AVPrintSource** so that instances print as follows when wrapped in an **annotatedValue**:

```
#, (Defer contentsOfLocalState)
```

---

### CAUTION

**FirstFetchAVs** cannot be shared. Unlike lists, SEdit does not make copies of active values. Hence, if active values are copied in SEdit, they will share structure, and if one is modified, all will be changed.

**Workaround:** Use **CopyActiveValue** to copy the active value instance and the local state into each instance which uses the **FirstFetchAV**. See Section 8.3.4, "Shared ActiveValues in Variable Inheritance," for information on **CopyActiveValue**.

---

**Example:** An example application of **FirstFetchAV** is an instance variable that stores a font descriptor. A font descriptor in a class definition does not save correctly; only the pointer to the descriptor is saved. A **FirstFetchAV** stores the expression used to create the descriptor. So, for example the expression held in the **localState** of the **FirstFetchAV** is

```
(FONTCREATE 'HELVETICA 12 'BOLD)
```

On the first access of the instance variable, the font descriptor produced by calling **FONTCREATE** replaces the **FirstFetchAV**.

The complete example follows.

```
29← (DefineClass 'TextObject)
#, ($C TextObject)

30← (← ($ TextObject) AddIV 'font)
font

31← (← ($ FirstFetchAV) New 'ffav1)
#, ($& FirstFetchAV (|DAW0.1Y:.H53.]99| . 535))

32← (←@ ($ ffav1) localState '(FONTCREATE 'HELVETICA 12 'BOLD)]
(FONTCREATE (QUOTE HELVETICA) 12 (QUOTE BOLD))

33← (PutClassIV ($ TextObject) 'font
 (create annotatedValue
 annotatedValue ← ($ ffav1)))
#, (Defer (FONTCREATE (QUOTE HELVETICA) 12 (QUOTE BOLD)))

34← (← ($ TextObject) Edit)
TextObject
```

```
SEdit #,($C TextObject) Package: INTERLISP
((MetaClass Class Edited%: ; Edited 4-Dec-87
 ; 14:22 by RBGMartin
)
 (Supers Object) (ClassVariables)
 (InstanceVariables
 (font #,(Defer (FONTCREATE (QUOTE HELVETICA) 12 (QUOTE BOLD)))
 doc (* IV added by MARTIN)))
 (MethodFns))
```

```
35← (← ($ TextObject) New 'to1)
#,($& TextObject (|DAW0.1Y:.H53.]99| . 536))

36← (INSPECT ($ to1))
{WINDOW}#47,125470
```

```
All Values of TextObject ($ to1).
font #,(Defer (FONTCREATE (QUOTE
```

```
37← (@ ($ to1) font)
{FONTDESCRIPTOR}#74,167334
```

```
All Values of TextObject ($ to1).
font {FONTDESCRIPTOR}#74,167334
```

### 8.2.3 InheritingAV

This specialization of **ActiveValue** is used as a mixin to add the **InheritedValue** method.

#### InheritingAV

[Class]

- Purpose: Used as a mixin to add the **InheritedValue** method.
- Behavior: An abstract class, adds a method **InheritedValue** which allows looking at the value a variable would have if it had no local value, as **NotSetValue** would work. Used as a mixin to add this capability to other specializations of **ActiveValue**.
- Example: Used as super class of **AppendSuperValue** to provide incremental menus in various parts of LOOPS.

(← self **InheritedValue** containingObj varName propName type)

[Method of InheritingAV]

- Purpose/Behavior: Allows viewing the value a variable would have inherited if it had no local value yet assigned. Similar to the way **NotSetValue** works, it is removed by an assignment to the variable.
- Arguments: *self* **InheritingAV** instance.
- containingObj* The instance or class that contains the variable to be viewed.
- varName* In the *containingObj* the variable to be viewed.
- propName* Name of an instance variable or class variable property to be looked at. If *propName* is NIL, the variable itself is viewed.

*type* One of IV, CV, or NIL: a *type* of IV or NIL indicates that the variable is an instance variable or an instance variable property of *containingObj*; a *type* of CV indicates a class variable or class variable property of *containingObj*.

Returns: The value which would have been inherited if the variable had no local value.

### 8.2.4 ReplaceMeAV

This specialization of the class **ActiveValue** sets up the functionality to replace itself on the first Put- access.

#### ReplaceMeAV

[Class]

- Purpose: Specializes the method **PutWrappedValue** to simply replace itself on the first Put- request.
- Behavior: No variables are defined in this class. It is an abstract class not intended for instantiation. It is a mixin (see Chapter 3, Classes) to be combined in specialization with another class to add its functionality to the subclass.
- Example: **FirstFetchAV** combines **LocalStateActiveValue** and **ReplaceMeAV** to get an **ActiveValue** that replaces itself with the value of an expression stored in the instance variable **localState**.

### 8.2.5 NotSetValue

This section describes where and when instances of this class appear in user-defined objects.

#### CAUTION

Do not specialize the classes **NotSetValue** and **NestedNotSetValue**. The documentation is provided here only to explain the functionality that these classes provide to the LOOPS system.

#### NotSetValue

[Class]

- Purpose: This specialization of the class **ActiveValue** is unique in that it was created primarily for implementing instance variable inheritance. It has no instance variable to hold a local value and is replaced after the first Put- variable access.
- Behavior: When an instance of any LOOPS object is created, its instance variables are initialized to contain the value of the variable **NotSetValue**. **NotSetValue** is an annotatedValue whose **ActiveValue** is the only instance of the class **NotSetValue**. The value of **NotSetValue** stored in an instance variable may be replaced within other initialization procedures of new instances that are invoked by the methods **NewWithValues** and **NewInstance** and the instance variable property **:initForm**.
- The class **NotSetValue** specializes the default **ActiveValue** protocol to trigger instance variable inheritance. An annotatedValue check is always done by **GetValue** and **PutValue**. LOOPS speeds up instance generation by always initializing instance variables to the value **NotSetValue**. If a retrieval attempt is made on the variable, **NotSetValue** finds the inherited value and returns that value. If no requests are made for the value of the variable, there is no overhead for the instance variable.

The term local value refers to the values LOOPS has actually written into that instance's instance variables. The local value is always equal to **NotSetValue** before the first Put- access, and to a new value after the first Put- access.

The annotatedValue **#,NotSetValue** is bound to the Lisp variable **NotSetValue**. It must always be on the inside of any sequence of nested **ActiveValues**. Its **WrappingPrecedence** method returns NIL, ensuring this functionality. **NotSetValue** has no **localState** instance variable to hold any nested **ActiveValues**.

See Section 8.3.4, "Shared ActiveValues in Variable Inheritance," for information on **ActiveValues** as default values.

Example: Consider the class **Datum** with the instance variable **idNumber**. Create a new instance named **Datum2**. A standard **GetValue** or **@** call returns the default value of **idNumber**, since nothing else has yet been assigned. The call **GetIVHere** shows that the value is not stored in the instance, but is actually returned by **NotSetValue**.

```
91←(← ($ Datum) New 'Datum2)
#, ($ Datum2)

92←(@ ($ Datum2) idNumber)
NIL

93←(GetIVHere ($ Datum2) 'idNumber)
#,NotSetValue
```

8.2.5.1 NestedNotSetValue

---

This subclass of the class **NotSetValue** is used by the internal of LOOPS to solve the problem of using active values as default values.

8.2.6 User Specializations of Active Values

---

If new specializations of the class **ActiveValue** are defined, the methods **GetWrappedValueOnly** and **PutWrappedValueOnly** might need to be specialized (LOOPS-defined specializations of **ActiveValue**, such as **LocalStateActiveValue**, have already done this). You may also want to specialize the following methods:

|                           |                                                                             |
|---------------------------|-----------------------------------------------------------------------------|
| <b>AVPrintSource</b>      | Prints an <b>ActiveValue</b> instance.                                      |
| <b>GetWrappedValue</b>    | Method associated with getting an <b>ActiveValue</b> .                      |
| <b>PutWrappedValue</b>    | Method associated with putting an <b>ActiveValue</b> .                      |
| <b>WrappingPrecedence</b> | Returns T, NIL, or a number to specify order of <b>ActiveValue</b> nesting. |
| <b>CopyActiveValue</b>    | Copies an annotatedValue and its wrapped <b>ActiveValue</b> .               |

8.3 ACTIVE VALUE METHODS

---

8.3 ACTIVE VALUE METHODS

---

8.3 Active Value Methods

---

Methods defined in the class **ActiveValue** describe how active values work.

### 8.3.1 Adding and Deleting Active Values

This section describes the methods to install, delete, and replace active values.

| Name                      | Type   | Description                                                    |
|---------------------------|--------|----------------------------------------------------------------|
| <b>AddActiveValue</b>     | Method | Makes a variable or property an active value.                  |
| <b>WrappingPrecedence</b> | Method | Returns a value which determines how to nest the active value. |
| <b>DeleteActiveValue</b>  | Method | Deletes an active value.                                       |
| <b>ReplaceActiveValue</b> | Method | Replaces an active value.                                      |

(← *self* **AddActiveValue** *containingObj* *varName* *propName* *type* *annotatedValue*) [Method of **ActiveValue**]

**Purpose:** Accomplishes two tasks fundamental in making a variable or property an active value. First, the **ActiveValue** is wrapped inside an *annotatedValue*. Second, the *annotatedValue* is placed as the value of the variable.

**Behavior:** **AddActiveValue** associates the *annotatedValue* with the variable specified by the arguments. If the argument *annotatedValue* is not specified or is NIL, a new *annotatedValue* is created containing the **ActiveValue** *self*. When the current value of the variable is already an *annotatedValue*, the **WrappingPrecedence** message determines if it should be nested in the current one or wrapped around it.

**Arguments:** *self* **ActiveValue** instance.

*containingObj*

The instance or class that contains the variable where the **ActiveValue** is to be added.

*varName* In the *containingObj* the variable to be made into an **ActiveValue**.

*propName* Name of an instance variable or class variable property to be made into an **ActiveValue**. If *propName* is NIL, the **ActiveValue** is associated with the variable itself.

*type* One of IV, CV, CLASS, METHOD, or NIL.

- A *type* of IV or NIL indicates that *varName* is an instance variable or an instance variable property of *containingObj*.
- A *type* of CV indicates a class variable or class variable property of *containingObj*.
- A *type* of CLASS indicates access to a class object's instance variables and properties.
- A *type* of METHOD indicates access to a method object's instance variables and properties.

*annotatedValue*

**AnnotatedValue** object used to contain this **ActiveValue**. If NIL, a new **annotatedValue** is created.

**Returns:** *annotatedValue*

**Example:** Adds the **ActiveValue** instance named (**\$ ActiveValueInstance**) to the object (**\$ ExampleLoopsWindowInstance**) in the instance variable **width**.

```
71←(← ($ ActiveValueInstance) AddActiveValue ($
ExampleLoopsWindowInstance) 'width)

#,$AV IndirectVariable (ActiveValueInstance (NCV0.0X:.SD7.KR . 8))
(object #,$ ExampleLoopsWindowInstance) (varName width))
```

---

**(← self WrappingPrecedence)****[Method of ActiveValue]**

**Purpose:** Returns a value which determines how to nest the **ActiveValue** associated with *self*.

**Behavior:** Varies according to the value returned.

- T

The **ActiveValue** associated with *self* goes on the outside of any other active values.

- NIL

This **ActiveValue** goes on the inside.

If two **ActiveValues** return either T or NIL, a break occurs.

- Number

Specifies precedence: **ActiveValues** with larger **WrappingPrecedence** values go outside ones with smaller **WrappingPrecedence** values.

---

**CAUTION**

It is potentially dangerous to have more than one class with a T or NIL precedence.

---

**ActiveValues** that have the instance variable **localState** nest in the following way. When a new **ActiveValue** is added to an existing one with equal **WrappingPrecedence**, the original **ActiveValue** is held in the **localState** of the new one. **ActiveValues** not having an instance variable **localState** must nest inside of ones that do.

To set the **WrappingPrecedence** for a user specialization of **ActiveValue**, specialize this method to return the proper value.

**Arguments:** *self*            **ActiveValue** instance.

**Returns:** The default method defined in the class **ActiveValue** returns 100. **WrappingPrecedence** for the class **NotSetValue** returns NIL. **WrappingPrecedence** for **IndirectVariable** returns 50.

---

**(← self DeleteActiveValue containingObj varName propName type)****[Method of ActiveValue]**

**Purpose:** Deletes an **ActiveValue** from *containingObj*.

**Behavior:** If the variable defined by the arguments is an **ActiveValue**, it is deleted. If it contains a nested **ActiveValue**, the one matching *self* is deleted; otherwise, nothing happens. No **ActiveValue** messages are triggered. If the deleted **ActiveValue** had a **localState**, it becomes the current value.

**Arguments:** *self*            **ActiveValue** instance.

*containingObj*

The instance or class that contains the variable where the **ActiveValue** is found.

*varName*

In the *containingObj* the variable that contains the **ActiveValue**.

*propName*

Name of an instance variable or class variable property where the **ActiveValue** resides. If *propName* is NIL, the **ActiveValue** is associated with the variable itself.

*type*

One of IV, CV, CLASS, METHOD, or NIL.

- A *type* of IV or NIL indicates that *varName* is an instance variable or an instance variable property of *containingObj*.
- A *type* of CV indicates a class variable or class variable property of *containingObj*.
- A *type* of CLASS indicates access to a class object's instance variables and properties.
- A *type* of METHOD indicates access to a method object's instance variables and properties.

Returns: The deleted annotatedValue if a match was found, NIL otherwise.

(← **self ReplaceActiveValue newVal containingObj varName propName type**) [Method of ActiveValue]

Purpose: Replaces an **ActiveValue**.

Behavior: Replaces the **ActiveValue** *self* with *newVal*. The location of the old **ActiveValue** is described by the arguments. No **ActiveValue** messages are triggered.

Arguments:

*self* **ActiveValue** instance.

*newVal* The new value used to replace *self*.

*containingObj*

The instance or class that contains the variable where the **ActiveValue** is found.

*varName*

In the *containingObj* the variable that holds the **ActiveValue**.

*propName*

Name of an instance variable or class variable property where the **ActiveValue** resides. If *propName* is NIL, the **ActiveValue** is associated with the variable itself.

*type*

*type* is one of IV, CV, or NIL: a *type* of IV or NIL indicates that the variable is an instance variable or an instance variable property of *containingObj*; a *type* of CV indicates a class variable or class variable property of *containingObj*.

Returns: The value of *newVal*.

### 8.3.2 Fetching and Replacing Wrapped Values

The value of a variable is wrapped in an **ActiveValue**, usually by keeping it in the instance variable **localState**. Specify the behavior of new **ActiveValue** specializations by specializing the methods **GetWrappedValue** and **PutWrappedValue**. For example, **IndirectVariable.GetWrappedValue** just does a **GetValue** on the slot specified by its **object**, **varName**, **propName**, and **type** instance variables. These methods may perform arbitrary work before returning a value, usually that of **localState**. The methods **GetWrappedValueOnly** and **PutWrappedValueOnly** are available for accessing **localState** and bypassing the **ActiveValue** mechanism.

The following table shows the items in this section.

| Name                       | Type   | Description                                                                                                       |
|----------------------------|--------|-------------------------------------------------------------------------------------------------------------------|
| <b>GetWrappedValue</b>     | Method | Contains the code to be triggered by a Get- reference to the variable which has been made an <b>ActiveValue</b> . |
| <b>GetWrappedValueOnly</b> | Method | Provides a mechanism to assist in handling nested <b>ActiveValues</b> .                                           |
| <b>PutWrappedValue</b>     | Method | Contains the code to be triggered by a Put- reference to the variable which has been made an <b>ActiveValue</b> . |
| <b>PutWrappedValueOnly</b> | Method | Provides a mechanism to assist in handling nested <b>ActiveValues</b> .                                           |

(← *self* **GetWrappedValue** *containingObj* *varName* *propName* *type*) [Method of **ActiveValue**]

**Purpose:** Contains the code to be triggered by a Get- reference to the variable which has been made an **ActiveValue**.

**Behavior:** Performs arbitrary actions, but when finished, it must return a value which will be returned as the value of the **Get** to the original variable.

This method is fundamental for **ActiveValues**. When **GetValue** or **GetClassValue** finds an annotatedValue in an instance, it does not return that as the value. Instead, it sends the contained **ActiveValue** the **GetWrappedValue** message. This method is not usually called explicitly by users, but is triggered when the **GetValue** function retrieves the value of a variable that contains an **ActiveValue**. It should be specialized when a new subclass of **ActiveValue** is defined.

**Arguments:** *self* **ActiveValue** instance.

*containingObj*

The instance or class that contains the variable where the **ActiveValue** is found.

*varName* In the *containingObj* the variable that holds the **ActiveValue**.

*propName* Name of an instance variable or class variable property where the **ActiveValue** resides. If *propName* is NIL, the **ActiveValue** is associated with the variable itself.

*type* One of IV, CV, or NIL: a *type* of IV or NIL indicates that the variable is an instance variable or an instance variable property of *containingObj*; a *type* of CV indicates a class variable or class variable property of *containingObj*.

**Returns:** The value returned from the actions performed by **GetWrappedValue** message.

(← *self* **GetWrappedValueOnly**) [Method of **ActiveValue**]

**Purpose:** Enables the **ActiveValue** mechanism to deal with different problems of nested **ActiveValues**. You will generally not need to specialize this method, as most uses of **ActiveValues** will specialize a subclass of **ActiveValue**.

**Behavior:** Specializations of the class **ActiveValue** may need to specialize this method. (**LocalStateActiveValue**, **IndirectVariable**, and **NotSetValue** all have specialized versions of this method.)

The class **LocalStateActiveValue** specialization simply returns the value of *self*'s **localState** without triggering the active value mechanism.

The class **IndirectVariable** specialization simply returns the value of tracked variable without triggering the active value mechanism.

The class **NotSetValue** specialization simply returns the value of **NotSetValue**.

Arguments: *self* **ActiveValue** instance.

Returns: See Behavior.

(← *self PutWrappedValue containingObj varName newValue propName type*) [Method of ActiveValue]

Purpose: Contains the code to be triggered by a Put- reference to the variable which has been made an **ActiveValue**.

Behavior: The **PutWrappedValue** message is similar to **GetWrappedValue** except that it is triggered when the local state of the value is to be replaced. When **PutValue** or **PutClassValue** attempts to replace an **ActiveValue**, it instead sends the contained **ActiveValue** the **PutWrappedValue** message.

The default method found in the class **ActiveValue** checks for nested **ActiveValues** by sending the **GetWrappedValueOnly** message to *self*. If the result is an **AnnotatedValue**, **PutWrappedValue** forwards the message on the nested **ActiveValue**; otherwise it sends the message **PutWrappedValueOnly** to *self* and returns the result.

Arguments: *self* **ActiveValue** instance.

*containingObj*

The instance or class that contains the variable where the **ActiveValue** is found.

*varName* In the *containingObj* the variable that holds the **ActiveValue**.

*newValue* The value used to replace the **ActiveValue** containing *self*.

*propName* Name of an instance variable or class variable property where the **ActiveValue** resides. If *propName* is NIL, the **ActiveValue** is associated with the variable itself.

*type* One of IV, CV, or NIL: a *type* of IV or NIL indicates that the variable is an instance variable or an instance variable property of *containingObj*; a *type* of CV indicates a class variable or class variable property of *containingObj*.

Returns: The value of *newValue*.

(← *self PutWrappedValueOnly newValue*) [Method of ActiveValue]

Purpose: Enables the **ActiveValue** mechanism to deal with different problems of nested **ActiveValues**. You will generally not need to specialize this method, as most uses of **ActiveValues** will specialize a subclass of **ActiveValue**.

Behavior: Specializations of the class **ActiveValue** may need to specialize this method. (**LocalStateActiveValue**, **IndirectVariable**, and **NotSetValue** all have specialized versions of this method.)

The class **LocalStateActiveValue** specialization simply stores *newValue* into *self*'s **localState** without triggering the active value mechanism.

The class **IndirectVariable** specialization simply stores *newValue* into tracked variable without triggering the active value mechanism.

The class **NotSetValue** specialization causes a break.

Arguments:    *self*            **ActiveValue** instance.  
                 *newValue*    The new value for **localState**.  
Returns:      See Behavior.

### 8.3.3 Get and Put Functions Bypassing the ActiveValue Mechanism

---

**ActiveValues** normally convert **GetValue**, **GetClassValue**, **PutValue**, and **PutClassValue** accesses into messages which invoke methods to return a value, usually from the **localState** instance variable of the **ActiveValue**. The following functions allow access to class variables and instance variables without triggering any installed **ActiveValue**. See Chapter 2, Instances, for details.

| Name                     | Type     | Description                                                                                                                                                                                                                     |
|--------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GetValueOnly</b>      | Function | Finds the value of an instance variable without triggering active values.                                                                                                                                                       |
| <b>PutValueOnly</b>      | Function | Writes the value of an instance variable without triggering active values.                                                                                                                                                      |
| <b>GetClassValueOnly</b> | Function | Returns the value of a class variable; does not trigger active values.                                                                                                                                                          |
| <b>PutClassValueOnly</b> | Function | Changes the value of a class variable and changes the value of a class variable. The change occurs within the class and therefore causes all instances to access the new value of the variable. Does not trigger active values. |

### 8.3.4 Shared ActiveValues in Variable Inheritance

---

When a **LocalStateActiveValue** is used as the default value for an instance variable in a class, it must be copied into each instance or else all of the instances try to share a single **localState**. This copying is done automatically by LOOPS when the instance variable is first accessed, which means that all instances will share the same **ActiveValue** until that first access. Copying an **ActiveValue** implies creating a new **annotatedValue**, so it must be done with the specialized method **CopyActiveValue**.

**ActiveValues** with no local state may be shared by several variables. In the most extreme case, one instance of **NotSetValue** is the default for the instance variables of all new instances of all classes.

---

(← *self* **CopyActiveValue** *annotatedValue*) [Method of ActiveValue]

---

Purpose:        Makes a copy of an **ActiveValue** instance.

Behavior:      Copies the *AnnotatedValue* and the wrapped **ActiveValue** handling instance variables as follows:

- Instance variables that contain **AnnotatedValues** are copied using the **CopyActiveValue** method.
- The instance variable **localState** is copied so that each copy has its own unique local state.
- All other instance variables are considered shared, and are not copied.

Arguments:    *self*            **ActiveValue** instance.

*annotatedValue*

The annotatedValue that surrounds *self*.

Returns: A new annotatedValue wrapped around a copy of the **ActiveValue** *self*.

### 8.3.5 Creating Your Own Active Value

This example defines a new kind of active value, a **BlippingActiveValue**, which prints out a "blip" of some kind whenever the variable it wraps is read or written.

First, define the new class as a specialization of **LocalStateActiveValue**, then specialize the **PutWrappedValue** and **GetWrappedValue** methods. This is done with the display editor, so in the example they are printed out via the **PPMethod** method. In each case, a **PRINTOUT** function was added before the call to **←Super**.

Create an instance of **Window** for a location to install a **BlippingActiveValue** for the example. Line 38 is required to set the value of **height** locally to instance **Window1**; if this is not done, its initial value is the active value **#,NotSetValue**, which would remove any active value as soon as it was accessed.

The last few statements in the example show how read and write accesses to **height** cause a blip character to be printed before **height** is either read or written, with a "!" character representing a write access triggering **PutWrappedValue**, and a "." character representing a read access triggering **GetWrappedValue**.

```

32← (DefineClass 'BlippingActiveValue ' (LocalStateActiveValue]
#, ($ BlippingActiveValue)

33← (← ($ BlippingActiveValue) SpecializeMethod 'PutWrappedValue]
BlippingActiveValue.PutWrappedValue

34← (← ($ BlippingActiveValue) SpecializeMethod 'GetWrappedValue]
BlippingActiveValue.GetWrappedValue

35← (← ($ BlippingActiveValue) PPMethod 'PutWrappedValue]

(BlippingActiveValue.PutWrappedValue
 (Method ((BlippingActiveValue PutWrappedValue)
 self containingObj varName newValue propName type)
 COMMENT **COMMENT**
 (PRINTOUT PPDefault "!")
 (←Super self PutWrappedValue containingObj varName newValue
 propName type)))
 (BlippingActiveValue.PutWrappedValue)

36← (← ($ BlippingActiveValue) PPMethod 'GetWrappedValue]

(BlippingActiveValue.GetWrappedValue
 (Method ((BlippingActiveValue GetWrappedValue)
 self containingObj varName propName type)
 COMMENT **COMMENT**
 (PRINTOUT PPDefault ".")
 (←Super self GetWrappedValue containingObj varName propName
 type)))
 (BlippingActiveValue.GetWrappedValue)

37← (← ($ Window) New 'Window1]

!!!!!!!!!!!!!!!!!!!!!!!!!!!!210

45←
```

---

## 8.4 Annotated Values

---

AnnotatedValue is a LOOPS pseudoclass, and instances of it, called pseudoinstances, are Interlisp data type instances.

The structure of the data type is simple. Each annotatedValue contains one field named annotatedValue. This field contains an **ActiveValue** object. The Interlisp record package macros discussed below let you create and work with instances of the data type annotateValue.

There is also a LOOPS class named **AnnotatedValue**. It is an abstract class so it cannot be instantiated, but paradoxically there are objects which consider it their class. (Actually, it is not paradoxical, but this behavior is implemented at a low level within the LOOPS system.) These are the Lisp data type annotatedValue. In normal use this class can be ignored.

---

|                       |         |
|-----------------------|---------|
| <b>AnnotatedValue</b> | [Class] |
|-----------------------|---------|

---

- |           |                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:  | LOOPS class equivalent of Lisp data type annotatedValue.                                                                                                                                                                                                                                                                                                                                              |
| Behavior: | This is a LOOPS class, but not a subclass of <b>Object</b> . Its super is the LOOPS class <b>Tofu</b> . (See Chapter 4, Metaclasses, for a description of <b>Tofu</b> .) <b>AnnotatedValue</b> is a LOOPS abstract class, and instances are Interlisp data type instances. LOOPS fields messages sent to the annotatedValue data type instances by using the class definition <b>AnnotatedValue</b> . |

---

### 8.4.1 Explicit Control over Annotated Values

---

This section describes the macros and methods that allow explicit control over annotated values.

| Name         | Type  | Description                                                                 |
|--------------|-------|-----------------------------------------------------------------------------|
| <b>type?</b> | Macro | Performs a type check for an instance of the Lisp data type annotatedValue. |

|                             |        |                                                                                                             |
|-----------------------------|--------|-------------------------------------------------------------------------------------------------------------|
| <b>create</b>               | Macro  | Creates a new instance of the data type <code>annotatedValue</code> .                                       |
| <b>fetch</b>                | Macro  | Retrieves the contents of the <code>annotatedValue</code> field of an <code>annotatedValue</code> instance. |
| <b>replace</b>              | Macro  | Replaces contents of the <code>annotatedValue</code> field of the <code>annotatedValue</code> instance.     |
| <b>_AV</b>                  | Macro  | Sends a message to the <b>ActiveValue</b> object wrapped in an <code>annotatedValue</code> .                |
| <b>MessageNotUnderstood</b> | Method | Forwards messages intended for the wrapped <b>ActiveValue</b> to that object.                               |

**(type? annotatedValue value)** [Macro]

Purpose: Performs a type check for an instance of the Lisp data type `annotatedValue`.

Arguments: *value* The value to type check.

Returns: T if *value* is an instance of the data type `annotatedValue`, NIL otherwise.

**(create annotatedValue annotatedValue ← object)** [Macro]

Purpose: Creates a new instance of the data type `annotatedValue`.

Arguments: *object* An **ActiveValue** object to initialize the field `annotatedValue` of the new `annotatedValue` instance. This must be an object that has a method **AVPrintSource** (a method of **ActiveValue**) or this form breaks on evaluation. No type checking of *object* will be performed by the macro.

Returns: An instance of `annotatedValue`.

**(fetch annotatedValue of value)** [Macro]

Purpose: Retrieves the contents of the `annotatedValue` field of an `annotatedValue` instance.

Arguments: *value* An `annotatedValue` instance.

Returns: Contents of field `annotatedValue`.

**(replace annotatedValue of value with object)** [Macro]

Purpose: Replaces contents of the `annotatedValue` field of `annotatedValue` instance with *object*.

Arguments: *value* An `annotatedValue` instance.

*object* **ActiveValue** object to be stored in the field. No type checking is done on *object*.

Returns: If *value* is not an `annotatedValue`, generates an error; otherwise the previous contents of the field is returned.

**(\_AV av selector . args)** [Macro]

Purpose: Sends a message to the **ActiveValue** object wrapped in an `annotatedValue`.

|            |                                                                                   |                                                                |
|------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------|
| Behavior:  | Equivalent to<br><br><code>(_ (fetch annotatedValue of av) selector .args)</code> |                                                                |
| Arguments: | <i>av</i>                                                                         | Instance of an <code>annotatedValue</code> .                   |
|            | <i>selector</i>                                                                   | Selector for message to send to the <b>ActiveValue</b> object. |
|            | <i>args</i>                                                                       | Arguments to be passed when the message is sent.               |
| Returns:   | Result of message.                                                                |                                                                |

---

`(← self MessageNotUnderstood)` [Method of AnnotatedValue]

---

|           |                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:  | Forwards messages intended for the wrapped <b>ActiveValue</b> to that object.                                                                    |
| Behavior: | Messages sent to an <code>annotatedValue</code> are forwarded to its wrapped <b>ActiveValue</b> . Users should not explicitly send this message. |

## 8.4.2 Saving and Restoring Annotated Values

---

The following are methods of the class **ActiveValue** that handle annotated values.

---

`(← self AVPrintSource)` [Method of ActiveValue]

---

|           |                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:  | Prints <b>ActiveValues</b> .                                                                                                                |
| Behavior: | An <code>annotatedValue</code> determines how it prints out by sending the <b>AVPrintSource</b> message to its wrapped <b>ActiveValue</b> . |

The default method in **ActiveValue** returns a list of the form:

```
("#," $AV className avNames(ivName value propName value ...) (ivName ...) ...)
```

which causes the `annotatedValue` to print out as

```
#, ($AV className avNames(ivName value propName value ...) (ivName ...) ...)
```

|            |                  |                                                                                                  |
|------------|------------------|--------------------------------------------------------------------------------------------------|
| Arguments: | <i>self</i>      | <b>ActiveValue</b> instance.                                                                     |
|            | <i>className</i> | Name of the class of the <b>ActiveValue</b> .                                                    |
|            | <i>avNames</i>   | List of names of <i>self</i> , the last element being the unique identifier (UID) of <i>self</i> |

The list *(ivName value propName value ...)* describes the state of the instance variables of the **ActiveValue**. Including the UID of the **ActiveValue** in the print form enables recovery of the identity of the **ActiveValue**. This enables different `annotatedValues` to share the same **ActiveValue**, and maintain this sharing across saving to a file and reloading into Lisp.

|          |                                                                                                                                                                                                                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Returns: | A form suitable for use by the Interlisp function <b>DEFPRINT</b> . Result should be a pair of the form (item1 . item2); item1 will be printed using <b>PRIN1</b> , and item2 will be printed using <b>PRIN2</b> (see <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference Manual</i> description of <b>DEFPRINT</b> ). |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|          |                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Example: | <pre>#, (\$AV IndirectVariable (HeightFromWidth (NCV0.0X:.SD7.KR . 8)) (object #.(\$ SquareWindow)) (varName width) (propName NIL) (type IV))</pre> |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|

(\$AV className avNames . ivForms)

[NLambda, NoSpread Function]

Purpose: Reconstructs an annotatedValue that has been saved to a file.

Arguments: *className* Name of the class of **ActiveValue**.

*avNames* A list of the LOOPS names of **ActiveValue** instances.

*ivForms* A list describing the state of the instance variables of the **ActiveValue**.

Returns: A new annotatedValue whose **ActiveValue** is reconstructed from the *avNames* and *ivForms*.

## 8.5 ACTIVE VALUES IN CLASS STRUCTURES

### 8.5 ACTIVE VALUES IN CLASS STRUCTURES

## 8.5 Active Values in Class Structures

It is possible to have an active value as the default value of an instance variable or the value of a class variable in a class. For example, the following class has an active value installed in the class variable **dontChange** and one installed in the instance variable **firstRead**.

```
SEdit #,($C test) Package: INTERLISP
((MetaClass Class Edited%: ; Edited 2-Dec-87 12:59
)
(Supers Object)
(ClassVariables
(dontChange
#,$AV NoUpdatePermittedAV ((IDAW0.1Y:H53.J99) . 540)) (localState 100)))
(InstanceVariables (firstRead #,(Defer (DATE)))) (MethodFns))
```

**LocalStateActiveValue** active values as default IV values are copied down into the instance when their **localState** is smashed, instead of being shared by all instances; this is different from normal default behavior. It is also possible to create a **LocalStateActiveValue** which inherits its **localState** value by giving it a **localState** value of the value of **NotSetValue**. These copy the inherited value down from the superclass when the **LocalStateActiveValue** is created; if the value in the superclass is changed after the **LocalStateActiveValue** is created, that change will not be reflected in the **LocalStateActiveValue**. Normally inherited values are always tracked by instances that inherit them.

There are two ways to enter active values into the structure of a class: with the editor or programmatically.

It is possible to create active values by typing in a form such as:

(\$AV activeValueClassName NIL (ivname value propName value ...) (ivname value propName value ...) ...). None of the arguments are evaluated.

To add an active value through the editor, you can type in the above form, select it, and mutate it with the function **EVAL**.

Programmatically, you can use the functions **PutClassIV**, **PutClassValue**, **PutClassValueOnly**, **AddCIV**, **AddCV**, etc. or different methods, such as **Add**, to modify or add class variables and instance variables.

For example, given the above class, **test**:

```
(← ($ test) Add 'CV 'randomJustOnce ($AV FirstFetchAV NIL
(localState (RAND 0 1000))))
```

and

```
(AddCIV ($ test) 'newIV ($AV LocalStateActiveValue NIL
(localState (1 2 3))))
```

will result in the following:

```
SEdit #,($C test) Package: INTERLISP
((MetaClass Class Edited%: ; Edited 2-Dec-87 13:20
)
(Supers Object)
(ClassVariables
(dontChange
#,$AV NoUpdatePermittedAV (([DAW0.1Y:.H53.]99] . 540)) (localState 100)))
(randomJustOnce #,(Defer (RAND 0 1000))))
(InstanceVariables (firstRead #,(Defer (DATE)))
(newIV
#,$AV LocalStateActiveValue (([DAW0.1Y:.H53.]99] . 541)) (localState (1 2 3)))
(MethodFns))
```

An even more general programmatic method that more easily allows customization of an active value uses the `annotatedValue` data type explicitly. First, you must create an instance of an **ActiveValue** class.

```
(← ($ MyActiveValue) New 'MyAV1)
```

Then the contents of the instance **MyAV1** are initialized. Finally, it is added as the value of a variable in a class structure.

```
(AddCIV ($ test) 'myNewIV (create annotatedValue
annotatedValue ← ($ MyAV1)))
```

[This page intentionally left blank]

## 9. DATA TYPE PREDICATES AND ITERATIVE OPERATORS

This chapter describes data type predicates and an operator for iterative statements.

### 9.1 Data Type Predicates

Data type predicates test the Lisp data type of some datum. For example, some predicates test whether a datum is an object, instance, or class.

LOOPS defines three Lisp data types: `annotatedValue`, `class`, and `instance`. LOOPS provides predicates that enable testing aspects of these types.

| Name                   | Type   | Description                                                                                        |
|------------------------|--------|----------------------------------------------------------------------------------------------------|
| <b>Object?</b>         | Macro  | Determines if a particular datum is a LOOPS object.                                                |
| <b>Class?</b>          | Macro  | Determines if a particular datum is a class.                                                       |
| <b>Instance?</b>       | Macro  | Determines if a particular datum is an instance of a class.                                        |
| <b>AnnotatedValue?</b> | Macro  | Determines if a particular datum is an instance of the <code>annotatedValue</code> Lisp data type. |
| <b>Understands</b>     | Method | Determines if an object will respond to a message.                                                 |

To determine if a particular datum has an instance variable, class variable, or a property, use **HasIV**, **HasIV!**, or **HasCV** (see Chapter 2, Instances, and Chapter 3, Classes). To determine if a particular datum is an instance of a class or its superclasses, use **InstOf** or **InstOf!** (see Chapter 2, Instances).

**(Object? X)**

[Macro]

Purpose/Behavior: Determines if `X` is a LOOPS object. **Object?** returns `T` for both instances and classes.

Arguments: `X` Possible object.

Returns: Returns `T` if a name is a pointer to a LOOPS object, and returns `NIL` otherwise.

Example: This example demonstrates the use of **Object?**.

```
3←(← ($ Window) New 'Window1)
#,($& Window (|OZW0.1Y:.;h.Qm:| . 495))

4←(Object? ($ Window1))
T
```

```
5←(Object? ($ Window))
T

6←(Object? ($ NotAnObject))
NIL

7←(Object? 'NotAnObject)
NIL
```

---

**(Class? X)****[Macro]**

**Purpose/Behavior:** Determines if *X* is a class.

**Arguments:** *X* Possible class.

**Returns:** Returns T if *X* is a class; returns NIL otherwise.

**Example:** This example demonstrates the use of the predicate **Class?** Since **(\$ Window)** is a class, the function returns T. Since **Window1** and **NotClass** are not class names, NIL is returned. (Class? X) is equivalent to (type? class X).

```
8←(Class? ($ Window))
T

9←(Class? ($ NotClass))
NIL

10←(Class? ($ Window1))
NIL
```

---

**(Instance? X)****[Macro]**

**Purpose/Behavior:** Determines if *X* is an instance of some class.

**Arguments:** *X* Possible instance.

**Returns:** Returns T if *X* is an instance; returns NIL otherwise.

**Example:** This example shows the use of **Instance?** (Instance? X) is equivalent to (type? instance X).

```
11←(Instance? ($ Window1))
T

12←(Instance? 'Unbound)
NIL

13←(Instance? ($ Window))
NIL
```

---

**(AnnotatedValue? X)****[Macro]**

**Purpose/Behavior:** Determines if *X* is an instance of the annotatedValue data type. For a complete explanation of annotated values, see Chapter 8, Active Values.

**Arguments:** *X* Possible annotatedValue.

**Returns:** Returns T if *X* is an annotated value; returns NIL otherwise.

**Example:** Instances of class Window are created with an active value in the window instance variable. **AnnotatedValue** returns T for the annotatedValue which "wraps" an active value, not for the active value itself.

```

100←(← ($ Window) New 'Window3]
#, ($& Window (|OZW0.1Y:.;h.Qm:| . 495))

1←(GetValue ($ Window3) 'window)
{WINDOW}#51,140000

2←(GetValueOnly ($ Window3) 'window)
#,$AV LispWindowAV ((|OZW0.1Y:.;h.Qm:| . 495))
(localState {WINDOW}#51,140000))

3←(AnnotatedValue? (GetValueOnly ($ Window3) 'window))
T

4←(AnnotatedValue? (GetValue ($ Window3) 'window))
NIL

5←(AnnotatedValue? (_ ($ LispWindowAV) New 'LWAV4]
NIL

```

**(← self Understands selector)**

[Method of Object]

**Purpose/Behavior:** Determines if the object *self* will respond to a message with *selector*.

**Arguments:** *self* Instance or class in question.  
*selector* Selector in question.

**Returns:** T if *self* is a class or an instance of a class that understands message selector; NIL otherwise.

**Note:** If *self* is not a LOOPS object, you get NIL and not an error.

**Categories:** Object

**Example:** Given that **Window** is a class, **MyWindow** is an instance, and **SpinAround** is a method of **MyWindow**, **Window** returns NIL, and **MyWindow** returns T. Since **Shape** is a method of **Window**, this also returns T.

```

90←(← ($ Window) Understands 'SpinAround)
NIL

91←(← ($ MyWindow) Understands 'SpinAround)
T

91←(← ($ MyWindow) Understands 'Shape)
T

```

## 9.2 ITERATIVE OPERATORS

## 9.2 ITERATIVE OPERATORS

---

## 9.2 Iterative Operators

---

LOOPS provides an iterative operator to be used with Interlisp-D iterative statements.

**in-supers-of X**

[Iterative Statement Operator]

**Purpose / Behavior:** Allows iteration up the supers chain of the object X. Used in an Interlisp-D iterative statement. (See the *Interlisp-D Reference Manual* for more information on iterative statements.)

Arguments:    X                   A LOOPS class or an instance.

Example:      This example shows one way to use this operator.

```
55←(FOR I in-supers-of ($ ClassBrowser) DO (PRINT (← I ClassName]
ClassBrowser
IndexedObject
LatticeBrowser
Window
Object
Tofu
NIL
```

[This page intentionally left blank]

As described in Chapter 1, Introduction, one of the key components in the LOOPS system is inheritance, in which structures have well-defined relationships to other structures. Class inheritance is a typical example of this relationship.

Since inheritance can be described by a two-dimensional graph, it is natural to create a user interface for LOOPS built on the Lisp Library Module, Grapher. This user interface is called a browser. Browsers are tools to assist in the development cycle of a product or vehicles for building user interfaces within a final product.

Much development time is spent building, examining, and modifying the relationships between classes. These tasks include specifying the contents of various classes: class variables, instance variables, properties, and methods. The location of the class within the inheritance structure must also be determined. After a number of classes have been built, the relationships between the classes may need to be reviewed. Often, the initial design is flawed and requires the following changes:

- Moving parts of one class to another class.
- Adding, subtracting, or changing data or functionality within classes.
- Adding new classes, or merging different classes.

Browsers are the facility within LOOPS which support these types of operations. This chapter describes how to use browsers both interactively with the mouse, and programmatically.

Browsers are most commonly used on the classes defined for an application. Many of the examples here browse objects which LOOPS uses internally; the functionality is exactly the same.

---

## 0.1 Types of Built-in Browsers 1

---

A number of different types of browsers are already built into LOOPS:

- Lattice browsers
- Class browsers
- File browsers
- Supers browsers
- Metaclass browsers

This section describes these browsers in detail.

### 10.1.1 Lattice Browsers

---

The most general class is called **LatticeBrowser**. Figure 10-1 shows a class inheritance lattice with the subclasses of **LatticeBrowser**.

Figure 10-1. Sample Lattice Browser

### 10.1.2 Class Browsers

---

A class browser shows the linkages between a class or classes and their subclasses. Super classes are shown on the left (or top) side of the browser window. Subclasses of these are connected by links moving to the right (or down). An example of a class browser is shown in the previous section. The class **LatticeBrowser** is the root object of this example. Subclasses of **LatticeBrowser** are **ClassBrowser** and **InstanceBrowser**. Subclasses of **ClassBrowser** are **FileBrowser**, **SupersBrowser**, and **MetaBrowser**.

### 10.1.3 File Browsers

---

A file browser is a class browser containing all classes defined within a file. Additionally, file browsers contain a menu interface to common operations on files.

### 10.1.4 Supers Browsers

---

A supers browser is an inverted class browser. A class browser is built by following subclass links from a class. A supers browser is built by following superclass links from a class. An example of a supers browser is shown in Figure 10-2.

Figure 10-2. Sample Supers Browser

### 10.1.5 Metaclass Browsers

---

A metaclass browser is like a supers browsers, but is built by following metaclass links. Figure 10-3 shows two root classes: **ActiveValue** and **ClassBrowser**.

Figure 10-3. Sample Metaclass Browser

### 10.1.6 Instance Browsers

An instance browser shows the relationships between instances. These relationships may be more dynamic than the inheritance relationships shown by the class browsers. Typically, the relationships are not defined until runtime, and may be changed often. By specializing the instance browser, you can show several relationships between a fixed set of objects.

10.2 OPENING BROWSERS

## 10.2 OPENING BROWSERS

## 10.2 Opening Browsers

A browser can be opened in several ways:

- Selecting a menu option from the Background Menu.
- Selecting a menu option from the LOOPS icon.
- Sending a **Browse** message to an instance of a browser.
- Calling either of the functions **Browse** or **FileBrowse**.

### 10.2.1 Using Menu Options to Open Browsers

Since browsers are an important part of LOOPS, you can use menus in several ways to create standard browsers. Once opened, via menu or program, any browser can be operated from both the appropriate menus and programmatic commands.

#### 10.2.1.1 Overview of Background Menu and LOOPS Icon

When LOOPS is loaded, the option **Loops Icon** is added to the background menu, as shown in this window:

The **Loops Icon** option has two suboptions:

- **Browse Class**
- **Browse File**

These suboptions are shown in the following windows:

Selecting **Loops Icon** puts a LOOPS icon on the screen; you are prompted to place the icon after it is created. The other commands are discussed in Section 10.2.1.2, "Command Summary."

The LOOPS icon, which appears in Figure 10-4, is a prototype instance of the class **LoopsIcon**. It is provided to give you another convenient menu interface to typical programming operations.

Figure 10-4. LOOPS Icon

Pressing the left button while the mouse is on the icon causes the following menu to appear with options appropriate for class browsers:

Pressing the middle button while the mouse is on the icon causes the following menu to appear with choices appropriate for file browsers:

Pressing the right button while the mouse is on the icon causes the following menu to appear with two options for operations on the icon itself:

**Close** removes the icon from the screen. It can be restored at any time from the background menu. **Move** lets the icon be moved to another location on the screen, just as any icon is moved in Lisp.

---

### 10.2.1.2 Command Summary

---

The background menu and the LOOPS icon provide the same functionalities. This section describes the commands available.

---

#### Browse Class, Browse Supers

---

Selecting either of these options causes the following prompt to appear in the prompt window.

Please tell me the name of the root object >

Enter the name of a class without using the "\$" notation. The system builds the appropriate type of browser and prompts you to move the window containing the browser.

### Browse File

Selecting this option causes the following menu to appear:

The top option on this menu is **\*newFile\*** which has three suboptions; the remaining options are the names of the files that are on **FILELST** (Lisp remembers what files are loaded and how they were loaded; **FILELST** files were loaded normally. See the *Interlisp-D Reference Manual* for a full explanation). Selecting one of the filenames will open a file browser on that file.

**\*newFile\*** Prompts you in the prompt window with the following prompt :

Please type in file name: >.

Enter the name of a file to create. The system checks to determine if a filecoms exists for that file name. If one exists, the system asks for confirmation before destroying the value of that filecoms and opening up an empty browser window. If no filecoms exists for that filename, an empty file browser window is opened.

**\*loadFile\*** Prompts you with:

Please type in file name to load: >

The system loads that file and opens a browser on it.

**\*hiddenFile\*** Causes a menu to appear with files that have been loaded but not **SYSLOADED** and are not on **FILELST**; that is, the files are on **LOADEDFILELST**, but not on **FILELST**. The **LOOPS** files, for example, the **.LCOMs** that add **LOOPS** to Lisp, are on this list.

### Edit Filecoms

Selecting this option brings up the same menu as the option **Browse File**. Instead of opening a browser on the file, a display editor window is opened on the filecoms of that file. If **\*newFile\*** is selected, you are prompted to enter a file name and an **SEdit** window is opened with a template containing the File Manager commands **CLASSES**, **METHODS**, **FNS**, **VARS**, and **INSTANCES**.

### CleanUp File

Selecting this option first calls **FILES?** and then builds a menu of files in **FILELST** that have changed. From this menu, select a file to be cleaned up; this calls **CLEANUP**.

## 10.2.2 Using Commands to Open Browsers

You can use the following methods and functions for opening browsers programmatically and from the Lisp Executive window.

| Name          | Type   | Description                                                |
|---------------|--------|------------------------------------------------------------|
| <b>Browse</b> | Method | Opens a browser showing the relationships between classes. |

|                   |          |                                                                      |
|-------------------|----------|----------------------------------------------------------------------|
| <b>BrowseFile</b> | Method   | Opens a browser showing the relationships between classes on a file. |
| <b>Browse</b>     | Function | Provides a short way to create a class browser.                      |
| <b>FileBrowse</b> | Function | Provides a short way to create a file browser.                       |

---

(← *self* **Browse** *browseList windowOrTitle goodList position*) [Method of LatticeBrowser]

---

Purpose/Behavior: Opens a browser showing inheritance relationships between classes.

Arguments: *self* An instance of **ClassBrowser**, **MetaBrowser**, or **SupersBrowser**.

*browseList* A LOOPS class name, a LOOPS pointer to a class name, or a list of those.

*windowOrTitle* A title to appear on the browser or a window to use (but which will be reshaped to fit the browser.) Title defaults to "Class browser."

*goodList* A **goodList** other than the *browseList*. (See Section 10.5.1, "Instance Variables of Class LatticeBrowser," for more information on **goodList**.)

*position* Lower left corner of browser. If NIL, position the window with the mouse.

Returns: Pointer to the browser object.

Examples: The following command opens a class browser on **Window**.

```
(←New ($ ClassBrowser) Browse 'Window)
```

The following command opens a supers browser on **InstanceBrowser** and **ClassBrowser**.

```
(←New ($ SupersBrowser) Browse (LIST 'InstanceBrowser ($ ClassBrowser)))
```

---

(← *self* **BrowseFile** *fileName*) [Method of FileBrowser]

---

Purpose: Opens a browser showing relationships between classes on a file.

Behavior: Classes defined within *fileName* are displayed within the browser. If *fileName* is NIL, a menu of files on **FILELST** opens. The selected file has a file browser opened on it.

Arguments: *self* An instance of the class **FileBrowser**

*fileName* File to browse; should not be a list.

Returns: *self*

Categories: FileBrowser

Example: The following command opens a file browser on the file **LoopsWindow**.

```
(←New ($ FileBrowser) BrowseFile 'LoopsWindow)
```

---

(**Browse** *classes title goodClasses position*) [Function]

---

|            |                                                                                                                                                                                                                                                                              |                                                                                                                                                             |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:   | Provides a short way to create a class browser.                                                                                                                                                                                                                              |                                                                                                                                                             |
| Behavior:  | Sends a <b>Browse</b> message to a new instance of a <b>ClassBrowser</b> passing <i>classes</i> , <i>title</i> , <i>goodClasses</i> , and <i>position</i> as arguments. If <i>goodClasses</i> is T, it is rebound to the value of <i>classes</i> before the message is sent. |                                                                                                                                                             |
| Arguments: | <i>classes</i>                                                                                                                                                                                                                                                               | A LOOPS class name, a LOOPS pointer to a class name, or a list of those.                                                                                    |
|            | <i>title</i>                                                                                                                                                                                                                                                                 | A title to appear on the browser. Title defaults to "Class browser."                                                                                        |
|            | <i>goodClasses</i>                                                                                                                                                                                                                                                           | A <b>goodList</b> other than <i>classes</i> . (See Section 10.5.1, "Instance Variables of Class LatticeBrowser," for more information on <b>goodList</b> .) |
|            | <i>position</i>                                                                                                                                                                                                                                                              | Lower left corner of browser. If NIL, position the window with the mouse.                                                                                   |
| Returns:   | A new instance of <b>ClassBrowser</b> .                                                                                                                                                                                                                                      |                                                                                                                                                             |
| Example:   | The following command creates a class browser on the class <b>ActiveValue</b> and all its subclasses.                                                                                                                                                                        |                                                                                                                                                             |
|            | <pre>11← (Browse 'ActiveValue)</pre>                                                                                                                                                                                                                                         |                                                                                                                                                             |

**(FileBrowse filename)**

[Function]

|            |                                                                                                                      |                 |
|------------|----------------------------------------------------------------------------------------------------------------------|-----------------|
| Purpose:   | Provides a short way to create a file browser.                                                                       |                 |
| Behavior:  | Sends a <b>BrowseFile</b> message to a new instance of a <b>FileBrowser</b> passing <i>filename</i> as the argument. |                 |
| Arguments: | <i>filename</i>                                                                                                      | File to browse. |
| Returns:   | New instance of <b>FileBrowser</b> .                                                                                 |                 |
| Example:   | The following command creates a file browser on the file <b>LoopsWindow</b> .                                        |                 |
|            | <pre>12← (FileBrowse 'LoopsWindow)</pre>                                                                             |                 |

## 10.3 USING CLASS BROWSERS, META BROWSERS, AND SUPERS BROWSERS

## 10.3 USING CLASS BROWSERS, META BROWSERS, AND SUPERS BROWSERS

## 10.3 Using Class Browsers, Meta Browsers, and Supers Browsers

Instances of **ClassBrowser**, **SupersBrowser**, **MetaBrowser** all have the same menu interface. This section shows examples of the various menus followed by descriptions of the actions performed after selecting particular options.

Three pop-up menus are associated with browsers:

- One menu appears by positioning the mouse on the title bar of the browser window and pressing either the left or the middle mouse button. This menu contains options that control the appearance of the browser.
- A second menu appears by positioning the mouse on one of the nodes in a browser and pressing the left mouse button. This menu contains informational options.

- A third menu appears by positioning the mouse on one of the nodes in a browser and pressing the middle mouse button. This menu contains editing options.

These menus differ depending on the browser type. The following sections describe the menus associated with class browsers, supers browsers, and metaclass (or, more simple, meta) browsers. Sections then describe the additional functionality associated with file browser menus.

### 10.3.1 Selecting Options in the Title Bar Menu

---

The following menu appears when you position the mouse on the title bar of the browser menu and press either the left or the middle mouse button:

This section describes each menu option.

#### 10.3.1.1 Recompute and its Suboptions

---

Selecting the **Recompute** option and dragging the mouse to the right causes the following submenu to appear:

Most of the **Recompute** suboptions change the appearance of a browser but not its contents. For example, **SaveValue** provides a pointer to the browser without changing anything in it.

|                        |                                                                                                                                                                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SaveValue</b>       | The browser instance is stored in the instance variable <b>savedValue</b> of the prototype instance of <b>LoopsIcon</b> and in the value of <b>IT</b> (see the <i>Interlisp-D Reference Manual</i> ). This value is returned from the function call <b>SavedValue</b> . |
| <b>Recompute</b>       | Recomputes the entire browser structure from the starting objects. It does not recompute the labels for each item if those labels have been cached in the property <b>objectLabels</b> of the instance variable <b>menus</b> .                                          |
| <b>RecomputeLabels</b> | Recomputes the entire browser structure from the starting objects and recomputes the labels for each item.                                                                                                                                                              |
| <b>InPlace</b>         | Recomputes the browser without affecting the scrolled location of the lattice within the window. This may be necessary for a browser containing a large lattice structure.                                                                                              |
| <b>ShapeToHold</b>     | Makes the window for the browser just large enough to hold all of the nodes in the browser, up to a maximum size. Browser windows may also be changed interactively or programmatically with <b>SHAPEW</b> .                                                            |
| <b>ChangeFontSize</b>  | Causes a menu to appear containing 8, 10, 12, and 16. Selecting one changes the font size used to display the nodes to that value. The font family is                                                                                                                   |

```
(@ self browseFont:,FontFamily)
```

The font face is

```
(@ self browseFont:,FontFace)
```

Note: An alternative way to change the font of a browser is to enter:

```
[PROGN (←@ ($ InstanceOfBrowser) browseFont
(FONTCREATE)) (← ($ InstanceOfBrowser)
RecomputeLabels)]
```

**Lattice/Tree** Causes the following menu to appear:

```
HORIZONTAL/LATTICE
VERTICAL/LATTICE
HORIZONTAL/TREE
VERTICAL/TREE
```

Using the example of a supers browser for the class **ClassBrowser**, this browser is drawn for each of the formatting options. A tree does not show branches recombining; a lattice does. A boxed node in a tree indicates the node shows up in more than one location in a tree. When a browser is constructed by the system the default formatting style is HORIZONTAL/LATTICE.

- HORIZONTAL/LATTICE

- VERTICAL/LATTICE

- HORIZONTAL/TREE

- VERTICAL/TREE

### 10.3.1.2 AddRoot and its Suboptions

The **AddRoot** options add items or subtrees to the browser.

Selecting the **AddRoot** option and dragging the mouse to the right causes the following submenu to appear:

#### AddRoot

A prompt appears in an attached window to enter the name of a class to be added to the browser. If the entered item is not an object, a message that nothing was added to the browser is printed. If the entered item is already in the browser, nothing occurs. If the entered name does not correspond to a class, nothing occurs.

#### RemoveFromBadList

Objects within a browser can be put on the instance variable **badList**. This can be done by positioning the mouse on the node in a browser, pressing the left mouse button, and selecting an option from the menu that appears. Items on the **badList** are not displayed in the browser. If you select the option **RemoveFromBadList**, a menu appears showing any objects on the **badList**. Selecting one of those objects removes it from the **badList** and causes it to be redisplayed in the browser.

### 10.3.1.3 Add Category Menu

The system searches all methods in all classes shown in the browser and computes the categories for these. These categories are made into a sorted menu with the categories **Any** and **Public** included at the top. This menu is attached to the left side of the browser. Selecting options in this menu acts as a toggle, either highlighting them or returning them to their normal display.

Selected options are stored on the browser instance variable **viewingCategories**. Options on this menu interact with the browser interface for editing methods as described in Section 10.3.2, "Selecting Options in the Left Menu."

Note: Very often when using a browser, you ask to see what items a class inherits from classes above it in the inheritance lattice. To keep this inherited information more manageable, information inherited from the classes **Tofu**, **Object**, and **Class** are filtered out from the information presented to you. As an example, see the description of **PP** in the following section.

### 10.3.2 Selecting Options in the Left Menu

When the mouse is inside a browser and you hold down the left mouse button, nodes within the browser become inverted when the cursor moves over them, as shown in the following window:

If you release the left mouse button while the cursor is over a node, the following menu appears:

The options shown on the menu operate on the node (class) selected. Several of these options have associated submenus. Common options are in the main menu, and less common ones are menu suboptions. The actions that occur as a result of selecting one of these options are described in the following subsections. An additional subsection describes extended functionality available with the left mouse button.

### 10.3.2.1 PrintSummary and its Suboptions

---

**PrintSummary** provides a quick way to see object and method definitions. For all printing that occurs as a result of selecting this option or one of its suboptions, the output is sent to the value of the variable **PPDefault**, which is by default the Common Lisp Executive Window.

Selecting the **PrintSummary** option and dragging the mouse to the right causes the following submenu to appear:

#### **PrintCategories**

Prints the categories and associated methods for the selected class, as shown in the following window:

```
#,($ DestroyedObject)
Object
 Destroy!
```

#### **PP**

Produces a standard **PrettyPrint** of class, as shown in the following window:

```
(DEFCLASS DestroyedObject
 (MetaClass Class Edited%:
 (* --))
 (Supers Object))
```

#### **PP!**

Produces a formatted **Print** of class, as shown in the following window:

```
#,($ DestroyedObject)
MetaClass and its Properties
 Class Edited: (*
TheCollaborators:
15-Oct-84 16:23)
Supers
 (Object Tofu)
Instance Variable Descriptions
Class Variables
Methods
 Destroy! DestroyedObject.Destroy!
 doc NIL args NIL
```

Information that is defined locally within the class is printed in the bold font. Inherited information is printed in the regular font. Inherited information from the classes **Object** and **Tofu** is not printed.

#### **PPV!**

Same as **PP!**, but does not include **Methods**, as shown in the following window:

```

#,$ DestroyedObject)
MetaClass and its Properties
 Class Edited: (*
TheCollaborators:
15-Oct-84 16:23)
Supers
 (Object Tofu)
Instance Variable Descriptions
Class Variables

```

**PPMethod**

Brings up a menu of the methods for this class followed by a list of the known categories. The menu is influenced by the shaded options on the **Method Categories** menu (see Section 10.3.1.3, "Add Category Menu"), whether or not it is opened. Selecting a category will include any methods under that category in the menu. After selecting one of the methods, the Lisp function for that method is prettyprinted.

For example, selecting **PPMethod** from the node **ClassBrowser** with the **Method Categories** menu as shown results in the following menu of methods:

```

PPMethod: ClassBrowser
AddRoot
BoxNode
CareAbout?
GetSubs
LeftShiftSelect
MessageFormForProcess
NewItem
** Any category **
** Public category **
** ClassBrowser category **

```

**MethodSummary**

Prints a summary of the methods defined for the class, as shown in the following window:

```

((Destroy! DestroyedObject.Destroy! args
 NIL doc NIL))

```

**PrintSummary**

Similar to **PP**, but default values or properties associated with variables and methods are not printed, as shown in the following window:

```

#,$ DestroyedObject)
Supers
 Object
IVs

CVs

Methods
 Destroy!

```

**10.3.2.2 Doc (ClassDoc) and its Suboptions**

Each part of an object's definition has a **doc** property containing strings. This menu option is a quick way to see the string for a specific part of a definition. For all printing that occurs as a result of selecting this option or one of its

suboptions, the output is sent to the value of the variable **PPDefault**, which is by default the Common Lisp Executive Window.

Selecting the **Doc (ClassDoc)** option and dragging the mouse to the right causes the following submenu to appear:

**ClassDoc** Prints documentation for class, that is, the **doc** property.

**MethodDoc** Causes a menu to appear in the same manner as **PPMethod** described in Section 10.3.2.1, "PrintSummary and its Suboptions." After selecting a method, information about that method is printed, as shown in the following window:

```
class: ClassBrowser selector: BoxNode
args: NIL
doc: NIL
```

The menu of methods reappears until a selection is made from outside the menu.

**IVDoc** Causes a menu to appear showing instance variables associated with the class. After selecting one, its documentation is printed, as shown in the following window:

```
ClassBrowser:menus:
Cache For Saved Menus. Will Cache Menus only
if value is T
```

The menu of instance variables reappears until a selection is made from outside the menu.

**CVDoc** Causes a menu to appear showing class variables associated with the class. After selecting one, its documentation is printed, as shown in the following window:

```
ClassBrowser::RightButtonItem:
Items to be done if Right button is selected
```

The menu of class variables reappears until no selection is made from the menu.

---

### 10.3.2.3 WhereIs and its Suboptions

**WhereIs** describes where each part of the object comes from. For all printing that occurs as a result of selecting this option or one of its suboptions, the output is sent to the value of the variable **PPDefault**, which is by default the Common Lisp Executive Window.

Selecting the **WhereIs** option and dragging the mouse to the right causes the following submenu to appear:

**WhereIsIV**

Causes a menu to appear at the current cursor position, showing the local and inherited instance variables. A sample menu appears here:

```
Finding IVS: ClassBrowser
LabelMaxCharsWidth
LabelMaxLines
badList
bottom
boxedNode
browseFont
goodList
graphFormat
height
lastSelectedObject
left
menus
showGraphFn
startingList
title
topAlign
viewingCategories
width
window
```

When you select an instance variable from this menu, these actions occur, as shown in the following window:

- A search starts with the selected class and then proceeds upwards through its supers. The first class that contains the selected instance variable flashes three times.
- All other classes in the browser that contain, that is, specialize, the instance variable are shaded.
- The name of the topmost class name is printed across the top of the window.

**WhereIsCV**

Same as above, but for class variables.

**WhereIsMethod**

Same as above, but for **Methods**. The menu of methods is not filtered by any category information.

#### 10.3.2.4 DeleteFromBrowser and its Suboptions

---

Browsers show all of the lattice or tree from the root to the leaves. The **DeleteFromBrowser** option and its suboptions, shown here, allow you to prune the tree.

##### DeleteFromBrowser

Deleting a class from a browser adds it to that browser's instance variable **badList**. Items listed in a browser's **badList** are not displayed by the browser. If a class on the **badList** has subclasses, these are made into roots. To redisplay a class once it has been deleted, refer to the command **RemoveFromBadList** in Section 10.3.1.2, "AddRoot and its Suboptions."

##### DeleteSubtreeFromBrowser

Deleting a class with this command places this class on the browser's **badList**. Additionally, any subclasses of the deleted class are also placed on the **badList**. If one uses the command **RemoveFromBadList** to redisplay the deleted class, only that class is redisplayed. Its subclasses remain on the **badList** until they are explicitly removed from it.

#### 10.3.2.5 SubBrowser

---

The following window shows the selection of this option:

For class and supers browsers, the SubBrowser option opens a new browser of the same type (for example, a **SubBrowser** of a supers browser is a supers browser) with the class selected becoming the root object of the browser. For file browsers, the **SubBrowser** becomes a class browser.

#### 10.3.2.6 TypeInName

---

The following window shows the selection of this option:

This option puts the class name in the type-in buffer.

#### 10.3.2.7 Extending Functionality with the Left Mouse Button

---

Using various keys in conjunction with the left mouse button extends the available options.

- **SHIFT** key

Pressing the **SHIFT** key while selecting a node with the left button causes the name of the class to be typed into the current type-in point. If a node is not selected, but the cursor is in the background of the browser, the entire graph is copied. This can be used to insert browser images into TEdit documents, for example. See the Lisp Library documentation on Grapher for more details.

- **Control (CTRL)** key

Pressing the **CTR** key while selecting a node with the left button causes the node to track movement by the cursor. This allows you to temporarily change the layout of the nodes in the graph. The next update of the browser recomputes the node positions.

- **META** key

Pressing the **META** key while selecting a node with the left button is the same as a **PrintSummary** selection.

---

### 10.3.3 Selecting Options in the Middle Menu

When you position the cursor on a browser node and press the middle mouse button, the following menu appears:

This section describes the actions that occur when you select an option from this menu.

Except for **BoxNode**, all options are followed by a parenthetical suboption. This suboption appears in the option's submenu and performs the same operation as the option itself. For example, selecting **Methods (EditMethod)** performs the same operation as selecting **EditMethod** from its submenu.

The prompt for these options usually appears in a small window at the top of the browser, unless otherwise stated.

---

#### 10.3.3.1 Box/UnBoxNode

Draws a box around the node, as shown here:

This also selects the node as a target for **Move** and **Copy** options. If a node is already boxed, **Box/UnBoxNode** unboxes it. Only one node in a class browser can be boxed at a time with this menu option.

---

#### 10.3.3.2 Methods (EditMethod) and its Suboptions

Selecting the **Methods (EditMethod)** option and dragging the mouse to the right causes the following submenu to appear:

#### EditMethod

Edits a method of class, selected from a menu of local methods. The menu that appears contains some or all of the methods of the class and some category choices. The menu options that appear depend on the shaded options on the **Method Categories** menu (see Section 10.3.1.3, "Add Category Menu").

For example, assume the following actions occur:

- A class browser is opened on the class **LatticeBrowser**.
- A category menu is added and the category **LatticeBrowser** is selected.
- **FileBrowser** under the class **ClassBrowser** is selected.
- The **EditMethod** suboption is selected.

The following menu appears:

If you select one of the method names, an edit window appears containing the source code for the method (assuming the source code was loaded). If you select one of the categories, a similar menu appears showing the changed methods and categories. The method/category menu continues to appear until you select a method or press a mouse button outside of the menu. This operation is provided by the method **PickSelector**.

#### EditMethod!

Edits a method selected from a menu of all the inherited methods, making the method local if necessary.

#### EditMethodObject

Edits the object representing the method, as shown in this display editor window:

```

SEdit #,($& Method (NEW0.1Y;.;h.eN6 , 453
((className FileBrowser)
 (selector Recompute)
 (method FileBrowser.Recompute)
 (args NIL)
 (doc NIL)
 (category (LatticeBrowser)))

```

This suboption uses the method **PickSelector** to provide the same menu interface for choosing a selector that **EditMethod** uses. Within this edit window, the only items you should change are the **doc** and **category** properties.

**MethodMenu** Creates a permanent menu of methods of this class, for example,

```

Edit methods for DestroyedObject
Destroy!

```

After you have placed the menu, pressing the left mouse when the cursor is over a menu option will cause the method to be printed; pressing the middle button will cause the method to be edited.

**EditCategory** This option has three suboptions:

- **EditCategory**

Opens a menu of available categories, similar to the following menu example:

```

Method category
Any
Public
Internal
LatticeBrowser
Window

```

After you select a category, another menu appears containing the methods of that category and a list of categories not chosen (using the method **PickSelector**). When a method is selected, it appears in an edit window.

- **ChangeMethodCategory**

Using the method **PickSelector**, this prompts you for a method. When one is selected, another menu appears containing the option **\*other\*** with all of the categories of the selected class.

If one of the categories is chosen, the category for the method is changed to this value.

If **\*other\*** is chosen, this prompts you in the **PROMPTWINDOW** for a symbol or a list of symbols that will become the new category or categories for the method.

See the method **Class.ChangeMethodCategory**.

- **CategorizeMethods**

Edits an association list of categories and the local methods they contain via the editor.

This is an example of the edit window that appears:

```
SEdit Package: INTERLISP
((Any (CreateClass DestroyInstance New NewWithValues))
 (Public (CreateClass DestroyInstance New NewWithValues))
 (Internal NIL)
 (MetaClass (CreateClass))
 (Class (DestroyInstance New NewWithValues)))
```

**BreakMethod** This option has three suboptions:

- **BreakMethod**

Places a break on a method of class, selected from a menu of local methods, by sending the message **BreakMethod**.

- **TraceMethod**

Places a trace on a method of class, selected from a menu of local methods, by sending the message **TraceMethod**.

- **UnbreakMethod**

Brings up a menu of methods local to class that have been broken, and removes any breaks or traces on the one selected by sending the message **UnbreakMethod**.

### 10.3.3.3 Add (AddMethod) and its Suboptions

Selecting the **Add (AddMethod)** option and dragging the mouse to the right causes the following submenu to appear:

**AddIV** Prompts you for the name of a new instance variable to be added to a class, and opens an editor as shown here:

```
* SEdit DestroyedObject Package: INTERLISP
(newIV **DefaultValue doc (* IV added by MCGILL))
```

From here, change the default value of the instance variable to the desired value, and change the documentation to add any other properties and values if necessary. When you exit from the editor, the instance variable is added to the class.

**AddCV** Same as **AddIV**, except that you add a class variable.

**AddMethod** Allows you to create and edit a new method for this class. You are prompted to type a selector for the new method. Next, an edit window appears with the following template:

```
SEdit DestroyedObject.newMethod Package: INTERLISP
(Method ((DestroyedObject newMethod) self)
 "Method documentation"
 (SubclassResponsibility))
```

Replace the form (SubclassResponsibility) with the functionality you want.

**SubclassResponsibility** is a macro that causes a call to **HELPCHECK**, so if you forget to remove it, or want to leave it in for debugging, it will break when the new method is invoked.

**SpecializeMethod** Causes a menu to appear, containing the selectors of inherited methods, the option **\*\* Generic Methods \*\***, and available categories.

If one of the selectors is chosen, a display editor window appears with a template that contains a **\_Super** and the same comment as the specialized method. An example of this window appears here:

```
SEdit DestroyedObject.Destroy! Package: INTERLISP
(Method ((DestroyedObject Destroy!) self)
 "Specialization"
 (<Super self Destroy!))
```

If **\*\* Generic methods \*\*** is chosen this causes a menu to appear, listing the methods inherited from **Object**, **Class**, or **Tofu**.

**AddSuper** Prompts you for a class name to be added to the beginning of the **Supers** list.

**SpecializeClass** Defines a subclass of this class. This subclass is initialized with no locally defined instance variables, class variables, or methods. You are prompted to give a name for the new class. The new class is added to the browser.

**NewInstance** Creates a new instance of this class, calls **PutSavedValue** with the new instance as an argument, and prints the instance.

#### 10.3.3.4 Delete (DeleteMethod) and its Suboptions

Selecting the **Delete (DeleteMethod)** option and dragging the mouse to the right causes the following submenu to appear:

|                              |              |
|------------------------------|--------------|
| Box/UnBoxNode                |              |
| Methods (EditMethod)         |              |
| Add (AddMethod)              |              |
| <b>Delete (DeleteMethod)</b> | DeleteIV     |
| Move (MoveMethodTo)          | DeleteCV     |
| Copy (CopyMethodTo)          | DeleteMethod |
| Rename (RenameMethod)        | DeleteClass  |
| Edit (EditClass)             |              |

**DeleteIV** Opens a menu containing the local instance variables, that is, those defined in the class. Selecting one removes it from the class.

**DeleteCV** Same as **DeleteIV**, but for class variables.

**DeleteMethod** Opens a menu containing the local selectors. Choosing one opens the following menu for confirmation:

```
Destroy!Confirm method deletion
Delete Method and Function
Abort
```

**DeleteClass** Deletes this class. Opens a menu similar to the following for confirmation:

```
Confirm
Destroy DestroyedObject
```

If the class has no subclasses it will be deleted. If it does have subclasses a **HELPCHECK** break occurs; you can then abort or type OK to destroy the class and all of its subclasses.

---

### 10.3.3.5 Move (MoveMethodTo) and its Suboptions

---

Selecting the **Move (MoveMethodTo)** option and dragging the mouse to the right causes the following submenu to appear:

|                            |          |
|----------------------------|----------|
| Box/UnBoxNode              |          |
| Methods (EditMethod)       | »        |
| Add (AddMethod)            | »        |
| Delete (DeleteMethod)      | »        |
| <b>Move (MoveMethodTo)</b> | <b>»</b> |
| Copy (CopyMethodTo)        | »        |
| Rename (RenameMethod)      | »        |
| Edit (EditClass)           | »        |

|                     |
|---------------------|
| <b>MoveIVTo</b>     |
| <b>MoveCVTo</b>     |
| <b>MoveMethodTo</b> |
| <b>MoveSuperTo</b>  |
| <b>MoveToFile</b>   |
| <b>MoveToFile!</b>  |

Moving methods and variables requires that you first have used **BoxNode** (see Section 10.3.3.1, "BoxNode") on the class which is to receive whatever is moved.

---

#### CAUTION

Moving methods and variables can have profound effects on the classes that inherit them.

---

**MoveIVTo** Opens a menu with the instance variables for the class. Choosing one causes it to be moved to the class that is boxed in the browser. When this operation is completed, the menu opens again prompting you for another instance variable to move, if desired.

**MoveCVTo** Similar to **MoveIVTo**, but for class variables.

**MoveMethodTo** Similar to **MoveIVTo**, but for methods.

**MoveSuperTo** Opens a menu of the Supers for the class. Choosing one of these will cause it to be removed as a super class, and the boxed class to be added to the Supers list.

**MoveToFile** Opens a menu of files on **FILELST** along with **\*newFile\***. (See Section 10.2.1.2, "Command Summary," for more information on **\*newFile\***.) The class and its methods are moved to the chosen file.

**MoveToFile!** Same as **MoveToFile**, but includes subclasses and their methods of the classes.

### 10.3.3.6 Copy (CopyMethodTo) and its Suboptions

Selecting the **Copy (CopyMethodTo)** option and dragging the mouse to the right causes the following submenu to appear:

Copy options operates similarly to Move options, but leave the original method or variable in its place while adding it to the destination. You can then specialize the original or copy.

- CopyIVTo** Similar to **MoveIVTo**, but copies the instance variables instead of moving them.
- CopyCVTo** Similar to **MoveCVTo**, but copies the class variables instead of moving them.
- CopyMethodTo** Similar to **MoveMethodTo**, but copies the methods instead of moving them.

### 10.3.3.7 Rename (RenameMethod) and its Suboptions

Selecting the **Rename (RenameMethod)** option and dragging the mouse to the right causes the following submenu to appear:

- RenameIV** A menu appears, showing the instance variables of the class. After selecting one of these, you are prompted to give a new name for that instance variable.
- RenameCV** Similar to **RenameIV**, but for class variables.
- RenameMethod** Similar to **RenameIV**, but for methods. You are prompted to give a new name for the selector of the method. The method function name is changed to reflect the change in the name of the selector.
- RetireMethod** A menu appears, showing the selectors of the class. After selecting one of these, the selector is changed by adding the prefix "Old" to it. The method function is also renamed appropriately.
- RenameClass** You are prompted for a new name for the class. After the new name is entered, the browser is updated to reflect the change. In addition, the method functions associated with the class are also renamed. For example, given a class **Foo** with selector **Fie**, when the class is renamed to **Fum**, the method function is automatically renamed from **Foo.Fie** to **Fum.Fie**.

### 10.3.3.8 Edit (EditClass) and its Suboptions

Selecting the **Edit (EditClass)** option and dragging the mouse to the right causes the following submenu to appear:

Editing options allow you to make quick, massive changes to object descriptions, and are sometimes the only menu-driven way to change certain items. See Chapter 13, Editing, for more details.

- |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EditClass</b>    | Edits the class definition of the class showing only the locally defined class variables, instance variables, and methods.                                                                                                                                                                                                                                                                                                                                         |
| <b>EditClass!</b>   | Edits the class definition of the class showing both the locally defined and inherited class variables, instance variables, and methods. Changes to the inherited information that are done during the edit have no effect. The inherited information is included for informational purposes only. For example, you may want to copy the definition of an instance variable from the list of inherited instance variables to the list of local instance variables. |
| <b>InspectClass</b> | Opens an inspector window on the class. See Chapter 18, User Input/Output Modules, for more details.                                                                                                                                                                                                                                                                                                                                                               |

---

## 10.4 Using File Browsers

---

File browsers are a specialization of class browsers. In addition to the capabilities of class browsers, file browsers allow you to manipulate files. This section explains the file browser menu options not available from class browser menus, or those that have been modified from the class browser menu options. This section lists all file browser menu options; references are made to class browser menus where appropriate.

Multiple files can be associated with a file browser. Thus, one of those files can be designated as the "selected" file. There are various options as to which classes should be displayed in a file browser. See Section 10.4.1.4, "Change display mode and its Suboptions," for more information.

When a file browser is opened, the window title displays the selected file:

The icon for a shrunk file browser contains the name of the selected file, as shown here:

### 10.4.1 Selecting Options in the Title Bar Menu

The title bar menu in a **FileBrowser**, shown here, is like the title bar menu in a **ClassBrowser**, but has additional entries for file system and Masterscope functions.

#### 10.4.1.1 Recompute and its Suboptions

Operates identically to the class browser. See Section 10.3.1.1, "Recompute and its Suboptions," for more information.

#### 10.4.1.2 AddRoot and its Suboptions

Prompts you for the name of a class to add. If the class already exists, it is added to the browser and shaded. If the class is not contained on the file, it will appear shaded in the browser. If the class does not exist, it is created and added to the selected file.

#### 10.4.1.3 Add Category Menu

Operates identically to the class browser. See Section 10.3.1.3, "Add Category Menu and its Suboptions," for more information.

#### 10.4.1.4 Change display mode and its Suboptions

Selecting the **Change display mode** option and dragging the mouse to the right causes the following submenu to appear:

A **FileBrowser** logically includes more display options than a **ClassBrowser**. A **FileBrowser** can display a class hierarchy as it is stored in the file, or as it exists in combination with other files and the system as a whole.

#### Change display mode

Selecting this option causes a sub-submenu to appear showing three options:

- **selectedFile**

Displays only the classes contained within the selected file or classes that have been added to the browser by **AddRoot** or **AddSubs** (by setting the browser's instance variable **goodList** to the appropriate value). See

Section 10.5.3, "Methods for the Class LatticeBrowser," for an explanation of **AddSubs**.

- **associatedFiles**

Same as **selectedFile**, but the browser also includes any classes defined in files associated with the browser. The instance variable **goodList** is bound to this list, slightly differently than the use of **goodList** in a class browser.

- **all**

Same as **associatedFiles**, but any subclasses, even if not defined in the files, are also displayed because the instance variable **goodList** is bound to NIL.

**Add file to browser**

Prompts you with a menu that is similar to the menu that is displayed when you select **Browse File** from the LOOPS Icon or the background menu, except that files already associated with the browser are not displayed on the menu.

**Select file**

Causes a menu to appear, showing the files associated with the browser. Selecting one causes that file to become the "selected file" of the browser. It clears the browser of any classes added to the browser by the **AddRoot** and **AddSubs** menu commands. That is, it resets the starting list of the browser to be only those classes contained within the selected file. The instance variable **badList** of the browser is set to NIL.

---

#### 10.4.1.5 Uses IV? and its Suboptions

---

Selecting the **Uses IV?** option and dragging the mouse to the right causes the following submenu to appear:

These menu options trigger various Masterscope operations. Most of these operations prompt you for information that is used in a Masterscope query. The results of this query are used to build a second menu. If the situation occurs that the second menu is empty, a message is printed in the prompt window of the browser similar to "someCV not used as a CV."

---

#### CAUTION

Source files being displayed in the file browser must be available or these functions cannot work. In addition, the LOOPS Library Module LOOPSMS must also be loaded (see the *LOOPS Library Modules Manual* for details).

---

Additionally, the first time one of these options is selected there may be a pause while Masterscope analyzes the file. A window will open, and fill with

"blips" as the analysis proceeds, until the file is analyzed and the original question is answered.

#### UsesIV

This first opens a menu of instance variables defined in classes contained in the selected file of the browser. Two additional options are placed at the top of the menu:

- **\*other\***

Selecting **\*other\*** causes a prompt to enter the name of an instance variable.

- **\*any\***

Selecting **\*any\*** creates a menu with all methods that reference any instance variable.

After an instance variable has been chosen, you are prompted to place a menu that contains the following options:

- A list of methods on the selected file that use that instance variable
- A list of classes on the selected file that contain that instance variable.
- **\*EditAll\***

If one of the methods or classes is selected, it is edited. Suboptions from the methods or classes include:

- **Edit**

Edits the method.

- **Substitute**

Prompts for a new name for the instance variable. Changes the instance variable name to the new name in the method and then brings up the display editor for you to edit the method.

- **Check**

Executes the Masterscope command CHECK <file> on the file associated with the LOOPS FileBrowser. See the *Lisp Library Modules Manual* for details.

**\*EditAll\*** has the following two suboptions:

- **\*EditAll\***

Edits each method and class in succession.

- **\*SubstituteAll\***

Prompts you for a new name for the instance variable. Substitutes this new name for the old name in all methods and classes listed in the menu.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>UsesCV</b>           | Same as <b>UsesIV</b> , but for class variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>UsesObject</b>       | Opens a menu of classes or instances defined on the selected file that are used by any of the methods or functions on the selected file. After you choose one of the objects, a menu similar to the one created for <b>UsesIV</b> is created, but contains the methods and functions that use the chosen objects.                                                                                                                                                                                                                                                                                                                       |
| <b>UsesLispVar</b>      | Same as <b>UsesIV</b> , but the initial menu displays Lisp variables instead of objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ImplementsMethod</b> | <p>This option has three suboptions:</p> <ul style="list-style-type: none"><li>• <b>ImplementsMethod</b><br/>Opens a menu of all of the selectors in the selected file. When one is chosen, a menu is created showing the methods that use that selector and the classes that are associated with those methods.</li><li>• <b>OverridesMethod</b><br/>Generates a menu of methods and classes that override (that is, does not invoke <b>_Super</b>) the selected method.</li><li>• <b>SpecializesMethod</b><br/>Generates a menu of methods and classes that specialize (that is, invoke <b>_Super</b>) the selected method.</li></ul> |
| <b>SendsMessage</b>     | Opens a menu of all of the selectors in the selected file. When one is chosen, a menu is created that lists the methods and functions that send messages using that selector. The following window shows a sample of this menu.                                                                                                                                                                                                                                                                                                                                                                                                         |
|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>CallsFunction</b>    | Opens a menu of all of the functions that are called by functions or methods in the selected file. After one is chosen, a menu is opened that contains the methods and/or functions that call the chosen function; the last option on the menu is the chosen function.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>AnalyzeFile</b>      | Begins a separate process analyzing the selected file. When the analysis is completed, "Done analyzing" is printed in the browser's prompt window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>CheckFile</b>        | Begins a separate process checking the selected file. When the checking is completed, "Done checking" is printed in the browser's prompt window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

---

#### 10.4.1.6 Edit FileComs and its Suboptions

Selecting the **Edit FileComs** option and dragging the mouse to the right causes the following submenu to appear:

The filecoms are variables that describe the contents of a file, for example, methods, classes, and Lisp functions and variables. LOOPS extends the File Manager to handle object oriented code and data, and the **FileBrowser** gives users a menu driven interface to deal with this extended file functionality.

### Edit Functions

Opens a sub-submenu giving options dealing with filecoms and with some of the items listed (functions in particular). This sub-submenu contains five suboptions:

- **EditFns**

Opens a menu of the functions contained within the selected file (those listed under FNS in the filecoms) and the option **\*NewFunction\***. Selecting one of the functions calls the editor on that function.

Selecting **\*NewFunction\*** causes a prompt for a name for the new function. An edit window then opens containing a template for a lambda expression. This newly defined function is added to the FNS list of the selected file's filecoms.

- **MakeFunctionMenu**

Does an **ADDMENU** (the Interlisp function which adds a permanent menu to the screen) of a menu containing functions on the selected file. Selecting one of the functions opens an editor on it.

- **BreakFunction**

Opens a menu containing functions on the selected file that are not on **BROKENFNS** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*). Selecting one of the functions causes it to break next time it is invoked.

- **TraceFunction**

Same as **BreakFunction**, except that the selected function is traced.

- **UnbreakFunction**

Creates a menu of functions that are members of **BROKENFNS** and are contained in the selected file. The selected file is unbroken.

**EditComs** Edits the filecoms of the selected file.

**EditMacros** Creates a menu of macros contained in the selected file. Selecting one of them opens an editor on it.

**EditRecords** Same as **EditMacros**, but for records.

**EditVars** Same as **EditMacros**, but for variables.

**EditInstances** Same as **EditMacros**, but for instances.

### 10.4.1.7 CLEANUP file and its Suboptions

---

This option invokes some or all of **CLEANUP**, which is the automatic file maintenance utility of Medley.

Selecting the **CLEANUP file** option and dragging the mouse to the right causes the following submenu to appear:

- |                       |                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CLEANUP file</b>   | Calls <b>FILES?</b> and then calls <b>CLEANUP</b> on the selected file.                                                                                    |
| <b>Hardcopy file</b>  | Sends the selected file to the <b>DEFAULTPRINTINGHOST</b> .                                                                                                |
| <b>Load PROP file</b> | Loads the selected file with <b>LDPLG</b> set to <b>PROP</b> , making sources available to Masterscope, but leaving any compiled code in place to execute. |

### 10.4.2 Selecting Options in the Left Menu

---

When the cursor is inside of a file browser and you press the left mouse button, nodes within the browser are inverted when the cursor moves over them. If you release the left mouse button while the cursor is over a node, the following menu appears:

These options include those in a class browser and add **AddSubs**, an option that expands the lattice of a file browser to look more like that of a class browser by showing related classes not stored in the browsed file.

#### 10.4.2.1 PrintSummary and its Suboptions

---

Operates identically to the class browser. See Section 10.3.2.1, "PrintSummary and its Suboptions," for more information.

#### 10.4.2.2 Doc (ClassDoc) and Its Suboptions

---

Operates identically to the class browser. See Section 10.3.2.2, "Doc (ClassDoc) and its Suboptions," for more information.

#### 10.4.2.3 WhereIs (WhereIsMethod) and Its Suboptions

---

Operates identically to the class browser. See Section 10.3.2.3, "WhereIs (WhereIsMethod) and its Suboptions", for more information.

#### 10.4.2.4 DeleteFromBrowser and Its Suboptions

Operates identically to the class browser. See Section 10.3.2.4, "DeleteFromBrowser and its Suboptions," for more information.

#### 10.4.2.5 SubBrowser

Creates an instance of a class browser with the selected class as the root node, not a file browser. See Section 10.3.2.5, "SubBrowser," for more information.

#### 10.4.2.6 TypeInName

Operates identically to the class browser. See Section 10.3.2.6, "TypeInName," for more information.

#### 10.4.2.7 AddSubs and its Suboptions

**AddSubs** fills out the class lattice in a file browser window. This shows classes, the file they are from (if any) and the inherited methods and variables from classes which are in the file.

**AddSubs** Adds the immediate subclasses of the class to the browser and shades the new subclasses, as shown here:

**AddSubs!** Adds all subclasses of the class to the browser and shades the new subclasses.

### 10.4.3 Selecting Options in the Middle Menu

When the cursor is over a node and you press the middle mouse button, the following menu appears:

The middle button commands are the same as those on a **ClassBrowser**, with some new functionality for **Add (AddMethod)**, and with Masterscope options added under the option **UsesIV**.

### 10.4.3.1 BoxNode

---

Operates identically to the class browser. See Section 10.3.3.1, "BoxNode/UnBoxNode," for more information.

### 10.4.3.2 Methods (EditMethod) and its Suboptions

---

Operates identically to the class browser. See Section 10.3.3.2, "Methods (EditMethod) and its Suboptions," for more information.

### 10.4.3.3 Add (AddMethod) and its Suboptions

---

Operates identically to the class browser, but with additional functionality to keep the added items associated with the file being browsed in the following suboptions.

- |                         |                                                                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SpecializedClass</b> | Prompts you to enter a name for the new subclass for the chosen class. If the chosen class is on the selected file, the new subclass is added to that file. If the chosen class is on another file, choose a file from a menu of files to which the new subclass is added. |
| <b>NewInstance</b>      | Creates a new instance of the class and calls <b>PutSavedValue</b> with the new instance as an argument. You are prompted to give the new instance a name, and the new instance is added to the selected file.                                                             |

### 10.4.3.4 Delete (DeleteMethod) and its Suboptions

---

Operates identically to the class browser. See Section 10.3.3.4, "Delete (DeleteMethod) and its Suboptions," for more information.

### 10.4.3.5 Move (MoveMethodTo) and its Suboptions

---

Operates identically to the class browser. See Section 10.3.3.5, "Move (MoveMethodTo) and its Suboptions," for more information.

### 10.4.3.6 Copy (CopyMethodTo) and its Suboptions

---

Operates identically to the class browser. See Section 10.3.3.6, "Copy (CopyMethodTo) and its Suboptions," for more information.

### 10.4.3.7 Rename (RenameMethod) and its Suboptions

---

Operates identically to the class browser. See Section 10.3.3.7, "Rename (RenameMethod) and its Suboptions," for more information.

### 10.4.3.8 Edit (EditClass) and its Suboptions

---

Operates identically to the class browser. See Section 10.3.3.8, "Edit (EditClass) and its Suboptions," for more information.

### 10.4.3.9 UsesIV and its Suboptions

Selecting the **UsesIV** option and dragging the mouse to the right causes the following submenu to appear:

These commands operate similarly to the **Uses IV?** commands in the title bar menu. See Section 10.4.1.5, "UsesIV? and its Suboptions," for more information. Here, however, the Masterscope queries are limited to the class in question instead of the entire file.

## 10.5 PROGRAMMER'S INTERFACE TO LATTICE BROWSERS

### 10.5 PROGRAMMER'S INTERFACE TO LATTICE BROWSERS

## 10.5 Programmer's Interface to Lattice Browsers

LOOPS browsers are standard LOOPS objects, so their functionality can be exercised programmatically by messages which invoke their methods. Many browser functions are based on the Lisp Library Module, Grapher, but browsers apply only to dealing with LOOPS objects. All of the functionality in the menu-driven interface to the browsers is available programmatically.

Note: Data not a part of LOOPS data can be graphed with LOOPS calls to the Lisp Library Module, Grapher.

**ClassBrowsers** show the inheritance structure of object classes, a relationship defined at application design time. Browsers can also be used to show dynamic information, not computed until runtime. The LOOPS class **InstanceBrowser** does this, showing links between instances defined at runtime.

**InstanceBrowser** is derived from **LatticeBrowser** by specializing just two methods, **GetSubs** and **NewPath**. In general, you can specialize browsers to your own purposes by specializing these methods and **GetLabel**. An example is given in Section 10.7, "Class Instance Browser Example," producing a class browser which also shows instances, connected with dashed lines.

### 10.5.1 Instance Variables for the Class LatticeBrowser

Instance variables appear in alphabetical order.

|                           |                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>badList</b>            | A list of objects that are not displayed in the browser window.                                                                                     |
| <b>boxedNode</b>          | The last object boxed, if any.                                                                                                                      |
| <b>browseFont</b>         | The font used for labels. This has two properties: <b>FontFamily</b> and <b>FontFace</b> which are referenced in the method <b>ChangeFontSize</b> . |
| <b>lastSelectedObject</b> | The last object selected.                                                                                                                           |
| <b>goodList</b>           | A list of objects that are displayed in the browser window; if NIL, no objects are displayed.                                                       |

|                           |                                                                                                                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>graphFormat</b>        | A list indicating the style of layout for the graph. See the method <b>ChangeFormat</b> and the Lisp Library Module, Grapher.                                                                                                                        |
| <b>LabelMaxCharsWidth</b> | Affects the way labels are generated. This limits the width of a label to <b>LabelMaxCharsWidth</b> times the width of the character "A". See the method <b>ChangeMaxLabelSize</b> . Default value is NIL, which puts no restrictions on label size. |
| <b>LabelMaxLines</b>      | Affects the way labels are generated. This limits the number of lines in a label to <b>LabelMaxLines</b> . Refer to the method <b>ChangeMaxLabelSize</b> . Default value is NIL which puts no restrictions on label size.                            |
| <b>startingList</b>       | List of objects used to compute this browser.                                                                                                                                                                                                        |
| <b>title</b>              | Title passed to Grapher module.                                                                                                                                                                                                                      |
| <b>topAlign</b>           | This flag is used to indicate whether the graph should be aligned with the top or bottom of the window. If <b>topAlign</b> = T (the default), then the Grapher module aligns the graph to the top of the window.                                     |

---

### 10.5.2 Class Variables for the Class **LatticeBrowser**

---

Except for **BoxLineWidth**, the following class variables determine the menus that appear when a mouse is positioned over a node within a browser and the left or middle button is pressed. The default behavior is to send a message to the object represented by the node with the selector returned from the menu selection. The form for the values that these class variables can have is described in Chapter 20, Windows.

Class variables appear in alphabetical order.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BoxLineWidth</b>     | The width of line that is drawn around a node when it is boxed. See the method <b>BoxNode</b> in Section 10.5.3, "Methods for the Class <b>LatticeBrowser</b> ."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>LeftButtonItem</b>   | Items for the menu that appears when the mouse is on a node in the browser and the left button is pressed. When an item is selected from a menu, the returned value is sent as a message to an object represented by the node. See <b>LocalCommands</b> , below.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>LocalCommands</b>    | <p>When the cursor is positioned over a node in a browser and you press the left or middle mouse button, the default behavior is to bring up a menu from which you select an item. The value returned from that item specifies the selector of a message that is sent to the object which is represented by the node in the browser.</p> <p>The class variable <b>LocalCommands</b> provides a way to override that behavior. If the value returned from the menu selection is on the list that is the value of <b>LocalCommands</b>, the message is not sent to the object, but is sent to the browser instead. The object is passed as an argument in that message.</p> |
| <b>MiddleButtonItem</b> | Options for the menu that appears when the mouse is on one of the nodes in a browser and the middle button is pressed. When an option is selected from a menu, the returned value is sent as a message to the object represented by the node. See <b>LocalCommands</b> , above.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>TitleItem</b>        | Options for the menu that appears when the mouse is on the title bar in a browser and the left or middle button is pressed. When an option is selected from the menu, the returned value is sent as message to the browser.                                                                                                                                                                                                                                                                                                                                                                                                                                               |

The following selectors are associated with this menu:

- **SaveInT**
- **Recompute**
- **RecomputeInPlace**

- **ShapeToHold**
- **ChangeFontSize**
- **ChangeFormat**
- **AddRoot**
- **RemoveFromBadList**

Examine the class **LatticeBrowser** for more information.

### 10.5.3 Methods for the Class LatticeBrowser

The following table shows the methods and variables for the class **LatticeBrowser**.

| Name                            | Type   | Description                                                                                  |
|---------------------------------|--------|----------------------------------------------------------------------------------------------|
| <b>AddRoot</b>                  | Method | Adds a LOOPS name or an object to the starting list of the browser.                          |
| <b>BoxNode</b>                  | Method | Puts a box around the node representing the object.                                          |
| <b>Browse</b>                   | Method | Uses a lattice or tree graph to display the relationship between a number of objects.        |
| <b>BrowserObjects</b>           | Method | Returns the list of objects currently in the graph.                                          |
| <b>ChangeFontSize</b>           | Method | Changes the size of the characters in the labels.                                            |
| <b>ChangeFormat</b>             | Method | Changes between lattice and tree graphs.                                                     |
| <b>ChangeMaxLabelSize</b>       | Method | Changes how labels are printed.                                                              |
| <b>ClearLabelCache</b>          | Method | Recomputes labels.                                                                           |
| <b>DeleteFromBrowser</b>        | Method | Prunes branches in a graph.                                                                  |
| <b>DeleteSubtreeFromBrowser</b> | Method | Prunes branches in a graph.                                                                  |
| <b>FlashNode</b>                | Method | Changes the label of a node from black-on-white to white-on-black several times.             |
| <b>FlipNode</b>                 | Method | Changes the label of a node that represents an object from black-on-white to white-on-black. |
| <b>GetDisplayLabel</b>          | Method | Finds the label for a node.                                                                  |
| <b>GetLabel</b>                 | Method | Computes a label for an object.                                                              |
| <b>GetSubs</b>                  | Method | Computes a list of subnodes of an object.                                                    |
| <b>GraphFits</b>                | Method | Determines if the graph in the browser can be contained within the browser window.           |
| <b>HasObject</b>                | Method | Returns T if an object is in the graph.                                                      |
| <b>HighlightNode</b>            | Method | Changes the way a node is displayed.                                                         |
| <b>IconTitle</b>                | Method | Computes the title to write in the icon.                                                     |
| <b>LeftSelection</b>            | Method | Controls the effect of using the left mouse button.                                          |

|                          |          |                                                                                                                    |
|--------------------------|----------|--------------------------------------------------------------------------------------------------------------------|
| <b>LeftShiftSelect</b>   | Method   | Sends the message <b>PP!</b> to an object.                                                                         |
| <b>MiddleSelection</b>   | Method   | Controls the effect of using the middle mouse button.                                                              |
| <b>MiddleShiftSelect</b> | Method   | Invoked by the mouse operations to edit an object in the TTY process context.                                      |
| <b>NewItem</b>           | Method   | Gets an object.                                                                                                    |
| <b>NodeRegion</b>        | Method   | Returns the region occupied in an object in the browser.                                                           |
| <b>ObjectFromLabel</b>   | Method   | Returns the object in the graph that has a specified label.                                                        |
| <b>PositionNode</b>      | Method   | Places a node at a particular position in the browser window.                                                      |
| <b>Recompute</b>         | Method   | Recomputes the browser graph in the same window.                                                                   |
| <b>RecomputeInPlace</b>  | Method   | Recomputes the browser graph in the same window, trying to maintain the same scroll position in the window.        |
| <b>RecomputeLabels</b>   | Method   | Recomputes the labels in a browser.                                                                                |
| <b>RemoveHighlights</b>  | Method   | Removes all highlights in any node in the graph.                                                                   |
| <b>RemoveShading</b>     | Method   | Removes all shading in any node in the graph.                                                                      |
| <b>SaveInIt</b>          | Method   | Places a pointer in a browser where it can be accessed.                                                            |
| <b>ShadeNode</b>         | Method   | Adds shading to a node.                                                                                            |
| <b>ShapeToHold</b>       | Method   | Reshapes the window to all items.                                                                                  |
| <b>MaxLatticeWidth</b>   | Variable | Restricts the maximum width of a browser window.                                                                   |
| <b>MaxLatticeHeight</b>  | Variable | Restricts the maximum height of a browser window.                                                                  |
| <b>Show</b>              | Method   | Displays items and their subitems in a browser window.                                                             |
| <b>Shrink</b>            | Method   | Shrinks a browser window.                                                                                          |
| <b>SubBrowser</b>        | Method   | Creates a browser that is an instance of the same class as <i>self</i> with a specified object as the root.        |
| <b>TitleSelection</b>    | Method   | Invokes an action when the mouse is in the title bar on a browser window and the left or middle button is pressed. |
| <b>UnmarkNodes</b>       | Method   | Sends the messages <b>RemoveHighlights</b> and <b>RemoveShading</b> to <i>self</i> .                               |

---

(← *self* **AddRoot** *newItem*)

[Method of LatticeBrowser]

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose:    | Adds <i>newItem</i> , which is a LOOPS name, to the starting list of the browser.                                                                                                                                                                                                                                                                                                                                                                                                |
| Behavior:   | First determines if the name <i>newItem</i> points to a LOOPS object. If it does not, a message is printed that nothing has been added to the browser. If <i>newItem</i> is NIL, you are prompted to enter a name through the method <b>NewItem</b> . If the object pointed to by <i>newItem</i> is on the browser's instance variable <b>badList</b> , it is removed from <b>badList</b> . If the instance variable <b>goodList</b> has a value, <i>newItem</i> is added to it. |
| Arguments:  | <i>newItem</i> LOOPS name.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Returns:    | Class object or NIL.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Categories: | LatticeBrowser                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Example: The following command adds class **Datum** to a class browser instance named **CB1**:

```
55← (← ($ CB1) AddRoot ($ Datum))
```

(← self **BoxNode** object objName unboxPrevious)

[Method of LatticeBrowser]

Purpose: Puts a box around the node in the graph representing the object.

Behavior: First checks to make sure *object* points to a LOOPS object. If not, nothing happens. The previous value of the instance variable **boxedNode** is returned.

- If the instance variable **boxedNode** is NIL, then a box is drawn around the node with a line width equal to the value of the class variable **BoxLineWidth**. The instance variable **boxedNode** is assigned the value of *object*, and *object* is returned.
- If *object* is EQ to the instance variable **boxedNode**, then the box is erased. That is, calling **BoxNode** twice in succession will draw and then erase the box. The instance variable **boxedNode** is assigned the value NIL, and NIL is returned.
- If none of the above conditions hold, the flag **unboxPrevious** is checked. If it is non-NIL, the previously boxed node is unboxed, and the node represented by *object* is boxed. The instance variable **boxedNode** is assigned the value of *object*, and *object* is returned.

It is possible that *object* is not a node in *self*.

Arguments: *object* LOOPS name or object.

*objName* Used internally; can be NIL.

*unboxPrevious*  
Can be NIL or T.

Returns: The object in the browser that is currently boxed, or NIL if nothing is currently boxed.

Categories: LatticeBrowser

Specializations: ClassBrowser

(← self **Browse** browseList windowOrTitle goodList position)

[Method of LatticeBrowser]

Purpose: Uses a lattice or tree graph to display the relationships between a number of objects. **Browse** is the proper message to use for initializing browsers.

Behavior: Sends the message **Show** to *self* passing the arguments *browseList*, *windowOrTitle*, and *goodList*. It next sends **ShapeToHold** to *self*. Finally it sends **Move** to *self* with the argument *position*.

Arguments: *browseList* A list, elements of which can be a LOOPS name or an object, or a single item which can be a LOOPS name or an object. Used as the starting node(s) of a browser. See the **Show** message later in this section for details.

*windowOrTitle*  
If a window, the browser is displayed in this window. If not a window, this becomes the title of the browser window.

*goodList* A list, elements of which can be a LOOPS name or an object. See the **Show** message later in this section for details.

*position*      A position to which the lower left corner of the browser is moved.  
Can be NIL.

Returns:      Used for side effect only.

Categories:    LatticeBrowser

Example:      The following command gets the class browser instance **CB1** to browse class **Datum** and its subclasses:

```
57← (← ($ CB1) Browse 'Datum)
```

---

(← *self* **BrowserObjects**) [Method of LatticeBrowser]

---

Purpose/Behavior: Returns the list of objects currently in the graph of the browser.

Categories:    LatticeBrowser

---

(← *self* **ChangeFontSize** *size*) [Method of LatticeBrowser]

---

Purpose:      Changes the size of the characters of the labels.

Behavior:    Changes the font used to display labels in a browser. The browser is redrawn and the window shaped to fit. If no size is given, this lets you select the size from a menu. This menu is bound to the top level binding of the variable **MenuSize** (the first time it is called). The font family used is the value of the **FontFamily** property of the instance variable **browseFont**. The font face used is the value of the **FontFace** property of the instance variable **browseFont**.

This sends the message **RecomputeLabels** to *self*.

Arguments:    *size*      Integer size of font for node labels.

Returns:      Used for side effect only.

Categories:    LatticeBrowser

---

(← *self* **ChangeFormat** *format*) [Method of LatticeBrowser]

---

Purpose:      Changes between lattice and tree graphs.

Behavior:    If *format* is NIL, then select a format from a menu that appears. The items in this menu are determined by the value of the **choices** property of the instance variable **graphFormat**. Changes the value of the instance variable **graphFormat** to *format* or the value selected from the menu.

Arguments:    *format*      Describes the format layout. The argument *format* is an unordered list of atoms or lists. The following options control the structure of the graph:

- COMPACT, the default, which lays out the graph as a forest (that is, a set of disjoint trees) using the minimal amount of screen space.
- FAST, which lays out the graph as a forest, sacrificing screen space for speed.
- LATTICE, which lays out the graph as a directed acyclic graph, that is, a lattice.

In addition, the following options control the direction of the graph:

- HORIZONTAL, the default, has roots at the left and links that run left-to-right.
- VERTICAL has roots at the top and links that run top-to-bottom.

See the function **LAYOUTGRAPH** in the Grapher library module documentation for more information.

Returns: Used for side effect only.

Categories: LatticeBrowser

Example: The commands:

```
58← (SETQ b1 (←New ($ SupersBrowser) Browse 'ClassBrowser))
#, ($& SupersBrowser (NEW0.1Y%:.;h.eN6 . 506))

59← (← b1 ChangeFormat ' (HORIZONTAL REVERSE (MARK BORDER 3 LABELSHADE 1)))
#, ($& SupersBrowser (NEW0.1Y%:.;h.eN6 . 506))
```

results in:

(← self **ChangeMaxLabelSize** *newMaxWidth* *newMaxLines*)

[Method of LatticeBrowser]

Purpose: Changes how labels are printed.

Behavior: Sets the maximum width of a node label. An argument value of zero means no maximum size, and NIL means no change.

By setting both *newMaxWidth* and *newMaxLines*, you get an abbreviation facility. This binds the values of the instance variables **LabelMaxCharsWidth** and **LabelMaxLines**. The default values for **LabelMaxCharsWidth** and **LabelMaxLines** are both 0, so to return a browser b1 to default performance, send

```
(← ($ b1) ChangeMaxLabelSize 0 0).
```

The resulting labels may be bitmaps or strings. The width of the bitmap is a product of *newMaxWidth* and the width of the character "A" in the current value of the instance variable **browsefont**.

Sends the message **RecomputeLabels** to self.

Arguments: *newMaxWidth*  
Maximum number of characters per line; default is 0.

*newMaxLines*  
Maximum number of lines; default is 0.

Returns: Used for side effect only.

Categories: LatticeBrowser

Example: The commands:

```
60← (SETQ b1 (←New ($ SupersBrowser) Browse 'ClassBrowser))
#, ($& SupersBrowser (NEW0.1Y%:.;h.eN6 . 506))
```

## 10.4 USING FILE BROWSERS

---

```
61←(← b1 ChangeMaxLabelSize 3 3)
#,($& SupersBrowser (NEW0.1Y%:.;h.eN6 . 506))
```

results in:

---

(← self **ClearLabelCache** *objects*)

[Method of LatticeBrowser]

Purpose: Forgets cached labels in the browser.

Behavior: Clears the label cache for item(s) in *objects*. If *objects* is the symbol T, then this clears the entire label cache. The cache for the labels is on the **objectLabels** property of the instance variable **menus**.

Arguments: *objects* An object or a list of objects.

Returns: Used for side effect only.

Categories: LatticeBrowser

---

(← self **DeleteFromBrowser** *object objname*)

[Method of LatticeBrowser]

Purpose: Prunes branches in a graph.

Behavior: Removes *object* from the browser by putting it on the instance variable **badList** and then sending the **Recompute** message to *self*. The object and its subtree are deleted from the browser.

Arguments: *object* An object in the browser.

*objname* Used internally; can be NIL.

Returns: Used for side effect only.

Categories: LatticeBrowser

---

(← self **DeleteSubtreeFromBrowser** *object*)

[Method of LatticeBrowser]

Purpose: Prunes branches in a graph.

Behavior: Similar to **DeleteFromBrowser**, but the subnodes of *object* are also added to the instance variable **badList**.

Arguments: *object* An object in the browser.

Returns: Used for side effect only.

Categories: LatticeBrowser

---

(← *self* **FlashNode** *node N flashTime leaveFlipped?*) [Method of LatticeBrowser]

---

Purpose/Behavior: Changes the label of a node from black-on-white to white-on-black several times.

Arguments: *node* LOOPS name or object.

*N* Number of times *node* will be flipped.

*flashTime* The amount of time in milliseconds that the node is held between transitions. If *flashTime* is NIL, this time defaults to 300 milliseconds.

*leaveFlipped?*  
Can be NIL or T. If T, *node* is left inverted from its original state.

Returns: Used for side effect only.

Categories: LatticeBrowser

---

(← *self* **FlipNode** *object*) [Method of LatticeBrowser]

---

Purpose: Inverts the label of a node.

Behavior: If the node is black-on-white then it is changed to white-on-black, and conversely.

Arguments: *object* LOOPS name or object.

Returns: Used for side effect only.

Categories: LatticeBrowser

---

(← *self* **GetDisplayLabel** *object*) [Method of LatticeBrowser]

---

Purpose: Finds the label for a node in the graph.

Behavior: If there is a cached label on the **objectLabels** property of the instance variable **menus**, return it.

If not, this takes the result of **GetLabel** and breaks it into multiple lines to fit in the maximum label size defined by the instance variables **LabelMaxCharsWidth** and **LabelMaxLines**, if these are non-NIL. This placement tries to break the label after special characters such as . , ; / or space, or at changes from lowercase to uppercase. The resulting bitmap is put into cache so that recomputing the graph is faster.

When a label is broken up into multiple lines, the label is changed from a string to a bitmap, thus causing shading not to work as described later in this section in the method **ShadeNode**.

Arguments: *object* An object.

Returns: Used for side effect only.

Categories: LatticeBrowser

---

(← *self* **GetLabel** *object*) [Method of LatticeBrowser]

---

Purpose: Computes a label for *object*. A label may be a symbol or a bitmap; bitmap labels should be freshly created since the method **ShadeNode** may smash them. (The method **GetDisplayLabel** is used internally to fetch labels for display; it caches label bitmaps to minimize the use of **GetLabel**.)

Behavior: Returns (**GetObjectName** *object*).

Arguments: *object* LOOPS name or object, which can be a bitmap.

Returns: (**GetObjectName** *object*)

Categories: LatticeBrowser

---

(← *self* **GetSubs** *object*) [Method of LatticeBrowser]

---

Purpose: Computes a list of subnodes of *object*.

Behavior: Determines next level of nodes in lattice. Specializations of **LatticeBrowser** typically specialize this method.

Arguments: *object* A LOOPS object.

Returns: NIL or the value of the instance variable **subs** of *object*.

Categories: LatticeBrowser

Specializations: ClassBrowser, InstanceBrowser, MetaBrowser, SupersBrowser

---

(← *self* **GraphFits** *snugly*) [Method of LatticeBrowser]

---

Purpose/Behavior: Determines if the graph in the browser can be contained within the window of the browser.

Arguments: *snugly* If *snugly?* is non-NIL the graph must fit in the window leaving less than twice the **FONTHEIGHT** of the browser's *browseFont* as empty space around it.

Returns: T if the entire graph can be displayed within the window; else NIL.

Categories: LatticeBrowser

---

(← *self* **HasObject** *object*) [Method of LatticeBrowser]

---

Purpose/Behavior: Returns T if *object* is in the graph of the browser.

Arguments: *object* LOOPS name or object.

Categories: LatticeBrowser

---

(← *self* **HighlightNode** *object width shade*) [Method of LatticeBrowser]

---

Purpose: Changes the way a node is displayed.

Behavior: Draws a box around a node for *object* using a given *width* and *shade* for the lines of the box. A shade is a 16-bit number representing a 4x4 bitmap. See **EDITSHADE** in the *Interlisp-D Reference Manual*.

Arguments: *object* LOOPS name or object.

*width* Integer width of box.

*shade* 16-bit number representing a 4x4 bitmap.

Returns: Used for side effect only.

Categories: LatticeBrowser

Example: The command

```
64← (← b1 HighlightNode 'IndexedObject 10 123)
```

results in the following window:

(← self **IconTitle**)

[Method of LatticeBrowser]

Purpose/Behavior: Computes the title to write in the icon.

Returns: The label of the first root entry in the lattice, that is, the **CAR** of the instance variable **startingList**. If this is NIL, then use "Browser". If **AddRoot** is called, the new root becomes the first entry on **startingList**.

Categories: LatticeBrowser

Specializations: FileBrowser

(← self **LeftSelection**)

[Method of LatticeBrowser]

Purpose: Controls the effect of using the left mouse button. LatticeBrowser provides defaults, but allows these methods to be overwritten or specialized.

Behavior: The instance variable **lastSelectedObject** is bound to the object of the node that the left button selected.

The remaining behavior varies according to the key pressed.

- If the **Move** key or the **Control** key is down, this allows you to move the node the mouse is over when you press the left mouse button.
- If the left shift key or **Copy** key is down while the cursor is over a node, the label of the node is copied to the system buffer. If the cursor is not over a node, the entire graph is copied. This allows you to copy browsers into TEdit documents.
- If the **Meta** key is pressed, the message **LeftShiftSelect** is sent to *self*

# 11. ERRORS AND BREAKS

LOOPS provides an interface to the Medley error system. This allows appropriate detection and recovery from errors that are LOOPS errors rather than Lisp errors. The full power of the Medley error system is available to help you determine and repair the causes of errors. In addition, under certain circumstances, LOOPS will attempt to repair an error and continue if you agree.

This chapter describes the functions and methods LOOPS uses to handle error conditions. It also describes the error messages generated by LOOPS.

## 11.1 Error Handling Functions and Methods

LOOPS provides several ways to trap and process many common errors. A default processing is available for most errors, and this processing can be specialized for actions you may require.

The following table shows the items in this section.

| Name                        | Type                 | Description                                                                                    |
|-----------------------------|----------------------|------------------------------------------------------------------------------------------------|
| <b>HELPCHECK</b>            | Function             | Provides an interface to the Common Lisp error system.                                         |
| <b>LoopsHelp</b>            | NoSpread<br>Function | Generates an error if <b>LoopsDebugFlg</b> =NIL, else calls <b>HELP</b> .                      |
| <b>LoopsDebugFlg</b>        | Variable             | Controls the behavior of <b>LoopsHelp</b> .                                                    |
| <b>ErrorOnNameConflict</b>  | Variable             | Calls <b>HELPCHECK</b> when you attempt to give an object the same name as an existing object. |
| <b>CVMissing</b>            | Method               | Sent by access functions when you attempt to access a class variable that does not exist.      |
| <b>CVValueMissing</b>       | Method               | Sent by access functions when you attempt to access a class variable that has no value.        |
| <b>IVMissing</b>            | Method               | Sent by access functions when you attempt to access an instance variable that does not exist.  |
| <b>IVValueMissing</b>       | Method               | Sent by access functions when you attempt to access an instance variable that has no value.    |
| <b>MessageNotUnderstood</b> | Method               | Sent when a message has no corresponding selector.                                             |

(**HELPCHECK** *mess1 ... messN*)

[Function]

Purpose/Behavior: **HELPCHECK** is the LOOPS interface with the Common Lisp error system. When LOOPS detects an error, it generally calls this function with up to four argument messages describing what is wrong and possibly what to do about

it. **HELPCHECK** calls **BREAK1** to put you into a break window and returns whatever the call to **BREAK1** returns. For example, if you type **OK**, it returns **T**. If you type "RETURN 'someValue'", it returns that value. In some instances, **LOOPS** uses such returned values to repair errors and continue execution.

Arguments: *mess1 ... messN*

Messages to print at the break.

Returns: Value depends on what you type in the break window; see Behavior.

Example: The following code causes a break window with the message "Are you certain?". If you type "OK" in the break window, the message "He said OK" will print.

```
(IF (HELPCHECK "Are you certain?")
 THEN (PRINT "He said OK"))
```

---

**(LoopsHelp *mess1 ... messN*)****[NoSpread Function]**

Purpose/Behavior: Generates an error. Calls **HELP** if **LoopsDebugFlg** is **T**, otherwise calls **ERROR**. Use **LoopsHelp** whenever you want to give the user a way to recover from errors when **LoopsDebugFlg** is **T**. For example, have **LoopsHelp** print messages like "FOO is not the name of a class. Type RETURN '<classname>' to continue using <classname>."

Arguments: *mess1 ... messN*

Messages to print at the break.

Returns: Value depends on what you type in the break window; see **HELPCHECK**, above.

---

**LoopsDebugFlg****[Variable]**

Purpose/Behavior: Controls the behavior of **LoopsHelp**. If it is **T**, all calls to **LoopsHelp** generate a break. If it is **NIL**, such calls that occur near the top of the stack or after a short computation cause a message to be printed and a return to the next level. The default value is **T**. See **BREAKCHK** in the *Interlisp-D Reference Manual* for more information.

---

**ErrorOnNameConflict****[Variable]**

Purpose/Behavior: If **T**, an attempt to give an object the same name as an existing object causes a call to **HELPCHECK**. If you type "OK" in the resulting break window, the process continues and the original object is unnamed. The default value is **NIL**.

---

**(← self **CVMissing** *object varName propName typeFlg newValue*)****[Method of Class]**

Purpose: Sent by access functions when there is an attempt to access a class variable that does not exist.

Behavior: Calls **LoopsHelp** with the message

*varName* not a CV of *self*

This method can be specialized to take more sophisticated action by using the other arguments which are provided.

When, in an instance, an attempt is made to access a class variable that does not exist, the message **CVMissing** is sent to the instance's class with the instance in question as *object*.

Note: This method can be invoked if an instance variable is missing.

Arguments: *object* The object upon which the access was attempted.

*typeFlg* The name of the access function (**GetValue**, **GetValueOnly**, **PutValue**, **PutValueOnly**) which caused this message to be sent. The function name allows the type of access to be determined.

*varName* The name of the variable on which access was attempted.

*propName* The name of the property on which access was attempted. If NIL, the value of the class variable *varName* was accessed.

*newValue* The value to which the class variable was to be set.

Categories: Class

Example: Specialize this method to automatically add the class variable which is missing to the class described by *self*. Assuming the class of *self* is **SomeClass**, the method definition is

```
(Method ((SomeClass CVMissing)
 self object varName propName typeFlg
 newValue)
(← self AddCV varName newValue))
```

(← self CVValueMissing object varName propName typeFlg)

[Method of Class]

Purpose: Sent by access functions when there is an attempt to access a class variable that has no value. This method can also be invoked if an instance variable is missing and you attempt to access it.

Behavior: If *propName* is NIL it returns the value of **NotSetValue**, otherwise it returns the value of **NoValueFound**.

The default setting for **NoValueFound** is NIL. The default setting **NotSetValue** is an annotatedValue. See Chapter 8, Active Values, for an explanation of **NotSetValue**.

This method can be specialized to take more sophisticated action by using the other arguments which are provided. See the example for **CVMissing**, above.

Arguments: *object* The object on which the access was attempted.

*typeFlg* The name of the access function (**GetValue**, **GetValueOnly**, **PutValue**, **PutValueOnly**) which caused this message to be sent. The function name allows the type of access to be determined.

*varName* The name of the variable on which access was attempted.

*propName* The name of the property on which access was attempted. If NIL, the value of the class variable *varName* was accessed.

Returns: Value depends on the arguments; see Behavior.

Categories: Class

(← self IVMissing varName propName typeFlg newValue)

[Method of Object]

Purpose: Sent by access functions when there is an attempt to access an instance variable that cannot be found in *self*.

Behavior: Tries to remedy the situation, but if it fails, it calls **LoopsHelp** with the message

*varName* not an IV of *self*

If the instance variable is present in the object's class, the instance variable will be copied to *self*. This can happen when a class is changed after an instance has been created.

If the instance variable is not present in the class, it attempts to find a class variable of the same name in the class. If one is found, it is used according to its **:allocation** property.

- If the property is **dynamicCached**, the instance variable is added by copying the class variable regardless of the type of access.
- If the property is **dynamic**, the type of access is determined from *typeFlg*, which is the name of the access function. The value of the class variable is returned for a get and the instance variable is created only on a put.
- If the property is **class**, the class variable's value is returned or set and no instance variable is created.

If all else fails, an attempt is made to fix the spelling of *varName* and, if a possible fixed spelling is found, the process starts over.

If an instance variable is not found, the arguments are not used, but could be in a specialization of this method. See the example in **CVMissing** above.

|             |                                               |                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments:  | <i>typeFlg</i>                                | The name of the access function ( <b>GetValue</b> , <b>GetValueOnly</b> , <b>PutValue</b> , <b>PutValueOnly</b> ) which caused this message to be sent. The function name allows the type of access to be determined. |
|             | <i>varName</i>                                | The name of the variable on which access was attempted.                                                                                                                                                               |
|             | <i>propName</i>                               | The name of the property on which access was attempted. If NIL, the value of the instance variable <i>varName</i> was accessed.                                                                                       |
|             | <i>newValue</i>                               | The value to which the instance variable was to be set.                                                                                                                                                               |
| Returns:    | Value depends on the arguments; see Behavior. |                                                                                                                                                                                                                       |
| Categories: | Object                                        |                                                                                                                                                                                                                       |

---

(← *self* **IVValueMissing** *varName propName typeFlg newValue*) [Method of Object]

---

Purpose: Sent by access functions when there is an attempt to access an instance variable which has no value in *self*.

Behavior: Looks up the class hierarchy to find a value. If none is found, **SHOULDNT** (see the *Interlisp-D Reference Manual*) is called with the message

Error in Put or GetValue.

The arguments are not used, but could be in a specialization of this method. See the example in **CVMissing**, above.

This method is used internally to handle inheritance of instance variable values. If this error occurs, the LOOPS system has probably been corrupted.

Arguments: *typeFlg* The name of the access function (**GetValue**, **GetValueOnly**, **PutValue**, **PutValueOnly**) and allows the type of access to be determined.

The other arguments are passed from the access function.

Categories: Object

(← self **MessageNotUnderstood** selector messageArguments superFlg) [Method of Object]

- Purpose: Sent when a message has no corresponding selector in *self*.
- Behavior: Attempts to fix the spelling of *selector*. If this fails, it generates an error.
- Arguments: *selector* The name of the message that was not understood.  
*messageArguments* The arguments of the message *selector*.  
*superFlg* If T, an attempt was made to locate the method *selector* in the supers of *self*.
- Categories: Object
- Example: Define a class that acts as the class of Lisp numbers, and use the **MessageNotUnderstood** message to translate messages into function calls.

```
37← (DefineClass 'Number)
#.($ Number)

38← (← ($ Number) SpecializeMethod 'MessageNotUnderstood)
```

The **MessageNotUnderstood** method is defined in the editor, making the body of the method as follows:

```
(if (GETD selector)
 then (APPLY selector messageArguments))
else (←Super))
Number.MessageNotUnderstood
```

Use the class **Number** as the LOOPS class for Lisp numbers.

```
39← (PUTHASH 'SMALLP ($ Number) LispClassTable)
#.($ Number)

40← (PUTHASH 'FIXP ($ Number) LispClassTable)
#.($ Number)

41← (PUTHASH 'FLOATP ($ Number) LispClassTable)
#.($ Number)
```

Test it out.

```
42← (← 4 PLUS 5)
9
```

## 11.2 ERROR MESSAGES

### 11.2 ERROR MESSAGES

## 11.2 Error Messages

This section contains the LOOPS error messages along with their explanations. Atoms which are in *italics* are replaced with specific values when the messages are generated. Messages generated by calls to **SHOULDNT** indicate problems in LOOPS system code. Messages generated by direct calls to **ERROR**, that is not via calls to the LOOPS function **LoopsHelp**, may indicate problems with the system or with user code.

Errors appear in their respective categories:

- Errors that occur when accessing classes and instances in LOOPS.

- Errors that occur when sending messages to LOOPS objects.
- Errors dealing with naming objects.
- Errors encountered when using annotated values and active values.
- Other error messages that may be encountered when using LOOPS.

### 11.2.1 Classes and Instances

---

This section describes errors that occur when accessing classes and instances.

---

#### *type* not recognized part of class

Explanation: The *type* argument to the method **ListAttribute** does not correspond to one of the parts of a class.

---

#### *name* not a CV of *self*

Explanation: A reference has been made to a class value that does not exist.

---

#### Error in Put or GetValue

Explanation: An attempt has been made to access an instance variable that has no value in an object or in any of its supers.

---

#### *varName* not an IV of *self*

Explanation: An attempt has been made to access an instance variable and it does not exist in the object or its supers, and a class variable of the same name does not exist either.

---

#### *varName* is not a local instance variable of class *name*. Type OK to ignore error and go on.

Explanation: An attempt has been made to delete an instance variable which is not in the class.

---

#### *newValue* is not a class. Type OK to replace metaclass of *classRec* with \$Class

Explanation: A call has been made to **PutClass** or **PutClassOnly** with either *propName* erroneously set to NIL or left out, or the new metaclass set to something that is not a valid class.

---

#### *varName* is not a CV of *Class* so cannot be moved from there

Explanation: An attempt has been made to move a class variable from a class where it does not exist. Possible causes include wrong source class or misspelled class variable name.

*class* has subclasses. You cannot **Destroy** classes that have subclasses.  
Type OK to use **Destroy!** if that is what you want.

---

Explanation: Sending the message **Destroy** to a class with subclasses will leave the subclasses referring to nonexistent superclasses. **Destroy!** destroys all of the subclasses as well. Be sure this is what you want before you type "OK" .

### 11.2.2 Methods and Messages

---

This section describes errors that occur when sending messages to LOOPS objects.

---

**GetValue, PutValue, GetValueOnly, PutValueOnly or GetIVHere self args not possible**

---

Explanation: An attempt has been made to access a value in an abstract class, which cannot have any values.

---

**← or ←Super self selector -- not understood**

---

Explanation: Neither the object to which the message was sent nor any of its ancestors has such a method selector.

---

**(← NIL selector --) not understood**

---

Explanation: An attempt has been made to send a message to NIL. One way to do this is to execute `(_$ foo ...)`, where foo does not name a LOOPS object.

---

**class does not contain the selector selector. Type RETURN 'selectorName to try again**

---

Explanation: An attempt has been made to delete a nonexistent method. If the problem is that the wrong method selector was typed or the selector was misspelled, typing "RETURN 'correctName" will fix the problem.

---

**selector is not local for self To copy anyway, type OK**

---

Explanation: The object to which **CopyMethod** was sent does not contain *selector*, but one of its supers does. This is not necessarily an error.

---

**selector is not a selector for self**

---

Explanation: Neither the object to which **CopyMethod** was sent nor any of its supers contains *selector*.

---

**newClass is not a class. Type OK to use oldClass**

---

Explanation: Something may be missing from the argument to **HELPCHECK**, since nothing is printed after oldClass. Alternatively, the destination class specified in **CopyMethod** is neither a class nor a valid class name.

Typing "OK" causes the method to be copied to the class to which the message was sent. The net result can be to copy a method down from one of the class's supers or to make a copy within the class with a new selector.

---

**name is not a defined function**

---

Explanation: The selector named in **CopyMethod** exists but it does not have a function defined for it. It is possible the class has been loaded but the method has not or that the function definition for the method was somehow erroneously destroyed.

---

**name not a currently defined class. Cannot add method to class.  
Type OK to create class and go on.**

---

Explanation: An attempt has been made to add a method to a nonexistent class.  
If the class should exist, but has not been created yet, type "OK" to let LOOPS create it automatically. If the class has yet to be loaded, abort and load it first.

---

Can't find source for *fn*

---

Explanation: The source file containing a method of a class that is being moved via **MoveToFile** cannot be found. **WHEREIS** is used to try to find it. Either add the necessary file to **FILELST** or use **LOADFNS** to load the function(s).

### 11.2.3 Naming Objects

---

This section describes errors that occur when naming objects.

---

*name* is already used as a name for an object

---

Explanation: **ErrorOnNameConflict** has been set to T and an object with the given name already exists. Typing "OK" will cause the new object to be created anyway.

---

Can't name object NIL

---

Explanation: The *name* argument to the method **SetName** has been left out.

---

*name* should be a symbol to be a name

---

Explanation: The method **SetName** has been given a non-symbolic name.

---

*name* cannot be a class name. Type OK to ignore

---

Explanation: A non-symbolic class name has somehow gotten into the CLASSES of a file.  
Typing "OK" will continue writing the file, but will not remove the offending name.

---

Can't rename a class without specifying name.  
Type RETURN <newName> to continue and rename class: *self*

---

Explanation: The *newName* argument has been left out of **Rename**. Classes can not be named NIL.

Typing "RETURN 'aNewName" renames the class.

---

*name* not defined as a class or an instance. Type OK to ignore and go on.

---

Explanation: A name which refers to a nonexistent class or instance is in the **CLASSES** or **INSTANCES** file command of a file.

Typing "OK" continues writing out the file, but does not remove the offending name.

*name* not the name of an instance! Type OK to proceed.

---

Explanation: A name that refers to a nonexistent instance is in the **THESE-INSTANCES** file command of a file.

Typing "OK" continues writing out the file, but does not do anything to correct the source of the problem; that is, it does not remove the name from the filecoms or find out why it does not exist.

*name* is a defined object, but is not a class.

---

Explanation: The name of some LOOPS object that is not a class has been used as an argument where a class name should have been used.

## 11.2.4 Annotated and Active Values

---

This section describes errors that occur when using annotated values and active values.

Active value not found, so can't replace it.

---

Explanation: The old active value specified in **ReplaceActiveValue** does not exist or has been specified incorrectly.

Unknown access type *type*

---

Explanation: An improper *type* has been given to the message **AddActiveValue** or **DeleteActiveValue**.

Invalid type *type*

---

Explanation: An active value has an incorrect type specifier.

Conflicting active value wrapping precedence *self activeValue otherPrecedence*

---

Explanation: An attempt has been made to add an annotated value with wrapping precedence T or NIL to an existing annotated value with the same wrapping precedence.

Unknown access type *type*

---

Explanation: **GetWrappedValue** or **PutWrappedValue** has been given an incorrect type.

Can't set the local state of *#.NotSetValue*

---

Explanation: **PutWrappedValueOnly** has been erroneously sent to a *#.NotSetValue*.

## 11.2.5 Miscellaneous

---

This section describes other errors that can occur when using LOOPS.

Use one of METHODS IVS CVS for type. RETURN one of these symbols to go on.

---

Explanation: An incorrect type has been specified to the method **WhereIs**.

To continue, enter the type into the break window. For example, enter "RETURN 'METHODS'".

---

*Name* not installed because of error in source

---

Explanation: The source specification of a class has been corrupted in some way. It may be necessary to manually redefine the class or edit the file.

---

Time is not set! Call (**SETTIME** dd-mmm-yy hh:mm:ss) and then type in OK

---

Explanation: LOOPS uses the date and time to create unique internal names for objects; thus, the time must be set before any objects are created. Call **SETTIME** and then type "OK". For example, (**SETTIME** "15-APR-87 12:00:00") sets time at noon on April 15, 1987.

---

*self varName propName* not broken. Type OK to go on

---

Explanation: Either an attempt has been made to unbreak a value which was not broken or the value was specified incorrectly.

[This page intentionally left blank]

## 12. BREAKING AND TRACING

A number of functions and methods are available in the LOOPS environment to facilitate the process of finding and correcting bugs in user-written LOOPS code. These give you the capability to interrupt or trace methods so that you can examine the state of the computations by using the Interlisp-D Break package; see the *Interlisp-D Reference Manual*.

In addition to being able to break and trace methods, you can break and trace accesses to data within objects. For example, you can determine when a process is attempting to change a class variable or is trying to read the value of an instance variable. This feature gives you a powerful tool to assist in the understanding of the behavior of a piece of code from both a functional view and a data view.

### 12.1 Breaking and Tracing Methods

The Interlisp-D environment provides a number of features for breaking and tracing functions. LOOPS methods are implemented as Lisp functions, so the breaking and tracing of method invocation is similar to Interlisp-D.

The following table describes the methods in this section.

| Name                      | Type   | Description                                                     |
|---------------------------|--------|-----------------------------------------------------------------|
| <b>BreakMethod</b>        | Method | Breaks a method of a class.                                     |
| <b>TraceMethod</b>        | Method | Traces a method of a class.                                     |
| <b>UnbreakMethod</b>      | Method | Unbreaks or untraces a method of a class.                       |
| <b>SelectorsWithBreak</b> | Method | Returns a list of selectors whose implementations have a break. |

(← *self* **BreakMethod** *selector*) [Method of Class]

Purpose: Breaks a method of a class.

Behavior: Varies according to the argument.

- If *selector* is NIL, a menu appears showing the selectors associated with the class *self* that have not already been broken. If you do not make a choice from the menu, this method returns the symbol **NothingBroken**.
- If *selector* is non-NIL and is not associated with *self*, an error occurs stating that *selector* was not found in *self*.

If a method is broken, this fact is printed in the Prompt Window. The broken method function is added to the list **BROKENFNS**. (See the *Interlisp-D Reference Manual* for more information on **BROKENFNS**.)

Arguments: *self* Must be bound to a class.

*selector*      Must be a selector associated with *self* or NIL.

Returns:      The symbol **NothingBroken** or NIL.

Categories:    Class

Example:      The following command causes a break when the message **Open** is sent to any window:

```
12← (← ($ Window) BreakMethod 'Open)
```

---

(← *self* **TraceMethod** *selector*) [Method of Class]

---

Purpose:      Traces a method of a class.

Behavior:      Varies according to the argument.

- If *selector* is NIL, a menu appears showing the selectors associated with the class *self* that have not already been broken. If you do not make a choice from the menu, this method returns the symbol **NothingTraced**.
- If *selector* is non-NIL and is not associated with *self*, an error occurs stating that *selector* was not found in *self*.

If a method is traced, this fact is printed in the Prompt Window. The traced method function is added to the list **BROKENFNS**. (See the *Interlisp-D Reference Manual* for more information on **BROKENFNS**.) Whenever the function is called a message will be printed to a trace window, when it is exited a message will be printed with the returned value.

Arguments:    *self*      Must be bound to a class.

*selector*      Must be a selector associated with *self* or NIL.

Returns:      The symbol **NothingTraced** or NIL.

Categories:    Class

---

(← *self* **UnbreakMethod** *selector*) [Method of Class]

---

Purpose:      Unbreaks or untraces a method of a class.

Behavior:      Varies according to the argument.

- If *selector* is NIL, a menu appears showing the selectors associated with the class *self* that have been broken. If you do not make a choice from the menu, this method returns the symbol **NothingUnbroken**.
- If *selector* is non-NIL and is not associated with *self*, an error occurs stating that *selector* was not found in *self*.

If a method is unbroken, its method function is removed the list **BROKENFNS**. (See the *Interlisp-D Reference Manual* for more information on **BROKENFNS**.) The value return is a list containing the name of the unbroken method function.

Arguments:    *self*      Must be bound to a class.

*selector*      Must be a selector associated with *self* or NIL.

Returns:      The symbol **NothingUnbroken** or a list containing the name of the unbroken method function.

Categories:    Class

(← *self* **SelectorsWithBreak**)

[Method of Class]

- Purpose: Return a list of selectors whose implementations have a break.
- Behavior: Searches through the list **BROKENFNS** collecting all selectors of method functions that begin with the class name of *self*. (See the *Interlisp-D Reference Manual* for more information on **BROKENFNS**.)
- Arguments: *self* Must be bound to a class.
- Returns: A list of selectors of *self*.
- Categories: Class

## 12.2 BREAKING AND TRACING DATA

## 12.2 BREAKING AND TRACING DATA

## 12.2 Breaking and Tracing Data

Breaking or tracing functions or methods cause interruptions to occur in a computation when a function or method is entered. Breaks or traces on data can be made to occur when either the data is to be read or changed. Only data that is contained within objects can be broken; this feature is not available to arbitrary Lisp data. Breaks and traces on data are implemented through the mechanism of active values. The following **ActiveValue** classes contain this mechanism:

- **BreakOnPut**
- **BreakOnPutOrGet**
- **TraceOnPut**
- **TraceOnPutOrGet**

You can use the methods and functions in this section to place or remove breaks on data. You can also add and remove traces and breaks through the inspector interface. See Chapter 18, User Input/Output Modules, for more information on the inspector.

Note: Breaking or tracing a variable effectively breaks or traces any **IndirectVariable** that points to it.

The following table describes the items in this section.

| Name                   | Type            | Description                                       |
|------------------------|-----------------|---------------------------------------------------|
| <b>BreakIt</b>         | Method          | Puts a break on data within an object.            |
| <b>BreakIt</b>         | Function        | Sends the message <b>BreakIt</b> to <i>self</i> . |
| <b>TraceIt</b>         | Method          | Puts a trace on data within an object.            |
| <b>TraceIt</b>         | Function        | Sends the message <b>TraceIt</b> to <i>self</i> . |
| <b>UnBreakIt</b>       | Function        | Unbreaks broken data; untraces traced data.       |
| <b>BrokenVariables</b> | Global Variable | Contains a list of broken or traced variables.    |

(← *self* **BreakIt** *varName propName* &OPTIONAL (type 'IV) *breakOnGetAlsoFlg*)

[Method of Object]

Purpose: Puts a break on data within an object.

Behavior: Adds an entry to the list **BrokenVariables**.

- If *breakOnGetAlsoFlg* is T, creates an instance of the class **BreakOnPutOrGet** and adds the active value to the data specified by *self*, *varName*, *propName*, and *type*.
- If *breakOnGetAlsoFlg* is NIL, the active value instance is of the class **BreakOnPut**.

When a break occurs, the break window shows the nature of the break and which object and what variable is broken. See examples below.

Arguments: *self* Points to the object that contains the data to be broken.

*varName* The name of the variable.

*propName* If a property access is to be broken, this is the name of the property.

*type* The type of the data. This can be IV, CV, or METHOD; the default is IV.

*breakOnGetAlsoFlg*  
If this is non-NIL, breaks will occur when data is read. If this is NIL, breaks will occur only on attempts to write the data.

Returns: *self*

Categories: Object

Example: The following commands check if a window's width and height are going to change.

```
(← ($ Window) New 'w)
(← ($ w) BreakIt 'width)
(← ($ w) BreakIt 'height NIL NIL T)
```

Trying to change the width causes this break:

```
Setting IV
Setting IV width of #,($ w)
Old value: #,NestedNotSetValue
Value: 100
28+;
```

Trying to read the height causes this break:

```
Fetching
Fetching IV height of #,($ w)
Value: 12
28+;
```

---

**(BreakIt self varName propName type breakOnGetAlsoFlg)**

[Function]

Behavior: Sends the message **BreakIt** to *self* passing the remainder of the arguments. See the method **BreakIt**, above, for details.

(← *self* **TraceIt** *varName propName &OPTIONAL (type 'IV) traceGetAlsoFlg*) [Method of Object]

**Purpose:** Puts a trace on data within an object.

**Behavior:** Adds an entry to the list **BrokenVariables**.

- If *traceGetAlsoFlg* is T, creates an instance of the class **TraceOnPutOrGet** and adds the active value to the data specified by *self*, *varName*, *propName*, and *type*.
- If *traceGetAlsoFlg* is NIL, the active value instance is of the class **TraceOnPut**.

When a trace occurs, a trace window appears if necessary, with the traced information printed in it. See examples below.

**Arguments:** *self* Points to the object that contains the data to be traced.

*varName* The name of the variable.

*propName* If a property access is to be traced, this is the name of the property.

*type* The type of the data. This can be IV, CV, or METHOD; the default is IV.

*traceOnGetAlsoFlg*

If this is non-NIL, trace messages will occur when data is read. If this is NIL, trace messages will occur only on attempts to write the data.

**Returns:** *self*

**Categories:** Object

**Examples:** To monitor if a window's width and height are going to change, enter

```
97←(← ($ Window) New 'w)
#,($& Window (NEW0.1Y%:.;h.eN6 . 495))

98←(← ($ w) TraceIt 'width)
#,($& Window (NEW0.1Y%:.;h.eN6 . 495))

99←(← ($ w) TraceIt 'height NIL NIL T)
#,($& Window (NEW0.1Y%:.;h.eN6 . 495))
```

Trying to change the width or the height causes a trace.

```
100←(change (@ ($ w) width) 100)
```

```
Trace-Output
Setting IV width of #,($ w)
Old value: #,NestedNotSetValue
Value: 100
```

```
100
```

```
101←(@ ($ w) height)
```

```
Trace-Output
Fetching IV height of #,($ w)
Value: 12
```

12

---

**(TraceIt self varName propName type breakOnGetAlsoFlg)** [Function]

Purpose/Behavior: Sends the message **TraceIt** to *self* passing the remainder of the arguments. See the method **TraceIt**, above, for details.

---

**(UnBreakIt self varName propName type)** [Function]

Purpose: Unbreaks broken data; untraces traced data.

Behavior: Varies according to the argument *self*.

- If *self* is NIL, iterates through the list **BrokenVariables** and removes the active values from the objects on that list. **BrokenVariables** is set to NIL.
- If *self* is not NIL, removes the active value from the data described by *self*, *varName*, *propName*, and *type*. The corresponding entry is removed from **BrokenVariables**. If there is no active value on the specified data, a break occurs saying that the specified data is not broken and type OK to continue.

Arguments: *self* Points to the object that contains the data to be traced.

*varName* The name of the variable.

*propName* If a property access is to be traced, this is the name of the property.

*type* The type of the data. This can be IV, CV, or METHOD; the default is IV.

Returns: Value depends on the arguments.

- If *self* is NIL, the value of **BrokenVariables** before it was bound to NIL is returned.
- If *self* is non-NIL and there were no errors, the list containing *self*, *varName*, and *propName* is returned.

Example: The following command removes a break from the instance variable **id#** in the instance named **Datum12**:

```
(UnBreakIt ($ Datum12) 'id#)
```

---

**BrokenVariables** [Global Variable]

Purpose/Behavior: This is initialized to NIL. As data within objects is traced or broken, an entry is added to this list. Each entry contains the object, the variable name, the active value created to implement the break, the property name, and the type.

[This page intentionally left blank]

LOOPS has an interface to the display-based editor, SEdit. This editor is most often used for modifying classes, functions, and methods, but it can also be invoked to modify instances. Instances are typically modified through the inspector interface (see Chapter 18, User Input/Output Modules).

The technique for editing methods is exactly the same as that for editing functions. LOOPS uses Method, an extension of the lambda form that is documented in Chapter 6, Methods, which also gives details about the form of methods and how to invoke the editor upon them.

The process of editing classes and instances is different from editing methods in that you are not editing structure directly. The data structures representing the objects are translated into list structures, those list structures are then edited, and, finally, on exiting from the editor, the list structure is translated back into LOOPS objects. Because of this process, changes in objects do not take effect until you have exited from the editor.

## 13.1 Editing Classes

The **Edit** and **Edit!** methods provide a screen-based way to modify class structure. You can quickly add and delete local class and instance variables, make inherited variables local, and change initial values. The other methods listed are used to interface LOOPS to the display editor.

| Name                      | Type   | Description                                                                   |
|---------------------------|--------|-------------------------------------------------------------------------------|
| <b>Edit</b>               | Method | Edits the structure of a class.                                               |
| <b>Edit!</b>              | Method | Edits a class in a form that includes inherited information.                  |
| <b>InstallEditSource</b>  | Method | Makes a class conform to a description.                                       |
| <b>MakeEditSource</b>     | Method | Makes a list structure for editing a class.                                   |
| <b>MakeFullEditSource</b> | Method | Makes a list structure, including inherited information, for editing a class. |

(← *self* **Edit** *commands*)

[Method of Class]

Purpose: Edits the structure of a class.

Behavior: Translates *self* from a data type to a list structure that is then passed to the editor through **EDITE** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*). If *commands* is non-NIL, this is passed as the second argument to **EDITE**.

The variable **LASTCLASS** is bound to the class name of *self*.

Generally, *commands* is NIL, which causes you to enter the editor interactively. From this point, you can perform the following actions:

- Change the metaclass of *self*
- Add or delete class properties
- Add or delete class variables, instance variables, and their properties.

Also, as a user convenience, the edited form has a list of methods that you can select and edit, although you cannot delete items from this **MethodFns** list and have that action disassociate the methods from the class.

Arguments: *commands* A list of editing commands to be passed to EDITE.

Returns: The class name of *self*.

Categories: Object

Specializes: Object

Example: The following editing window is generated as a result of

```
(← ($ IndirectVariable) Edit)
```

```
SEdit #,($C IndirectVariable) Package: INTERLISP
((MetaClass Class doc
 (* Active Value for redirecting references to
 another variable)
 Edited%: (* smL " 9-May-86 09:52"))
(Supers ActiveValue) (ClassVariables)
(InstanceVariables
 (object NIL doc
 (* The object with the "real" variable))
 (varName NIL doc (* The name of the "real" variable))
 (propName NIL doc
 (* The prop name of the "real" variable))
 (type NIL doc (* The type of the "real" variable)))
(MethodFns IndirectVariable.GetWrappedValueOnly
 IndirectVariable.PutWrappedValueOnly))
```

The following information describes this window:

- The title of the window contains the name of the class being edited and package it uses for displaying symbols. This package should be INTERLISP when using LOOPS.
- It has the metaclass **Class**.
- It has the two class properties **doc** and **Edited%:**.
- It has one super class, the class **ActiveValue**.
- It has no class variables.
- It has four instance variables: **object**, **varName**, **propName**, and **type**. Each instance variable has a **doc** property.
- It has two local methods: **GetWrappedValueOnly** and **PutWrappedValueOnly**.

(← *self* **Edit!** *commands*)

[Method of Class]

Purpose: Edits a class in a form that includes inherited information.

Behavior: This is similar is behavior to the method **Class.Edit**.

The form you are editing includes not only items local to *self* but also class variables and instance variables that are inherited. This allows you to easily move inherited information into *self*. Editing operations that modify the inherited values have no effect.

Arguments: *commands* A list of editing commands to be passed to **EDITE**.

Returns: The class name of *self*.

Categories: Class

Example: The following command puts you into the display editor. Compare this display with the previous one.

```
(← ($ IndirectVariable) Edit!)
```

```
SEdit #,($C IndirectVariable) Package: INTERLISP
((MetaClass Class doc
 (* Active Value for redirecting references to
 another variable)
 Edited%: (* sml " 9-May-86 09:52"))
(Supers ActiveValue) (ClassVariables) (CVsInherited)
(InstanceVariables
 (object NIL doc
 (* The object with the "real" variable))
 (varName NIL doc (* The name of the "real" variable))
 (propName NIL doc
 (* The prop name of the "real" variable))
 (type NIL doc (* The type of the "real" variable)))
(IVsInherited))
```

(← *self* **InstallEditSource** *editedDescription*)

[Method of Class]

Purpose: Makes a class conform to a description.

Behavior: Called by the system to change a class data structure to correspond to a list structure you have edited. If there are errors in the structure, the editor is activated again. If there are errors in the edited structure, an error message is printed in the prompt window and you are returned to the editor to fix it.

If there are no errors in the structure, this successfully translates the structure into the class data type structure. In addition, a class property **Edited:** is added to *self* with the value returned by (**EDITDATE** NIL INITIALS).

Arguments: *editedDescription*  
A list structure similar to that returned by the message **MakeEditSource**.

Returns: Used for side effect only.

Categories: Object

Specializes: Object

**(← self MakeEditSource)**

[Method of Class]

Purpose: Makes a list structure for editing a class.

Behavior: This builds a list structure containing metaclass, super, class variable and instance variable information. In addition, the method function names are included in this list.

Returns: List expression of class structure.

Categories: Object

Specializes: Object

Example: The command

```
(← ($ BreakOnPutOrGet) MakeEditSource)
```

returns

```
((MetaClass Class Edited%: (* nbm " 5-May-87 17:53")
 doc "This is the default metaClass for all classes")
 (Supers BreakOnPut)
 (ClassVariables)
 (InstanceVariables)
 (MethodFns BreakOnPutOrGet.GetWrappedValue))
```

**(← self MakeFullEditSource)**

[Method of Class]

Purpose: Makes a list structure, including inherited information, for editing a class.

Behavior: This is similar to **MakeEditSource**. The constructed list also includes instance variables and class variables that are inherited.

The list does not contain the method functions associated with self that **MakeEditSource** includes.

Returns: List expression of class structure.

Categories: Class

Example: The command

```
(← ($ BreakOnPutOrGet) MakeFullEditSource)
```

returns:

```
((MetaClass Class Edited%: (* nbm " 5-May-87 17:53")
 doc "This is the default metaClass for all classes")
 (Supers BreakOnPut)
 (ClassVariables)
 (CVsInherited)
 (InstanceVariables)
 (IVsInherited
 (localState NIL doc (* The local state of the active value))))
```

13.1 EDITING INSTANCES

---

**13.1 EDITING INSTANCES**

---

## 13.2 Editing Instances

LOOPS instances can also be edited by the standard Medley code editor. From this editor, you can change the values of instance variables and properties, and add new instance variables. Instances follow the same basic editing protocol that classes do.

The following table shows the methods in this section.

| Name                     | Type   | Description                                               |
|--------------------------|--------|-----------------------------------------------------------|
| <b>Edit</b>              | Method | Allows you to change the values contained in an instance. |
| <b>InstallEditSource</b> | Method | Makes an instance conform to a description.               |
| <b>MakeEdit</b>          | Method | Makes a list structure for editing an instance.           |

(← *self* **Edit** *commands*)

[Method of Object]

Purpose: Allows you to change the values contained in an instance.

Behavior: Changes the data structure of *self* to a list and passes that list to **EDITE** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*.) If *commands* is non-NIL, this is passed as the second argument to **EDITE**.

Deleting a variable does not delete it from the instance.

Arguments: *commands* A list of editing commands to be passed to **EDITE**.

Returns: *self*

Categories: Object

Specializations: Class

Example: The following commands create the edit window shown.

```
71←(← ($ Window) New 'w1)
#,($& Window (NEW0.1Y%:.;h.eN6 . 495))

72←(←@ ($ w1) width 123)
123

73←(←($ w1) Edit)
```

(←*self* **MakeEditSource**)

[Method of Object]

Purpose: Makes a list structure for editing an instance.

|                  |                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------|
| Behavior:        | Returns a list showing all instance variables, values, and properties.                                         |
| Returns:         | A list showing all instance variables, values, and properties.                                                 |
| Categories:      | Object                                                                                                         |
| Specializations: | Class                                                                                                          |
| Example:         | The following shows <b>MakeEditSource</b> results as values are assigned to the instance variables of (\$ w1). |

```
38←(← ($ Window) New 'w1)
#,($& Window (NEW0.1Y%:.;h.eN6 . 495))

39←(← ($ w1) MakeEditSource)
((left) (bottom) (width) (height) (window) (title) (menus))

40←(←@ ($ w1) width 123)
123

41←(← ($ w1) MakeEditSource)
((left) (bottom) (width 123) (height) (window) (title) (menus))

42←(←@ ($ w1) menus Title T)
T

43←(← ($ w1) MakeEditSource)
((left) (bottom) (width 123) (height) (window) (title) (menus
#,NotSetValue Title T))

44←(@ ($ w1) window)
{WINDOW}#74,25554

45←(← ($ w1) MakeEditSource)
((left 31) (bottom 407) (width 123) (height 12) (window #,($AV
LispWindowAV ((NEW0.1Y%:.;h.eN6 . 495)) (localState {WINDOW}#74,25554)))
(title) (menus #,NotSetValue Title T))
```

---

(← *self* **InstallEditSource** *editedDescription*)

[Method of Object]

|             |                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------|
| Purpose:    | Makes an instance conform to a description.                                                                          |
| Behavior:   | This is called by the system to change an instance data structure to correspond to a list structure you have edited. |
| Arguments:  | <i>editedDescription</i><br>A list structure similar to that returned by the message <b>MakeEditSource</b> .         |
| Returns:    | Used for side effect only.                                                                                           |
| Categories: | Object                                                                                                               |

[This page intentionally left blank]

LOOPS data structures are fully integrated into Medley. This includes the definition of new File Manager commands so that any LOOPS object or method can be saved on files and loaded into the environment in exactly the same way that normal Medley data types are saved and loaded.

In addition, the LOOPS file browser provides a menu-driven interface to the File Manager. When using a LOOPS file browser, newly created objects are associated with files automatically. If you are not familiar with LOOPS file browsers see Chapter 10, Browsers.

This chapter describes the functions, methods, and variables used to load and store files containing LOOPS objects. It describes the File Manager commands related to LOOPS objects. It also describes how to add objects to files, delete them from files, and move them from file to file. These are primarily of interest when customizing either the File Manager or LOOPS file browser.

---

## 14.1 Manipulating Files

---

LOOPS takes advantage of the ability to create user-defined File Manager commands to fully integrate LOOPS into the Medley environment. As a result, the same steps used to manipulate files containing Medley data structures are used to manipulate files containing LOOPS data structures. Furthermore, both LOOPS and Medley data structures can be saved together in the same file. This section contains a brief review of the three basic functions used to manipulate files. For a more detailed description which includes additional functions, see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*.

In addition, there is a LOOPS file browser which provides a convenient way of loading files and guaranteeing that newly created classes and methods are associated with files during the development of LOOPS programs. The LOOPS file browser is different from the Lisp Library Module **FILEBROWSER**. Files can be loaded and put into new or existing file browsers by a series of menu selections.

You can manipulate files with these basic steps:

- Assign data structures to a specific file using **FILES?**.
- Write data structures to a file using **MAKEFILE**.
- Enter data structures stored in a file into the environment using **LOAD**.

The following example shows these steps.

```
30← (FILES?)
PIPEANDTANK, LOOPSPRINT, LOOPSUTILITY...to be dumped.
 plus the instances: FFAV1, Datum1, TestW
 plus the class definitions: Datum
 want to say where the above go ? Yes
(instances)
FFAV1 File name: LOOPSFILE
create new file LOOPSFILE ? Yes
Datum1 File name: LOOPSFILE
TestW File name: LOOPSFILE
(class definitions)
Datum File name: LOOPSFILE
NIL

31← (MAKEFILE 'LOOPSFILE)
Copyright owner for file LOOPSFILE: XEROX
{DSK}<LISPFILS>LOOPSFILE.;1

32← (LOAD 'LOOPSFILE)
{DSK}<LISPFILS>LOOPSFILE.;1
FILE CREATED 7-Jan-87 16:25:24
LOOPSFILECOMS
{DSK}<LISPFILS>LOOPSFILE.;1
```

See the *Lisp Release Notes* and the *Interlisp-D Reference Manual* for more information on **FILES?** and **MAKEFILE**. See the following section for details on **LOAD**.

14.2 Loading Files

The following table shows the functions and commands described in this section.

| Name    | Type        | Description                                                                                                            |
|---------|-------------|------------------------------------------------------------------------------------------------------------------------|
| LOAD    | Function    | Loads Medley symbolic files which includes LOOPS objects and methods.                                                  |
| LOADFNS | Function    | Allows selective loading from Medley symbolic files.                                                                   |
| UNDO    | Prog. Asst. | Undoes previous entries into the Medley Executive which are stored on a history list, including calls to <b>LOAD</b> . |

(LOAD FILE LDFLG ) [Function]

|                   |                                                                                                                                                           |                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Purpose/Behavior: | Loads Medley symbolic files which includes all LOOPS objects and methods; see the <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference Manual</i> . |                                                                                                                                                                                                                                                                                                     |
| Arguments:        | FILE                                                                                                                                                      | File to be loaded.                                                                                                                                                                                                                                                                                  |
|                   | LDFLG                                                                                                                                                     | Alters the effect of loading a file. <ul style="list-style-type: none"><li>If it is set to <b>PROP</b>, the definitions of functions, including <b>METHOD</b> functions, are stored on the property <b>EXPR</b> of the function name. Thus, any existing definitions are not overwritten.</li></ul> |

- If it is set to **ALLPROP**, the values of variables are also saved on property lists.

Returns: Full file name.

**(LOADFNS FNS FILE)**

[Function]

Purpose/Behavior: Allows selective loading from Medley symbolic files including LOOPS files. The most likely use for this facility is to load the source code for method functions when the compiled versions are already loaded. The methods must be specified by their explicit function names in the form **ClassName.Selector**, for example,

```
(LOADFNS ' (SomeClass.AMethod OtherClass.AMethod) ' {DSK}<LISPFILES>SOMEFILE ' PROP)
```

It is not recommended that LOOPS objects be selectively loaded by using **VARs** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*), because it is not possible to guarantee that all necessary related objects, such as superclasses or methods of a class, are also loaded.

Arguments: **FNS** Selected functions to be loaded.  
**FILE** File from which functions specified in **FNS** are to be loaded.

Returns: List of functions that have been loaded

**UNDO**

[Program Assistant Command]

Purpose/Behavior: LOOPS saves enough information about objects that are created as a result of loading a file to allow the call to **LOAD** to be undone. The objects are destroyed and any preexisting objects that were deleted by the load are restored. See the *Lisp Release Notes* and the *Interlisp-D Reference Manual*.

## 14.3 LOOPS FILE PACKAGE COMMANDS

## 14.3 LOOPS FILE PACKAGE COMMANDS

**14.3 LOOPS File Manager Commands**

Four File Manager types are defined to allow LOOPS objects to be stored in Medley files:

- CLASSES
- METHODS
- INSTANCES
- THESE-INSTANCES

These types and the functions and methods used by LOOPS to process these types are described in this section.

Note: The order of items in the filecoms is important. In particular, class definitions must appear in the file before any methods on that class or any instances of that class. Similarly, methods on a class must appear before any instances of that class.

| Name              | Type             | Description                                                                                          |
|-------------------|------------------|------------------------------------------------------------------------------------------------------|
| <b>CLASSES</b>    | File Mgr Command | Writes the appropriate <b>DEFCLASSES</b> and <b>DEFCLASS</b> expressions for the named classes.      |
| <b>DEFCLASSES</b> | NLambda NoSpread | Creates a series of empty classes in preparation for reading their definitions via <b>DEFCLASS</b> . |

|                        |                     |                                                                                                                           |
|------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>DEFCLASS</b>        | NLambda<br>NoSpread | Takes a source specification of a class from a file and causes the appropriate internal representation to be constructed. |
| <b>METHODS</b>         | File Mgr<br>Command | Writes the appropriate <b>METH</b> and <b>DEFINEQ</b> expressions for each method object and its associated function.     |
| <b>METH</b>            | NLambda<br>NoSpread | Creates a method object and attaches it to the appropriate class.                                                         |
| <b>INSTANCES</b>       | File Mgr<br>Command | Writes the appropriate <b>DEFINST</b> expressions for each instance in the list.                                          |
| <b>THESE-INSTANCES</b> | File Mgr<br>Command | Appears as a sublist in a filecoms.                                                                                       |
| <b>DEFINSTANCES</b>    | NLambda<br>NoSpread | Creates empty structures for each instance name in a list.                                                                |
| <b>DEFINST</b>         | NLambda<br>NoSpread | Creates internal representations for source specifications of an instance.                                                |
| <b>FileIn</b>          | Method              | Creates internal representations for source specifications of an instance.                                                |

---

**(CLASSES *ClassName1...ClassNameN*)** [File Manager Command]

Purpose/Behavior: Appears as a sublist in a filecoms. The keyword **CLASSES** tells the File Manager to use the appropriate **DEFCLASSES** and **DEFCLASS** expressions for the named classes when writing to a file.

Arguments: *ClassName* Accepts any symbol, but only gives meaningful result when you use **DEFCLASS** to actually create the class.

Example: (CLASSES Myclass)

---

**(DEFCLASSES CLASSES)** [NLambda NoSpread Function]

Purpose/Behavior: Used in a file to create a series of empty classes in preparation for reading in their definitions via **DEFCLASS**. This allows the classes to be read in any order. Otherwise, superclasses would have to be read in before their subclasses.

Arguments: **CLASSES** Accepts any symbol, but only gives meaningful result when you use **DEFCLASS** to actually create the class.

Returns: NIL

Example: The command  
(DEFCLASSES MyClass)  
returns NIL.

---

**(DEFCLASS FORM)** [NLambda NoSpread Function]

Purpose/Behavior: Takes a source specification of a class, such as produced by the method **MakeFileSource**, from a file and causes the appropriate internal representation to be constructed.

Arguments: **FORM** The source specification of a class.

Returns: NIL

Example: 

```
(DEFCLASS MyClass
 (MetaClass Class doc (* Something for my project)
 Edited: (* nbm "18-Oct-87 13:20"))
 (Supers Object)
 (InstanceVariables (Iv1 (22) doc
 (* Initial value for my instances])
```

**(METHODS** *ClassName.Message1...ClassName.MessageN*) [File Manager Command]

Purpose/Behavior: Appears as a sublist in a filecoms. The keyword **METHODS** tells the File Manager to use the appropriate **METH** and **DEFINEQ** expressions for each method object and its associated function.

Arguments: *ClassName.Message*  
The source specification of a class.

Example: 

```
(METHODS MyClass.Method1)
```

**(METH** *methDescr*) [NLambda NoSpread Function]

Purpose/Behavior: Creates a method object and attaches it to the appropriate class.

Arguments: *methDescr* Method object to create.

Returns: NIL

Example: 

```
(METH MyClass MyClass.Method1 NIL
 (category (Datum)))
```

**(INSTANCES** *InstName1...InstNameN*) [File Manager Command]

Purpose/Behavior: Appears as a sublist in a filecoms. The keyword **INSTANCES** tells the File Manager to use the appropriate **DEFINST** expressions for each instance in the list and also for any other instances that are referenced inside any instances in the list. This assures that there are no references to nonexistent instances when read back in. The method **SaveInstance?** can be specialized to prevent instances from being saved in more than one file when they are referred to by instances in different files.

Example: 

```
(INSTANCES TestW)
```

**(THESE-INSTANCES** *InstName1...InstNameN*) [File Manager Command]

Purpose/Behavior: Appears as a sublist in a filecoms. The keyword **THESE-INSTANCES** tells the File Manager to use the appropriate **DEFINST** expressions for each instance in the list. Unlike the **INSTANCES** File Manager command, **THESE-INSTANCES** does not recursively dump instances that are pointed by *InstName1...InstNameN*.

**(DEFINSTANCES *Instances*)**

[NLambda NoSpread Function]

Purpose/Behavior: Takes a list of instance names and creates empty structures for them in preparation for reading in their structures from a file.

Arguments: *Instances* Accepts any symbol but result is useless unless you use **DEFINST** to actually create the *Instance*.

Returns: NIL

Example: (DEFINSTANCES TestW)

**(DEFINST *DEFINST% FORM*)**

[NLambda NoSpread Function]

Purpose/Behavior: Takes a source specification of an instance and causes the appropriate internal representation to be created. It does this by sending the message **FileIn** to the instance's class. It creates the class if it does not exist.

Arguments: *DEFINST% FORM*  
The source specification of an instance.

Returns: NIL

Example: [DEFINST Window  
(TestW (JEW0.0X:.H<4.NZ9 . 532))  
(left 179)  
(bottom 446)  
(width 12)  
(height 12)]

**(← *self FileIn fileSource*)**

[Method of Class]

Purpose/Behavior: Takes a source specification for an instance as it appears in a file and causes the appropriate internal representation to be constructed.

Arguments: *self* Class of the instance to be created.  
*fileSource* Loadable form of an instance as stored in a file.

Returns: *self*

Categories: Class

14.4 SAVING LOOPS OBJECTS ON FILES

---

14.4 SAVING LOOPS OBJECTS ON FILES

---

---

**14.4 Saving LOOPS Objects on Files**

---

Adding LOOPS classes, methods and instances to files can be done in the same way that functions and variables are saved in Medley. In addition, the LOOPS browser allows newly created objects to be automatically associated with files. LOOPS also provides the means for moving objects from file to file.

Whenever a class, method, or named instance is created or edited, it is marked as changed. This allows the File Manager to prompt for a file in which to store new objects and see to it that changed objects are written out when **MAKEFILE** is called.

The following table shows the items in this section.

| Name                  | Type       | Description                                                                                                                                          |
|-----------------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FILES?</b>         | Function   | LOOPS adds a prompt for classes, methods and instances along with the normal Medley types.                                                           |
| <b>ObjectModified</b> | Method     | Notifies the File Manager that an object has been changed or created.                                                                                |
| <b>OnFile</b>         | Method     | Determines if a class is in <b>FILELST</b> .                                                                                                         |
| <b>SaveInstance</b>   | Method     | Causes newly created instances to be noticed by the File Manager.                                                                                    |
| <b>SaveInstance?</b>  | Method     | Determines if an instance needs to be added to the list of instances to be saved.                                                                    |
| <b>DelFromFile</b>    | Method     | Deletes an object from any file in <b>FILELST</b> in which it appears.                                                                               |
| <b>MoveToFile</b>     | Method     | <b>Class.MoveToFile</b> moves a class and its methods from one file to another. <b>Object.MoveToFile</b> moves an instance from one file to another. |
| <b>MoveToFile!</b>    | Method     | Moves a class, all of its methods, and all of its subclasses and their methods from one file to another.                                             |
| <b>DontSave</b>       | IVProperty | Controls what parts of an instance are saved in a file.                                                                                              |
| <b>OldInstance</b>    | Method     | Sends a message to an object after it is loaded from a file.                                                                                         |

**(FILES?)**

[Function]

**Purpose/Behavior:** The File Manager types have been extended so that, when a call is made to **FILES?**, you are prompted to add classes, methods and instances to files along with the normal Medley. For an example of **FILES?**, see Section 14.1, "Manipulating Files."

After a class is associated with a file, any methods that are added to it are automatically added to that file as well. Thus, it makes sense to put classes in files as soon as possible. This could be done by repeated calls to **FILES?**, but the LOOPS file browser allows classes to be automatically added to files as they are created. Any class that is created by adding a root to a file browser or by specializing a class in a file browser is added to that browser's file. If more than one file is associated with the browser, a menu appears to prompt you to specify a file for the new class. The LOOPS browser also can be used to create a new file and associate it with a file browser. Thus, there is never any need to wait until the end of a session to put classes and methods in files.

You can also save instances on files. Of course, only those instances which should be present after a file is first loaded should be saved. Instances which are constructed "on the fly" as a consequence of running a LOOPS program should not be saved. Only named instances are marked as changed so many such temporary instances may never be noticed. However, if named instances which should not be saved are created, then you are prompted to put them into files after a call to **FILES?** and must respond by typing a right square bracket (]) to each one. Alternatively, it is possible to specialize the method **ObjectModified** so that it does not call **MARKASCHANGED**. Then any instances of classes which have or inherit the specialized method are not noticed by the File Manager regardless of whether or not they are named.

**(← self ObjectModified name)**

[Method of Object]

**Purpose:** Notifies the File Manager that an object has been changed or newly created.

|                  |                                                                                                                                          |                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Behavior:        | Uses the File Manager command <b>MARKASCHANGED</b> . It does nothing if <i>name</i> is not given, thus unnamed objects are never marked. |                                                                                                                          |
| Arguments:       | <i>self</i>                                                                                                                              | A LOOPS object.                                                                                                          |
|                  | <i>name</i>                                                                                                                              | Name of object specified in <i>self</i> .                                                                                |
|                  | <i>reason</i>                                                                                                                            | Reason is <b>MARKEDASCHANGED</b> (see the <i>Interlisp Reference Manual</i> for information on <b>MARKEDASCHANGED</b> ). |
| Returns:         | <i>self</i>                                                                                                                              |                                                                                                                          |

[Method of Object]

|           |                                                                                                                                                                                                                                                                                                                         |  |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Purpose:  | Determines whether an instance needs to be added to the list of instances to be saved in <i>file</i> .                                                                                                                                                                                                                  |  |
| Behavior: | Checks to see if the current instance is a member of <i>outInstances</i> . It is used by the LOOPS File Manager command <b>INSTANCES</b> to guarantee that the same instance does not appear more than once in a given file. <p>This method must be specialized to be used; it cannot be used directly by the user.</p> |  |

Arguments: *self* A LOOPS object.  
*file* The file to be searched.  
*outInstances* A list of LOOPS names. See Behavior.

Returns: T if the instance should be saved on the file; NIL if it should not be saved.

Categories: Object

---

(← *self* **DelFromFile**) [Method of Object]

Purpose: Deletes an object from any file in **FILELST** in which it appears.

Behavior: Searches through the filecoms of all files in **FILELST** and deletes the object everywhere it appears.

Arguments: *self* A LOOPS object.

Returns: Used for side effect only.

Categories: Object

Specializations: Class, Method

---

(← *self* **MoveToFile** *file*) [Method of Class]

Purpose: Moves an object from one file to another. If an object is a class, it, and all its methods, move.

Behavior: Adds the object to the filecoms of *file* so that the object will be saved on that file. If *file* is NIL, it prompts for a file form **FILELST** via a menu.

Arguments: *self* A class or method.  
*file* File to which object is moving.

Returns: NIL

Categories: Object

Specializes: Object

---

(← *self* **MoveToFile!** *file fromFiles*) [Method of Class]

Purpose: Moves a class, all of its methods, and all of its subclasses and their methods from one file to another.

Behavior: Similar to **MoveToFile**.

Arguments: *self* A LOOPS class.  
*file* File to which object is moving.  
*fromFiles* A list of files from which classes may be moved.

Returns: NIL

Categories: Class

---

**DontSave** [IV Property Name]

Purpose/Behavior: Controls what parts of an instance are saved in a file. Its value is a list of property names of the instance variable which should not be written out when

the instance is dumped. If **Value** is in the list, the instance variable's value is not saved. If the property is **Any**, nothing is saved except the instance variable name. (Must be added by the user.)

|                                                          |                                                                                                                                                                                                                                                                                                                                                     |                                                                    |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| (←self <b>OldInstance</b> name arg1 arg2 arg3 arg4 arg5) |                                                                                                                                                                                                                                                                                                                                                     | [Method of Object]                                                 |
| Purpose:                                                 | Sends a message to an object after it is loaded from a file. This method can be specialized by applications that need to perform some operation on every object when it is created.                                                                                                                                                                 |                                                                    |
| Behavior:                                                | If <i>name</i> is non-NIL, the message <b>SetName</b> is sent to <i>self</i> .<br><br>Instance variables with an <b>:initForm</b> property are filled. See the discussion of <b>:initForm</b> in Chapter 2, Instances.<br><br>Sends the message <b>SaveInstance</b> to <i>self</i> with the arguments <i>name</i> , <i>arg1</i> , and <i>arg2</i> . |                                                                    |
| Arguments:                                               | <i>self</i>                                                                                                                                                                                                                                                                                                                                         | Evaluates to a class.                                              |
|                                                          | <i>name</i>                                                                                                                                                                                                                                                                                                                                         | LOOPS name of the class or instance.                               |
|                                                          | <i>arg1...arg5</i>                                                                                                                                                                                                                                                                                                                                  | Optional arguments referenced by user-written specialization code. |
| Categories:                                              | Object                                                                                                                                                                                                                                                                                                                                              |                                                                    |

## 14.5 Storing Files

This section describes the functions and methods used by LOOPS and Medley to store files.

| Name                       | Type     | Description                                                                            |
|----------------------------|----------|----------------------------------------------------------------------------------------|
| <b>MAKEFILE</b>            | Function | Writes files that contain Medley data types which include LOOPS objects and methods.   |
| <b>PrettyPrintClass</b>    | Function | Prints classes in a file in a form that can be read back in.                           |
| <b>PrettyPrintInstance</b> | Function | Prints instances in a file in a form that can be read back in.                         |
| <b>MakeFileSource</b>      | Method   | Constructs the representation of an object that is appropriate for printing in a file. |
| <b>FileOut</b>             | Method   | Controls the printing of a LOOPS object in a file.                                     |

|                   |                                                                                                                                                                                                                                                                                      |                                 |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| (MAKEFILE FILE )  |                                                                                                                                                                                                                                                                                      | [Function]                      |
| Purpose/Behavior: | When all LOOPS objects are associated with their files, the files are written by a call to <b>MAKEFILE</b> or <b>MAKEFILES</b> . This is identical to the standard use of <b>MAKEFILE</b> in Medley. See the <i>Lisp Release Notes</i> and the <i>Interlisp-D Reference Manual</i> . |                                 |
| Arguments:        | FILE                                                                                                                                                                                                                                                                                 | Name of file to be written out. |

Returns: Full file name

**(PrettyPrintClass *className file*)**

[Function]

Purpose/Behavior: Used by the File Manager command **CLASSES** to print out classes in a file in a form that can be read back in. It checks to make sure the class exists and then sends it the message **FileOut**. It is also used by the method **PP** to print classes to a display stream.

Arguments: *className* The name of the class to be printed on the file *file*.  
*file* The file on which the class *className* is to be printed.

Returns: Pointer to class in the form #,(\$ *className*)

**(PrettyPrintInstance *instanceName file*)**

[Function]

Purpose: Used by the File Manager command **INSTANCES** to print instances in a file in a form which can be read back in. Sends the message **FileOut** to instance.

Arguments: *instanceName* Name of a LOOPS instance.  
*file* The file on which the instance *instancename* is to be printed.

Returns: NIL

**(← self MakeFileSource *file*)**

[Method of Object]

Purpose: Constructs the representation of an object that is appropriate for printing in a file.

Behavior: Uses the relevant access functions to obtain the parts of the object and then stores them into a list structure.

Arguments: *self* A LOOPS object.  
*file* The file on which *self* is to be printed.

Returns: Loadable form of a LOOPS object.

Categories: Object

Specializations: Class, Method

Example: 63← (← (\$ TestW) MakeFileSource)  
 (DEFINST Window  
 (TestW (NEW0.1Y%.:;h.eN6 . 501)))

**(← self FileOut *file*)**

[Method of Object]

Purpose: Controls the printing of a LOOPS object in a file.

Behavior: Gets the appropriate source representation by sending the object the message **MakeFileSource** and prettyprints the result.

Arguments: *self* A LOOPS object.  
*file* The file on which *self* is to be printed on if T prints to the Lisp Executive window.

Returns: *self*

Categories: Object

Specializations:    Class, Method

Example:

```
62_(_ ($ TestW) FileOut T)
(DEFINST Window (TestW (NEW0.1Y%:.;h.eN6 . 501)))
#,$& TestW (NEW0.1Y%:.;h.eN6 . 501))
```

14.6 COMPILING FILES

---

## 14.6 COMPILING FILES

---

---

## 14.6 Compiling Files

---

LOOPS uses the new XAIE compiler and its macrolet facilities. When doing **CLEANUP** on LOOPS files your **\*DEFAULT-CLEANUP-COMPILER\*** should be set to 'CL:COMPILE-FILE. More information on this cleanup flag and the new compiler are available in the *Lisp Release Notes*.

[This page intentionally left blank]

## 15. PERFORMANCE ISSUES

---

Three main areas in LOOPS can affect performance:

- Garbage collection
- Instance variable access
- Method lookup

This chapter describes the impact of these areas on LOOPS. Also included is a section on cache clearing.

---

### 15.1 Garbage Collection

---

The Interlisp-D garbage collector maintains reference counts of each piece of data in the system. (Refer to the *Lisp Release Notes* and the *Interlisp-D Reference Manual* for information on reference counts.) There is potential for noticeable performance degradation if many items have reference counts greater than one. Object-oriented systems in general, and LOOPS in particular, can easily create objects that have multiple references.

The LOOPS system uses a number of methods to avoid creating items with large reference counts. Classes, for example, can easily have large reference counts since each instance of the class points to the class. Because of this, LOOPS does not maintain reference counts of classes. Performance is enhanced, but classes in LOOPS are not garbage collected. This should not present a problem as classes are not often destroyed.

Unique Identifiers (UIDs) also have multiple references: from the instance they name and from the table used by the LOOPS system to associate UIDs with instances. LOOPS avoids this problem by storing copies of the instance UID in the instance. This complicates testing for equality of UIDs, which is a rare event, but removes a potential garbage collection problem.

These and other implementation details substantially reduce the impact of LOOPS on the Interlisp-D garbage collector. In a typical running system, LOOPS objects accounted for less than 16% of the data items with reference count greater than one.

15.2 INSTANCE VARIABLE ACCESS

---

### 15.2 INSTANCE VARIABLE ACCESS

---

---

### 15.2 Instance Variable Access

---

LOOPS uses macros to speed the instance variable access from compiled code. Instance variable property access is compiled differently from instance variable value access, and various caching schemes are used to speed up repeated access to a given slot.

LOOPS uses two layers of caching to speed up instance variable access:

- Local cache.

Instance variable access from compiled code uses a local cache. This cache remembers the class of *self* and the instance variable index the last time this piece of code was executed. If the class of *self* on the next pass through the code matches the stored value, then the stored instance variable index is used. In this case, instance variable access is very fast.

- Global cache.

A global cache is used by the instance variable access functions when the local cache fails. This global cache is a fixed size table of instance variable pairs. Looking in this cache for a given class is typically faster than computing the instance variable index.

You should be aware that instance variable access is optimized to be faster than accessing the properties of instance variables. Also, be aware that when instances are first created, the data for an instance variable may need to be found by performing a lookup through the class hierarchy. If the lookup goes through several classes, this can be slow. By guaranteeing that the instance variable data is stored in the instance, this lookup delay can be avoided.

The following macros are used to access instance variables. They are mentioned here to point out that calls to **GetValue** and **PutValue** could result in the compilation of any one of several different functions.

---

**(GetValue self varName &OPTIONAL propName)** [Macro]

Purpose/Behavior: Compiles to a call to one of the functions **Cached-GetIVValue**, **Cached-GetIVProp**, **GetIVValue**, or **GetIVProp**. The particular function depends on details of the arguments to **GetValue**.

Arguments: *self* A class or an instance.  
*varName* Instance or class variable name.  
*propName* Property name.

Returns: Used for side effect only.

---

**(PutValue self varName value &OPTIONAL propName)** [Macro]

Purpose/Behavior: Compiles to a call to one of the functions **Cached-PutIVValue**, **Cached-PutIVProp**, **PutIVValue**, or **PutIVProp**. The particular function depends on details of the arguments to **PutValue**.

Arguments: *self* A class or an instance.  
*varName* Instance or class variable name.  
*value* The new value for *varName* or *propName*.  
*propName* Property name.

Returns: Used for side effect only.

15.3 METHOD LOOKUP

---

## 15.3 METHOD LOOKUP

---

---

## 15.3 Method Lookup

---

LOOPS uses two layers of caching to speed the method lookup:

- Local cache

Method lookup from compiled code uses a local cache when the selector can be determined at compile time. This cache remembers the class of *self* and the computed method the last time this message was sent. If the class of *self* on the next pass through the code matches the stored value, then the method is used. In this case, method lookup is very fast.

- Global cache

A global cache is used by the method lookup functions when the local cache fails. This global cache is a fixed size table of class / selector / method triples. Looking in this cache for a given class and selector is typically faster than searching the class hierarchy for the appropriate method.

15.4 CACHE CLEARING

---

## 15.4 CACHE CLEARING

---

---

## 15.4 Cache Clearing

---

Code that directly manipulates the structure of LOOPS objects sometimes needs to invalidate the caches used for instance variable access and message sending.

The following functions can be used to clear these caches if you suspect that they might be invalid.

---

**(ClearAllCaches)****[Function]**

Purpose/Behavior: Clears all LOOPS and Interlisp-D runtime caches. This includes local and global instance variable access caches, local and global method lookup caches, and the system CLISP translations hash array.

Returns: NIL

[This page intentionally left blank]

LOOPS provides two special versions of message sending that start a separate process to run LOOPS methods. These are `←Process` and `←Process!` which are analogous to `←` and `←!`.

`(←Process obj sel arg1 ... argn)`

[Macro]

Purpose: Starts a new process to run the selected method on the object, *obj*.

Behavior: The method indicated by *sel* is run in a separate process for the given instance or class, *obj*. See the *Interlisp-D Reference Manual* for a discussion of processes.

Arguments: *obj* A LOOPS object.  
*sel* Name of the method to be executed as a process.  
*arg1 ... argn* Arguments for the method specified in *sel*.

Returns: Pointer to a process data type.

Example: Assume the method **ClockTime** is added to the class **LCD**, as follows:

```
[Method ((LCD ClockTime
self WaitTime DisplaySeconds?)
(while T
 do (←@ self reading
 [MKATOM (DATE (if DisplaySeconds?
 then (DATEFORMAT NO.DATE)
 else (DATEFORMAT NO.DATE NO.SECONDS])
 (← self Update)
 (BLOCK (OR WaitTime 1000]))
(LCD.ClockTime)
```

**ClockTime** takes two arguments: **WaitTime**, the wait time between updates of the **LCD** reading, and **DisplaySeconds?**, a flag used to determine if seconds are to be displayed on the **LCD**. **ClockTime** runs an infinite loop which sets the **LCD** reading, updates the **LCD** display, and blocks the **ClockTime** loop to allow other system processes to run. The command

```
(←Process ($ LCDInstance1) ClockTime 60000)
```

adds the process **ClockTime** to the process list and (**\$ LCDInstance1**) becomes a digital clock which updates itself every minute.

**19:33**

**(←Process! obj sel arg1 .... argn)**

[Macro]

- Purpose:** Starts a new process to run the selected method on the object *obj*. Like ←**Process**, except the argument *sel* is evaluated.
- Behavior:** Evaluates *sel* returns a selector for a method of *obj*. This method is run on a separate process for the given instance or class, *obj*.
- Arguments:** *obj*            A LOOPS object.  
*sel*                Name of the method to be executed as a process.  
*arg1 .... argn*            Arguments needed for the method.
- Returns:** Pointer to the process data type.
- Example:** Assume the variable **LCDClock** is set to **ClockTime**, which is the method added to the **LCD** class as described for ←**Process**. The command
- ```
(←Process! ($ LCDInstance1) LCDClock 2000 T)
```
- adds the process **LCDClock** to the process list and (**\$ LCDInstance**) becomes a digital clock with a seconds display which updates itself every two seconds.

19:49:39

18. USER INPUT/OUTPUT MODULES

This chapter presents two modules that have been developed for displaying and allowing you to enter information. The Interlisp-D Inspector module and ?= handler have been enhanced to support LOOPS data types and message sending.

18.1 Inspector

The LOOPS interface uses and extends the capabilities of the Medley Inspector module. Instances and classes can be easily examined and modified through the interface that the Inspector module provides. This section describes the operations available with the LOOPS interface. For information on the Inspector module, see the *Interlisp-D Reference Manual*.

An inspector is a window opened on a specific piece of data, which for LOOPS means a class or an instance. Figure 18-1 shows an inspector on an instance of a window.

All Values of Window (\$ (MWX0.;F5.o28.Z:	
left	NIL
bottom	NIL
width	12
height	12
window #	(\$AV LispWindowAV ((YI
title	NIL
menus	T

Figure 18-1. Sample Inspector

Inspector windows contain two columns of information; the left column is called the property column, and the right column is called the value column.

You can scroll inspector windows, but these windows are not reshaped by actions such as switching from instance variables inspection to property inspection or adding new instance variables. This may cause some confusion, for example, if you create an inspector to be the correct size and add an instance variable, and that instance variable fails to appear.

An inspector is primarily an interactive facility. A programmatic interface is also available, which uses the LOOPS methods to customize the generic Interlisp-D functionality.

18.1.1 Overview of the User Interface

LOOPS provides two ways to create an inspector:

- Call the Lisp function **INSPECT** with the object to be inspected as the first argument.

- Use the LOOPS method **Inspect**, which is described below.

The user interface to the inspector is the same as that for the Medley environment; that is, you select an option from the left or right column with the left mouse button, and then trigger an action with the middle mouse button. The action opens a menu from which you can choose further options, like assigning a new value or adding an active value for breaking.

Another menu appears when you position the cursor on the title bar of an inspect window and press the middle mouse button. This menu allows you to change the inspector's contents, for instance to show all values or local ones for instance variables.

Three types of inspectors are available in LOOPS:

- Instance inspector
- Class inspector
- Class instance variable inspector

The following sections describe the user interface for each inspector.

<code>(← self Inspect <i>INSPECTLOC</i>)</code>	<code>[Method of Object]</code>

Purpose:	This provides a message form of the function to inspect the item <i>self</i> .
Behavior:	Calls <code>(INSPECT self NIL <i>INSPECTLOC</i>)</code> .
Arguments:	<i>INSPECTLOC</i> A region where the inspector window should appear. If it is NIL, you are prompted to place a ghost image.
Categories:	Object
Example:	The following command inspects an instance (\$ W1). <code>17← (← (\$ W1) Inspect)</code>

18.1.2 Using Instance Inspectors

Using an inspector window on an instance provides a clear, direct interface to all of the instance's variables and values. This interface also provides the mouse and keyboard options to change the contents of the inspector to show various aspects of the instance.

18.1.2.1 Titles of Instance Inspector Windows

When you inspect an object, the title of the inspector window reflects the contents of the inspector. If the object is an instance, the title contains the name of the class of the instance and the LOOPS name of the instance, if it has one, or the UID of the instance. Other types of inspectors have different title bars, as described in Section 18.1.3, "Using Class Inspectors," and Section 18.1.4, "Using ClassIV Inspectors."

Contrast the title bar of the following two examples.

`(INSPECT (← ($ Window) New))` generates

```

All Values of Window ($ (MWX0.:F5.o28.Z;
left    NIL
bottom  NIL
width   12
height  12
window  #,($AV LispWindowAV ((YI
title   NIL
menus   T

```

(INSPECT (← (\$ Window) New 'w1)) generates

```

All Values of Window ($ w1).
left    NIL
bottom  NIL
width   12
height  12
window  #,($AV LispWindowAV ((YI
title   NIL
menus   T

```

18.1.2.2 Menu for the Title Bar

The following menu appears when you position the cursor on the title bar of the inspector window and press the middle mouse button.

```

Local Values of Window ($ w1).
left    468
bottom  472
width   116
height  74
window  #,($AV LispWindowAV ((|MWX0.:F5
title   #,NotSetValue
menus   #,NotSetValue

```

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

Class Opens a second inspector, a Class Inspector as described in Section 18.1.3, "Using Class Inspectors," which inspects the class of the instance within this inspector.

AllValues The default mode for instance inspectors. The values displayed in the right column of the inspector are determined by the function **GetValueOnly**, so active values (except #,NotSetValue) can be seen. The title of the inspector states that all values are being displayed.

```

All Values of Window ($ w1).
left
  NIL
bottom
  NIL
width
  12
height
  12
window
  #,($AV LispWindowAV ((YIV0.C=N5.W←7 . 10)))
title
  NIL
menus
  T

```

LocalValues The values displayed in the right column of the inspector are determined by the function **GetIVHere**. The title of the inspector states that only local values are being displayed. As with **AllValues**, active values are seen, and values that are not yet stored locally in the instance show a value of **#,NotSetValue**.

```
Local Values of Window ($ w1).
left      200
bottom    429
width     139
height    63
window    #, ($AV LispWindowAV
title     #,NotSetValue
menus     #,NotSetValue
```

Add/Delete Allows you to add or delete instance variables. Selecting this option pops up a new menu with two options:

- **Add**

If you select **Add**, you are prompted to enter a name for the new instance variable. That instance variable is added locally to the instance and given the value of the variable **NotSetValue**. If you enter a name for an instance variable that currently exists, its value is reset to the value defined in the class.

- **Delete**

If you select **Delete**, a menu appears with options that are the instance variables of the instance. If you select one that is not defined within the class, it is deleted. If the selected instance variable is defined by the class, a break occurs.

If the inspector is viewing the properties of an instance variable as opposed to all of the instance variables (see **IVs** below), the name entered under **Add** will be added as a property to that instance variable and given the value of the variable **NotSetValue**. If you try to delete an existing property, the menu that appears is a menu of property names.

IVs Changes the view to be one that shows all of the instance variables and their values, not the properties. It is possible to change the view an inspector has on an instance to show only the properties of a given instance variable. This is described in Section 18.1.2.3, "Using Commands in the Left Column," in the description of the Properties option.

Save Value Calls **PutSavedValue** with its value argument bound to the instance being inspected.

Refetch Refreshes the inspector. Inspectors do not automatically update when a change is made to an instance, unless made with the **Edit** command.

Edit Opens a display editor window in which you can modify the value of instance variables and properties, and add or delete instance variables local to the instance.

18.1.2.3 Menu for the Left Column

The following menu appears when the view of the inspector is all of the instance variables of the instance, and you select an item in the left column and press the middle mouse button.

If the view of the inspector is only of properties, this menu contains only one option: **PutValue**.

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

PutValue Allows you to assign a new value to the variable selected. Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:

- **PutValue**

Prompts you to enter a new value for this instance variable. The new value is stored using **PutValue**.

- **PutValueOnly**

Prompts you to enter a new value for this instance variable. The new value is stored using **PutValueOnly**.

- **Use saved value**

The new value to be stored using **PutValueOnly** is the value of **(SavedValue)**.

Properties Changes the view of the inspector to include only the value and properties of the selected instance variable as shown here:

All IVProps of Window (\$ w1).menus	
Value	T
doc	"Cache For Saved Menus. Will Cache
TitleItems	NIL
MiddleButtonItem	NIL
LeftButtonItem	NIL
Title	NIL
DontSave	Any

The title bar changes to indicate that the properties of an instance variable are being displayed, which instance is being displayed, and which instance variable of that instance is being displayed.

The Value item is provided purely as a convenience in this view and its menu options will only allow Putting a new value in it.

The following menu appears when the view of the inspector is an instance variable's properties, and you select an item in the left column and press the middle mouse button.

When the inspector's view is limited to IV properties the menu options act in a manner similar to that of IVs. This allows Putting, Breaking, Tracing and unBreaking of the properties instead of the IVs themselves.

If you now select the option **LocalValues** from the title bar menu, the title of the inspector changes to indicate that fact, and only properties that are stored locally in the instance appear, as shown here:

To return to a view that shows all instance variables, choose the **IVs** option from the title bar menu.

BreakIt Wraps a **BreakOnPutOrGet** active value around the value of an instance variable. Any read or write accesses to this instance variable will cause a break (see Chapter 12, Breaking and Tracing).

Note: Breaking a variable effectively breaks any IndirectVariable that points to it.

Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:

- **Break on Access**

Performs the same action as **BreakIt**.

- **Break on Put**

Installs a **BreakOnPut** active value. Trying to store a new value into this instance variable will cause a break, but reading the variable will not.

TraceIt Wraps a **TraceOnPutOrGet** active value around the value of this field. Any read or write accesses to this instance variable will be traced (see Chapter 12, Breaking and Tracing).

Note: Tracing a variable effectively traces any IndirectVariable that points to it.

Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:

- **Trace on Access**

Performs the same action as **TraceIt**.

- **Trace on Put**

Installs a **TraceOnPut** active value. All writes into this instance variable will be traced, but reads will not.

UnBreakIt Removes any of the breaks or traces that have been installed on an instance variable. If there are multiple traces or breaks, this will remove the outermost one.

18.1.2.4 Menu for the Right Column

The following menu appears when the view of the inspector is all of the instance variables of the instance, and you select an item in the right column and press the middle mouse button.

If the view of the inspector is only of properties of an instance variable, this menu contains only three options: **PutValue**, **Save Value**, and **Inspect**.

The only differences between these menus and the ones associated with the left column is the addition of two more options: **Save Value** and **Inspect**. The remaining options trigger identical behaviors as those of the menu associated with the left column.

Save Value Calls **PutSavedValue** with the selected value as its argument.

Inspect Calls the Lisp function **INSPECT** with the selected value as its argument, opening an additional inspector window.

In an inspector viewing the properties of an IV the right hand column middle button menu allows only the Put Value, SaveValue and Inspect options.

18.1.3 Using Class Inspectors

Classes can be inspected by using the Lisp **INSPECT** function or the LOOPS **Inspect** method (see Section 18.1.1, "Overview of the User Interface"). For example, to inspect the class **Window**, enter either of the following commands:

```
(INSPECT ($ Window))
(← ($ Window) Inspect)
```

The contents of a class cannot be changed from within an inspector window, so it is generally used for display as opposed to editing. However, the menu interface does provide ways to edit the contents of a class.

18.1.3.1 Titles of Class Inspector Windows

When you inspect a class, the title states that you are inspecting only local properties, and contains the name of the class.

The title contains the name of the class. The following example shows an inspector on the class **Window**. Since the value column is quite long, it has been truncated here.

18.1.3.2 Menu for the Title Bar

The title bar menu is associated with each inspector of a class. This menu appears when you position the cursor inside the title bar of the class inspector window and press the middle mouse button.

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

Browse Provides a quick way to open a class browser on the class being inspected. Selecting this option and dragging the mouse to the right pops up a submenu with the following options:

- **Browse**

Opens a class browser with the class being inspected as the root class.

- **BrowseSupers**

Open a supers browser on the inspected class.

Edit Opens an editing window on the class.

All Causes the values shown in the right column to contain inherited as well as locally defined information. The title bar of the inspector changes to indicate this, as shown here:

Local The default mode for class inspectors. This causes the values shown in the right column to contain only locally defined information, which is indicated in the title bar of the inspector.

Refetch Refreshes the inspector. Inspectors do not automatically update when a change is made to an instance, unless made with the **Edit** command.

18.1.3.3 Menu for the Left Column

No actions occur when you select an item in the left column of a class inspector and press the middle mouse button.

18.1.3.4 Menu for the Right Column

Only one option, **Inspect**, is in the menu that appears when you select an item in the right column of a class inspector and press the middle mouse button.

For the fields **MetaClass**, **Supers**, **CVs**, and **Methods**, selecting **Inspect** from the menu allows a choice of Interlisp-D inspectors. If the selected item in the class inspector is the values of the **IVs** field, then a ClassIVs inspector, described below, is created.

18.1.4 Using ClassIVs Inspectors

ClassIV inspectors provide an interface to the default values for all of the instance variables defined in a class. To create a ClassIV inspector,

- Open a class inspector.
- Select the values of the **IVs** field.
- Press the middle mouse button. This pops up and selects and **Inspect** menu, and automatically opens a ClassIVs inspector.

18.1.4.1 Titles of ClassIVs Inspector Windows

The title for a ClassIVs inspector indicates that the instance variables of a particular class are being inspected. This example shows how a ClassIVs inspector looks for the class **ClassBrowser**.

All IVs of Class ClassBrowser	
left	NIL
bottom	NIL
width	64
height	32
window	#,(\$AV LispWindowAV ((YIV0.C=N5.W←7 . 10)))
title	"Class browser"
menus	T
topAlign	NIL
startingList	NIL
goodList	NIL
badList	NIL
lastSelectedObject	NIL
browseFont	#, (Defer (FONTCREATE (QUOTE (HELVETICA 10 BOLD)
labelMaxLines	NIL
labelMaxCharsWidth	NIL
boxedNode	NIL
graphFormat	(LATTICE)
showGraphFn	SHOWGRAPH
viewingCategories	(Public)

18.1.4.2 Menu for the Title Bar

The following title bar menu is associated with each inspector of an instance. This menu appears when you position the cursor inside the title bar of the inspector window and press the middle mouse button.

AllValues
LocalValues
Add/Delete
IVs
Refetch

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

AllValues

The default mode for ClassIV inspectors. Causes the inspector to show all instance variables, whether inherited or locally defined for the class, and states "AllIVs" in the title.

LocalValues Causes the inspector to show only locally defined instance variables. The following window shows how the title changes to indicate this:

Add/Delete Allows you to add or delete a ClassIV.

Selecting this option and dragging the mouse to the right causes a submenu with the following options to appear:

- **Add**

If you select **Add**, you are prompted to enter a name for the new instance variable. That instance variable is added to the class and given the default value NIL and a **doc** property with the value (* IV added by (USERNAME)). If you enter a name for an instance variable that currently exists, its default value is reset to NIL.

- **Delete**

If you select **Delete**, a menu appears with the locally defined instance variables of the class. Selecting one deletes it from the class.

If the inspector is viewing the properties of an instance variable as opposed to all of the instance variables (see **IVs** below), the name entered under **Add** is added as a property to that instance variable and given the value NIL. If you try to delete an existing property, the menu that appears is a menu of property names.

IVs Returns the view to show the instance variables and their values, not the properties.

It is possible to change the view a ClassIVs inspector has on the instance variables of a class to show only the properties of a given instance variable. This is described in Section 18.1.4.4, "Menu for the Right Column."

Refetch Refreshes the inspector.

18.1.4.3 Menu for the Left Column

No actions occur if you select an item in the left column of a ClassIVs inspector with the middle mouse button.

18.1.4.4 Menu for the Right Column

The following menu appears when you select an item in the right column and press the middle mouse button:

The rest of this section describes the actions that occur as a result of selecting one of the menu options.

Inspect Calls the Lisp function **INSPECT** with the selected value as its argument.

Save Value Calls **PutSavedValue** with the selected value as its argument.

Properties Changes the view of the inspector to display the value and properties of the selected instance variable, as shown in this example:

```

All properties of window of Class ClassBrowser
Value      #,($AV LispWindowAV ((YIV0.C=N5.W←7 . 1
doc        "Holds real window. Ensured to be window
DontSave   (Value)

```

The title changes to include the following information:

- The properties of an instance variable.
- The name of the instance variable.
- The name of the class.

If you now select either **AllValues** or **LocalValues** from the title menu, the title of the inspector changes to indicate that fact, and the appropriate information is displayed.

18.1.5 Functional Interface for Instance Inspectors

The methods described in this section belong mostly to the classes **Class** or **Object**. Inspectors are not LOOPS objects, so these methods are invoked indirectly within the system functionality of the inspector as a customization of the Interlisp-D inspectors. These methods are meant to be called only from within the context that you create interactively by pressing a mouse button when the cursor is on some portion of an inspector window; you do not invoke them directly. Many of the parameters are simply passed along in case the method creates a menu, and the option selected from the menu needs additional arguments.

In these methods, the arguments *self* and *datum* may be the same; that is, the item being inspected. The message is sent to the item being inspected, so its position in the inheritance lattice determines which method from the classes **Class** or **Object** is invoked.

The following table shows the items in this section.

Name	Type	Description
InspectFetch	Method	Returns the value of a left column inspector property that is displayed in the right column of an inspector window.
InspectStore	Method	Stores the value for an instance variable or its property.
InspectPropCommand	Method	After an item is selected in the left column of an inspector window, this triggers an action when the middle mouse button is pressed.
InspectProperties	Method	Determines what is displayed in the left column of an inspector window.
InspectTitle	Method	Creates a string to be used for an inspector window's title.
InspectValueCommand	Method	After an item is selected in the right column of an inspector window, this triggers an action when the middle button is pressed.
TitleCommand	Method	Triggers an action when the cursor is inside the title bar of the inspector window and the middle mouse button is held down.

(← *self* **InspectFetch** *datum property window*)

[Method of Object]

Purpose/Behavior:	Message sent by inspector to get the value of a left column inspector property that is displayed in the right column of an inspector window. Either GetValueOnly or GetIVHere is used to determine the value.	
Arguments:	<i>self</i>	The object being inspected.
	<i>datum</i>	This may or may not be a list. If it is not a list, it is bound to the object being inspected; that is, <i>self</i>. It is set to a list within various methods associated with the inspectors. The contents of this list are interpreted by a number of the methods to control what data is displayed within the inspector window. • The first element of the list is the object being inspected. • The second element of the list, if not NIL, is typically the name of an instance variable. In the terminology of the inspector, it is an inspector property. For inspectors of instances, the inspector properties (the items in the left column) are the instance variables of the object being inspected. (There can be some confusion here caused by using the word properties either when referring to the left column data of an inspector or when referring to the properties associated with an instance variable). • The third element of the list, if NIL, indicates that inherited values are to be displayed in the inspector window; if its value is LocalValues, then only locally stored information is displayed. The value of <i>datum</i> is stored on the inspector window property DATUM.
	<i>property</i>	Used if <i>datum</i> is not a list. Refers to an element (instance variable or property name) contained within the left column of an inspector. For an instance inspector, this could be either the name of an instance variable or the name of a property, depending upon the state of the inspector; that is, whether you are viewing instances variable or the properties of a particular variable.
	<i>window</i>	Lisp window of the inspector.
Returns:	The value of a left column <i>property</i> that is displayed in the right column.	
Categories:	Object	
Specializations:	Class, InspectorClassIVs	
Example:	The following command fetches the value of instance W1's instance variable bottom: <pre>15←(← (\$ W1) InspectFetch (LIST (\$ W1) 'window)) #,\$AV LispWindowAV ((YIV0.C=N5.W←7 . 10)))</pre> The following command fetches the value of class Window's supers: <pre>16←(← (\$ Window) InspectFetch (\$ Window) 'Supers) (Object)</pre>	

($\leftarrow$ *self* **InspectStore** *datum property newValue window*)

[Method of Object]

Purpose/Behavior: Stores *newValue* as the value for an instance variable or its property using **PutValueOnly**. Where the value is stored, whether in the instance variable or one of its properties, depends upon the values for *datum* and *property*.

Arguments:

- datum* Instance or class being inspected. See **InspectFetch**, above, for details.
- property* Instance variable or property where value is to be stored. See **InspectFetch**, above, for details.
- newValue* New value for *property*.
- window* Lisp window of the inspector.

Categories: Object

Specializations: Class, InspectorClassIVs

Example: The following command changes the value of instance **W1**'s instance variable **height**:

```
17←(← ($ W1) InspectStore ($ W1) 'height 400)
400
```

or

```
18←(← ($ W1) InspectStore 'W1 'height 400)
400
```

($\leftarrow$ *self* **InspectPropCommand** *datum property window*)

[Method of Object]

Purpose: This method is an interface between LOOPS and the mouse functions of the inspector, and should only be called through the inspector. It is invoked when an item is selected in the left column of an inspector window and the middle mouse button is pressed.

Behavior: Opens a menu with a number of options. See Section 18.1.2.3, "Menu for the Left Column."

Arguments:

- datum* Instance or class being inspected. See **InspectFetch**, above, for details.
- property* Instance variable or property where value is to be stored. See **InspectFetch**, above, for details.
- window* Lisp window of the inspector. A prompt window will be attached to this window if you ask to **PutValue**, and the window's **INSPECTW.FETCH** function will be called, so the window must be an inspector window.

Categories: Object

Specializations: Class

($\leftarrow$ *self* **InspectProperties** *datum*)

[Method of Object]

Purpose: Determines what should be displayed in the left column of an inspector.

Behavior: Depending on the value of *datum* as described above, this will return either the instance variables of the object being inspected, or the properties of a particular instance variable.

Arguments:	<i>datum</i>	Instance or class being inspected. See InspectFetch , above, for details.
Returns:	Value depends on the arguments; see Behavior.	
Categories:	Object	
Specializations:	Class, InspectorClassIVs	
Example:	The following command first shows the instance variables of instance W1 , then the properties of the instance variable height : <pre>27←(← (\$ W1) InspectProperties 'W1') (left bottom width height window title menus) 28←(← (\$ W1) InspectProperties (LIST 'W1 'height)) (Value doc)</pre>	

(← self InspectTitle datum)	[Method of Object]

Purpose:	Creates a string to be used as a title for an inspector window.	
Behavior:	If <i>datum</i> is not a list, this sets <i>datum</i> to (<i>datum</i> NIL NIL). Depending on the values within the list <i>datum</i> , this creates a title showing whether all values or local values are shown and whether all instance variables or the properties of an instance variable are shown. The title also contains the LOOPS name or UID of <i>self</i> .	
Arguments:	<i>datum</i>	Instance or class being inspected. See InspectFetch , above, for details.
Categories:	Object	
Specializations:	Class, InspectorClassIVs	
Example:	Some examples of the behavior of InspectTitle : <pre>35←(← (\$ Window) InspectTitle) "Local properties of Class Window" 36←(← (\$ W1) InspectTitle) "All Values of Window (\$ W1)." 37←(← (\$ Window) InspectTitle (LIST 'Window T)) "All properties of Class Window" 38←(← (\$ W1) InspectTitle (LIST 'W1 'height)) "All IVProps of Window (\$ W1).height"</pre>	

(← self InspectValueCommand datum property value window)	[Method of Object]

Purpose:	This method is an interface between LOOPS and the mouse functions of the inspector, and should only be called through the Inspector. It is invoked when an item is selected in the right column of an inspector window and the middle mouse button is pressed.	
Behavior:	Opens a menu with several options. See Section 18.1.2.4, "Menu for the Right Column."	
Arguments:	<i>datum</i>	Instance or class being inspected. See InspectFetch , above, for details.
	<i>property</i>	Instance variable or property being inspected. See InspectFetch , above, for details.

value This is inspected only if you select **Inspect** from menu.

window Lisp window of the inspector.

Categories: Object

Specializations: Class, InspectorClassIVs

Example: When the value of the instance variable **height** in instance **W1** is selected in an inspector window, and the middle mouse button is pressed, a message like the following is sent:

```
(← ($ W1) InspectValueCommand ($ W1) 'height 200 (WHICHW))
```

(← self **TitleCommand** datum window)

[Method of Object]

Purpose: This method is an interface between LOOPS and the mouse functions of the inspector, and should only be called through the Inspector. It is invoked when the cursor is in the title bar of an inspector window and the middle mouse button is pressed.

Behavior: Brings up a menu with several options. See Section 18.1.2.2, "Menu for the Title Bar."

Arguments: *datum* Instance or class being inspected. See **InspectFetch**, above, for details.

window Lisp window of the inspector.

Categories: Object

Specializations: Class, InspectorClassIVs

Example: If you position the cursor inside the title bar of the inspector window for instance **W1** and press the middle mouse button, you send a message like the following:

```
(← ($ W1) TitleCommand NIL (WHICHW))
```

18.1.6 Customizing the Inspector

The methods in Section 18.1.5, "Functional Interface for Instance Inspectors," have been specialized in the classes **Class** and **InspectorClassIVs** to create the behavior of the inspectors described in Section 18.1.1, "Overview of the User Interface."

If you want to create a specialized inspector, you need to create a subclass of **Object** or perhaps **Class** and specialize the methods within that new class. The class **InspectorClassIVs** has an instance variable named **class** that contains the name of the class being inspected within a particular instance of **InspectorClassIVs**. Similarly, the user-created inspector class may need an instance variable which contains the object being inspected so that the methods of this class can easily access it.

The methods that you need to specialize will depend upon how the behavior of the newly created inspector class should differ from those of an instance or class inspector.

As an example, assume that you want an inspector to show a subset of the instance variables of an instance. You could specialize the method **InspectProperties** to return that subset. To make **Window** show only the dimensions of a window, define the following method:

```
SEdit Window.InspectProperties Package; INTERLISP
(Method ((Window InspectProperties) self)
  "Have Window inspectors show only the window dimensions"
  '(width height left bottom))
```

(←New (\$ Window) Inspect) creates the following:

```
All Values of W
width 12
height 12
left NIL
bottom NIL
```

18.2 EXTENSIONS TO ?=

18.2 EXTENSIONS TO ?=

18.2 Extensions to ?=

The Interlisp-D environment allows you to begin typing a function to be evaluated in the Executive and pause in the midst of typing the arguments. At this point, if you type a "?=" followed by a carriage return, Interlisp-D prints the arguments to the pending function call and shows the bindings. LOOPS has extended this facility to include similar functionality for message sending and for record creation.

18.2.1 Message Sending

The ?= interface works with the following message-sending forms:

- ←
- ←Super
- ←New
- ←Proto
- ←Process
- SEND

LOOPS first tries to determine the class of the object receiving the message by examining the form following one of the above. If the message form begins with one of ←**New** or ←**Proto**, the object receiving the message is the class desired.

- If the system cannot determine the class of the object, you are prompted in the Prompt Window to enter in the name of the class or to type a right square bracket (]) to evaluate the form and determine that class from that. This handles cases such as

```
(← (← ($ Window) New) ?=<CR>
```

- If the class can be determined and if you have not typed in a selector, a menu appears containing the options ***generics*** and ***inherited*** and any selectors local to the class. A submenu is associated with ***generics*** that contains selectors from the classes **Tofu**, **Object**, or **Class**, depending

upon the class previously determined. The submenu associated with ***inherited*** are those selectors that are neither generic nor local to the class.

This is the menu that appears when you type

```
(←New ($ NonRectangularWindow) ?= <CR>
```

If you choose one of these options, it is placed into the input buffer and the system prints the binding for *self*, what method will be executed, and the arguments expected. In the prompt window, the system prints the documentation of the method to be executed.

As an example, if you create an instance of a class browser **cb1**, type

```
22← (← ($ cb1) ?= <CR>
```

and then choose **Shape** from the ***inherited*** drag-through menu, the Executive changes as shown here.

```
22← (← ($ cb1) Shape
(←
self = ($ cb1)
Method = Window.Shape
newRegion noUpdateFlg)
```

A similar output occurs if you type in a selector and "!=" instead of choosing a selector from the menu.

If you type "!=" after entering one or more of the arguments, the arguments are printed with the bindings, as shown here.

```
23← (← ($ cb1) Shape ' (100 150 200 250) ?= <CR>
(←
self = ($ cb1)
Method = Window.Shape
newRegion (QUOTE (100 150 ...))
noUpdateFlg)
```

This interface also works when you are typing to the edit buffer window when using the display editor. It does not work to pick a selector within a display editor window and choose the **?=** item from the **EditCom** submenu.

18.2.2 Record Creation

The same mechanism the LOOPS uses to handle **?=** for LOOPS objects is also used to extend it for the Interlisp Record module.

If you begin an input to the Executive with one of **CREATE**, **Create**, or **create**, type the record name or data type to be created next, and then type

```
?=<CR>
```

the system prints the names but not the bindings of the fields within the record being created.

For example, when you type

```
48← (CREATE POSITION XCOORD ← 123 ?=<CR>
```

the response is

```
(XCOORD YCOORD)
```

on the next line. The caret moves to the position of the ?= in the original line, and waits for you to enter a value.

[This page intentionally left blank]

This chapter describes the ways to manipulate LOOPS windows.

19.1 The Class Window

The class **Window** is the LOOPS interface to the Medley environment window system, which is used by LOOPS browsers and inspectors.

Window

[Class]

Description: This class provides a mechanism for manipulating Lisp windows through an object-oriented interface. See Section 19.4, "Mouse and Menu Functionality," for a discussion of how menus work with LOOPS Windows.

When an instance of a LOOPS window is created, it has an instance variable that points to a Lisp window. This Lisp window is initialized with various window properties:

- The property **LoopsWindow** points to the window object.
- The property **RIGHTBUTTONFN** is set to **WindowRightButtonFn**.
- The property **BUTTONEVENTFN** is set to **WindowButtonEventFn**.
- The property **AFTERMOVEFN** is set to **WindowAfterMoveFn**.
- The property **RESHAPEFN** is set to **WindowReshapeFn**.

MetaClass: Class

Supers: Object

Class Variables: **TitleItems** A list that defines the menu that will appear when the left or middle mouse button is pressed and the cursor is in the title bar of the window. The default value is NIL.

LeftButtonItem

A list that defines the menu for the left button in the main window. The default value is ((Update ...)).

ShiftLeftButtonItem

A list that defines the menu for the left button in the main window when the **Meta** key is down. The default value is NIL.

MiddleButtonItem

A list that defines the menu for the middle button in the main window. The default value is NIL.

ShiftMiddleButtonItem

A list that defines the menu for the middle button in the main window when the **Meta** key is down. The default value is NIL.

RightButtonItems

A list that defines the menu for the right button in the main window. The default value is ((Close ...)).

Instance Variables:	left	The location of the left side of the outside of the window in screen coordinates. The default value is NIL.
	bottom	The location of the bottom side of the outside of the window in screen coordinates. The default value is NIL.
	width	The outside width of the window. The default value is 12.
	height	The outside height of the window. The default value is 12.
	window	An active value that contains the Lisp window. The default value is #,\$AV LispWindowAV ...).
	title	The title of the window. Default Value: NIL.
	menus	Also has the properties Title , LeftButtonItems , MiddleButtonItems , and TitleItems . These properties are caches for menus only if the value of the instance variable is T. Default Value: T.

19.2 BASIC WINDOW METHODS

19.2 BASIC WINDOW METHODS

19.2 Basic Window Methods

This section describes the basic methods to operate on windows.

Name	Type	Description
AfterMove	Method	Updates the instance variables left and bottom.
AfterReshape	Method	Updates the instance variables left, bottom, width, and height.
Blink	Method	Causes the window to blink.
Bury	Method	Buries the window.
Clear	Method	Clears the window.
Close	Method	Closes the window.
CursorInside?	Method	Determines if the cursor is inside a window.
Destroy	Method	Destroys the window instance.
GetProp	Method	Gets a property from a specified window.
Hardcopy	Method	Makes a hardcopy on the default device.
HardcopyToFile	Method	Makes a hardcopy on a file.
HardcopyToPrinter	Method	Makes a hardcopy to a printer.
Invert	Method	Inverts the window; that is, reverses its black-white pattern.
Move	Method	Moves the window.

MousePackage	Method	Returns a package (defined to return the INTERLISP package).
MouseReadtable	Method	Returns a readtable (defined to return the INTERLISP readtable).
Open	Method	Opens the window.
Paint	Method	Calls PAINTW on the window.
ScrollWindow	Method	Scrolls the window.
SetProp	Method	Sets the property in the specified window.
Shape	Method	Reshapes the window.
Shape?	Method	Returns the current region for the window.
Shrink	Method	Shrinks the window to an icon.
Snap	Method	Takes a snapshot of the screen.
ToTop	Method	Opens the window and brings it to the top.
Update	Method	Makes the window consistent with the instance variables.
WindowAfterMoveFn	Function	Sends the message AfterMove .
WindowReshapeFn	Function	Sends the message AfterReshape .

(← *self* **AfterMove**) [Method of Window]

Purpose/Behavior: Updates the instance variables **left** and **bottom** of *self*.

Arguments: *self* An instance of a window.

Returns: Used for side effect only.

Categories: Window

(← *self* **AfterReshape** *oldBitmapImage oldRegion oldScreenRegion*) [Method of Window]

Purpose/Behavior: Updates the instance variables **left**, **bottom**, **width**, and **height** of *self*. Calls **RESHAPEBYREPAINTFN**; see the *Interlisp-D Reference Manual*.

Arguments: *self* An instance of a window.

Returns: Used for side effect only.

Categories: Window

(← *self* **Blink** *numBlinks*) [Method of Window]

Purpose/Behavior: Inverts the window; that is, reverses its black-white pattern, and then returns to normal *numBlinks* times.

Arguments: *self* Pointer to a window instance.

numBlinks Number of times for window to blink.

Returns: NIL

Categories: Window

Example: The command

(← *self* Blink 5)

sends a message to *self* to blink five times.

(← *self* **Bury**)

[Method of Window]

Purpose/Behavior: Calls **BURYW** to bury the specified window.

Arguments: *self* Pointer to a window instance.

Returns: The LOOPS window.

Categories: Window

(← *self* **Clear**)

[Method of Window]

Purpose/Behavior: Calls **CLEARW** to clear the specified window.

Arguments: *self* Pointer to a window instance.

Returns: NIL

Categories: Window

Specializations: LatticeBrowser

(← *self* **Close**)

[Method of Window]

Purpose/Behavior: Closes the specified window and prompt window, if there is one.

Arguments: *self* Pointer to a window instance.

Returns: NIL

Categories: Window

(← *self* **CursorInside?**)

[Method of Window]

Purpose/Behavior: Determines if the cursor is inside the window.

Arguments: *self* Pointer to a LOOPS window.

Returns: Returns T if the cursor is inside the window, otherwise returns NIL.

Categories: Window

(← *self* **Destroy**)

[Method of Window]

Purpose/Behavior: Destroys the calling instance, removes all **ButtonFns**, and closes the window.

Arguments: *self* Pointer to a window instance.

Returns: NIL

Categories: Object

Specializes: Object

(← *self* **GetProp** *prop*) [Method of Window]

Purpose/Behavior: Gets a property from a window.

Arguments: *self* Pointer to a window instance.
prop Property to get.

Returns: The value of the specified property, if it exists; else NIL.

Categories: Window

Example: To determine the value of the window property **BUTTONEVENTFN**, enter
 (← (\$ window) GetProp 'BUTTONEVENTFN)

(← *self* **Hardcopy**) [Method of Window]

Purpose/Behavior: Makes a hardcopy of the window on the default printer.

Arguments: *self* Pointer to a window instance.

Categories: Window

(← *self* **HardcopyToFile**) [Method of Window]

Purpose/Behavior: Makes a hardcopy of the window to a file. You are prompted for the file name.

Arguments: *self* Pointer to a window instance.

Categories: Window

(← *self* **HardcopyToPrinter**) [Method of Window]

Purpose/Behavior: Makes a hardcopy of the window on a printer. You are prompted for the name of the printer.

Arguments: *self* Pointer to a window instance.

Categories: Window

(← *self* **Invert**) [Method of Window]

Purpose/Behavior: Inverts the window; that is, reverses its black-white pattern.

Arguments: *self* Pointer to a window instance.

Returns: T if successful.

Categories: Window

Specializations: NonRectangularWindow

(← *self* **Move** *xOrPos* *y*) [Method of Window]

Purpose/Behavior: Moves the specified window. If no arguments are supplied, you will be prompted to position the window.

Arguments: *self* Pointer to a window instance.

x New **left** in screen coordinates or a new position for **left** and **bottom**. If *x* is a position, *y* is ignored.

y New **bottom** in screen coordinates.

Returns: (*x* . *y*)

Categories: Window

Example: The command
 (`← ($ window) Move`)
 causes window to become attached to the cursor, prompting for new location.

 The command
 (`← self Move 200 100`)
 moves the lower left corner of the window to (200 . 100).

`(←self MousePackage)` [Method of Window]

Purpose/Behavior: Returns the package used during mouse interactions with the window *self*. (LOOPS now uses the INTERLISP package exclusively.) The **MousePackage** method protects LOOPS windows from the new packages. To remove this protection, specialize this method to return **PACKAGE**.

Arguments: *self* An instance of a window.

Returns: The INTERLISP package.

`(←self MouseReadtable)` [Method of Window]

Purpose/Behavior: Returns the readtable used during mouse interactions with the window *self*. Medley now has many different readtables; some readtables do not work well with LOOPS. (The Common Lisp readtables are not case-sensitive.) This method protects LOOPS windows from the new readtables. To remove this protection, specialize this method to return **READTABLE**.

Arguments: *self* An instance of a window.

Returns: The INTERLISP readtable.

`(← self Open)` [Method of Window]

Purpose/Behavior: Opens the specified window instance.

Arguments: *self* Pointer to a window instance.

Returns: NIL

Categories: Window

`(← self Paint)` [Method of Window]

Purpose/Behavior: Calls **PAINTW** on the specified window. You are prompted for instructions in the prompt window.

Arguments: *self* Pointer to a window instance.

Returns: NIL

Categories: Window

(← *self* **ScrollWindow** *dspX dspY windowX windowY*)

[Method of Window]

Purpose/Behavior: Scrolls the window to move the point *dspX*, *dspY* to *windowX*, *windowY*. If *windowX* and *windowY* are NIL, the default is to scroll so that the point *dspX*, *dspY* appears in the lower left corner of the window. Any of the arguments can be **FIXP** or **FLOATP**. If the value is **FIXP**, then it is treated as an absolute coordinate. If the value is **FLOATP**, then it is treated as a relative position.

Arguments:

<i>self</i>	Pointer to a window instance.
<i>dspX</i>	The x point in the given window to move; x is in window coordinates if FIXP . If FLOATP , the value to move is based upon the width of the EXTENT property of the window; see the <i>Interlisp-D Reference Manual</i> .
<i>dspY</i>	The y point in the given window to move; y is in window coordinates if FIXP . If FLOATP , the value to move is based upon the height of the EXTENT property of the window; see the <i>Interlisp-D Reference Manual</i> .
<i>windowX</i>	The x point to scroll to in window coordinates if FIXP . If FLOATP , the value to move is based upon the width of the window.
<i>windowY</i>	The y point to scroll to in window coordinates if FIXP . If FLOATP , the value to move is based upon the height of the window.

Returns: The lower left corner of the new **DSPCLIPPINGREGION**; see the *Interlisp-D Reference Manual*.

Categories: Window

(← *self* **SetProp** *prop value*)

[Method of Window]

Purpose/Behavior: Sets the Interlisp window property of the specified LOOPS window, passing its *prop* and *value* arguments through Interlisp function **WINDOWPROP**.

Arguments:

<i>self</i>	Pointer to a window instance.
<i>prop</i>	Property to set.
<i>value</i>	New value for property.

Returns: Previous value of *prop* if it existed; else NIL.

Categories: Window

(← *self* **Shape** *newRegion noUpdateFlg*)

[Method of Window]

Purpose/Behavior: Reshapes the specified window. If *newRegion* is not specified, you are prompted to reshape the window with the cursor.

Arguments:

<i>self</i>	Pointer to a window instance.
<i>newRegion</i>	A list specifying the new outer dimensions; the format for the list is (left bottom height width).
<i>noUpdateFlg</i>	If NIL, reshapes the window.

Returns: A list specifying the new region.

Categories: Window

Specializations: NonRectangularWindow

Example: The command

```
(← ($ window1) Shape ' (100 200 300 400))
```

returns

```
(100 200 300 400)
```

(← *self* **Shape?**)

[Method of Window]

Purpose/Behavior: Returns the current region for the window.

Arguments: *self* Pointer to a window instance.

Returns: A list specifying outer dimensions of the window.

Categories: Window

Example: The command

```
(← ($ window1) Shape?)
```

returns

```
(100 200 300 400)
```

(← *self* **Shrink** *toWhat* *iconPos* *expandFn*)

[Method of Window]

Purpose/Behavior: Shrinks the window to a given icon.

Arguments: *self* Pointer to a window instance.

toWhat The icon to shrink to; if NIL, an icon is created.

iconPos Position of icon on screen.

expandFn Function to be called on expansion.

Returns: The icon.

Categories: Window

Specializations: LatticeBrowser

(← *self* **Snap**)

[Method of Window]

Purpose/Behavior: Calls **SnapW** to take a snapshot of the window.

Arguments: *self* Pointer to a window instance.

Returns: The window.

Categories: Window

(← *self* **ToTop**)

[Method of Window]

Purpose/Behavior: Opens the window and brings it to the top of the screen.

Arguments: *self* Pointer to a window instance.

Returns: The window.

Categories: Window

(← *self* **Update**)

[Method of Window]

Purpose/Behavior: Makes the window consistent with the instance variables.

Arguments: *self* Pointer to a window instance.

Returns: NIL

Categories: Window

Specializations: NonRectangularWindow

(**WindowAfterMoveFn** *window*)

[Function]

Purpose/Behavior: This function is installed as the **AFTERMOVEFN** property of the Lisp window pointed to by a window object. This function extracts the window object from the property **LoopsWindow** and sends it the message **AfterMove**.

This **AFTERMOVEFN** is installed automatically by the system.

Arguments: *window* The window just moved.

Returns: Used for side effect only.

(**WindowShapeFn** *window oldBitmapImage oldRegion*)

[Function]

Purpose/Behavior: This function is installed as the **RESHAPEFN** property of the Lisp window pointed to by a window. This function extracts the window object from the property **LoopsWindow** and sends it the message **AfterReshape** with the arguments *oldBitmapImage oldRegion*.

This **RESHAPEFN** is installed automatically by the system.

Arguments: *window* The window just reshaped.

oldBitmapImage

See the *Lisp Release Notes* and the *Interlisp-D Reference Manual* for a discussion of window **ReShapeFns**.

oldRegion

See the *Lisp Release Notes* and the *Interlisp-D Reference Manual* for a discussion of window **ReShapeFns**.

Returns: Used for side effect only.

19.3 PROMPT WINDOWS

19.3 PROMPT WINDOWS

19.3 Prompt Windows

Prompt windows are windows attached to other windows and are used for displaying messages and for getting input. In LOOPS, these operate similarly to prompt windows in Lisp. Prompt windows are not instances of the class Window; they are only instances of the Interlisp data type **Window**.

The following table lists the methods and functions described in this section.

Name	Type	Description
Clear PromptWindow	Method	Clears the prompt window.
ClosePromptWindow	Method	Closes the prompt window.
GetPromptWindow	Method	Associates a prompt window with a LOOPS window.
PromptEval	Function	Prompts for, reads, and evaluates an expression.
PromptForList	Method	Prompts for a list of items.
PromptForString	Method	Prompts for a string.
PromptForWord	Method	Prompts for a word.
PromptPrint	Method	Prints a message in the prompt window.
PromptRead	Function	Prompts for and reads data.
NiceMenu	Function	Creates a menu.
SelectFile	Lambda NoSpread	Prompts for a file name.

Note: The methods **PromptForList**, **PromptForString**, and **PromptForWord**, as well as the functions **PromptRead** and **PromptEval** when called with a prompt window for a LOOPS window, all disable normal mouse button events in the prompting browser and will not allow it to close until the prompt is completed.

(← *self* **ClearPromptWindow**) [Method of Window]

Purpose/Behavior: Clears the prompt window associated with the window *self*.

Arguments: *self* Evaluates to a window instance.

Returns: NIL

Categories: Window

(← *self* **ClosePromptWindow**) [Method of Window]

Purpose/Behavior: Closes the prompt window associated with the window *self*.

Arguments: *self* Evaluates to a window instance.

Returns: The symbol **CLOSED** if a prompt window existed; else NIL.

Categories: Window

(← *self* **GetPromptWindow** *lines fontDef*) [Method of Window]

Purpose/Behavior: Gets a prompt window for window *self*. If one exists, it is returned; else a prompt window is created.

Arguments: *self* Pointer to a window instance.

lines Number of lines in window; default is 2.

fontDef Font used in the window; if NIL, this defaults to DEFAULTFONT.

Returns: Pointer to a prompt window.

Categories: Window

(PromptEval *promptString window sameLine?*)

[Function]

Purpose: Prompts for, reads, and evaluates an expression.

Behavior: Temporarily moves the TTYDISPLAYSTREAM to *window*, if *window* is non-NIL, else to the system prompt window.

The *promptString* is printed followed by a carriage return and the string "The expression read will be EVALuated."

The prompt "> " is printed on the same line as the above if *sameLine?* is non-NIL, else it is printed on a new line. Data entered by the user is evaluated and returned. **LISPX** and **LISPXREAD** are used so that the entered data is placed on the **LISPX** history list. (See the *Lisp Release Notes* and the *Interlisp-D Reference Manual*).

Note: When called with a prompt window for a LOOPS window, **PromptEval** disables normal mouse button events in the prompting browser and will not allow it to close until the prompt is completed.

Arguments: *promptString*

A string to be printed.

window

A window where the prompting and reading should occur. Defaults to the system prompt window.

sameLine?

If non-NIL, the data is read from the same line as the string "The expression read will be EVALuated."

Returns: The data entered by the user after it has been evaluated.

Example: The command

```
26←(← ($ Window) New (PromptEval "Specify new window for object name."))
```

causes the following to appear in the Prompt Window:

```
Specify new window for object name.
The expression read will be EVALuated.
```

```
>
```

Entering

```
`NewWindow
```

after the > causes the following return in the Executive Window.

```
#, ($& Window (NEW0.1Y%:.;h.eN6 . 501))
```

(← self PromptForList *promptStr initialString*)

[Method of Window]

Purpose/Behavior: Prompts you in prompt window for a list of symbols. If prompt window does not exist, one is created. Input is terminated by a carriage return.

TTYIN is used for editing the user's input; see the *Interlisp-D Reference Manual*.

Note: **PromptForList** disables normal mouse button events in the prompting browser and will not allow it to close until the prompt is completed.

Arguments: *self*

Pointer to a window instance.

promptStr Displayed in prompt window.

initialString Can be used as the default or the first item of the list.

Returns: The list of words entered in prompt window.

Categories: Window

Example: If (\$ Window1) is a window, then the command

```
27←(← ($ Window1) PromptForList "ENTER THE CODES ")
```

causes the prompt ENTER THE CODES to be displayed in an attached prompt window. The system waits for user input.

(← *self* **PromptForString** *promptStr initialStr*)

[Method of Window]

Purpose/Behavior: Prompts you in prompt window for a string. If a prompt window does not exist, one is created. Input is terminated by a carriage return.

TTYIN is used for editing the user's input; see the *Interlisp-D Reference Manual*.

Note: **PromptForString** disables normal mouse button events in the prompting browser and will not allow it to close until the prompt is completed.

Arguments: *self* Pointer to a window instance.

promptStr Displayed in prompt window.

initialStr Can be used as the default or the prefix to the string.

Returns: The string entered in prompt window.

Categories: Window

Example: If (\$ Window1) is a window, then the command

```
28←(← ($ Window1) PromptForString "ENTER THE CODES ")
```

causes the prompt ENTER THE CODES to be displayed in an attached prompt window. The system waits for user input.

(← *self* **PromptForWord** *promptStr initialWord*)

[Method of Window]

Purpose/Behavior: Returns (CAR (← *self* **PromptForList** *promptStr initialWord*))

Arguments: *self* Evaluates to a window instance.

promptStr Displayed in prompt window.

initialWord Can be used as the default.

Returns: See Behavior.

Categories: Window

Example: If (\$ Window1) is a window, then the command

```
29←(← ($ Window1) PromptForWord "NEW WORD " )
```

prompts you with NEW WORD in an attached prompt window.

(← *self* **PromptPrint** *msg*) [Method of Window]

Purpose/Behavior: Displays a message in the prompt window associated with the specified window instance. Creates the prompt window if it does not exist.

Arguments: *self* Evaluates to a window instance.
msg Message displayed.

Returns: The message printed.

Categories: Window

(**PromptRead** *promptString window sameLine?*) [Function]

Purpose: Prompts for and reads data.

Behavior: Temporarily moves the **TTYDISPLAYSTREAM** to *window*, if *window* is non-NIL, else to the system prompt window.

The *promptString* is printed. The prompt "> " is printed on the same line as the above if *sameLine?* is non-NIL, else it is printed on a new line. Data that you entered is read and returned.

This contrasts with **PromptEval** in that the entered data is not placed on the **LISPX** history list (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*).

Note: When called with a prompt window for a LOOPS window **PromptRead** disables normal mouse button events in the prompting browser and will not allow it to close until the prompt is completed.

Arguments: *promptString* A string to be printed.
window A window where the prompting and reading should occur. Defaults to the system prompt window.
sameLine? If non-NIL, the data is read from the same line as the *promptString*.

Returns: The data entered by the user.

(**NiceMenu** *items title*) [Function]

Purpose: Provides an interface to create a menu and displays the menu.

Behavior: Varies according to the arguments.

- If *items* is NIL, prints "No items for *title*" in the system prompt window and returns NIL.
- If *items* is non-NIL, this builds a menu with the **TITLE** *title*, with the **ITEMS** *items*, and with **CHANGEOFFSETFLG** set to T (see the *Interlisp-D Reference Manual*). If the length of *items* is more than 35, the menu has multiple columns.

Arguments: *items* A form that can be placed in the **ITEMS** field of a menu.
title A value that will be placed in the **TITLE** field of a menu.

Returns: Value depends on the arguments; see Behavior.

(**SelectFile** *prompts*) [Lambda NoSpread Function]

Purpose:	Prompts you for a file name.
Behavior:	Takes on unlimited number of arguments and will PROMPTPRINT all the arguments. Builds a menu with the items *newFile* and the files found on the variable FILELST. If you select one of the files, that is returned. If you select *newFile*, you are prompted to enter a file name. An empty filecoms is built for that file name, and the file name is returned. *newFile* has three subitems: • *newFile* See Behavior. • *loadFile* You are prompted to enter a file name. A search is performed to try to find and load the compiled file. If that is not found, an attempt is made to load the source file. Returns NIL if the file is not found. • *hiddenFile* A menu is displayed containing files that are on the variable LOADEDFILELST but not on FILELST.
Arguments:	<i>prompts</i> A number of expressions to be printed in the system prompt window.
Returns:	Value depends on the arguments; see Behavior.

19.4 MOUSE AND MENU FUNCTIONALITY

19.4 MOUSE AND MENU FUNCTIONALITY

19.4 Mouse and Menu Functionality

When a LOOPS window is instantiated, its instance variable **window** points to an instance of a Lisp window. This window has several properties set, among which are the following that are described in this section:

- The property **RIGHTBUTTONFN** that is set to **WindowRightButtonFn**.
- The property **BUTTONEVENTFN** that is set to **WindowButtonEventFn**.

This section will also explain the functionality of the above and how menus associated with LOOPS windows operate. For more information on Medley windows, see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*.

Name	Type	Description
ButtonEventFn	Method	Sends either the message TitleSelection , LeftSelection , or MiddleSelection .
ClearMenuCache	Method	Deletes menus saved on the menus field of a browser.
ItemMenu	Method	Creates a simple one-level menu.
LeftSelection	Method	Triggers functionality when the cursor is in a window and the left button is pressed.

MiddleSelection	Method	Triggers functionality when the cursor is in a window and the middle button is pressed.
RightButtonFn	Method	Sends the message RightSelection .
RightSelection	Method	Triggers functionality when the cursor is in a window and the right button is pressed.
TitleSelection	Method	Triggers functionality when the cursor is in a window's title bar and the left or middle button is pressed.
WhenMenuItemHeld	Method	Displays in the prompt window what happens when option is selected.
WindowButtonEventFn	Function	Invokes the method ButtonEventFn .
WindowRightButtonFn	Function	Invokes the method RightButtonFn .

(← *self* **ButtonEventFn**)

[Method of Window]

Purpose/Behavior:	If the cursor is not inside of the window pointed to by <i>self</i> , this sends the message TitleSelection to <i>self</i> . If the left mouse button is pressed, this sends the message LeftSelection to <i>self</i> . If the left middle button is pressed, this sends the message MiddleSelection to <i>self</i> .	
Arguments:	<i>self</i>	An instance of a window.
Returns:	Used for side effect only.	
Categories:	Window	

(← *self* **ClearMenuCache**)

[Method of Window]

Purpose/Behavior:	Deletes menus saved in any properties of the instance variable menus of a window. Use this method if you ever change the class variables describing a menu, and you want the new menu to take effect.	
Arguments:	<i>self</i>	Pointer to a window instance.
Returns:	<i>self</i>	
Categories:	Window	

(← *self* **ItemMenu** *items* *title*)

[Method of Window]

Purpose/Behavior:	Creates a simple one-level menu guaranteed not to be more than 750 bits high. A large number of menu options will cause a multiple column menu to be formed.	
Arguments:	<i>self</i>	Pointer to a window instance.
	<i>items</i>	The value of this is passed to the ITEMS field when the menu is created.
	<i>title</i>	The title for the menu's window.
Returns:	A menu.	

Categories: Window

Example: The command

```
32← (← (←New ($ Window)) ItemMenu ' (a b c))
```

will create a menu with the three options.

(← self LeftSelection)**[Method of Window]**

Purpose/Behavior: Invokes a number of internal methods of **Window**. A menu will pop up. The options in the menu will be defined by the class variable **LeftButtonItems** (or **ShiftLeftButtonItems** if the **Meta** key is also pressed). If an option is selected from the menu, a message will be sent to *self* with a selector as specified by the chosen menu option.

Arguments: *self* Pointer to a window instance.

Returns: Used for side effect only.

Categories: Window

Specializations: LatticeBrowser

(← self MiddleSelection)**[Method of Window]**

Purpose/Behavior: Invokes a number of internal methods of **Window**. A menu will pop up. The options in the menu will be defined by the class variable **MiddleButtonItems** (or **ShiftMiddleButtonItems** if the **Meta** key is also pressed). If an option is selected from the menu, a message will be sent to *self* with a selector as specified by the chosen menu option.

Arguments: *self* Pointer to a window instance.

Categories: Window

Specializations: LatticeBrowser

(← self RightSelection)**[Method of Window]**

Purpose/Behavior: Invokes a number of internal methods of **Window**. A menu will pop up. The options in the menu will be defined by the class variable **RightButtonItems**. If an option is selected from the menu, a message will be sent to *self* with a selector as specified by the chosen menu option.

Arguments: *self* Pointer to a window instance.

Returns: The menu.

Categories: Window

(← self TitleSelection)**[Method of Window]**

Purpose/Behavior: Invokes a number of internal methods of **Window**. A menu will pop up. The options in the menu will be defined by the class variable **TitleItems**. If an option is selected from the menu, a message will be sent to *self* with a selector as specified by the chosen menu option .

Arguments: *self* Pointer to a window instance.

Returns: The choice if selected; else NIL.

Categories: Window

Specializations: LatticeBrowser

(← *self* **WhenMenuItemHeld** *item* - -)

[Method of Window]

Purpose/Behavior: Displays in the system prompt window what will happen when the menu item is chosen. The information displayed will either be the help string for the item or the documentation for the method pointed to by the item.

Arguments: *self* Pointer to a window instance.

item The menu item selector.

Returns: NIL

Categories: Window

WindowButtonEventFn

[Function]

Purpose/Behavior: Invokes the method **ButtonEventFn**.

WindowRightButtonFn

[Function]

Purpose/Behavior: Invokes the method **RightButtonFn**.

(**WindowButtonEventFn** *window*)

[Function]

Purpose/Behavior: This retrieves the value of the Lisp window property **LoopsWindow**. It sends the message **ButtonEventFn** to that window object. If the window object is an instance of **NonRectangularWindow** or one of its subclasses and if the cursor is not within the icon bitmap, nothing occurs.

This is invoked automatically by the system when the cursor is inside of a window object and the left or middle mouse button is pressed.

Arguments: *window* The window that contained the cursor when the mouse button was pressed.

Returns: Used for side effect only.

(**WindowRightButtonFn** *window*)

[Function]

Purpose/Behavior: This retrieves the value of the Lisp window property **LoopsWindow**. It sends the message **RightButtonFn** to that window object. If the window object is an instance of **NonRectangularWindow** or one of its subclasses and if the cursor is not within the icon bitmap, nothing occurs.

This is invoked automatically by the system when the cursor is inside of a window object and the left or middle mouse button is pressed.

Arguments: *window* The window that contained the cursor when the mouse button was pressed.

Returns: Used for side effect only.

19.4.1 Menu Item Structure

The default behavior for the methods **LeftSelection**, **MiddleSelection**, and **RightSelection** causes a menu to pop up. The options that will appear in a menu are defined in various class variables of the window object being selected. (**IconWindows** are an exception). When an option is selected from a menu, a message is sent to the window with no arguments.

The value of the various class variables can be an item list, such as (item1....itemn) where each item can be one of:

- *selector*

In this case, the *selector* appears in the menu, and it is the selector of the message sent to the window.

- (*prompt selector help-string*)

In this case, the *prompt* appears in the menu, and *selector* is the selector of the message sent to the window. *help-string* is printed when the cursor is over the item and the mouse is pressed.

- (*prompt subitemStructure help-string*) where *subitemStructure* = (*defaultSelector itemList*)

This form allows a menu to contain submenus. In this case, the *prompt* appears in the main menu, and *defaultSelector* is the selector of the message sent to the window if the main menu item is selected. *itemlist* defines the submenu behavior.

For example, in the class **Window**, the class variable **LeftButtonItem**s has the following value:

```
((Update (QUOTE Update) "Update window to agree with object IVs"))
```

The class variable **RightButtonItem**s has the value:

```
((Close (Close (Close Destroy))) Snap Paint Clear Bury Repaint  
(Hardcopy (Hardcopy (HardcopyToFile HardcopyToPrinter))) Move Shape  
Shrink)
```

19.4.2 Caching Menus

When a menu is created by pressing a mouse button on a LOOPS window, the menu is cached on a property of the instance variable **menus** if **menus** has the value T. The name of the property where it is stored has the same name as the class variable that describes the menu. The method **ClearMenuCache** will set these properties to NIL, causing the menus to be deleted from the window instance.

19.5 SUBCLASSES OF WINDOW

19.5 SUBCLASSES OF WINDOW

19.5 Subclasses of Window

This section describes the classes **NonRectangularWindow**, **IconWindow**, and **LoopsIcon** and functionality associated with them.

Name	Type	Description
NonRectangularWindow	Class	Provides the capability for windows to act as icons.
CreateWindow	Method	Creates a window that acts like an icon.
EditIcon	Method	Edits an icon bitmap.
EditMask	Method	Edits a mask bitmap.
Invert	Method	Inverts the image of an icon; that is, reverses its black-white pattern.
Shape	Method	Prevents the window from being shaped by calling LoopsHelp .
IconWindow	Class	Provides some menu options for icon windows.
LoopsIcon	Class	Provides an icon that is part of the LOOPS user interface.
PutSavedValue	Function	Stores a value. This is called from within browser and inspector menu events.
SavedValue	Function	Retrieves a saved value.

NonRectangularWindow [Class]

Description:	Provides the capability for windows to act as icons.	
MetaClass:	Class	
Supers:	Window	
Instance Variables:	icon	Allows a bitmap to be used as an icon to be stored in the instance. If the bitMap property is set to a symbol whose value is a bitmap, then that bitmap will be used. The default value is NIL.
	mask	Allows a bitmap to be used as an icon mask to be stored in the instance. If the bitMap property is set to a symbol whose value is a bitmap, then that bitmap will be used. The default value is NIL.

(← self CreateWindow) [Method of NonRectangularWindow]

Purpose:	Creates a window that acts like an icon.	
Behavior:	Determines if icon and mask or the property bitMap have values. If so, it uses those within a call to ICONW . If not, it sends the messages EditIcon and EditMask .	
	This method is invoked by the system if the instance variable window is not yet bound to a value and it is accessed.	
Arguments:	<i>self</i>	A window instance.
Returns:	Value returned from ICONW .	
Categories:	Window	
Specializes:	Window	

(← self EditIcon) [Method of NonRectangularWindow]

Purpose: Edits an icon bitmap.

Behavior: Calls **EDITBM** with the value of the instance variable **icon** and assigns **icon** to the returned value.

Arguments: *self* A window instance.

Returns: Value returned from **EDITBM**.

Categories: NonRectangularWindow

(← *self* **EditMask**) [Method of NonRectangularWindow]

Purpose: Edits a mask bitmap.

Behavior: Calls **EDITBM** with the value of the instance variable **mask** if it is non-NIL, or a copy of **icon**, and assigns **mask** to the returned value.

Arguments: *self* A window instance.

Returns: Value returned from **EDITBM**.

Categories: NonRectangularWindow

(← *self* **Invert**) [Method of NonRectangularWindow]

Purpose: Inverts the image of an icon; that is, reverses its black-white pattern.

Behavior: Modifies the bitmap of the **ICONIMAGE** window property of the Lisp window pointed to by *self*.

Arguments: *self* A window instance.

Returns: Used for side effect only.

Categories: Window

Specializes: Window

(← *self* **Shape**) [Method of NonRectangularWindow]

Purpose/Behavior: Prevents the window from being shaped by calling **LoopsHelp**.

This method is provided to restrict the shaping of this class of window, not to provide additional functionality.

Arguments: *self* A window instance.

Returns: Used for side effect only.

Categories: Window

Specializes: Window

IconWindow [Class]

Description: Provides some menu options for icon windows.

The menu behavior of this class is different from the class **Window** in that the item lists are stored on instance variables and not class variables.

MetaClass: Class

Supers: NonRectangularWindow

Instance Variables: **RightButtonItem**s

A list that defines the menu that will appear when the right mouse button is pressed when the cursor is in the window. The default value is (Move).

MiddleButtonItems

A list that defines the menu that will appear when the middle mouse button is pressed when the cursor is in the window. The default value is NIL.

LeftButtonItems

A list that defines the menu that will appear when the left mouse button is pressed when the cursor is in the window. The default value is (Move).

ShiftMiddleButtonItems

A list that defines the menu that will appear when the middle mouse button is pressed when the cursor is in the window and the **Meta** key is pressed. The default value is NIL.

ShiftLeftButtonItems

A list that defines the menu that will appear when the left mouse button is pressed when the cursor is in the window and the **Meta** key is pressed. The default value is (Move).

LoopsIcon

[Class]

Description: Implements the LOOPS icon which is part of the LOOPS user interface to LatticeBrowsers (see Chapter 10, Browsers).

MetaClass: Class

Supers: NonRectangularWindow

Class Variables: **RightButtonItem**s

A list that defines the menu that will appear when the right mouse button is pressed when the cursor is in the window. The default value is (Close Move).

MiddleButtonItems

A list that defines the menu that will appear when the middle mouse button is pressed when the cursor is in the window. The default value is ("Browse File" (...)).

LeftButtonItems

A list that defines the menu that will appear when the left mouse button is pressed when the cursor is in the window. The default value is ("Browse Class" (...)).

Instance Variables: **savedValue** Used by the functions **PutSavedValue** and **SavedValue**. The default value is NIL.

icon The property **bitMap** has the value **BlackLoopsIconBM**. The default value is NIL.

mask The property **bitMap** has the value **LoopsIconShadow**. The default value is NIL.

(PutSavedValue value)

[Function]

Purpose: Stores a value. This is called from within browser and inspector menu events.

Behavior: Sets the instance variable **savedValue** of the prototype instance of the class **LoopsIcon** to *value*. Also sets the top level binding of **IT** to *value*; see the *Interlisp-D Reference Manual* for information on **IT**.

Arguments: *value* Any arbitrary data.

Returns: *value*

(**SavedValue**)

[Function]

Purpose: Retrieves a saved value.

Behavior/Returns: Gets the value of the instance variable **savedValue** of the prototype instance of the class **LoopsIcon**.

19.6 LISP WINDOWS

19.6 LISP WINDOWS

19.6 Lisp Windows

The methods in this section define the interface between LOOPS windows and Lisp windows. These methods are used internally by the system, and will rarely be used or specialized by users.

Name	Type	Description
AttachLispWindow	Method	Gives a LOOPS window a Lisp window.
CreateWindow	Method	Creates a Lisp window.
DetachLispWindow	Method	Forgets about the current Lisp window.
GetWrappedValue	Method	Gets the value wrapped in the active value.
HasLispWindow	Method	Checks if a Lisp window has ever been created for the LOOPS window.
PutWrappedValue	Method	Replaced the value wrapped in the active value.

(← *self* **AttachLispWindow** *window*)

[Method of Window]

Purpose/Behavior: Used to associate a LOOPS window with a Medley window. This detaches any currently attached window before attaching a new one, and fills in the instance variables **left**, **bottom**, **width**, **height**, and **title** from the Lisp window.

Arguments: *self* An instance of a LOOPS window.
window Must be a window pointer.

Returns: Used for side effect only.

Categories: Window

(← *self* **CreateWindow**)

[Method of Window]

Purpose/Behavior: Creates a Lisp window for a LOOPS window but does not open it.

Arguments: *self* Pointer to a LOOPS window.

Returns: The window.
 Categories: Window
 Specializations: NonRectangularWindow

(← *self* **DetachLispWindow**) [Method of Window]

Purpose/Behavior: Removes the pointer from the LOOPS window to the Lisp window.
 Arguments: *self* Pointer to a LOOPS window.
 Returns: Used for side effect only.
 Categories: Window

(← *self* **GetWrappedValue** *containingObj* *varName* *propName* *type*) [Method of LispWindowAV]

Purpose/Behavior: Used by the system to fetch the Medley window from a LOOPS window. If the local state of this active value is not a window, it is made a window.
 Arguments: *self* An instance of **LispWindowAV**.
 containingObj A LOOPS window.
 varName Variable associated with the wrapped value.
 propName Used internally.
 type Used internally.
 Returns: A Lisp window.
 Categories: LispWindowAv
 Specializes: LocalStateActiveValue

(← *self* **HasLispWindow**) [Method of Window]

Purpose/Behavior: Checks if Lisp window has ever been created for this LOOPS window.
 Arguments: *self* A LOOPS window.
 Returns: The window pointer, if one exists; else NIL.
 Categories: Window

(← *self* **PutWrappedValue** *containingObj* *varName* *newvalue* *propName*) [Method of LispWindowAV]

Purpose/Behavior: Places the window *newvalue* as local state of the active value.
 Arguments: *self* An instance of **LispWindowAV**.
 containingObj A LOOPS window.
 varName Variable associated with the wrapped value.
 propName Used internally.
 type Used internally.

Returns: The window pointer, if one exists.

Categories: LispWindowAV

Specializes: LocalStateActiveValue

20. SYSTEM VARIABLES AND FUNCTIONS

This section describes the following system variables and functions. These variables are set within the file **LOADLOOPS** or when the function **LOADLOOPS** is executed.

Name	Type	Description
LoopsVersion	Variable	Identifies a release of LOOPS.
LoopsDate	Variable	Identifies the date when the function LOADLOOPS is executed.
FEATURES	Variable	Has the symbol LOOPS added to it when the function LOADLOOPS is evaluated.
LoadLoopsForms	Variable	Contains a list of forms that are evaluated when LOOPS is loaded.
LispUserFilesForLoops	Variable	Contains a list of files required by LOOPS .
OptionalLispuserFiles	Variable	Contains a list of files that is loaded when LOOPS is loaded.
LOOPSDIRECTORY	Variable	Contains the connected directory when LOADLOOPS is loaded.
LOOPSLIBRARYDIRECTORY	Variable	Contains the directory where the LOOPS library files reside.
LOOPUSERSDIRECTORY	Variable	Contains the directory where the LOOPS Users' Modules files reside.
LOOPUSERSRULESDIRECTORY	Variable	Contains the directory where the LOOPS Rules User Module file resides.
LoopsPatchFiles	Variable	Contains a list of LOOPS files that are loaded when LOOPS is loaded.
LOOPFILES	Variable	Contains a list of LOOPS files that are loaded by the function LOADLOOPS .
ClearAllCaches	Function	Clears all caches used by LOOPS .
ClearAllCaches	Variable	Contains a list of forms that are evaluated within a call to the function ClearAllCaches .

LoopsVersion	[Variable]

Set to uniquely identify a release of **LOOPS**.

LoopsDate	[Variable]

Set to the value of (DATE) when the function **LOADLOOPS** is evaluated.

FEATURES [Variable]

Has the symbol **LOOPS** added to it when the function **LOADLOOPS** is evaluated. See the *Common Lisp: the Language* for more information on ***FEATURES***.

LoadLoopsForms [Variable]

Contains a list of forms that are evaluated when **LOOPS** is loaded. Initialized to **NIL** using the File Manager command **INITVARS** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*).

LispUserFilesForLoops [Variable]

Contains a list of files required by **LOOPS**. Initialized to (**GRAPHER**).

OptionalLispuserFiles [Variable]

Contains a list of files that is loaded when **LOOPS** is loaded. Initialized to **NIL** using the File Manager command **INITVARS**.

LOOPSDIRECTORY [Variable]

Initialized to the directory from which the file **LOADLOOPS** is loaded using the File Manager command **INITVARS**.

LOOPSLIBRARYDIRECTORY [Variable]

Contains the directory where the **LOOPS** library files reside.

LOOPUSERSDIRECTORY [Variable]

Contains the directory where the **LOOPS** Users' Modules files reside.

LOOPUSERSRULESDIRECTORY [Variable]

Contains the directory where the **LOOPS** Rules User Module file resides.

LoopsPatchFiles [Variable]

Contains a list that can be passed to **FILESLOAD** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*) and is used during the loading of **LOOPS**. Initialized to ((**LOAD FROM VALUEOF LOOPSDIRECTORY**) **MASTERSCOPE MSPARSE**).

LOOPFILES [Variable]

Contains the list of **LOOPS** files loaded by **LOADLOOPS** when building a **LOOPS** sysout.

(ClearAllCaches) [Function]

Purpose: Clears all caches used by **LOOPS**

Behavior: In addition to clearing some caches used to speed up method and instance variable lookup, this clears the hash array **CLISPARRAY** (see the *Lisp Release Notes* and the *Interlisp-D Reference Manual*) and sends the **ClearMenuCache** message to any open LOOPS windows or their icons.

Returns: NIL

ClearAllCaches

[Variable]

Contains a list of forms, each of which is evaluated within a call to the function **ClearAllCaches**. Initially set to NIL.

Overview of the Manual

The *Xerox LOOPS Reference Manual* provides a detailed description of all the methods, functions, classes, and other items available in Xerox's Lisp Object-Oriented Programming System, Xerox LOOPS (TM). This manual describes the Lyric/Medley Release of Xerox LOOPS, which runs under the Lyric and Medley (with a small patch) releases of Xerox Lisp.

This manual is for people who are familiar with Xerox LOOPS programming principles, and is not intended to teach you Xerox LOOPS or how to use it. Please contact your LOOPS distributor for information about classes and training material.

Organization of the Manual and How to Use It

This manual is divided into chapters, with most chapters focusing on a particular aspect of Xerox LOOPS. The organization of this manual is similar to the *Interlisp-D Reference Manual*.

A Table of Contents is included at the beginning of the manual to help you find specific material. Chapters that have four levels of headings also have internal Tables of Contents. At the end of the manual, a Glossary is included to define terms within the context of Xerox LOOPS.

All readers should review Chapter 1, Introduction, before referring to specific material.

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type. Optional arguments are indicated by a dash (-).
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a message sending form appears as follows:

```
(_ self Selector Arg1 Arg2 -)
```

- Examples appear in the following typeface:

```
89_(_LOGIN)
```

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Method names often appear in the form **ClassName.SelectorName**.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

Purpose:	Gives a short statement of what the item does.		
Behavior:	Provides the details of how the item operates.		
Arguments:	Describes each argument in the following format: <table> <tr> <td><i>argument</i></td><td>Description</td></tr> </table>	<i>argument</i>	Description
<i>argument</i>	Description		
Returns:	States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.		
Categories:	A way to group related methods. For example, all the methods related to Masterscope on the class FileBrowser have the category Masterscope, not FileBrowser . This item appears only for methods.		
Specializes:	The next higher class in the class hierarchy that contains a method with the same selector; only appear for methods. For example, the manual entry for RectangularWindow.Open would say that it specializes Window.Open , since Window is the first superclass of RectangularWindow that implements a method for Open .		
Specializations:	The next lower class(es) in the class hierarchy that contains method(s) with the same selector; only appears for methods. For example, the manual entry for Window.Open would say that it has a specialization of RectangularWindow.Open since RectangularWindow is a subclass of Window and has its own version of Open method.		
Example:	An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See Chapter 18, Reading and Printing, for details.

Writer's Notes -- Conventions

This file includes notes on conventions for *Xerox LOOPS Reference Manual*, Koto Release. This manual is packaged with the *Xerox LOOPS Release Notes* and *Xerox LOOPS Library Packages Manual* to form one binder, part number 3103310.

Writer: Rosie (Raven) Kontur

Printing Date: <DD> <MM> 1987

Directories and Files

The directory {ERIS}<Doc>LoopsKoto>Ref> contains the files for the manual. This directory has the following subdirectories:

- {ERIS}<Doc>LoopsKoto>Ref>X-Index> contains IMPTR files needed to produce the index as well as the index itself.
- {ERIS}<Doc>LoopsKoto>Ref>Z-ReleaseInfo> contains this file on writing conventions and a file on production details.

Filenames describe the contents of the file. For example, the filename

{ERIS}<Doc>LoopsKoto>Ref>Ch01-Intro.tedit

contains Chapter 1, Introduction.

Some chapters (for example, 5, 10, and 19) have internal tables of contents. Chapter 10, which is the largest chapter and has the most bitmaps, is divided among three files.

Assemble the files in the following order for the manual:

```
{ERIS}<Doc>LoopsKoto>Ref>A1-TitlePage.tedit
{ERIS}<Doc>LoopsKoto>Ref>A2-TOC.tedit
{ERIS}<Doc>LoopsKoto>Ref>A3-LOF.tedit
{ERIS}<Doc>LoopsKoto>Ref>A4-Preface.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch01-Intro.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch02-Instances.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch03-Classes.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch04-Metaclasses.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch05-TOC.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch05-ActiveValue.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch06-Methods.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch07-MsgForms.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch08-IterStmts.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch09-Misc.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch10-TOC.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch10a-Browsers1.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch10b-Browsers2.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch10c-Browsers3.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch11-Errors.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch12-Breaking.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch13-Editing.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch14-FilePkg.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch15-Masterscope.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch16-Performance.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch17-Processes.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch18-ReadPrint.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch19-TOC.tedit
{ERIS}<Doc>LoopsKoto>Ref>Ch19-UserIOPkgs.tedit
```

```
{ERIS}<Doc>LoopsKoto>Ref>Ch20-Windows.tedit  
{ERIS}<Doc>LoopsKoto>Ref>PndxA-Previous.tedit  
{ERIS}<Doc>LoopsKoto>Ref>ZZ-Glossary.tedit  
{ERIS}<Doc>LoopsKoto>Ref>X-Index>Index-Final.tedit
```

About the Index

Creating a properly formatted index takes a certain amount of work (about 2 hours).

- Type in your Executive (`TEDIT (MAKE.IM.INDEX T NIL '(filenames) NIL)`)
- Save the resulting file in {ERIS}<Doc>LoopsKoto>Ref>RefIndex-Raw.tedit.
- Now start dithering. The task is to change all the separators in the file. For example, the index program returns pages in the form 1.2; 10.5,38; 18.3-4. The Index format we use is in the form 1-2; 10-5; 10-38; 18-3. Unfortunately, you can't make all the necessary changes in a global substitute, since many of the separators are also in the text and the comma requires that you repeat the chapter number. Here goes:
 - Fix the commas. Do a Find on a comma (,). Everywhere a comma occurs in a page number, change it to a semicolon (;) and repeat the chapter number and a dot before the page number. For example, 10.5,38 becomes 10-5; 10-38.
 - Fix the dashes. Do a Find on a dash (-). Everywhere a dash occurs in a page number, delete it and the following page number.
 - Fix the period. Except for the form #., you can use a global substitute from a period to a dash (. to -). This takes about 20-30 minutes, as there are about 700 substitutions.

I really recommend saving the file at this point.

- Hardcopy the index. Make whatever page breaks and other changes you feel are necessary. Make a final hardcopy and save the file.

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

```
(_ self Selector Arg1 Arg2)
```

- Examples appear in the following typeface:

```
89_ ( _ LOGIN )
```

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form **ClassName.SelectorName**.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

This manual describes the Xerox LOOPS items (functions, methods, etc.) by using the following template:

Purpose:	Gives a short statement of what the item does.		
Behavior:	Provides the details of how the item operates.		
Arguments:	Describes each argument in the following format: <table><tr><td><i>argument</i></td><td>Description</td></tr></table>	<i>argument</i>	Description
<i>argument</i>	Description		
Returns:	States what the item returns, and does not appear if the item does not return a value. The phrase "Used as a side effect only." means that the purpose of the item is to perform a computation or action that is independent of any returned value, not to return a particular value.		
Categories:	A way to group related methods. For example, all the methods related to Masterscope on the class FileBrowser have the category Masterscope, not FileBrowser . This item appears only for methods.		
Specializes:	The next higher class in the class hierarchy that contains a method with the same selector. For example, RectangularWindow.Open can specialize Window.Open . This appears only for methods.		
Specializations:	The next lower class in the class hierarchy that contains a method with the same selector. For example, Window.Open is a specialization of RectangularWindow.Open . This appears only for methods.		
Example:	An example is often included to show how to use the item and what result it produces. Some examples may appear differently on your system, depending on the settings of various print flags. See Chapter 18, Reading and Printing, for details.		

Style Sheet Addenda

Here are some guidelines I used when writing the LOOPS manuals. Items appear in rather random order.

- Avoid contractions.
- Avoid subscripts. Use WORD1 rather than WORD to avoid inconsistent line leading.
- Avoid wording that starts "Note that..." or "Notice that...". Either make it a note with correct format or eliminate the "Note that".
- Use semicolons rather than m-dashes.
- Each item in the template starts with an initial capital letter; e.g., "Describes..."
- The arguments are identical in the call and in the argument description.
- Parentheses appear around expressions and square brackets appear around the name of the functionality.
- The arrow in the expression is the NS character ←, not _ . These characters appear similarly when printed, but differently on the screen. See the section, "Special Notes and Cautions," for details.
- A period appears after the word None, after argument descriptions, and Returns: item.
- Items are set to or return T (instead of true).

- Menus contain options, not items or selections.
- You drag (not roll) the mouse to the right of a menu option to see its submenu.
- Use "above" and "below" when referring to things in the same section, section numbers and names when referring to things in the same chapter, and chapter numbers and names when referring to things in another chapter.
- Please study the following style sheet carefully before you start to edit. The various appearances of active value and annotated values are especially crazy making.

These things appear in **bold**:

class variables
functions
instance variables
messages
methods
variables

ActiveValue - specific class/instance

active value - general information

activeValue - previous implementation of **ActiveValue**

annotatedValue - data type

AnnotatedValue - specific class

annotated values - general information

bitmap

data type

file package

filecoms

inspector

Lisp Library package

localState - instance variable

non-NIL

prettyprints

supers list

Paragraph Formatting

The text has the following format:

Paragraph-Looks Menu

Bitmaps, Graphs, and Sketches

Scale for bitmaps is 0.8.

Special Notes and Cautions

Make sure you have changed the underscore to be a left arrow before loading any files. To do this,

- Enter the following commands into your Executive:

```
(GETCHARBITMAP (CHARCODE _) '(MODERN 10 MRR))
(EDITBM IT)
```

- When the bitmap editor appears, delete the underscore and insert the following left arrow:

```
.....
.....
.....
.....
.....
...X....
...XX...
..XXXXXX.
...XX...
...X....
.....
.....
.....
.....
```

- Finally, enter the following commands into your Executive to store the pattern:

```
(PUTCHARBITMAP (CHARCODE _) '(MODERN 10 MRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(MODERN 10 BRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 MRR) IT)

(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 BRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 12 BRR) IT)
```

Writer's Notes -- Production Details

This file includes notes on the production of *Xerox LOOPS Reference Manual*, Koto Release. This manual is packaged with the *Xerox LOOPS Release Notes* and *Xerox LOOPS Library Packages Manual* to form one binder, part number 3103310.

Writer: Rosie (Raven) Kontur

Printing Date: <DD> <MM> 1987

Files Needed

To edit or print the manual, make sure you have the following files loaded:

IMTOOLS
SKETCH
GRAPHER

Fonts Used

{ERIS}<LISP>FONTS>

Modern font

18-point bold
14-point bold
12-point bold
10-point regular
10-point italic
10-point bold

Terminal font

12-point bold
10-point regular
10-point bold

Printing Information

The manual was printed under a Lyric sysout on the Tsunami printer.

Artwork

- The art for the Beta Release was created in Pasadena, and is not in any files here.
- The file {ERIS}<Dc>LoopsBeta>BinderCover.tedit contains the cover page for the binder.
- The file {ERIS}<Doc>LoopsBeta>CommentForm.tedit contains the comment form for the entire documentation set. The prepaid mailer (see department file) must be added to complete this form.

WRITER'S NOTES

- The details for packaging are in the following files:
 {ERIS}<Doc>loops>ProductionSpecs>onfiguration-request.tedit
 {ERIS}<Doc>loops>ProductionSpecs>Packaging.tedit

abstract class	A class which cannot be instantiated, for example, ActiveValue .
active value	The mechanism that carries out access-oriented programming for variables in Xerox LOOPS. Active values send messages as a side effect of having an object's variable referenced.
activeValue	The previous implementation of the active value concept.
ActiveValue	An abstract class that defines the general protocol followed by all active value objects.
annotatedValue	A special Interlisp-D data type that wraps each ActiveValue instance.
AnnotatedValue	An abstract class that allows an annotatedValue to be treated as an object.
browser	A window that allows you to examine and change items in a data structure.
class	A description of one or more similar objects; that is, objects containing the same types of data fields and responding to the same messages.
class inheritance	The means by which a class inherits variables, values, and methods from its super class(es).
class lattice	A network showing the inheritance relationship among classes.
class variable (CV)	A variable that contains information shared by all instances of the class. A class variable is typically used for information about a class taken as a whole.
inheritance	The means by which you can organize information in objects, create objects that are similar to other objects, and update objects in a simplified way.
Inspector	A Xerox Lisp display program that has been modified to allow you to view classes, objects, and active values.
instance	An object described by a particular class. Every object within Xerox LOOPS is an instance of exactly one class.
instance variable (IV)	A variable that contains information specific to an instance.
instantiate	To make a new instance of a class.
lattice	An arrangement of nodes in a hierarchical network, which allows for multiple parents of each node.
Masterscope	A Xerox Lisp Library Module program analysis tool that has been modified to allow analysis of Xerox LOOPS files.
message	A command sent to an object that activates a method defined in the object's class. The object responds by computing a value that is returned to the sender of the message.
metaclass	Classes whose instances are classes or abstract classes.
method	What an object applies to the arguments of a message it receives. This is similar to a procedure in procedure-oriented programming, except that here, you determine the message to send and the object receiving the message.

	determines the method to apply, instead of the calling routine determining which procedure to apply.
mixin	A class that is used in conjunction with another class to create a subclass. Mixins never have instances, and hence have AbstractClass as their metaclass.
object	A data structure that contains data and a pointer to functionality that can manipulate the data.
property list	A place for storing additional information on classes, their variables, and their methods.
selector	Part of a message that is sent to an object. The object uses the selector to determine which method is appropriate to apply to the message arguments.
self	A method argument that represents the receiver of the message.
specialization	The process of creating a subclass from a class, or the result of that process.
subclass	A class that is a specialization of another class.
super class	A class from which a given class inherits variables, values, and methods.
Tofu	An acronym for Top of the universe, which is the highest class in the Xerox LOOPS hierarchy.
Unique Identifier (UID)	An alphanumeric identifier that Xerox LOOPS uses to store and retrieve objects. Objects do not have UIDs unless they are named, are instances of indexed objects, or are instances printed to a file.
wrap	Objects have fields that can contain data. Some ActiveValue can be added so this data is stored within it. When this occurs, the ActiveValue wraps the data.

1. **RELEASE OVERVIEW**

LOOPS is a multiple-paradigm programming system designed to be used in a variety of artificial intelligence applications. LOOPS requires the Medley Release of Lisp.

1.1 System Configuration

You need the following minimum configuration to run Xerox LOOPS:

1186 Workstation	1108 Workstation
40 megabyte disk drive	40-42 megabyte disk drive
2 megabyte memory	2 megabyte memory

1.2 What's Included in This Release

Xerox LOOPS includes the following items:

- Software on floppy disks.

See Chapter 2, Changes from Koto LOOPS, for how the Lyric/Medley Release of LOOPS is different from the Koto Release.

- Documentation in binders.

See Chapter 3, Release Documentation, for details of release documentation.

[This page intentionally left blank]

2. CHANGES FROM KOTO LOOPS

This chapter describes how the current release of LOOPS, Lyric/Medley LOOPS, differs from the Koto Release. With the addition of a patch file, the current Loops release will also run under the Medley release. The inclusion of the patch file is automatically handled by the LOOPS installation process. To convert Koto LOOPS files into Lyric/Medley LOOPS files, see the LOOPS Users' Modules CONVERT-LOOPS-FILES.

A number of significant fixes to both the documentation and software have been made. In addition, LOOPS behaves differently due to new features of Lisp found beginning with the Lyric release:

- LOOPS vs. Packages

Lyric has Common Lisp functionality, including packages and new case-insensitive readtables. All LOOPS symbols are in the INTERLISP: or IL: package, and LOOPS is case-sensitive, so it is much easier to type LOOPS expressions into an Interlisp Exec (see the *Lisp Release Notes, Lyric Release*, for more on different Exec types).

- Editing

Lyric has a new default structure editor, SEdit. DEdit is still available as a Lyric Library Module, but most people find SEdit to be much faster and easier to use. SEdit has no specific LOOPS support features yet, but the features it has support LOOPS rather well. As an example, all Lyric LOOPS development was done using SEdit. See the *Lisp Release Notes, Lyric and Medley Releases*, for more information on SEdit.

- Source File Management

LOOPS source forms are no longer LAMBDATRAN forms; instead they use the definer system which also handles Common Lisp forms in Lyric and Medley (see the *Common Lisp Implementation Notes* for more on definers). This has several consequences:

- The source file format for Lyric/Medley LOOPS is different. A conversion utility is provided which takes Koto LOOPS source files and converts them to Lyric/Medley LOOPS format. The converter will not work correctly on source files from the prototype Buttress version of LOOPS. These files must first be converted using Koto LOOPS.
- LOOPS source forms are no longer of filetype FNS; they are instead METHOD-FNS.
- Comments may appear anywhere in a definer form, since the definer system removes them before making the form executable. This also means that various comments that the LOOPS system uses as help information (doc properties and first comments in method code) now need to be strings rather than comments, so the definer system will not remove them. The conversion utility handles this for most important comments; new code should use strings in these places.
- Method bodies can now be CL:LAMBDA or IL:LAMBDA, by using the **Method** function and specifying a keyword when creating the method. A

LOOPS CL:LAMBDA method can have Common Lisp features like &rest and :keywords.

- Masterscope

Masterscope is now a LOOPS Library Module, to match Masterscope becoming a Lisp Library Module in the Lyric release of XAIE, primarily because Masterscope does not support Common Lisp yet. Masterscope still supports LOOPS, however, and many bugs in that support from Buttress and Koto LOOPS have been fixed.

When using LOOPS Masterscope, quote all Method Names that you use. The Masterscope parser currently will not recognize Method Names unless they are quoted.

- ICONW

ICONW is now a part of Lisp and no longer needs to be loaded to run LOOPS.

- New Compiler

Lyric/Medley LOOPS uses the new Lyric compiler, which handles Common Lisp. This has several consequences:

- **_Super** and the other similar functions are now lexically scoped; that is, it is now illegal to call **_Super** anywhere but within a method body, and any selector given must be the same as the selector for that method.

- Files compiled by the new compiler have no FILECOMS. Use

```
(LOADFROM <FILE> NIL 'ALLPROP)
```

to load Source files so that LOOPS browsers can find them.

- The .DFASL output of the new compiler loads much faster than .DCOMs or the .LCOMs of Lyric.

The ByteCompiler is no longer supported for compilation of LOOPS files. With the new compiler and its macrolet facilities, a cleanup of LOOPS files requires that *DEFAULT-CLEANUP-COMPILER* be set to 'CL:COMPILE-FILE. The *Lisp Release Notes*, *Lyric Release*, contain more information on the new compiler and the cleanup flag. The ByteCompiler is no longer supported for compilation of LOOPS files.

- LOOPS Library Modules

SSDigiMeter will be removed from Gauges in the next release of LOOPS. DigiMeters are inherently self scaling because Meters are. Therefore, **SSDigiMeter** is redundant. Note that SSDigiMeters are also generally slower than DigiMeters.

[This page intentionally left blank]

Overview of the Manual

These Release Notes describe the Lyric/Medley Release of software for Xerox's Lisp Object-Oriented Programming System, LOOPS (TM). This document is directed to the people responsible for installing and testing LOOPS.

This manual describes the Lyric/Medley Release of LOOPS, which runs under the Lyric and Medley (with a small patch) Releases of Lisp.

Organization of the Manual and How to Use It

These Release Notes contain important information about the Lyric/Medley Release of LOOPS. The following chapters outline the major features of LOOPS, and highlight the principal differences between this and previous versions of LOOPS.

All readers should carefully read Chapter 1, Release Overview, Chapter 5, Reporting Procedure, and Chapter 6, Known Problems. Reading Chapter 2, Changes from Koto LOOPS, and Chapter 3, Release Documentation, is recommended for all readers. People responsible for installing LOOPS should read Chapter 4, Installation Procedures.

Conventions

These Release Notes use the following conventions:

- Case is significant in LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(← *self* **Selector** *Arg1 Arg2*)

- Examples appear in the following typeface:

89← (←LOGIN)

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

Xerox Lisp Release Notes, Lyric and Medley Releases

Xerox Lisp Library Modules Manual, Lyric and Medley Releases

1. **RELEASE OVERVIEW**

Xerox LOOPS is a multiple-paradigm programming system designed to be used in a variety of artificial intelligence applications. Xerox LOOPS runs on the Xerox 1100 series of Artificial Intelligence Workstations and requires the Lyric or Medley Release of Lisp running on the Xerox Artificial Intelligence Environment (XAIE).

1.1 System Configuration

You need the following minimum configuration to run Xerox LOOPS:

1186 Workstation	1108 Workstation
40 megabyte disk drive	40-42 megabyte disk drive
2 megabyte memory	2 megabyte memory

1.2 What's Included in This Release

Xerox LOOPS includes the following items:

- Software on floppy disks.

See Chapter 2, Changes from Koto LOOPS, for how the Lyric/Medley Release of Xerox LOOPS is different from the Koto Release.

- Documentation in binders.

See Chapter 3, Release Documentation, for details of release documentation.

[This page intentionally left blank]

2. CHANGES FROM KOTO LOOPS

This chapter describes how the current release of Xerox LOOPS, Lyric/Medley LOOPS, differs from the Koto Release. The current Xerox LOOPS release runs under the Lyric release of Xerox Lisp. With the addition of a patch file, the current Xerox Loops release will also run under the Xerox Lisp Medley release. The inclusion of the patch file is automatically handled by the LOOPS installation process. To convert Koto LOOPS files into Lyric/Medley LOOPS files, see the Xerox LOOPS Users' Modules CONVERT-LOOPS-FILES.

A number of significant fixes to both the documentation and software have been made. In addition, Xerox LOOPS behaves differently due to new features of Xerox Lisp found beginning with the Lyric release:

- Xerox LOOPS vs. Packages

Lyric has Common Lisp functionality, including packages and new case-insensitive readtables. All Xerox LOOPS symbols are in the INTERLISP: or IL: package, and Xerox LOOPS is case-sensitive, so it is much easier to type Xerox LOOPS expressions into an Interlisp Exec (see the *Xerox Lisp Release Notes, Lyric Release*, for more on different Exec types).

- Editing

Lyric has a new default structure editor, SEdit. DEdit is still available as a Lyric Library Module, but most people find SEdit to be much faster and easier to use. SEdit has no specific Xerox LOOPS support features yet, but the features it has support Xerox LOOPS rather well. As an example, all Lyric LOOPS development was done using SEdit. See the *Xerox Lisp Release Notes, Lyric and Medley Releases*, for more information on SEdit.

- Source File Management

Xerox LOOPS source forms are no longer LAMBDATRAN forms; instead they use the definer system which also handles Common Lisp forms in Lyric and Medley (see the *Xerox Common Lisp Implementation Notes* for more on definers). This has several consequences:

- The source file format for Lyric/Medley LOOPS is different. A conversion utility is provided which takes Koto LOOPS source files and converts them to Lyric/Medley LOOPS format. The converter will not work correctly on source files from the prototype Buttress version of LOOPS. These files must first be converted using Koto LOOPS.
- Xerox LOOPS source forms are no longer of filetype FNS; they are instead METHOD-FNS.
- Comments may appear anywhere in a definer form, since the definer system removes them before making the form executable. This also means that various comments that the Xerox LOOPS system uses as help information (doc properties and first comments in method code) now need to be strings rather than comments, so the definer system will not remove them. The conversion utility handles this for most important comments; new code should use strings in these places.
- Method bodies can now be CL:LAMBDA's or IL:LAMBDA's, by using the **Method** function and specifying a keyword when creating the method. A

Xerox LOOPS CL:LAMBDA method can have Common Lisp features like &rest and :keywords.

- Masterscope

Masterscope is now a Xerox LOOPS Library Module, to match Masterscope becoming a Xerox Lisp Library Module in the Lyric release of XAIE, primarily because Masterscope does not support Common Lisp yet. Masterscope still supports Xerox LOOPS, however, and many bugs in that support from Buttress and Koto LOOPS have been fixed.

When using LOOPS Masterscope, quote all Method Names that you use. The Masterscope parser currently will not recognize Method Names unless they are quoted.

- ICONW

ICONW is now a part of Xerox Lisp and no longer needs to be loaded to run LOOPS.

- New Compiler

Lyric/Medley LOOPS uses the new Lyric compiler, which handles Common Lisp. This has several consequences:

- **_Super** and the other similar functions are now lexically scoped; that is, it is now illegal to call **_Super** anywhere but within a method body, and any selector given must be the same as the selector for that method.

- Files compiled by the new compiler have no FILECOMS. Use

```
(LOADFROM <FILE> NIL 'ALLPROP)
```

to load Source files so that Xerox LOOPS browsers can find them.

- The .DFASL output of the new compiler loads much faster than .DCOMS or the .LCOMS of Lyric.

The ByteCompiler is no longer supported for compilation of LOOPS files. With the new compiler and its macrolet facilities, a cleanup of LOOPS files requires that *DEFAULT-CLEANUP-COMPILER* be set to 'CL:COMPILE-FILE. The *Xerox Lisp Release Notes*, *Lyric Release*, contain more information on the new compiler and the cleanup flag. The ByteCompiler is no longer supported for compilation of LOOPS files.

- LOOPS Library Modules

SSDigiMeter will be removed from Gauges in the next release of LOOPS. DigiMeters are inherently self scaling because Meters are. Therefore, **SSDigiMeter** is redundant. Note that SSDigiMeters are also generally slower than DigiMeters.

[This page intentionally left blank]

3. RELEASE DOCUMENTATION

This chapter describes the documentation that is part of Xerox LOOPS.

3.1 Xerox LOOPS Reference Manual

This manual provides a detailed description of all the methods, functions, classes, and other items available in Xerox LOOPS. This manual is for people who are already familiar with Xerox LOOPS programming principles.

3.2 Xerox LOOPS Library Modules Manual

This manual describes the Xerox LOOPS Library Modules: Gauges, Masterscope, and Virtual Copies. This manual is for people who want to use the additional features that these Library Modules provide.

3.3 Xerox LOOPS Users' Modules Manual

This manual describes the various Xerox LOOPS Users' Modules. This manual is for people who want to use the additional features that these Users' Modules provide.

[This page intentionally left blank]

4. INSTALLATION PROCEDURES

This chapter describes how to install the Xerox LOOPS program files, Library Modules program files, and Users' Modules program files on both the 1186 and 1108 workstations. The installation procedure for Xerox LOOPS is the same for both the Lyric and Medley releases.

4.1 Overview of the Distribution Kits

The distribution kits for Xerox LOOPS are different for the 1186 and the 1108.

4.1.1 1186 Distribution Kit

The distribution kit for Xerox LOOPS on the 1186 consists of four 5-1/4" diskettes:

- Lyric/Medley LOOPS System #1, which contains Xerox LOOPS program files.
- Lyric/Medley LOOPS System #2, which contains Xerox LOOPS program files.
- Lyric/Medley LOOPS Library, which contains the program files for the Xerox LOOPS Library Modules.
- Lyric/Medley LOOPS Users, which contains the program files for Xerox LOOPS Users' Modules.

4.1.2 1108 Distribution Kit

The distribution kit for Xerox LOOPS on the 1108 consists of three 8" diskettes:

- Lyric/Medley LOOPS System, which contains Xerox LOOPS program files.
- Lyric/Medley LOOPS Library, which contains the program files for the Xerox LOOPS Library Modules.
- Lyric/Medley LOOPS Users, which contains the program files for Xerox LOOPS Users' Modules.

4.2 Preparation

Before installing Xerox LOOPS, make sure that you have performed the following steps:

- Load the Lyric or Medley version of Xerox Lisp. Have your Lyric or Medley Release Kit handy if you are not on a network, as you may need to load parts of Lyric or Medley Xerox Lisp not previously loaded.

A standard partition of 8 MB is acceptable. A LOOPS sysout with an average number of LISP Library and LOOPS Users' Modules will require about 11,000 pages or 5 MB.

- Boot Xerox Lisp
- Open an Interlisp Executive Window.
- Make certain the time is set.

Machines on a Xerox network automatically get the current time of day from the net when they boot. If you are not on a network, make certain that the function (DATE) returns the current date and time. If it does not, then use the function (SETTIME) to correct it.

CAUTION

Rebooting a VMEM.PURE.STATE sysout without an Ethernet connection and without the time being set will erroneously allow you to create objects without informing you that the time is not set.

4.3 Installation

The Lyric/Medley LOOPS installation tool makes the installation of Xerox LOOPS, its Library Modules, and Users' Modules almost identical for 1186 and 1108 workstations. The differences are in the names of floppies. 1186 floppies are smaller, so there are more of them to hold the same data. The installation tool will determine what workstation you are using and prompt you with the appropriate floppy names.

1. Have your Lyric/Medley Release Kit handy, or, if you are connected to a network, set the **DIRECTORIES** and **DISPLAYFONTDIRECTORIES** variables appropriately so the sysout can find your Lyric library and font files.

2. Make the floppy drive your connected directory:

```
CONN {FLOPPY}
```

```
DIR {FLOPPY}
```

3. If you are using an 1108 workstation, insert the floppy labeled *Lyric LOOPS System*. If you are using an 1186 workstation, insert the floppy labeled *Lyric LOOPS System #1*. Enter the following into your Exec:

```
LOAD (LOOPS)
```

A menu will appear that looks like this:

```

Loops System
Install from floppies
Load into sysout

```

4. Select the menu option **Install from floppies**.

The following menu will appear:

Loops directories	Click here when done
LOOPSDIRECTORY	{DSK}<LISPFILS>LOOPS>
LOOPSLIBRARYDIRECTORY	{DSK}<LISPFILS>LOOPS>LIBRARY>
LOOPUSERSDIRECTORY	{DSK}<LISPFILS>LOOPS>USERS>
LOOPUSERSRULESDIRECTORY	{DSK}<LISPFILS>LOOPS>RULES>

This menu shows the current (or default, if unset) values of the variables LOOPS examines when it loads things.

- If you want LOOPS installed on your local disk under {DSK}<LISPFILS>LOOPS>, just select **Click here when done**. LOOPS requires approximately 2200 pages on the local disk.
- If you want LOOPS installed somewhere else, select the directory names using the left mouse button. Change the directory names by backspacing over them and typing new locations; select **Click here when done** when you are finished.

5. The installation tool prompts you for floppies with this menu:

```

Please insert floppy Lyric LOOPS System
Click here when done

```

It copies the LOOPS files from the floppies to the directories you just specified in the menu.

When the installation tool asks you for a floppy, insert the floppy in the drive, then select **Click here when done**.

As the last installation step, the installation tool modifies the file LOOPS, writes it out to LOOPSDIRECTORY, and compiles it.

When installation is finished, the first menu reappears:

```

Loops System
Install from floppies
Load into sysout

```

6. Select the menu option **Load into sysout** to load LOOPS into your system. The following menu appears:

```

Load Which?
Loops
Loops Masterscope
Gauges
LoopsBackwards
VirtualCopy

```

7. Select **LOOPS** from the menu to load LOOPS from the location where you installed it.

Once LOOPS is loaded the LOOPS System menu reappears. To load one of the other LOOPS library or User modules, select the appropriate name in the Load Which? menu.

8. Position your mouse cursor anywhere on the screen except for the Load Which? menu, then press the left mouse button to exit the installation procedure.

To load LOOPS in the future, after the installation procedure is finished, load the LOOPS.DFASL file which the installation procedure created:

```
(CNDIR LOOPS DIRECTORY)
```

```
(LOAD 'LOOPS.DFASL)
```

This will load the rest of LOOPS.

When you perform a CNDIR, LOOPS DIRECTORY in the example above is the directory you defined in Step 4; e.g.,

```
(CNDIR ' {DSK}<LISPFILES>LOOPS>)
```

LISPUSERSDIRECTORIES should point to a directory containing GRAPHER.LCOM, and DISPLAYFONTDIRECTORIES should point to a directory containing the Helvetica display font files from your Lyric or Medley XAIE distribution floppies.

CAUTION

LOOPS uses the new XAIE compiler and its macrolet facilities. When LOOPS is loaded, it sets your ***DEFAULT-CLEANUP-COMPILER*** to **'CL:COMPILE-FILE**. More information on this cleanup flag and the new compiler is available in the *Xerox Lisp Release Notes, Lyric Release*.

[This page intentionally left blank]

5. REPORTING PROCEDURE

If you have problems with this release, file an Action Request (AR) Bug Report.

[This page intentionally left blank]

6. KNOWN PROBLEMS

This chapter is a compilation of known problems in the Lyric/Medley Release of Xerox LOOPS. These problems are in the form of Action Requests (ARs) from the Xerox AR data base, followed by a brief description.

The ARs are divided into the following categories:

- Installation
- Instances
- Classes
- MetaClasses
- Active values
- Browsers
- Breaking and tracing
- File Manager
- Masterscope
- Extensions to ?=
- Windows
- System Variables and Functions
- Xerox LOOPS Library Packages
- Conversion to newer releases

6.1 Installation

AR	Description
10169	During the installation process, if fonts need to be loaded the LOOPS installer will try to write them to the directory on the front (CAR) of the list DISPLAYFONTDIRECTORIES. Workaround: Be sure that this is a directory you can write to, e.g. by pushing the name of a local directory onto the list like "{dsk}<lispfiles>fonts>." Grapher is loaded into the current sysout without being copied to a local directory; you may wish to do this and put that directory on your DIRECTORIES list.

6.2 Instances

AR	Description
9225	The implementation of multiple names for instances has NOT been changed in the Lyric/Medley release of LOOPS. However, some conditions which previously caused instances to appear twice on a file have been fixed.

6.3 Classes

AR	Description
8881	The Supers MACRO is not documented. It retrieves the supers of the given class. It accepts a class object as an argument and returns a list of class objects.
9134	Caution: ListAttribute (page 3-27) finds non-local IVPROPS on classes.
9881	To use the method CVMissing, it is necessary to define a class called MyClass which is a specialization of the class Class. Then the CVMissing method is specialized at this level (in MyClass). Finally, a class Foo is defined whose metaclass is MyClass. At this point the expression <pre>(GetClassValue (_ (\$ Foo) New) 'NewCV)</pre> can be evaluated and a new class variable will be created.
9884	To create a class / instance variable without a value the variable should be set to the value of NotSetValue .

6.4 MetaClasses

AR	Description
10049	A new low level accessor function has been defined for programmers who wish to implement their own inheritance schemes. (FetchMethodLocally classobj selector) If <i>classobj</i> has a method for <i>selector</i> returns its name, otherwise NIL.

6.5 Active Values

AR	Description
9158	If an IndirectVariable points at an ActiveValue in a remote object then the remote active value's Get or PutWrappedValue method is

triggered with the **containingObj** argument holding the object containing the **IndirectVariable**.

6.6 Browsers

AR	Description
9244	The behavior of LatticeBrowser and ClassBrowser are different for AddRoot. Workaround: The example for AddRoot in section 10.5.3 should be changed to: The following creates an instance of LatticeBrowser and adds Tofu as a root: <pre>54_ (_ (\$ LatticeBrowser) New 'LB1) 55_ (_ (\$ LB1) AddRoot 'Tofu)</pre>
9851	Section 10.3.2.7 "Extending Functionality with the Left Mouse Button:" should be modified as follows. On the 1186 the COPY key is similar to SHIFT, the MOVE and CTRL keys behave similarly, and META and SAME are similar as well.
9859	The specialization of LatticeBrowser methods into ClassBrowser methods is not enumerated. In section 10.5 "Programmer's Interface to Lattice Browsers," some methods are described which take different arguments when invoked on Class Browsers, e.g., BoxNode sent to a ClassBrowser does not allow the unboxPrevious flag.
10010	The documentation for NewItem in section 10.5.3 has the following additional information: Purpose: Gets an object, prompting the user if necessary. Behavior: ...to be added. NewItem accepts only names and maps them to objects using \$!. If no name is entered at the prompt (by pressing return), NewItem returns NIL.
10367	When specializing a method from the class browser, if there are no methods to inherit, other than generic methods from Object, the menu lists methods already defined in the current class. Be careful about specializing methods defined directly under Object.

6.7 Breaking and Tracing

AR	Description
10356	BT will not show the send frames for broken methods. Workaround: You can do BT! and grab the method name from the *APPLY* frame. Inspect the METHOD-FNS definition of it.

6.8 File Manager

AR	Description
9159	Renaming a method does not smash the associated old symbol's function definition.
9166	Renaming a method does not remove the associated old method-fns definition from the file manager's change list.
10484	CLASS coms compiled by Lyric/Medley LOOPS are combined into a single large form that is read all at once. This causes occasional "Class x not defined, defining one now." messages to appear. Aside from the inconvenience of not seeing the names of classes during compilation, this should not cause problems.

6.9 MasterScope

AR	Description
9911	When LOOPS MasterScope analyzes forms like <pre>(LET* ((A B) (C (F A))) --)</pre> dwim asks about what it thinks is an unbound use of A. The analysis is correct, however.

6.10 Extensions to ?=

AR	Description
9828	? = documentation for the ClassBrowser methods is not available.

6.11 Windows

AR	Description
9243	PutSavedValue and SavedValue have not been removed from this release of Xerox LOOPS. We no longer plan to remove them.
10040	There are two new methods on the Window class: <pre>(_ window Open?)</pre> returns non-NIL if window is a LOOPS Window and is open. <pre>(_ window Shade shade)</pre> shades a LOOPS Window if it's open. The <i>shade</i> argument defaults to the value of GRAYSHADE1 .

6.12 System Variables and Functions

AR	Description
9222	The variable LispUserFilesForLoops actually names Lisp Library modules.

6.13 Xerox LOOPS Library Modules

AR	Description
9797	After VirtualCopyMixin classes are "destroyed," instances of them can still be created without an error occurring.
9868	If a gauge is Attach 'ed to one value, and then Attach 'ed to another value the title of the gauge will not change even though the gauge will display the new value.
9871	Sending a Shape message to a Meter with the ExtraSpaceFlag set to T has no effect.

6.14 Conversion to Newer Releases

AR	Description
10404	There is currently no really convenient way of converting instance files from Buttriss into Koto and Lyric/Medley. However, one can load LOOPSBACKWARDS , which modifies the OLD-INTERLISP-FILE readtable to handle the older style instances. Then one can read instances individually from the file and write them into a new file. In the new file they will be correctly formatted in the new manner.

This appendix describes how to install the LOOPS System files, Library Modules files, and Users' Modules files on the Sun Workstation.

Overview of the Distribution Kit

The distribution kit for LOOPS on the Sun consists of a single ¼-inch tape cartridge. It contains the complete release in "tar" format and creates appropriate directories when its contents are extracted.

Preparation

Preparing to install LOOPS requires that the Medley release of Lisp is already installed and that adequate file space is available.

Before installing LOOPS, remember that

- the Medley 1.0-S release of Lisp must already be installed on your Sun Workstation;
- the complete LOOPS distribution requires about 1.2 MBytes of file space.

Installation

The software installation procedure shows the steps required for installing the Lyric/Medley LOOPS software on a Sun Workstation with Medley 1.0-S already installed. Examples are given where appropriate. Only those users who are system administrators and have **root** privileges can install the LOOPS, Lyric/Medley release.

Before starting software installation, remember that the LOOPS software requires about 1.2 MBytes of file space.

1. Log in under your username.

```
login yourname
```

```
prompt%
```

where **yourname** is replaced by your username.

2. Check for available space with the **df** command:

```
prompt% df
```

Filesystem	kbytes	used	avail	capacity	Mounted on
/dev/xy0a	7437	5470	1223	82%	/
/dev/xy0h	148455	4900	128709	96%	/usr/misc

3. Determine if you need to run **su** to make a directory for the distribution. If so, type in **su**:

```
prompt% su
```

4. Make a directory for the distribution. This directory should be named **/usr/local/lde/loops**. If you have enough space on the file system containing **/usr/local/lde**, then

```
prompt# mkdir /usr/local/lde/loops/
```

If you don't have enough space on **/usr/local/lde**, go to step 6.

5. Make yourself owner of this directory:

```
prompt# /etc/chown yourname /usr/local/lde/loops/
```

where **yourname** is your username.

6. If you don't have space on the file system which contains **/usr/local/lde**, but do have space somewhere else, for instance on **/usr1**, then make the directory there and link **/usr/local/lde/loops** to it:

```
prompt# mkdir /usr1/loops
```

```
prompt# /etc/chown yourname /usr/usr1/loops
```

```
prompt# ln -s /usr1/loops /usr/local/lde/loops
```

7. If you ran **su**, leave the privileged shell by typing:

```
prompt% exit
```

8. Insert the ¼-inch cartridge tape, containing the LOOPS software, in the drive.

9. Connect to **/usr/local/lde/loops**:

```
prompt# cd /usr/local/lde/loops
```

10. Load the Medley software from tape. Indicate the appropriate device abbreviation for your tape by replacing **xx** in the example below with

ar for the Archive drive,

st for a SCSI tape drive.

This example shows the command entry sequence:

```
prompt# tar xvpf /dev/rxx0
```

As the software is loaded (a process that takes some time) the system prints a series of lines in the following form:

```
x ./system/LOOPS., 28552 bytes, 56 tape blocks
```

The x at the beginning of the line indicates that the file is being extracted from the tape.

This creates directories named:

```
/usr/local/lde/loops/system/
```

```
/usr/local/lde/loops/library/
```

```
/usr/local/lde/loops/users/
```

This is a good time to set the protection of the extracted directories and files so that the work group using LOOPS has at least read access to them.

11. Boot Medley Lisp.
12. Open an Interlisp Executive Window.
13. Make certain the time is set correctly.
14. Set the **DIRECTORIES** and **DISPLAYFONTDIRECTORIES** variables appropriately so the sysout can find your Lyric/Medley library and font files.
15. Make the LOOPS System directory your connected directory:

```
CONN {DSK}/usr/local/lde/loops/system/
```

16. Enter the following into your Exec:

```
LOAD (LOOPS)
```

A menu appears that looks like this:

```

Loops system
Install from distribution
Load into sysout

```

17. Select the menu option **Install from distribution**.

The following menu appears:

Loops directories	Click here when
LOOPSDIRECTORY	{DSK}<LISPFILS>LOOPS>
LOOPSLIBRARYDIRECTORY	{DSK}<LISPFILS>LOOPS>LIB
LOOPSUSERSDIRECTORY	{DSK}<LISPFILS>LOOPS>USE
LOOPSUSERSRULESDIRECTORY	{DSK}<LISPFILS>LOOPS>RUL

This menu shows the current (or default, if unset) values of the variables LOOPS examines when it loads things.

If you have installed LOOPS under /usr/local/lde/loops/ click the mouse on the menu items to set these directories to point where the tape was unloaded:

```

LOOPSDIRECTORY      {dsk}/usr/local/lde/loops/system/
LOOPSLIBRARYDIRECTORY {dsk}/usr/local/lde/loops/library/
LOOPSUSERSDIRECTORY  {dsk}/usr/local/lde/loops/users/
LOOPSUSERSRULESDIRECTORY {dsk}/usr/local/lde/loops/users/

```

As the last installation step, the installation tool automatically modifies the file LOOPSSITE, writes it out to **LOOPSDIRECTORY**, and compiles it.

When this setp is finished, the first menu reappears:

```
Loops system
Install from distribution
Load into sysout
```

18. Select the menu option **Load into sysout** to load LOOPS into your system. The following menu appears:

```
Load Which?
Loops
Loops Masterscope
Gauges
LoopsBackwards
VirtualCopy
```

19. Select **LOOPS** from the menu to load LOOPS from the location where you installed it.

Once LOOPS is loaded the LOOPS System menu reappears. To load one of the other LOOPS library or Users' modules, select the appropriate name in the Load Which? menu.

20. Position your mouse cursor anywhere on the screen except for the Load Which? menu, then press the left mouse button to exit the installation procedure.

Lyric/Medley LOOPS is now installed on your Sun Workstation.

Loading After Installation

This section describes how to reload LOOPS into a newly started Lisp sysout after LOOPS has been previously installed.

1. Start up Medley on your Sun Workstation.
2. Open an INTERLISP Exec window.
3. Make sure **DIRECTORIES** points to a directory containing GRAPHER.LCOM, and **DISPLAYFONTDIRECTORIES** points to a directory containing the Helvetica display font files from your Lisp distribution kit.

4. Connect to the directory containing the LOOPS system files:

```
(CNDIR ' {DSK} /USR/LOCAL/LDE/LOOPS/SYSTEM/)
```

5. Load LOOPS loader program:

```
(FILESLOAD LOADLOOPS)
```

6. Run the LOOPS loader program:

```
(LOADLOOPS)
```

This procedure loads only the LOOPS system files. Please see the manuals describing the LOOPS Library and Users' Modules for their loading procedures.

CAUTION

LOOPS uses the new compiler and its macrolet facilities. When LOOPS is loaded, it sets your ***DEFAULT-CLEANUP-COMPILER*** to **'CL:COMPILE-**

FILE. More information on this cleanup flag and the new compiler is available in the *Lisp Release Notes*, in your Lyric or Medley Lisp kit.

1. INTRODUCTION TO RULE-ORIENTED PROGRAMMING IN LOOPS

The core of decision-making expertise in many kinds of problem solving can be expressed succinctly in terms of rules. The following sections describe facilities in LOOPS for representing rules, and for organizing knowledge-based systems with rule-oriented programming. The LOOPS rule language provides an experimental framework for developing knowledge-based systems. The rule language and programming environment are integrated with the object-oriented, data-oriented, and procedure-oriented parts of LOOPS.

Rules in LOOPS are organized into production systems (called RuleSets) with specified control structures for selecting and executing the rules. The work space for RuleSets is an arbitrary LOOPS object.

Decision knowledge can be factored from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions. An audit trail records inferential support in terms of the rules and data that were used. Such trails are important for knowledge-based systems that must be able to account for their results. They are also essential for guiding belief revision in programs that need to reason with incomplete information.

1.1 Introduction

Production rules have been used in expert systems to represent decision-making knowledge for many kinds of problem-solving. Such rules (also called *if-then* rules) specify actions to be taken when certain conditions are satisfied. Several rule languages have been developed in the past few years and used for building expert systems. The following sections describe the concepts and facilities for rule-oriented programming in LOOPS.

LOOPS has the following major features for rule-oriented programming:

- (1) Rules in LOOPS are organized into ordered sets of rules (called RuleSets) with specified control structures for selecting and executing the rules. Like subroutines, RuleSets are building blocks for organizing programs hierarchically.
- (2) The work space for rules in LOOPS is an arbitrary LOOPS object. The names of the instance variables provide a name space for variables in the rules.
- (3) Rule-oriented programming is integrated with object-oriented, data-oriented, and procedure-oriented programming in LOOPS.
- (4) RuleSets can be invoked in several ways: In the object-oriented paradigm, they can be invoked as methods by sending messages to objects. In the data-oriented paradigm, they can be invoked

as a side-effect of fetching or storing data in active values. They can also be invoked directly from Lisp programs. This integration makes it convenient to use the other paradigms to organize the interactions between RuleSets.

- (5) RuleSets can also be invoked from rules either as predicates on the LHS of rules, or as actions on the RHS of rules. This provides a way for RuleSets to control the execution of other RuleSets.
- (6) Rules can automatically leave an audit trail. An audit trail is a record of inferential support in terms of rules and data that were used. Such trails are important for programs that must be able to account for their results. They can also be used to guide belief revision in programs that must reason with incomplete information.
- (7) Decision knowledge can be separated from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions.
- (8) The rule language provides a concise syntax for the most common operations.
- (9) There is a fast and efficient compiler for translating RuleSets into Interlisp functions.
- (10) LOOPS provides facilities for debugging rule-oriented programs.

The following sections are organized as follows: Section 1.2, "Basic Concepts," outlines the basic concepts of rule-oriented programming in LOOPS. It contains many examples that illustrate techniques of rule-oriented programming. Section 1.3, "Organizing a Rule-Oriented Program," describes the rule syntax, and the remaining sections in this chapter discuss the facilities for creating, editing, and debugging RuleSets in LOOPS.

1.2 Basic Concepts

Rules express the conditional execution of actions. They are important in programming because they can capture the core of decision-making for many kinds of problem-solving. Rule-oriented programming in LOOPS is intended for applications to expert and knowledge-based systems.

The following sections outline some of the main concepts of rule-oriented programming. LOOPS provides a special language for rules because of their central role, and because special facilities can be associated with rules that are impractical for procedural programming languages. For example, LOOPS can save specialized audit trails of rule execution. Audit trails are important in knowledge systems that need to explain their conclusions in terms of the knowledge used in solving a problem. This capability is essential in the development of large knowledge-intensive systems, where a long and sustained effort is required to create and validate knowledge bases. Audit trails are also important for programs that do non-monotonic reasoning. Such programs must work with incomplete information, and must be able to revise their conclusions in response to new information.

1.3 Organizing a Rule-Oriented Program

In any programming paradigm, it is important to have an organizational scheme for composing large systems from smaller ones. Stated differently, it is important to have a method for partitioning large programs into nearly-independent and manageably-sized pieces. In the procedure-oriented paradigm, programs are decomposed into procedures. In the object-oriented paradigm, programs are decomposed into objects. In the rule-oriented paradigm, programs are decomposed into *RuleSets*. A LOOPS program that uses more than one programming paradigm is factored across several of these dimensions.

There are three approaches to organizing the invocation of RuleSets in LOOPS:

Procedure-oriented Approach. This approach is analogous to the use of subroutines in procedure-oriented programming. Programs are decomposed into RuleSets that call each other and return values when they are finished. *SubRuleSets* can be invoked from multiple places. They are used to simplify the expression in rules of complex predicates, generators, and actions.

Object-oriented Approach. In this approach, RuleSets are installed as methods for objects. They are invoked as methods when messages are sent to the objects. The method RuleSets are viewed analogously to other procedures that implement object message protocols. The value computed by the RuleSet is returned as the value of the message sending operation.

Data-oriented Approach. In this approach, RuleSets are installed as access functions in active values. A RuleSet in an active value is invoked when a program gets or puts a value in the LOOPS object. As with active values with Lisp functions for the *getFn* or *putFn*, these RuleSet active values can be triggered by any LOOPS program, whether rule-oriented or not.

These approaches for organizing RuleSets can be combined to control the interactions between bodies of decision-making knowledge expressed in rules. For example, Figure 1 shows the RuleSet of consumer instructions for testing a washing machine. The work space for the ruleSet is a LOOPS object of the class **WashingMachine**. The control structure *While1* loops through the rules trying an escalating sequence of actions, starting again at the beginning of some rule is applied. Some rules, called one-shot rules, are executed at most once. These rules are indicated by preceding them with a one in braces ({1}).

```

RuleSet Name: CheckWashingMachine;
Workspace Class: WashingMachine;
Control Structure: while1;
While Condition: ruleApplied;

(* What a consumer should do when a washing machine failes.)

  IF .Operational THEN (STOP T);

  IF load>1.0 THEN .ReduceLoad;

  If ~pluggedInTo THEN .PlugIn;

{1} IF pluggedInTo:voltage=0 THEN breaker.Reset;
{1} IF pluggedInTo:voltage<110 THEN SPGE.Call;
{1} THEN dealer.RequestService;
{1} THEN manufacturer.Complain;
{1} THEN $ConsumerBoard.Complain;
{1} THEN (STOP T);

```

Figure 1. Basic RuleSet

1.4 Control Structures for Selecting Rules

RuleSets in LOOPS consist of an ordered list of rules and a control structure. Together with the contents of the rules and the data, a RuleSet control structure determines which rules are executed. Execution is determined by the contents of rules in that the conditions of a rule must be satisfied for it to be executed. Execution is also controlled by data in that different values in the data allow different rules to be satisfied. Criteria for iteration and rule selection are specified by a RuleSet control structure. There are two primitive control structures for RuleSets in LOOPS which operate as follows:

Do1	[RuleSet Control Structure]
The first rule in the RuleSet whose conditions are satisfied is executed. The value of the RuleSet is the value of the rule. If no rule is executed, the RuleSet returns NIL. The Do1 control structure is useful for specifying a set of mutually exclusive actions, since at most one rule in the RuleSet will be executed for a given invocation. When a RuleSet contains rules for specific and general situations, the specific rules should be placed before the general rules.	

DoAll

[RuleSet Control Structure]

Starting at the beginning of the RuleSet, every rule is executed whose conditions are satisfied. The value of the RuleSet is the value of the last rule executed. If no rule is executed, the RuleSet returns **NIL**.

The **DoAll** control structure is useful when a variable number of additive actions are to be carried out, depending on which conditions are satisfied. In a single invocation of the RuleSet, all of the applicable rules are invoked.

Figure 2 illustrates the use of a **Do1** control structure to select one of three mutually exclusive actions.

```
RuleSet Name: SimulateWashingMachine;
Workspace Class: WashingMachine;
Control Structure: Do1 ;

(* Rules for controlling the wash cycle of a washing machine.)

IF controlSetting = 'RegularFabric
THEN .Fill .Wash .Pause .SpinAndDrain
    .SprayAndRinse .SpinAndDrain
    .Fill. DeepRinse .Pause .DampDry;

IF controlSetting = 'PermanentPress
THEN .Fill .Wash .Pause .SpinAndPartialDrain
    .FillCold .SpinAndPartialDrain
    .FillCold .Pause .SpinAndDrain
    .FillCold. DeepRinse .Pause .DampDry;

IF controlSetting = 'DelicateFabric
THEN .FillSoak1 .Agitate .Soak4 .Agitate
    .Soak1 .SpinAndDrain .SprayAndRinse
    .SpinAndDrain .Fill .DeepRinse .Pause .DampDry;
```

Figure 2. RuleSet showing Do1

There are two control structures in LOOPS that specify iteration in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

While1

[RuleSet Control Structure]

This is a cyclic version of **Do1**. If the while-condition is satisfied, the first rule is executed whose conditions are satisfied. This is repeated as long as the while condition is satisfied or until a **Stop** statement or transfer call is executed (see Section 2.14, "Stop Statements"). The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

WhileAll

[RuleSet Control Structure]

This is a cyclic version of **DoAll**. If the while-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the while condition is satisfied or until a **Stop** statement is executed. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

The "while-condition" is specified in terms of the variables and constants accessible from the RuleSet. The constant **T** can be used to specify a RuleSet that iterates forever (or until a **Stop** statement or transfer is executed). The special variable **ruleApplied** is used to specify a RuleSet that continues as long as some rule was executed in the last iteration. Figure 3 illustrates a simple use of the **WhileAll** control structure to specify a sensing/acting feedback loop for controlling the filling of a washing machine tub with water.

```

RuleSet Name: FillTub;
Workspace Class: WashingMachine;
Control Structure: WhileAll ;
Temp Vars: waterLimit;
WhileCond: T;

(* Rules for controlling the filling of a washing tub with
water.)

{1!} IF loadSetting = 'Small THEN waterLimit_10;
{1!} IF loadSetting = 'Meduim THEN waterLimit_13.5;
{1!} IF loadSetting = 'Large THEN waterLimit_17;
{1!} IF loadSetting = 'ExtraLarge THEN waterLimit_20;

(* Respond to a change of temperature setting at any time.)

IF termperatureSetting = 'Hot
THEN HotWaterValve.Open ColdWaterValve.Close;

IF termperatureSetting = 'Warm
THEN HotWaterValve.Open ColdWaterValve.Open;

IF termperatureSetting = 'Cold
THEN HotWaterValve.Close ColdWaterValve.Open;

(* Stop when the water reaches its limit.)

IF waterLevelSensor.Test >= waterLimit
THEN HotWaterValve.Close ColdWaterValve.Close
(Stop T);

```

Figure 3. RuleSet with WhileAll

There are two control structures in LOOPS that specify iteration over a set of elements in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

FOR1

[RuleSet Control Structure]

This is a cyclic version of **Do1**. If the iteration-condition (or while-condition) is satisfied, the first rule is executed whose conditions are satisfied or until a **Stop** statement is executed. This is repeated as long as the iteration condition is satisfied. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

FORALL

[RuleSet Control Structure]

This is a cyclic version of **DoAll**. If the iteration-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the iteration condition is satisfied or until a **Stop** statement is executed. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

The "iteration-condition" is specified in terms of the variables and constants accessible from the RuleSet. The simplest condition is

(FOR <iterVar> IN <setExpr> DO ruleSet) ;

The **setExpr** will be parsed with the RuleSet parser. The symbol **ruleSet** is a reserved word, and must be spelled as shown (no changes in capitalization).

Here is an example of iteration:

Control Structure: FORALL;

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO ruleSet) ;

For each buyer in the list produced by RoadStops, the ruleSet will be run. In a **FOR1**, the iteration will go on to the next buyer as soon as one rule executes. In a **FORALL**, all rules in the RuleSet will be tried.

For nested iteration one can use a slightly more complicated form, as illustrated by the following example:

**Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO
(FOR seller in (RoadStops (\$ Producer)) DO ruleSet)) ;**

An experienced Lisp user can see that this resembles the CLISP iteration construct. In fact, except that you can (must) use the RuleSet syntax in the construct, it is the CLISP construct, and any such construct can be used. A DO1 or DOALL ruleSet will be substituted for the occurrence of the atom ruleSet, depending on whether the Control Structure is a FOR1 or FORALL.

As an abbreviation, if the construct does not contain the atom ruleSet, then (DO ruleSet) is appended to the Iteration Condition for a **FOR1** or **FORALL**. Thus one could write the first example as:

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)))

1.5 One-Shot Rules

One of the design objectives of LOOPS is to clarify the rules by factoring out control information whenever possible. This objective is met in part by the declaration of a control structure for RuleSets.

Another important case arises in cyclic control structures in which some of the rules should be executed only once. This was illustrated in the Washing Machine example in Figure 1 where we wanted to prevent the RuleSet from going into an infinite loop of resetting the breaker, when there was a short circuit in the Washing Machine. Such rules are also useful for initializing data for RuleSets as in the example in Figure 3.

In the absence of special syntax, it would be possible to encode the information that a rule is to be executed only once as follows:

Control Structure: While1
Temporary Vars: triedRule3;

...

IF ~triedRule3 condition condition THEN triedRule3_T action ;

In this example, the variable **triedRule3** is used to control the rule so that it will be executed at most once in an invocation of a RuleSet. However, the prolific use of rules with such control clauses in large systems has led to the common complaint that control clauses in rule languages defeat the expressiveness and conciseness of the rules. For the case above, LOOPS provides a shorthand notation as follows:

{1} IF condition condition THEN action ;

The brace notation means exactly the same thing in the example above, but it more concisely and clearly indicates that the rule executes only once. These rules are called "one shot" or "execute-once" rules.

In some cases, it is desired not only that a rule be executed at most once, but that it be tested at most once. This corresponds to the following:

Control Structure: While1
Temporary Vars: triedRule3;

...

IF ~triedRule3 triedRule3_T condition condition THEN action ;

In this case, the rule will not be tried more than once even if some of the conditions fail the first time that it is tested. The LOOPS shorthand for these rules (pronounced "one shot bang") is

{1!} **IF** *condition* *condition* **THEN** *action* ;

These rules are called "try-once" rules.

The two kinds of one-shot rules are our first examples of the use of meta-descriptions preceding the rule body in braces. See Section 1.7, "Saving an Audit Trail of Rule Invocation," for information on using meta-descriptions for describing the creation of audit trails.

1.6 First/Last Rules

It is sometimes useful to have rules which fire before or after the ordinary part of the RuleSet is invoked, independent of the form of the control structure. For example, in a DO1, such "FIRST " rules could be used for initialization. These now exist, and are notated by putting a {F} for a first rule in the MetaDescription field, and a {L} for a last rule. If a RuleSet has L rules which execute, the value of the RuleSet is the value of the last rule which executed.

1.7 Saving an Audit Trail of Rule Invocation

A basic property of knowledge-based systems is that they use knowledge to infer new facts from older ones. (Here we use the word "facts" as a neutral term, meaning any information derived or given, that is used by a reasoning system.) Over the past few years, it has become evident that reasoning systems need to keep track not only of their conclusions, but also of their reasoning steps. Consequently, the design of such systems has become an active research area in AI. The audit trail facilities of LOOPS support experimentation with systems that can not only use rules to make inferences, but also keep records of the inferential process itself.

1.7.1 Motivations and Applications

Debugging. In most expert systems, knowledge bases are developed over time and are the major investment. This places a premium on the use of tools and methods for identifying and correcting bugs in knowledge bases. By connecting a system's conclusions with the knowledge that it uses to derive them, audit trails can provide a substantial debugging aid. Audit trails provide a focused means of identifying potentially errorful knowledge in a problem solving context.

Explanation Facilities. Expert systems are often intended for use by people other than their creators, or by a group of people *pooling* their knowledge. An important consideration in validating expert systems is that reasoning should be *transparent*, that is, that a system should be able to give an account of its reasoning process. Facilities for doing this are sometimes called *explanation systems*

and the creation of powerful explanation systems is an active research area in AI and cognitive science. The audit trail mechanism provides an essential computational prerequisite for building such systems.

Belief Revision. Another active research area is the development of systems that can "change their minds". This characteristic is critical for systems that must reason from incomplete or errorful information. Such systems get leverage from their ability to make assumptions, and then to recover from bad assumptions by efficiently reorganizing their beliefs as new information is obtained. Research in this area ranges from work on non-monotonic logics, to a variety of approaches to belief revision. The facilities in the rule language make it convenient to use a user-defined calculus of belief revision, at whatever level of abstraction is appropriate for an application.

1.7.2 Overview of Audit Trail Implementation

When *audit mode* is specified for a RuleSet, the compilation of assignment statements on the right-hand sides of rules is altered so that audit records are created as a side-effect of the assignment of values to instance variables. Audit records are LOOPS objects, whose class is specified in RuleSet declarations. The audit records are connected with associated instance variables through the value of the **reason** properties of the variables.

Audit descriptions can be associated with a RuleSet as a whole, or with specific rules. Rule-specific audit information is specified in a property-list format in the meta-description associated with a rule. For example, this can include *certainty factor* information, categories of inference, or categories of support. Rule-specific information overrides RuleSet information.

During rule execution in audit mode, the audit information is evaluated after the rule's LHS has been satisfied and before the rule's RHS is applied. For each rule applied, a single audit record is created and then the audit information from the property list in the rule's meta-description is put into the corresponding instance variables of the audit record. The audit record is then linked to each of the instance variables that have been set on the RHS of the rule by way of the **reason** property of the instance variable.

Additional computations can be triggered by associating active values with either the audit record class or with the instance variables. For example, active values can be specified in the audit record classes in order to define a uniform set of side-effects for rules of the same category. In the following example, such an active value is used to carry out a "certainty factor" calculation.

1.7.3 An Example of Using Audit Trails

The following example illustrates one way to use the audit trail facilities. Figure 4 illustrates a RuleSet which is intended to capture the decisions for evaluating the potential purchase of a washing machine. As with any purchasing situation, this one includes the difficulty of incomplete information about the product. For example in this RuleSet, the reliability of the washing machine is estimated to be 0.5 in the absence of specific information from *Consumer Reports*. The meta-descriptions for the rules, which appear in braces, categorize them in terms of the *basis of belief* (the category *basis* is either a fact or estimate) and a *certainty factor* (*cf*) that is supposed to measure the "implication power" of the

rule. Within the braces, the variable on the left of the assignment statement is always interpreted as meaning a variable in the audit record, and the variables on the right are always interpreted as variables accessible within the RuleSet. This makes it straightforward to experiment with user-defined audit trails and experimental methods of belief revision. (Realistic belief revision systems are usually more sophisticated than this example.)

The result of running the RuleSet is an evaluation report for each candidate machine. Since the RuleSet was run in audit mode, each entry in the evaluation report is tagged with a reason that points to an audit record. Figure 5 illustrates the evaluation report for one machine and one of its audit records. In this example, each of the entries in the report has a reason and a cumulative certainty (cc) property in addition to the value. The value of the reason properties are audit records created as a side effect of running the RuleSet. The auditing process records the meta-description information of each rule in its audit record. This information can be used later for generating explanations or as a basis for belief revision. The auditing process can have side effects. For example, the active in the **cf** variable or the audit record performs a computation to maintain a calculated cumulative certainty in the reliability variable of the evaluation report.

The meta-descriptions for **basis** and **cf** are saved directly in the audit record. The *certainty factor* calculation in this combines information from the audit description with other information already associated with the object. To do this, the **cf** description triggers an active value inherited by the audit record from its class. This active value computes a *cumulative certainty* in the evaluation report. (Other variations on this idea would include certainty information descriptive of the premises of the rule.)

1.8 Comparison with Other Rule Languages

This section considers the rationale behind the design of the LOOPS rule language, focusing on ways that it diverges from other rule languages. In general, this divergence was driven by the following observation:

When a rule is heavy with control information, it obscures the domain knowledge that the rule is intended to convey.

Rules are harder to create, understand, and modify when they contain too much control information. This observation led us to find ways to factor control information out of the rules.

1.8.1 The Rationale for Factoring Meta-Level Syntax

One of the most striking features of the syntax of the LOOPS rule language is the factored syntax for meta-descriptions, which provides information about the rules themselves. Traditional rule languages only factor rules into conditions on the left hand side (LHS) and actions on the right hand side (RHS), without general provisions for meta-descriptions.

Decision knowledge expressed in rules is most perspicuous when it is not mixed with other kinds knowledge, such as control knowledge. For example, the following rule:

```

IF ~triedRule4 pluggedInTo:voltage=0
THEN triedRule4_T breaker.Reset;

```

is more obscure than the corresponding one-shot rule from Figure 1:

```

{1} IF pluggedInTo:voltage=0 THEN breaker.Reset;

```

which factors the control information (that the rule is to be applied at most once) from the domain knowledge (about voltages and breakers). In the LOOPS rule language, a meta-description (MD) is specified in braces in front of the LHS of a rule. For another example, the following rule from Figure 4:

```

{{(basis_Fact cf_.8)}}

```

IF buyer:familySize>2 machine:capacity<20
THEN suitability_ 'Poor;

uses an MD to indicate that the rule has a particular **cf** ("certainty factor") and **basis** category for belief support. The MD in this example factors the description of the inference category of the rule from the action knowledge in the rule.

In a large knowledge-based system, a substantial amount of control information must be specified in order to preclude combinatorial explosions. Since earlier rule languages fail to provide a means for factoring meta-information, they must either mix it with the domain knowledge or express it outside the rule language. In the first option, intelligibility is degraded. In the second option, the transparency of the system is degraded because the knowledge is hidden.

1.8.2 The Rationale for RuleSet Hierarchy

Some advocates of production systems have praised the flatness of traditional production systems, and have resisted the imposition of any organization to the rules. The flat organization is sometimes touted as making it *easy to add rules*. The argument is that other organizations diminish the power of pattern-directed invocation and make it more complicated to add a rule.

In designing LOOPS, we have tended to discount these arguments. We observe that there is no inherent property of production systems that can make rules additive. Rather, *additivity* is a consequence of the independence of particular sets of rules. Such independence is seldom achieved in large sets of rules. When rules are dependent, rule invocation needs to be carefully ordered.

Advocates of a flat organization tend to organize large programs as a single very large production system. In practice, most builders of production systems have found it essential to create groups of rules.

Grouping of rules in flat systems can be achieved in part by using *context* clauses in the rules. Context clauses are clauses inserted into the rules which are used to alter the flow of control by naming the context explicitly. Rules in the same "context" all contain an extra clause in their conditions that compares the context of the rules with a current context. Other rules redirect control by switching the current context. Unfortunately, this approach does not conveniently lend itself to the reuse of groups of rules by different parts of a program. Although context clauses admit the creation of "subroutine contexts", they require you to explicitly program a stack of return locations in cases where contexts are invoked from more than one place. The decision to use an implicit calling stack for RuleSet invocation in LOOPS is another example of the our desire to simplify the rules by factoring out control information.

1.8.3 The Rationale for RuleSet Control Structures

Production languages are sometimes described as having a *recognize-act cycle*, which specifies how rules are selected for execution. An important part of this cycle is the *conflict resolution strategy*, which specifies how to choose a production rule when several rules have conditions that are satisfied. For example, the **OPS5** production language has a conflict resolution strategy (**MEA**) which prevents rules

from being invoked more than once, prioritizes rules according to the recency of a change to the data, and gives preference to production rules with the most specific conditions.

In designing the rule language for LOOPS, we have favored the use of a small number of specialized control structures to the use of a single complex conflict resolution strategy. In so doing, we have drawn on some control structures in common use in familiar programming languages. For example, **Do1** is like Lisp's **COND**, **DoAll** is like Lisp's **PROG**, **WhileAll** is similar to **WHILE** statements in many programming languages.

The specialized control structures are intended for concisely representing programs with different control relationships among the rules. For example, the **DoAll** control structure is useful for rules whose effects are intended to be additive and the **Do1** control structure is appropriate for specifying mutually exclusive actions. Without some kind of iterative control structure that allows rules to be executed more than once, it would be impossible to write a simulation program such as the washing machine simulation in Figure 1.

We have resisted a reductionist argument for having only one control structure for all programming. For example, it could be argued that the control structure **Do1** is not strictly necessary because any RuleSet that uses **Do1** could be rewritten using **DoAll**. For example, the rules

Control Structure: Do1;

```
IF a b c THEN d e ;
IF a b c THEN d e ;
IF a b c THEN d e ;
```

could be written alternatively as

Control Structure: DoAll;
Task Vars: firedSomeRule;

```
IF a b c THEN firedSomeRule_T d e ;
IF ~firedSomeRule a b c THEN firedSomeRule_T d e ;
IF ~firedSomeRule a b c THEN firedSomeRule_T d e ;
```

However, the **Do1** control structure admits a much more concise expression of mutually exclusive actions. In the example above, the **Do1** control structure makes it possible to abbreviate the rule conditions to reflect the assumption that earlier rules in the RuleSet were not satisfied.

For some particular sets of rules the conditions are naturally mutually exclusive. Even for these rules **Do1** can yield additional conciseness. For example, the rules:

Control Structure: Do1;

```
IF a b c THEN d e ;
IF ~a b c THEN d e ;
IF ~a ~b c THEN d e ;
```

can be written as

Control Structure: Do1;

```
IF a b c THEN d e ;  
IF  b c THEN d e ;  
IF   c THEN d e ;
```

Similarly it could be argued that the **Do1** and **DoAll** control structures are not strictly necessary because such RuleSets can always be written in terms of **While1** and **WhileAll**. Following this reductionism to its end, we can observe that every RuleSet could be re-written in terms of **WhileAll**.

1.8.4 The Rationale for an Integrated Programming Environment

RuleSets in LOOPS are integrated with procedure-oriented, object-oriented, and data-oriented programming paradigms. In contrast to single-paradigm rule systems, this integration has two major benefits. It facilitates the construction of programs which don't entirely fit the rule-oriented paradigm. Rule-oriented programming can be used selectively for representing just the appropriate decision-making knowledge in a large program. Integration also makes it convenient to use the other paradigms to help organize the interactions between RuleSets.

Using the object-oriented paradigm, RuleSets can be invoked as methods for LOOPS objects. Figure 6 illustrates the installation of the RuleSet **SimulateWashingMachineRules** to carry out the **Simulate** method for instances of the class **WashingMachine**. This definition of the class **WashingMachine** specifies that Lisp functions are to be invoked for Fill and Wash messages. For example, the Lisp function **WashingMachine.Fill** is to be applied when a Fill message is received. When a Simulate message is received, the RuleSet **SimulateWashingMachineRules** is to be invoked with the washing machine as its work space. Simulate message to invoke the RuleSet may be sent by any LOOPS program, including other RuleSets.

The use of object-oriented paradigm is facilitated by special RuleSet syntax for sending messages to objects, and for manipulating the data in LOOPS objects. In addition, RuleSets, work spaces, and tasks are implemented as LOOPS objects.

```

[DEFCLASS WashingMachine
  (MetaClass Class Edited (* "rtk: 12-Jun-87 07:57")
    doc (* Home appliance for wachine clooths.))
  (Supers ElectricalDevice PlumbedDevice CleaningDevice)
  (ClassVariables)
  (InstanceVariables
    (controlSetting Meduim
      doc (* One of Small, Medium, Large, ExtraLarge))...)
  (Methods
    (Fill WashingMachine.Fill doc (* Fill the tub with water.))
    (Wash WashingMachine.Wash doc (* Perofrm the wash cycle.))
    (Simulate UseRuleSet RuleSet SimulateWashingMachineRules)
    .
    .
    .
  ]

```

Figure 6. RuleSet Invoked as a Method

Using the data-oriented paradigm, RuleSets can be installed in active values so that they are triggered by side-effect when LOOPS programs get or put data in objects. For example:

```

[DEFINST WashingMachine (StefiksMaytagWasher "uid2")
  (controlSetting RegularFabric)
  (loadSetting #(Medium NIL RSPut) RSPutFn CheckOverLoadRules)
  (waterLevelSensor "uid3")
]

```

The above code illustrates a RuleSet named **CheckOverLoadRules** which is triggered whenever a program changes the **loadSetting** variable in the **WashingMachine** instance in the figure. This data-oriented triggering can be caused by any LOOPS program when it changes the variable, whether or not that program is written in the rules language.

2. THE RULE LANGUAGE

This chapter describes the syntax and semantics of the rule language.

2.1 Language Introduction

A rule in LOOPS describes actions to be taken when specified conditions are satisfied. A rule has three major parts called the *left hand side* (LHS) for describing the conditions, the *right hand side* (RHS) for describing the actions, and the *meta-description* (MD) for describing the rule itself. In the simplest case without a meta-description, there are two equivalent syntactic forms:

LHS -> *RHS*;

IF *LHS* **THEN** *RHS*;

The **If** and **Then** tokens are recognized in several combinations of upper and lower case letters. The syntax for LHSs and RHSs is given below. In addition, a rule can have no conditions (meaning always perform the actions) as follows:

-> *RHS*;

if T then *RHS*;

Rules can be preceded by a meta-description in braces as in:

{*MD*} *LHS* -> *RHS*;

{*MD*} **If** *LHS* **Then** *RHS*;

{*MD*} *RHS*;

Examples of meta-information include rule-specific control information, rule descriptions, audit instructions, and debugging instructions. For example, the syntax for one-shot rules shown in Section 1.5, "One-Shot Rules:"

{1} IF *condition* *condition* **THEN** *action* ;

is an example of a meta-description. Another example is the use of meta-assignment statements for describing audit trails and rules. These statements are discussed in Section 1.7, "Saving an Audit Trail of Rule Invocation."

LHS Syntax: The clauses on the LHS of a rule are evaluated in order from left to right to determine whether the LHS is satisfied. If they are all satisfied, then the rule is satisfied. For example:

A B C+D (Prime D) -> RHS;

In this rule, there are four clauses on the LHS. If the values of some of the clauses are **NIL** during evaluation, the remaining clauses are not evaluated. For example, if **A** is non-**NIL** but **B** is **NIL**, then the LHS is not satisfied and **C+D** will not be evaluated.

RHS Syntax: The RHS of a rule consists of actions to be performed if the LHS of the rule is satisfied. These actions are evaluated in order from left to right. Actions can be the invocation of RuleSets, the sending of LOOPS messages, Interlisp function calls, variables, or special termination actions.

RuleSets always return a value. The value returned by a RuleSet is the value of the last rule that was executed. Rules can have multiple actions on the right hand side. Unless there is a **Stop** statement or transfer call as described later, the value of a rule is the value of the last action. When a rule has no actions on its RHS, it returns **NIL** as its value.

Comments: Comments can be inserted between rules in the RuleSet. They are enclosed in parentheses with an asterisk for the first character as follows:

(* This is a comment)

2.2 Kinds of Variables

LOOPS distinguishes the following kinds of variables:

RuleSet arguments: All RuleSets have the variable **self** as their workspace. References to **self** can often be elided in the RuleSet syntax. For example, the expression **self.Print** means to send a **Print** message to **self**. This expression can be shortened to **.Print**. Other arguments can be defined for RuleSets. These are declared in an **Args:** declaration.

Instance variables: All RuleSets use a LOOPS object for their workSpace. In the LHS and RHS of a rule, the first interpretation tried for an undeclared literal is as an instance variable in the work space. Instance variables can be indicated unambiguously by preceding them with a colon, (e.g., **:varName** or **obj:varName**).

Class variables: Literals can be used to refer to class variables of LOOPS objects. These variables must be preceded by a double colon in the rule language, (e.g., **::classVarName** or **obj::classVarName**).

Temporary variables: Literals can also be used to refer to temporary variables allocated for a specific invocation of a RuleSet. These variables are initialized to **NIL** when a RuleSet is invoked. Temporary variables are declared in the **Temporary Vars** declaration in a RuleSet.

Audit record variables: Literals can also be used to refer to instance variables of audit records created by rules. These literals are used only in *meta-assignment* statements in the MD part of a rule. They are used to describe the information saved in audit records, which can be created as a side-effect of rule execution. These variables are ignored if a RuleSet is not compiled in *audit* mode. Undeclared variables appearing on the left side of assignment statements in the MD part of a rule are treated as

audit record variables by default. These variables are declared indirectly -- they are the instance variables of the class declared as the *Audit Class* of the RuleSet.

Interlisp variables: Literals can also be used to refer to Interlisp variables during the invocation of a RuleSet. These variables can be global to the Interlisp environment, or are bound in some calling function. Interlisp variables can be used when procedure-oriented and rule-oriented programs are intermixed. Interlisp variables must be preceded by a backSlash in the syntax of the rule language (e.g., *VispVarName*).

Reserved Words: The following literals are treated as *read-only* variables with special interpretations:

self	[Variable]
The current work space.	
rs	[Variable]
The current RuleSet.	
caller	[Variable]
The RuleSet that invoked the current RuleSet, or NIL if invoked otherwise.	
ruleApplied	[Variable]
Set to T if some rule was applied in this cycle. (For use only in while-conditions).	

The following reserved words are intended mainly for use in creating audit trails:

ruleObject	[Variable]
Variable bound to the object representing the rule itself.	
ruleNumber	[Variable]
Variable bound to the sequence number of the rule in a RuleSet.	
ruleLabel	[Variable]
Variable bound to the label of a rule or NIL .	
reasons	[Variable]
Variable bound a list of audit records supporting the instance variables mentioned on the LHS of the rule. (Computed at run time.)	

auditObject [Variable]

Variable bound to the object to which the reason record will be attached. (Computed at run time.)

auditVarName [Variable]

Variable bound to the name of the variable on which the reason will be attached as a property.

Other Literals: As described later, literals can also refer to Interlisp functions, LOOPS objects, and message selectors. They can also be used in strings and quoted constants.

The determination of the meaning of a literal is done at compile time using the declarations and syntax of RuleSets. The characters used in literals are limited to alphabetic characters and numbers. The first character of a literal must be alphabetic.

The syntax of literals also includes a compact notation for sending unary messages and for accessing instance variables of LOOPS objects. This notation uses *compound literals*. A compound literal is a literal composed of multiple parts separated by a periods, colons, and commas.

2.3 Rule Forms

Quoted Constants: The quote sign is used to indicate constant literals:

a b=3 c='open d=f e='(This is a quoted expression) -> ...

In this example, the LHS is satisfied if **a** is non-NIL, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** is the list **(This is a quoted expression)**.

Strings: The double quote sign is used to indicate string constants:

IF a b=3 c='open d=f e=="This is a string"
THEN (WRITE "Begin configuration task") ... ;

In this example, the LHS is satisfied if **a** is non-NIL, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** equal to the string **"This is a string"**.

Interlisp Constants: The literals **T** and **NIL** are interpreted as the Interlisp constants of the same name.

a (Foo x NIL b) -> x_T ...;

In this example, the function **Foo** is called with the arguments **x**, **NIL**, and **b**. Then the variable **x** is set to **T**.

2.4 Infix Operators and Brackets

To enhance the readability of rules, a few infix operators are provided. The following are infix binary operators in the rule syntax:

+	[Rule Infix Operator]
Addition.	
++	[Rule Infix Operator]
Addition modulo 4.	
-	[Rule Infix Operator]
Subtraction.	
--	[Rule Infix Operator]
Subtraction modulo 4.	
*	[Rule Infix Operator]
Multiplication.	
/	[Rule Infix Operator]
Division.	
>	[Rule Infix Operator]
Greater than.	
<	[Rule Infix Operator]
Less than.	
>=	[Rule Infix Operator]
Greater than or equal.	
<=	[Rule Infix Operator]
Less than or equal.	
=	[Rule Infix Operator]
EQ -- simple form of equals. Works for atoms, objects, and small integers.	
~=	[Rule Infix Operator]
NEQ. (Not EQ.)	

== [Rule Infix Operator]

EQUAL -- long form of equals.

<< [Rule Infix Operator]

Member of a list. (**FMEMB**)

In addition, the rule syntax provides two unary operators as follows:

- [Rule Unary Operator]

Minus.

~ [Rule Unary Operator]

Not.

The precedence of operators in rule syntax follows the usual convention of programming languages. For example

1+5*3 = 16

and

[3 < 2 + 4] = T

Brackets can be used to control the order of evaluation:

[1+5]*3 = 18

Ambiguity of the minus sign: Whenever there is an ambiguity about the interpretation of a minus sign as a unary or binary operator, the rule syntax interprets it as a binary minus. For example

a-b c d -e [-f] (g -h) (_ (\$ Foo) Move -j) -> ...

In this example, the first and second minus signs are both treated as binary subtraction statements. That is, the first three clauses are (1) **a-b**, (2) **c** and (3) **d-e**. Because the rule syntax allows arbitrary spacing between symbols and there is no syntax to separate clauses on the LHS of a rule, the interpretation of "**d -e**" is as a single clause (with the subtraction) instead of two clauses. To force the interpretation as a unary minus operator, one must use brackets as illustrated in the next clause. In this clause, the minus sign in the clause **[-f]** is treated as a unary minus because of the brackets. The minus sign in the function call **(g -h)** is treated as unary because there is no preceding argument. Similarly, the **-j** in the message expression is treated as unary because there is no preceding argument.

2.5 Interlisp Functions and Message Sending

Calls to Interlisp functions are parenthesized with the function name as the first literal after the left parenthesis. Each expression after the function name is treated as an argument to the function. For example:

a (Prime b) [a -b] -> c (Display b c+4 (Cursor x y) 2) ;

In this example, **Prime**, **Display**, and **Cursor** are interpreted as the names of Interlisp functions. Since the expression **[a -b]** is surrounded by brackets instead of parentheses, it is recognized as meaning **a** minus **b** as opposed to a call to the function **a** with the argument minus **b**. In the example above, the call to the Interlisp function **Display** has four arguments: **b**, **c+4**, the value of the function call **(Cursor x y)**, and **2**.

The use of Interlisp functions is usually outside the spirit of the rule language. However, it enables the use of Boolean expressions on the LHS beyond simple conjunctions. For example:

a (OR (NOT b) x y) z -> ... ;

LOOPS Objects and Message Sending: LOOPS classes and other named objects can be referenced by using the dollar notation. The sending of LOOPS messages is indicated by using a left arrow. For example:

**IF cell_ ((\$ LowCell) Occupied? 'Heavy)
THEN (_ cell Move 3 'North);**

In the LHS, an **Occupied?** message is sent to the object named **LowCell**. In the message expression on the RHS, there is no dollar sign preceding **cell**. Hence, the message is sent to the object that is the value of the variable **cell**.

For unary messages (i.e., messages with only the selector specified and the implicit argument **self**), a more compact notation is available as described below.

Unary Message Sending: When a period is used as the separator in a compound literal, it indicates that a unary message is to be sent to an object. (We will alternatively refer to a period as a *dot*.) For example:

tile.Type='BlueGreenCross command.Type='Slide4 -> ... ;

In this example, the object to receive the unary message **Type** is referenced indirectly through the **tile** instance variable in the work space. The left literal is the variable **tile** and its value must be a LOOPS object at execution time. The right literal must be a method selector for that object.

The dot notation can be combined with the dollar notation to send unary messages to named LOOPS objects. For example,

\$Tile.Type='BlueGreenCross ...

In this example, a unary **Type** message is sent to the LOOPS object whose name is **Tile**.

The dot notation can also be used to send a message to the work space of the RuleSet, that is, **self**. For example, the rule

IF scale>7 THEN .DisplayLarge;

would cause a **DisplayLarge** message to be sent to **self**. This is an abbreviation for

IF scale>7 THEN self.DisplayLarge;

2.6 Variables and Properties

When a single colon (:) is used in a literal, it indicates access to an instance variable of an object. For example:

tile:type='BlueGreenCross command:type=Slide4 -> ... ;

In this example, access to the LOOPS object is indirect in that it is referenced through an instance variable of the work space. The left literal is the variable **tile**, and its value must be a LOOPS object when the rule is executed. The right literal **type** must be the name of an instance variable of that object. The compound literal **tile:type** refers to the value of the **type** instance variable of the object in the instance variable **tile**.

The colon notation can be combined with the dollar notation to access a variable in a named LOOPS object. For example,

\$TopTile:type='BlueGreenCross ...

refers to the **type** variable of the object whose LOOPS name is **TopTile**.

A double colon notation (::) is provided for accessing class variables. For example

truck::MaxGas<45 ::ValueAdded>600 -> ... ;

In this example, **MaxGas** is a class variable of the object bound to **truck**. **ValueAdded** is a class variable of **self**.

A colon-comma notation (:,) is provided for accessing property values of class and instance variables. For example

wire:,capacitance>5 wire:voltage:,support='simulation -> ...

In the first clause, **wire** is an instance variable of the work space and **capacitance** is a property of that variable. The interpretation of the second clause is left to right as usual: (1) the object that is the value of the variable **wire** is retrieved, and (2) the **support** property of the **voltage** variable of that object is retrieved. For properties of class variables

::Wire:,capacitance>5 node::Voltage:,support='simulation -> ...

In the first clause, **wire** is a class variable of the work space and **capacitance** is a property of that variable. In the second clause, **node** is an instance variable bound to some object. **Voltage** is a class variable of that object, and **Support** is a property of that class variable.

The property notation is illegal for ruleVars and lispVars since those variables cannot have properties.

2.7 Computing Selectors and Variable Names

The short notations for instance variables, properties, and unary messages all show the selector and variable names *as they actually appear* in the object.

```
object.selector
object:ivName
object::cvName
object:varname:,propName
```

```
(_ object selector arg arg )
```

For example,

apple:flavor

refers to the **flavor** instance variable of the object bound to the variable **apple**. In Interlisp terminology, this implies implicit quoting of the name of the instance variable (**flavor**).

In some applications it is desired to be able to compute the names. For this, the LOOPS rule language provides analogous notations with an added exclamation sign (!). After the exclamation sign, the interpretation of the variable being evaluated starts over again. For example

apple:!x

refers to the same thing as **apple:flavor** if the Interlisp variable **x** is bound to **flavor**. The fact that **x** is a Lisp variable is indicated by the backslash. If **x** is an instance variable of **self** or a temporary variable, we could use the notation:

apple:!x

If **x** is a class variable of **self**, we could use the notation:

apple!:::x

All combinations are possible, including:

```
object.!selector
object.!\\selector
object!:::selector
object:!ivName
object!:!cvName
object:!varname:,propName
```

```
(_! object selector arg arg )
```

2.8 Recursive Compound Literals

Multiple colons or periods can be used in a literal, For example:

a:b:c

means to (1) get the object that is the value of **a**, (2) get the object that is the value of the **b** instance variable of **a**, and finally (3) get the value of the **c** instance variable of that object.

Similarly, the notation

a.b:c

means to get the **c** variable of the object returned after sending a **b** message to the object that is the value of the variable **a**. Again, the operations are carried out left to right: (1) the object that is the value of the variable **a** is retrieved, (2) it is sent a **b** message which must return an object, and then (3) the value of the **c** variable of that object is retrieved.

Compound literal notation can be nested arbitrarily deeply.

2.9 Assignment Statements

An assignment statement using a left arrow can be used for setting all kinds of variables. For example,

x_a;

sets the value of the variable **x** to the value of **a**. The same notation works if **x** is a task variable, rule variable, class variable, temporary variable, or work space variable. The right side of an assignment statement can be an expression as in:

x_a*b + 17*(LOG d);

The assignment statement can also be used with the colon notation to set values of instance variables of objects. For example:

y:b_0 ;

In this example, first the object that is the value of **y** is computed, then the value of its instance variable **b** is set to **0**.

Properties: Assignment statements can also be used to set property values as in:

box:x:,origin_47 fact:,reason_currentSupport;

Nesting: Assignment statements can be nested as in

a_b_c:d_3;

This statement sets the values of **a**, **b**, and the **d** instance variable of **c** to **3**. The value of an assignment statement itself is the new assigned value.

2.10 Meta-Assignment Statements

Meta-assignment statements are assignment statements used for specifying rule descriptions and audit trails. These statements appear in the MD part of rules.

Audit Trails: The default interpretation of meta-assignment statements for undeclared variables is as audit trail specifications. Each meta-assignment statement specifies information to be saved in audit records when a rule is applied. In the following example from Figure 4, the audit record must have variables named **basis** and **cf**:

```
{{(basis_Fact cf_1.)}
IF buyer:familySize>2 machine:capacity<20
THEN suitability_'Poor';
```

In this example, the RHS of the rule assigns the value of the work space instance variable **suitability** to **'Poor'** if the conditions of the rule are satisfied. In addition, if the RuleSet was compiled in *audit* mode, then during RuleSet execution an audit record is created as a side-effect of the assignment. The audit record is attached to the **reason** property of the suitability variable. It has instance variables **basis** and **cf**.

In general, an audit description consists of a sequence of meta-assignment statements. The assignment variable on the left must be an instance variable of the audit record. The class of the audit record is declared in the *Audit Class* declaration of the RuleSet. The expression on the right is in terms of the variables accessible by the RuleSet. If the conditions of a rule are satisfied, an audit record is instantiated. Then the meta-assignment statements are evaluated in the execution context of the RuleSet and their values are put into the audit record. A separate audit record is created for each of the object variables that are set by the rule.

2.11 Push and Pop Statements

A compact notation is provided for pushing and popping values from lists. To push a new value onto a list, the notation **_+** is used:

```
myList_+newItem;
```

```
focus:goals_+newGoal;
```

To pop an item from a list, the **_-** notation is used:

```
item_-myList;
```

nextGoal_-focus:goals;

As with the assignment operator, the push and pop notation works for all kinds of variables and properties. They can be used in conjunction with infix operator << for membership testing.

2.12 Invoking RuleSets

One of the ways to cause RuleSets to be executed is to invoke them from rules. This is used on the LHS of rules to express predicates in terms of RuleSets, and on the RHS of rules to express actions in terms of RuleSets. A short double-dot syntax(..) for this is provided that invokes a RuleSet on a work space:

Rs1..ws1

In this example, the RuleSet bound to the variable **Rs1** is invoked with the value of the variable **ws1** as its work space. The value of the invocation expression is the value returned by the RuleSet. The double-dot syntax can be combined with the dollar notation (\$) to invoke a RuleSet by its LOOPS name, as in

\$MyRules..ws1

which invokes the RuleSet object that has the LOOPS name **MyRules**.

This form of RuleSet invocation is like subroutine calling, in that it creates an implicit stack of arguments and return addresses. This feature can be used as a mechanism for *meta-control* of RuleSets as in:

IF breaker:status='Open
THEN source_\$OverLoadRules..washingMachine;

IF source='NotFound
THEN \$ShortCircuitRules..washingMachine;

In this example, two "meta-rules" are used to control the invocation of specialized RuleSets for diagnosing overloads or short circuits.

2.13 Transfer Calls

An important optimization in many recursive programs is the elimination of tail recursion. For example, suppose that the RuleSet A calls B, B calls C, and C calls A recursively. If the first invocation of A must do some more work after returning from B, then it is useful to save the intermediate states of each of the procedures in frames on the calling stack. For such programs, the space allocation for the stack must be enough to accommodate the maximum depth of the calls.

There is a common and special case, however, in which it is unnecessary to save more than one frame on the stack. In this case each RuleSet has no more work to do after invoking the other RuleSets, and the value of each RuleSet is the value returned by the RuleSet that it invokes. RuleSet invocation in this case amounts to the evaluation of arguments followed by a direct transfer of control. We call such invocations transfer calls.

The LOOPS rule language extends the syntax for RuleSet invocation and message sending to provide this as follows:

RS..*ws

The RuleSet **RS** is invoked on the work space **ws**. With transfer calls, RuleSet invocations can be arbitrarily deep without using proportional stack space.

2.14 Stop Statements

To provide premature terminations in the execution of a RuleSet, the Stop statement is provided.

<u>(Stop <i>value</i>)</u>	<u>[RuleSet Statement]</u>

value is the value to be returned by the RuleSet.

[This page intentionally left blank]

Overview of the Manual

This manual describes the Users' Modules for Xerox's Lisp Object-Oriented Programming System, LOOPS (TM), to developers.

Note: Venue does not support LOOPS Users' Modules. However, each Users' Module contains the name and network mailing address of the person who wrote or last modified that module, and the date it was written or last modified.

This manual describes the Lyric/Medley Release of the LOOPS Users' Modules, which run under the Lyric and Medley Releases of Lisp.

Organization of the Manual and How to Use It

This manual is divided into chapters, with each chapter describing a separate Users' Module.

To use the manual, read the chapter that corresponds to the Users' Module you want to use. A general Table of Contents is provided to help you locate specific information.

Conventions

This manual uses the following conventions:

- Case is significant in LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

`(← self Selector Arg1 Arg2)`

- Examples appear in the following typeface:

`89← (←LOGIN)`

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.

- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form **ClassName.SelectorName**.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

3. USING RULES IN LOOPS

The LOOPS rules language is supported by an integrated programming environment for creating, editing, compiling, and debugging RuleSets. This section describes how to use that environment.

3.1 Creating RuleSets

RuleSets are named LOOPS objects and are created by sending the class **RuleSet** a **New** message as follows:

```
(_ ($ RuleSet) New)
```

After entering this form, the user will be prompted for a LOOPS name as

RuleSet name: *RuleSetName*

Afterwards, the RuleSet can be referenced using LOOPS dollar sign notation as usual. It is also possible to include the RuleSet name in the **New** message as follows:

```
(_ ($ RuleSet) New NIL RuleSetName)
```

3.2 Editing RuleSets

A RuleSet is created empty of rules. The RuleSet editor is used to enter and modify rules. The editor can be invoked with an **EditRules** message (or **ER** shorthand message) as follows:

```
(_ RuleSet EditRules)
```

```
(_ RuleSet ER)
```

If a RuleSet is installed as a method of a class, it can be edited conveniently by selecting the **EditMethod** option from a browser containing the class. Alternatively, the **EditMethod** message can be used:

```
(_ ClassName EditMethod selector) [Message]
```

Both approaches to editing retrieve the source of the RuleSet and put the user into the TTYIN or TEdit editor, treating the rule source as text.

Initially, the source is a template for RuleSets as shown in Figure 7. The rules are entered after the comment at the bottom. The declarations at the beginning are filled in as needed and superfluous declarations can be discarded.

```

RuleSet Name: RuleSetName;
Workspace Class:  ClassName;
Control Structure: doAll;
While Condition:  ;
Audit Class:  StandardAuditRecord;
Rule Class:  Rule;
Task Class:  ;
Meta Assignments:  ;
Temporary Vars:  ;
Lisp Vars:  ;
Debug Vars:  ;
Compiler Options:  ;

(* Rules for whatever.  Comment goes here.)

```

Figure 7. Initial Template for a RuleSet

You can then edit this template to enter rules and set the declarations at the beginning. In the current version of the rule editor, most of these declarations are left out. If you choose the **EditAllDecls** option in the RuleSet editor menu, the declarations and default values will be printed in full.

The template is only a guide. Declarations that are not needed can be deleted. For example, if there are no temporary variables for this RuleSet, the **Temporary Vars** declaration can be deleted. If the control structure is not one of the **while** control structures, then the **While Condition** declaration can be deleted. If the compiler option **A** is not chosen, then the **Audit Class** declaration can be deleted.

When you leave the editor, the RuleSet is compiled automatically into a Lisp function.

If a syntax error is detected during compilation, an error message is printed and you are given another opportunity to edit the RuleSet.

3.3 Copying RuleSets

Sometimes it is convenient to create new RuleSets by editing a copy of an existing RuleSet. For this purpose, the method **CopyRules** is provided as follows:

```

(_ oldRuleSet CopyRules newRuleSetName) [Message]

```

This creates a new RuleSet by some of the information from the perspectives of the old RuleSet. It also updates the source text of the new RuleSet to contain the new name.

3.4 Saving RuleSets on Lisp Files

RuleSets can be saved on Lisp files just like other LOOPS objects. In addition, it is usually useful to save the Lisp functions that result from RuleSet compilation. In the current implementation, these functions have the same names as the RuleSets themselves. To save RuleSets on a file, it is necessary to add two statements to the file commands for the file as follows:

```
(FNS * MyRuleSetNames)
(INSTANCES * MyRuleSetNames)
```

where **MyRuleSetNames** is a Lisp variable whose value is a list of the names of the RuleSets to be saved.

If RuleSets are methods associated with a class, and they are saved by using (FILES?), then the file package saves the appropriate entries. The user does not have to be concerned with editing the filecoms of the file being made.

3.5 Printing RuleSets

To print a RuleSet without editing it, one can send a **PPRules** or **PPR** message as follows:

```
( _ RuleSet PPRules) [Message]
( _ RuleSet PPR) [Message]
```

A convenient way to make hardcopy listings of RuleSets is to use the function **ListRuleSets**. The files will be printed on the **DEFAULTPRINTINGHOST** as is standard in Interlisp-D. **ListRuleSets** can be given four kinds of arguments as follows:

```
(ListRuleSets RuleSetName)
(ListRuleSets ListOfRuleSetNames)
(ListRuleSets ClassName)
(ListRuleSets FileName)
```

In the *ClassName* case, all of the RuleSets that have been installed as methods of the class will be printed. In the last case, all of the RuleSets stored in the file will be printed.

3.6 Running RuleSets from LOOPS

RuleSets can be invoked from LOOPS using any of the usual protocols.

Procedure-oriented Protocol: The way to invoke a RuleSet from LOOPS is to use the **RunRS** function:

(RunRS RuleSet workSpace arg2 ... argN) [Function]

workSpace is the LOOPS object to be used as the work space.
This is "procedural" in the sense that the RuleSet is invoked by its name. *RuleSet* can be either a RuleSet object or its name.

Object-oriented Protocol: When RuleSets are installed as methods in LOOPS classes, they can be invoked in the usual way by sending a message to an instance of the class. For example, if **WashingMachine** is a class with a RuleSet installed for its **Simulate** method, the RuleSet is invoked as follows:

(_ washingMachineInstance Simulate)

Data-oriented Protocol: When RuleSets are installed in active values, they are invoked by side-effect as a result of accessing the variable on which they are installed.

3.7 Installing RuleSets as Methods

RuleSets can also be used as methods for classes. This is done by installing automatically-generated invocation functions that invoke the RuleSets. For example:

```
[DEFCLASS WashingMachine
  (MetaClass Class doc (* comment) ...)
  ...
  (InstanceVariables (owner ...))
  (Methods
    (Simulate RunSimulateWMRules)
    (Check RunCheckWMRules
      doc (* Rules to Check a washing machine.))
  )
...]
```

When an instance of the class **WashingMachine** receives a **Simulate** message, the RuleSet **SimulateWMRules** will be invoked with the instance as its work space.

To simplify the definition of RuleSets intended to be used as Methods, the function **DefRSM** (for "Define Rule Set as a Method") is provided:

(DefRSM ClassName Selector RuleSetName) [Function]

If the optional argument *RuleSetName* is given, **DefRSM** installs that RuleSet as a method using the *ClassName* and *Selector*. It does this by automatically generating an installation function as a method to invoke the RuleSet. **DefRSM** automatically documents the installation function and the method.
If the argument *RuleSetName* is **NIL**, then **DefRSM** creates the RuleSet object, puts the user into an Editor to enter the rules,

compiles the rules into a Lisp function, and installs the RuleSet as before.

DefRSM can be invoked with the browser as follows:

- Position the cursor over a class in a browser.
- Press the middle mouse button. A menu pops up.
- Select the Add option in this menu, and drag the mouse to the right to display the submenu that includes the "DefRSM" option. You are prompted to enter a selector name.

After a RuleSet has been installed as a method by using **DefRSM**, you can then edit that RuleSet by selecting the "EditMethod" option from the browser editing menu.

3.8 Installing RuleSets in Active Values

Note: The following section and any other references to active values within the rule documentation refer to active values as they were implemented in the Buttriss release. The functionality of triggering rules from active values has not been tested using the current implementation of active values. It should work to use the **ExplicitFnActiveValue** class to implement this behavior.

RuleSets can also be used in data-oriented programming so that they are invoked when data is accessed. To use a RuleSet as a *getFn*, the function **RSGetFn** is used with the property **RSGet** as follows:

```
...
(InstanceVariables
  (myVar #(myVal RSGetFn NIL) RSGet RuleSetName))
...
```

RSGetFn is a LOOPS system function that can be used in an active value to invoke a RuleSet in response to a LOOPS get operation (e.g., **GetValue**) is performed. It requires that the name of the RuleSet be found on the **RSGet** property of the item. **RSGetFn** activates the RuleSet using the local state as the work space. The value returned by the RuleSet is returned as the value of the get operation.

To use a RuleSet as a *putFn*, the function **RSPutFn** is used with the property **RSPut** as follows:

```
...
(InstanceVariables
  (myVar #(myVal NIL RSPutFn) RSPut RuleSetName))
...
```

RSPutFn is a function that can be used in an active value to invoke a RuleSet in response to a LOOPS put operation (e.g., **PutValue**). It requires that the name of the RuleSet be found on the **RSPut** property of the item. **RSGetFn** activates the RuleSet using the *newValue* from the put

operation as the work space. The value returned by the RuleSet is put into the local state of the active value.

3.9 Tracing and Breaking RuleSets

LOOPS provides breaking and tracing facilities to aid in debugging RuleSets. These can be used in conjunction with the auditing facilities and the rule executive for debugging RuleSets. The following summarizes the compiler options for breaking and tracing:

T	Trace if rule is satisfied. Useful for creating a running display of executed rules.
TT	Trace if rule is tested.
B	Break if rule is satisfied.
BT	Break if rule is tested. Useful for stepping through the execution of a RuleSet.

Specifying the declaration **Compiler Options: T**; in a RuleSet indicates that tracing information should be displayed when a rule is satisfied. To specify the tracing of just an individual rule in the RuleSet, the **T** meta-descriptions should be used as follows:

{T} IF *cond* THEN *action*;

This tracing specification causes LOOPS to print a message whenever the LHS of the rule is tested, or the RHS of the rule is executed. It is also possible to specify that the values of some variables (and compound literals) are to be printed when a rule is traced. This is done by listing the variables in the **Debug Vars** declaration in the RuleSet:

Debug Vars: a a:b a:b.c;

This will print the values of **a**, **a:b**, and **a:b.c** when any rule is traced or broken.

Analogous specifications are provided for breaking rules. For example, the declaration **Compiler Options: B**; indicates that LOOPS is to enter the rule executive (see Section 3.10, "The Rule Exec") after the LHS is satisfied and before the RHS is executed. The rule-specific form:

{B} IF *cond* THEN *action*;

indicates that LOOPS is to break before the execution of a particular rule.

Sometimes it is convenient in debugging to display the source code of a rule when it is traced or broken. This can be effected by using the **PR** compiler option as in

Compiler Options: T PR;

which prints out the source of a rule when the LHS of the rule is tested and

Compiler Options: B PR;

which prints out the source of a rule when the LHS of a rule is satisfied, and before entering the break.

3.10 The Rule Exec

A Read-Compile-Evaluate-Print loop, called the rule Executive, is provided for the rule language. The rule Executive can be entered during a break by invoking the Lisp function **RE**. During RuleSet execution, the rule executive can be entered by typing **^f** (<control>-f) on the keyboard.

On the first invocation, **RE** prompts the user for a window. It then displays a stack of RuleSet invocations in a menu to the left of this window in a manner similar to the Interlisp-D Break Package. Using the left mouse button in this window creates an Inspector window for the work space for the RuleSet. Using the middle mouse button pretty prints the RuleSet in the default prettyprint window.

In the main rule Executive window, **RE** prompts the user with "**re:**". Anything in the rule language (other than declarations) that is typed to this Executive will be compiled and executed immediately and its value printed out. For example, you may type rules to see whether they execute or variable names to determine their values. For example:

re: trafficLight:color

Red

re:

this example shows how to get the value of the **color** variable of the **trafficLight** object. If the value of a variable was set by a RuleSet running with auditing, then a **why** question can be typed to the rule executive as follows:

re: why trafficLight:color

IF highLight:color = 'Green farmRoadSensor:cars timer.TL
THEN highLight:color _ 'Yellow timer.Start;

Rule 3 of RuleSet LightRules

Edited: Conway "13-Oct-82"

re:

The rule executive may be exited by typing **OK**.

3.11 Auditing RuleSets

Two declarations at the beginning of a RuleSet affect the auditing. Auditing is turned on by the compiler option **A**. The simplest form of this is

Compiler Options: A;

The **Audit Class** declaration indicates the class of the audit record to be used with this RuleSet if it is compiled in *audit* mode.

Audit Class: StandardAuditRecord;

A **Meta Assignments** declaration can be used to indicate the audit description to be used for the rules unless overridden by a rule-specific meta-assignment statement in a meta-descriptor.

Meta Assignments: cf_ .5 support_ 'GroundWff;

3.12 Loading Rules

Set the variable LOOPSUSERSDIRECTORIES to include the directory where the Rules files are stored.

Load the file LOOPSRULES-ROOT.LCOM, which will load the following files from LOOPSUSERSDIRECTORIES:

- LOOPSBACKWARDS.LCOM
- LOOPSMIXIN
- LOOPSRULES.LCOM
- LOOPSRULESP.LCOM
- LOOPSRULESC.LCOM
- LOOPSRULESD.LCOM, which will load the file TTY.LCOM from LISPUSERSDIRECTORIES.

Editing rules will be easier if TEdit is loaded. Loading the Rules does not automatically load TEdit.

3.13 Known Problems

In a rule, the expression \$pipe.ri..\$p compiles to (RunRS (QUOTE (\$ pipe)) (\$ p)), which fails.

Meta-assignment statements cannot handle expressions. This means that statements like {cf _ .5} work fine, but {validity _ 'fact} fails.

A value of 1 in a meta-descriptor statement is always taken to be a one-shot designator. You cannot have a meta-descriptor statement like {cf_1}. However, the number 1.0 can be used; the meta-descriptor statement, {cf_1.0}, works.

Rules have not been tested without loading TEdit in order to edit RuleSets.

CONVERT-LOOPS-FILES

By: Bob Bane (Bane.pa@Xerox.com)

5-Feb-88

INTRODUCTION

CONVERT-LOOPS-FILES allows you to convert files from the Koto release of LOOPS to the Medley release. The changes from the Koto release are described in detail in the *LOOPS Release Notes*.

PROCEDURE

To convert Koto LOOPS Files to Lyric/Medley Loops:

1. Your files must be from Koto LOOPS. Pre-Koto LOOPS files must first be run through the Buttrech->Koto converter in a Koto LOOPS sysout.
2. Install and load your Lyric LOOPS sysout. You need to have TEdit loaded, as the converter uses it.
3. Load the file CONVERSION-AIDS.DFASL, which defines the function

```
(CONVERT-LOOPS-FILES <list-of-files> <dump-files-p>)
```

where:

<list-of-files> A filename or a list of filenames to be converted.

<dump-files-p> Determines disposition of files.

- If non-NIL, converted files will be dumped back out immediately.
- If :COMPILE, they will be compiled.
- If :COMPILE/LOAD, they will be compiled and the compiled code loaded.

4. Call CONVERT-LOOPS-FILES with the names of the files you want converted and an appropriate option.

Note the following:

- CONVERT-LOOPS-FILES makes more than one pass over the files being converted; the first pass is a TEdit textual change to make the files loadable into Medley LOOPS. If you specify version numbers in your <list-of-files>, these changes will be made in place on your original files.
- The converter doesn't work completely automatically on systems consisting of several files that automatically load themselves with FILES coms; the converter may try to load subfiles before they are converted. It may be necessary to RETURN NIL from the LOAD calls in the break windows that will occur when this problem comes up. Aside from that, the converter works reasonably well, and has been used to convert large LOOPS systems with almost no source code changes from Koto Loops.

LOOPSBACKWARDS

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSBACKWARDS allows you to run files which were previously converted from the Buttriss release of LOOPS to the Koto release. Unlike the Koto version of LOOPSBACKWARDS conversion methods for moving files from Buttriss LOOPS to Koto LOOPS are included but **not supported**. *We strong recommend that you convert LOOPS source code from Buttriss to Koto using the Koto release of LOOPS.* Conversion of Koto LOOPS source code to Lyric LOOPS is done using the CONVERSION-AIDS users' module.

The changes between the Buttriss and Koto releases are described in detail in the *LOOPS Release Notes* for the **Koto** release. Old features that are included in LOOPSBACKWARDS are summarized here:

- Many functions that were removed from the Buttriss release are defined.
- The messages **List** and **List!** are available.
- The operation of old style active values, from the Buttriss release, are provided.
- Support for reading old style macros, such as `$(localState getFn putFn)` or `#$Mumble`, is available.

LOOPSBACKWARDS is an unsupported LOOPS users module. It is strongly recommended that it only be used as part of an effort to upgrade very old LOOPS code to newer releases. It will allow very old LOOPS code to run well enough that it can be rewritten for a newer release.

INSTALLATION

LOOPSVCOPY will be automatically loaded by LOOPSBACKWARDS.

FUNCTIONS

LOOPSBACKWARDS includes **ExplicitFnActiveValue** and **DefAVP**. **ExplicitFnActiveValue** allows the user code triggered by Get- or Put- accesses to be stored within functions which are pointed to by instance variables rather than requiring the redefinition of **GetWrappedValue** or **PutWrappedValue**. These functions must have the form specified in the **DefAVP** function.

ExplicitFnActiveValue

[Class]

Purpose: Mimics the behavior of the Buttruss style of active values.

Behavior: Get- accesses to the wrapped variable cause the **getFn** to be called, Put- accesses cause **putFn** to be called. Enables the old style activeValue to look like the new style without changing any functionality.

The **getFn** is called by the **ExplicitFnActiveValue** **GetWrappedValue** method. This method passes to the **getFn** the arguments defined by **DefAVP** as described in the *LOOPS Users' Modules*.

The **putFn** is called by the **ExplicitFnActiveValue** **PutWrappedValue** method. This method passes to the **putFn** the arguments defined by **DefAVP** as described in the *LOOPS Users' Modules*.

Instance Variables: **localState** A place for data storage.

getFn The name of a function applied when the active variable is read.

putFn The name of a function applied when the active variable is changed.

Example:

```
32← (← ($ Bin) New 'bin4)
#, ($& Bin (|DAW0.1Y:.H53.]99| . 521))

33← (← ($ ExplicitFnActiveValue) New 'EFAV1)
#, ($& ExplicitFnActiveValue (|DAW0.1Y:.H53.]99| . 522))

34← (DEFINEQ (PrintOnGet
  (self varName localSt propName activeVal type)
  (PRINTOUT T "I am:" , activeVal T) localSt))
(PrintOnGet)

35← (←@ ($ EFAV1) getFn 'PrintOnGet)
PrintOnGet

36← (← ($ EFAV1) AddActiveValue ($ bin4) 'height)
#, ($A #,NestedNotSetValue PrintOnGet NIL)

37← (←@ ($ bin4) height 123)
123

38← (@ ($ bin4) height)
```

```
I am: #, ($ EFAV1)
123
```

(DefAVP *fnName putFlg*) [Function]

Purpose: Creates a template for defining an active value function.

Behavior: Creates a template and leaves you in the Interlisp function display editor.

Arguments: *fnName* Name of the function.
 putFlg T indicates function is a **putFn**, NIL indicates a **getFn**.

Returns: The function name on exit from the editor .

Example: In each of the following cases the template only is shown. User code is to be added immediately after the comment by using the display editor.

```
66← (DefAVP 'AGetFn)
AGetFn

67←PP* AGetFn
(AGetFn
  [LAMBDA (self varName localSt propName activeVal type)
    (* This is a getFn. The value of this getFn is
    returned as the value of the enclosing GetValue.)
    localSt])
(AGetFn)

68← (DefAVP 'APutFn T)
APutFn

69←PP* APutFn
(APutFn
  [LAMBDA (self varName newValue propName activeVal type)
    (* This is a putFn. ***NOTE*** The value of this
    function will be returned as the value of any enclosing
    PutValue. This usually means that you want to return the value
    returned by PutLocalState.)
    (PutLocalState activeVal newValue self varName propName
    type)])
(APutFn)
```

LOOPSMIXIN

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSMIXIN defines several small classes that can be mixed into your application classes. It also defines the class **Perspective** and its support classes, which are used in the implementation of LOOPS Rules. Perspectives allow you to view one object as having more than one class at a time; they have not been tested extensively outside of Rules and are known to have major bugs which don't affect Rules, so they are not documented here.

LOOPSMIXIN Classes

DatedObject - Defines the instance variables **created** and **creator** which are set at object creation time to the values of (DATE) and (USERNAME).

NamedObject - Defines the instance variable **name** and initializes it to an ActiveValue that insures that the LOOPS system name for the containing object is uniquely name; i.e. storing a name for the object in **name** causes the previous name for the object to be removed with **DeleteObjectName** and the new name for the object to be asserted with **NameEntity**.

GlobalNamedObject - A subclass of **NamedObject** that works the same way as **NamedObject**.

ListMetaClass - Specializes the **New** and **DestroyInstance** methods to keep a list of all instances of that class in the class property **AllInstances** for that class.

StrucMeta - A MetaClass useful for creating new classes. Specializes the **New** method to create a Class object by copying the instance variable and class variable descriptions of the current class. Class variables with a non-NIL Local property will not be copied.

TempClass - Specializes the **New** method to always create objects of this class using the **NewTemp** method, insuring that the objects will be temporary objects.

Perspective, Node, Template, TextItem - These classes are used in LOOPS Rules.

[This page intentionally left blank]

Overview of the Manual

This manual describes the Users' Modules for Xerox's Lisp Object-Oriented Programming System, Xerox LOOPS (TM), to developers.

Note: Xerox does not support Xerox LOOPS Users' Modules. However, each Users' Module contains the name and network mailing address of the person who wrote or last modified that module, and the date it was written or last modified.

This manual describes the Lyric/Medley Release of the Xerox LOOPS Users' Modules, which run under the Lyric and Medley Releases of Xerox Lisp.

Organization of the Manual and How to Use It

This manual is divided into chapters, with each chapter describing a separate Users' Module.

To use the manual, read the chapter that corresponds to the Users' Module you want to use. A general Table of Contents is provided to help you locate specific information.

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

`(_ self Selector Arg1 Arg2)`

- Examples appear in the following typeface:

`89_ (_ LOGIN)`

- All examples are typed into an Interlisp Exec. This is the recommended Exec for all Xerox LOOPS expressions.
- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.

- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form **ClassName.SelectorName**.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

References

The following books and manuals augment this manual.

Xerox LOOPS Reference Manual

Xerox LOOPS Release Notes

Writer's Notes -- Conventions

This file includes notes on conventions for *Xerox LOOPS Users' Modules Manual*, Lyric Beta Release. This manual is packaged in one binder.

Writer: Raven Kontur Brewster

Printing Date: 22 February 1988

Directories and Files

The directory {ERIS}<Doc>Loops>Lyric>Beta>UserMods> contains the files for the manual. This directory has the following subdirectories:

- {ERIS}<Doc>Loops>Lyric>Beta>UserMods>Z-ReleaseInfo> contains this file on writing conventions and a file on production details.

Filenames describe the contents of the file. For example, the filename

{ERIS}<Doc>Loops>Lyric>Beta>UserMods>LoopsMixin.tedit

contains the chapter on LoopsMixin.

Assemble the files in the following order for the manual:

{ERIS}<Doc>Loops>Lyric>Beta>UserMods>A1-TitlePage.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>A2-TOC.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>A3-Preface.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Converter.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>LoopsBackwards.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>LoopsMixin.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules-A1-TitlePage.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules-A2-TOC.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules-A3-LOF.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules1-Intro.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules2-Language.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>Rules3-Use.tedit
{ERIS}<Doc>Loops>Lyric>Beta>UserMods>RulesA-Convert.tedit

Conventions

This manual uses the following conventions:

- Case is significant in Xerox LOOPS and Lisp. All selectors, methods, arguments, etc., must be typed as shown. Typically, this means that method names are capitalized and variables are not.
- Arguments appear in italic type.
- Selectors, methods, functions, objects, classes, and instances appear in bold type.

For example, a method appears as follows:

(_ self **Selector** *Arg1 Arg2*)

- Examples appear in the following typeface:

89_ (_ LOGIN)

- Methods with an exclamation mark (!) suffix usually perform operations deeply into class structure instead of only on a given object.
- Methods with a question mark (?) suffix usually are predicates; that is, truth functions.
- Methods often appear in the form **ClassName.SelectorName**.
- Cautions describe possible dangers to hardware or software.
- Notes describe related text.

Style Sheet Addenda

Here are some guidelines I used when writing the LOOPS manuals. Items appear in rather random order.

- Avoid contractions.
- Avoid subscripts. Use WORD1 rather than WORD to avoid inconsistent line leading.
- Avoid wording that starts "Note that..." or "Notice that...". Either make it a note with correct format or eliminate the "Note that".
- Use semicolons rather than m-dashes.
- Each item in the template starts with an initial capital letter; e.g., "Describes..."
- The arguments are identical in the call and in the argument description.
- Parentheses appear around expressions and square brackets appear around the name of the functionality.
- The arrow in the expression is the NS character $\leftarrow$, not $\rightarrow$. These characters appear similarly when printed, but differently on the screen. See the section, "Special Notes and Cautions," for details.
- A period appears after the word None, after argument descriptions, and Returns: item.
- Items are set to or return T (instead of true).
- Menus contain options, not items or selections.
- You drag (not roll) the mouse to the right of a menu option to see its submenu.
- Use "above" and "below" when referring to things in the same section, section numbers and names when referring to things in the same chapter, and chapter numbers and names when referring to things in another chapter.
- Please study the following style sheet carefully before you start to edit. The various appearances of active value and annotated values are especially crazy making.

These things appear in **bold**:

class variables
functions
instance variables
messages
methods
variables

ActiveValue - specific class/instance
 active value - general information
 activeValue - previous implementation of **ActiveValue**

annotatedValue - data type
AnnotatedValue - specific class
 annotated values - general information

bitmap

data type

file package
 filecoms

inspector

Lisp Library package
localState - instance variable

non-NIL

prettyprints

supers list

Bitmaps, Graphs, and Sketches

Scale for bitmaps is 0.75.

Special Notes and Cautions

Make sure you have changed the underscore to be a left arrow before loading and printing any files. To do this,

- Enter the following commands into your Executive:

```
(GETCHARBITMAP (CHARCODE _) '(MODERN 10 MRR))
(EDITBM IT)
```

- When the bitmap editor appears, delete the underscore and insert the following left arrow:

```
.....
.....
.....
.....
.....
...X....
...XX...
..XXXXX.
...XX...
...X....
.....
.....
.....
.....
```

- Finally, enter the following commands into your Executive to store the pattern:

```
(PUTCHARBITMAP (CHARCODE _) '(MODERN 10 MRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(MODERN 10 BRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 MRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 10 BRR) IT)
(PUTCHARBITMAP (CHARCODE _) '(TERMINAL 12 BRR) IT)
```

CONVERT-LOOPS-FILES

By: Bob Bane (Bane.pa@Xerox.com)

5-Feb-88

INTRODUCTION

CONVERT-LOOPS-FILES allows you to convert files from the Koto release of Xerox LOOPS to the Lyric/Medley release. The changes from the Koto release are described in detail in the *Xerox LOOPS Release Notes*.

PROCEDURE

To Convert Koto LOOPS Files to Lyric/Medley Loops:

1. Your files must be from Koto LOOPS. Pre-Koto LOOPS files must first be run through the Buttress->Koto converter in a Koto LOOPS sysout.
2. Install and load your Lyric LOOPS sysout. You need to have TEdit loaded, as the converter uses it.
3. Load the file CONVERSION-AIDS.DFASL, which defines the function

```
(CONVERT-LOOPS-FILES <list-of-files> <dump-files-p>)
```

where:

<list-of-files> A filename or a list of filenames to be converted.

<dump-files-p> Determines disposition of files.

- If non-NIL, converted files will be dumped back out immediately.
- If :COMPILE, they will be compiled.
- If :COMPILE/LOAD, they will be compiled and the compiled code loaded.

4. Call CONVERT-LOOPS-FILES with the names of the files you want converted and an appropriate option.

Note the following:

- CONVERT-LOOPS-FILES makes more than one pass over the files being converted; the first pass is a TEdit textual change to make the files loadable into Lyric/Medley LOOPS. If you specify version numbers in your <list-of-files>, these changes will be made in place on your original files.
- The converter doesn't work completely automatically on systems consisting of several files that automatically load themselves with FILES coms; the converter may try to load subfiles before they are converted. It may be necessary to RETURN NIL from the LOAD calls in the break windows that will occur when this problem comes up. Aside from that, the converter works reasonably well, and has been used to convert large LOOPS systems with almost no source code changes from Koto Loops.

LOOPSBACKWARDS

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSBACKWARDS allows you to run files which were previously converted from the Buttriss release of Xerox LOOPS to the Koto release. Unlike the Koto version of LOOPSBACKWARDS conversion methods for moving files from Buttriss LOOPS to Koto LOOPS are included but **not supported**. *We strong recommend that you convert LOOPS source code from Buttriss to Koto using the Koto release of LOOPS.* Conversion of Koto LOOPS source code to Lyric LOOPS is done using the CONVERSION-AIDS users' module.

The changes between the Buttriss and Koto releases are described in detail in the *Xerox LOOPS Release Notes* for the **Koto** release. Old features that are included in LOOPSBACKWARDS are summarized here:

- Many functions that were removed from the Buttriss release are defined.
- The messages **List** and **List!** are available.
- The operation of old style active values, from the Buttriss release, are provided.
- Support for reading old style macros, such as `$(localState getFn putFn)` or `#$Mumble`, is available.

LOOPSBACKWARDS is an unsupported LOOPS users module. It is strongly recommended that it only be used as part of an effort to upgrade very old LOOPS code to newer releases. It will allow very old LOOPS code to run well enough that it can be rewritten for a newer release.

INSTALLATION

LOOPSVCOPY will be automatically loaded by LOOPSBACKWARDS.

FUNCTIONS

LOOPSBACKWARDS includes **ExplicitFnActiveValue** and **DefAVP**. **ExplicitFnActiveValue** allows the user code triggered by Get- or Put- accesses to be stored within functions which are pointed to by instance variables rather than requiring the redefinition of **GetWrappedValue** or **PutWrappedValue**. These functions must have the form specified in the **DefAVP** function.

ExplicitFnActiveValue

[Class]

Purpose: Mimics the behavior of the Buttruss style of active values.

Behavior: Get- accesses to the wrapped variable cause the **getFn** to be called, Put- accesses cause **putFn** to be called. Enables the old style activeValue to look like the new style without changing any functionality.

The **getFn** is called by the **ExplicitFnActiveValue GetWrappedValue** method. This method passes to the **getFn** the arguments defined by **DefAVP** as described in the *Xerox LOOPS Users' Modules*.

The **putFn** is called by the **ExplicitFnActiveValue PutWrappedValue** method. This method passes to the **putFn** the arguments defined by **DefAVP** as described in the *Xerox LOOPS Users' Modules*.

Instance Variables: **localState** A place for data storage.

getFn The name of a function applied when the active variable is read.

putFn The name of a function applied when the active variable is changed.

Example:

```

32_(_ ($ Bin) New 'bin4)
#,($& Bin (|DAW0.1Y:.H53.]99| . 521))

33_(_ ($ ExplicitFnActiveValue) New 'EFAV1)
#,($& ExplicitFnActiveValue (|DAW0.1Y:.H53.]99| . 522))

34_(DEFINEQ (PrintOnGet
  (self varName localSt propName activeVal type)
  (PRINTOUT T "I am:" , activeVal T) localSt))
(PrintOnGet)

35_(@ ($ EFAV1) getFn 'PrintOnGet)
PrintOnGet

36_(_ ($ EFAV1) AddActiveValue ($ bin4) 'height)
#,($A #,NestedNotSetValue PrintOnGet NIL)

37_(@ ($ bin4) height 123)
123

38_(@ ($ bin4) height)

```

```
I am: #, ($ EFAV1)
123
```

(DefAVP *fnName putFlg*)

[Function]

Purpose: Creates a template for defining an active value function.

Behavior: Creates a template and leaves you in the Interlisp function display editor.

Arguments: *fnName* Name of the function.
putFlg T indicates function is a **putFn**, NIL indicates a **getFn**.

Returns: The function name on exit from the editor .

Example: In each of the following cases the template only is shown. User code is to be added immediately after the comment by using the display editor.

```
66_ (DefAVP 'AGetFn)
AGetFn
```

```
67_PP* AGetFn
(AGetFn
 [LAMBDA (self varName localSt propName activeVal type)
  (* This is a getFn. The value of this getFn is
 returned as the value of the enclosing GetValue.)
  localSt])
(AGetFn)
```

```
68_ (DefAVP 'APutFn T)
APutFn
```

```
69_PP* APutFn
(APutFn
 [LAMBDA (self varName newValue propName activeVal type)
  (* This is a putFn. ***NOTE*** The value of this
 function will be returned as the value of any enclosing
 PutValue. This usually means that you want to return the value
 returned by PutLocalState.)
  (PutLocalState activeVal newValue self varName propName
 type)])
(APutFn)
```

LOOPSMIXIN

By: Bob Bane (Bane.pa@Xerox.com)

15-Dec-87

INTRODUCTION

LOOPSMIXIN defines several small classes that can be mixed into your application classes. It also defines the class **Perspective** and its support classes, which are used in the implementation of Xerox LOOPS Rules. Perspectives allow you to view one object as having more than one class at a time; they have not been tested extensively outside of Rules and are known to have major bugs which don't affect Rules, so they are not documented here.

LOOPSMIXIN Classes

DatedObject - Defines the instance variables **created** and **creator** which are set at object creation time to the values of (DATE) and (USERNAME).

NamedObject - Defines the instance variable **name** and initializes it to an ActiveValue that insures that the Xerox LOOPS system name for the containing object is uniquely name; i.e. storing a name for the object in **name** causes the previous name for the object to be removed with **DeleteObjectName** and the new name for the object to be asserted with **NameEntity**.

GlobalNamedObject - A subclass of **NamedObject** that works the same way as **NamedObject**.

ListMetaClass - Specializes the **New** and **DestroyInstance** methods to keep a list of all instances of that class in the class property **AllInstances** for that class.

StrucMeta - A MetaClass useful for creating new classes. Specializes the **New** method to create a Class object by copying the instance variable and class variable descriptions of the current class. Class variables with a non-NIL Local property will not be copied.

TempClass - Specializes the **New** method to always create objects of this class using the **NewTemp** method, insuring that the objects will be temporary objects.

Perspective, Node, Template, TextItem - These classes are used in Xerox LOOPS Rules.

Printing Information

The manual was printed under a Lyric sysout on the Tsunami printer.

1. INTRODUCTION TO RULE-ORIENTED PROGRAMMING IN XEROX LOOPS

The core of decision-making expertise in many kinds of problem solving can be expressed succinctly in terms of rules. The following sections describe facilities in Xerox LOOPS for representing rules, and for organizing knowledge-based systems with rule-oriented programming. The Xerox LOOPS rule language provides an experimental framework for developing knowledge-based systems. The rule language and programming environment are integrated with the object-oriented, data-oriented, and procedure-oriented parts of Xerox LOOPS.

Rules in Xerox LOOPS are organized into production systems (called RuleSets) with specified control structures for selecting and executing the rules. The work space for RuleSets is an arbitrary Xerox LOOPS object.

Decision knowledge can be factored from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions. An audit trail records inferential support in terms of the rules and data that were used. Such trails are important for knowledge-based systems that must be able to account for their results. They are also essential for guiding belief revision in programs that need to reason with incomplete information.

1.1 Introduction

Production rules have been used in expert systems to represent decision-making knowledge for many kinds of problem-solving. Such rules (also called *if-then* rules) specify actions to be taken when certain conditions are satisfied. Several rule languages have been developed in the past few years and used for building expert systems. The following sections describe the concepts and facilities for rule-oriented programming in Xerox LOOPS.

Xerox LOOPS has the following major features for rule-oriented programming:

- (1) Rules in Xerox LOOPS are organized into ordered sets of rules (called RuleSets) with specified control structures for selecting and executing the rules. Like subroutines, RuleSets are building blocks for organizing programs hierarchically.
- (2) The work space for rules in Xerox LOOPS is an arbitrary Xerox LOOPS object. The names of the instance variables provide a name space for variables in the rules.
- (3) Rule-oriented programming is integrated with object-oriented, data-oriented, and procedure-oriented programming in Xerox LOOPS.
- (4) RuleSets can be invoked in several ways: In the object-oriented paradigm, they can be invoked as methods by sending messages to objects. In the data-oriented paradigm, they can be invoked

as a side-effect of fetching or storing data in active values. They can also be invoked directly from Lisp programs. This integration makes it convenient to use the other paradigms to organize the interactions between RuleSets.

- (5) RuleSets can also be invoked from rules either as predicates on the LHS of rules, or as actions on the RHS of rules. This provides a way for RuleSets to control the execution of other RuleSets.
- (6) Rules can automatically leave an audit trail. An audit trail is a record of inferential support in terms of rules and data that were used. Such trails are important for programs that must be able to account for their results. They can also be used to guide belief revision in programs that must reason with incomplete information.
- (7) Decision knowledge can be separated from control knowledge to enhance the perspicuity of rules. The rule language separates decision knowledge from meta-knowledge such as control information, rule descriptions, debugging instructions, and audit trail descriptions.
- (8) The rule language provides a concise syntax for the most common operations.
- (9) There is a fast and efficient compiler for translating RuleSets into Interlisp functions.
- (10) Xerox LOOPS provides facilities for debugging rule-oriented programs.

The following sections are organized as follows: Section 1.2, "Basic Concepts," outlines the basic concepts of rule-oriented programming in Xerox LOOPS. It contains many examples that illustrate techniques of rule-oriented programming. Section 1.3, "Organizing a Rule-Oriented Program," describes the rule syntax, and the remaining sections in this chapter discuss the facilities for creating, editing, and debugging RuleSets in Xerox LOOPS.

1.2 Basic Concepts

Rules express the conditional execution of actions. They are important in programming because they can capture the core of decision-making for many kinds of problem-solving. Rule-oriented programming in Xerox LOOPS is intended for applications to expert and knowledge-based systems.

The following sections outline some of the main concepts of rule-oriented programming. Xerox LOOPS provides a special language for rules because of their central role, and because special facilities can be associated with rules that are impractical for procedural programming languages. For example, Xerox LOOPS can save specialized audit trails of rule execution. Audit trails are important in knowledge systems that need to explain their conclusions in terms of the knowledge used in solving a problem. This capability is essential in the development of large knowledge-intensive systems, where a long and sustained effort is required to create and validate knowledge bases. Audit trails are also important for programs that do non-monotonic reasoning. Such programs must work with incomplete information, and must be able to revise their conclusions in response to new information.

1.3 Organizing a Rule-Oriented Program

In any programming paradigm, it is important to have an organizational scheme for composing large systems from smaller ones. Stated differently, it is important to have a method for partitioning large programs into nearly-independent and manageably-sized pieces. In the procedure-oriented paradigm, programs are decomposed into procedures. In the object-oriented paradigm, programs are decomposed into objects. In the rule-oriented paradigm, programs are decomposed into *RuleSets*. A Xerox LOOPS program that uses more than one programming paradigm is factored across several of these dimensions.

There are three approaches to organizing the invocation of RuleSets in Xerox LOOPS:

Procedure-oriented Approach. This approach is analogous to the use of subroutines in procedure-oriented programming. Programs are decomposed into RuleSets that call each other and return values when they are finished. *SubRuleSets* can be invoked from multiple places. They are used to simplify the expression in rules of complex predicates, generators, and actions.

Object-oriented Approach. In this approach, RuleSets are installed as methods for objects. They are invoked as methods when messages are sent to the objects. The method RuleSets are viewed analogously to other procedures that implement object message protocols. The value computed by the RuleSet is returned as the value of the message sending operation.

Data-oriented Approach. In this approach, RuleSets are installed as access functions in active values. A RuleSet in an active value is invoked when a program gets or puts a value in the Xerox LOOPS object. As with active values with Lisp functions for the *getFn* or *putFn*, these RuleSet active values can be triggered by any Xerox LOOPS program, whether rule-oriented or not.

These approaches for organizing RuleSets can be combined to control the interactions between bodies of decision-making knowledge expressed in rules. For example, Figure 1 shows the RuleSet of consumer instructions for testing a washing machine. The work space for the ruleSet is a Xerox LOOPS object of the class **WashingMachine**. The control structure *While1* loops through the rules trying an escalating sequence of actions, starting again at the beginning of some rule is applied. Some rules, called one-shot rules, are executed at most once. These rules are indicated by preceding them with a one in braces ({1}).

```

RuleSet Name: CheckWashingMachine;
Workspace Class: WashingMachine;
Control Structure: while1;
While Condition: ruleApplied;

(* What a consumer should do when a washing machine failes.)

  IF .Operational THEN (STOP T);

  IF load>1.0 THEN .ReduceLoad;

  If ~pluggedInTo THEN .PlugIn;

{1} IF pluggedInTo:voltage=0 THEN breaker.Reset;
{1} IF pluggedInTo:voltage<110 THEN SPGE.Call;
{1} THEN dealer.RequestService;
{1} THEN manufacturer.Complain;
{1} THEN $ConsumerBoard.Complain;
{1} THEN (STOP T);

```

Figure 1. Basic RuleSet

1.4 Control Structures for Selecting Rules

RuleSets in Xerox LOOPS consist of an ordered list of rules and a control structure. Together with the contents of the rules and the data, a RuleSet control structure determines which rules are executed. Execution is determined by the contents of rules in that the conditions of a rule must be satisfied for it to be executed. Execution is also controlled by data in that different values in the data allow different rules to be satisfied. Criteria for iteration and rule selection are specified by a RuleSet control structure. There are two primitive control structures for RuleSets in Xerox LOOPS which operate as follows:

Do1

[RuleSet Control Structure]

The first rule in the RuleSet whose conditions are satisfied is executed. The value of the RuleSet is the value of the rule. If no rule is executed, the RuleSet returns **NIL**.

The **Do1** control structure is useful for specifying a set of mutually exclusive actions, since at most one rule in the RuleSet will be executed for a given invocation. When a RuleSet contains rules for specific and general situations, the specific rules should be placed before the general rules.

DoAll

[RuleSet Control Structure]

Starting at the beginning of the RuleSet, every rule is executed whose conditions are satisfied. The value of the RuleSet is the value of the last rule executed. If no rule is executed, the RuleSet returns **NIL**.

The **DoAll** control structure is useful when a variable number of additive actions are to be carried out, depending on which conditions are satisfied. In a single invocation of the RuleSet, all of the applicable rules are invoked.

Figure 2 illustrates the use of a **Do1** control structure to select one of three mutually exclusive actions.

```
RuleSet Name: SimulateWashingMachine;
Workspace Class: WashingMachine;
Control Structure: Do1 ;

(* Rules for controlling the wash cycle of a washing machine.)

IF controlSetting = 'RegularFabric
THEN .Fill .Wash .Pause .SpinAndDrain
    .SprayAndRinse .SpinAndDrain
    .Fill. DeepRinse .Pause .DampDry;

IF controlSetting = 'PermanentPress
THEN .Fill .Wash .Pause .SpinAndPartialDrain
    .FillCold .SpinAndPartialDrain
    .FillCold .Pause .SpinAndDrain
    .FillCold. DeepRinse .Pause .DampDry;

IF controlSetting = 'DelicateFabric
THEN .FillSoak1 .Agitate .Soak4 .Agitate
    .Soak1 .SpinAndDrain .SprayAndRinse
    .SpinAndDrain .Fill .DeepRinse .Pause .DampDry;
```

Figure 2. RuleSet showing Do1

There are two control structures in Xerox LOOPS that specify iteration in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

While1

[RuleSet Control Structure]

This is a cyclic version of **Do1**. If the while-condition is satisfied, the first rule is executed whose conditions are satisfied. This is repeated as long as the while condition is satisfied or until a **Stop** statement or transfer call is executed (see Section 2.14, "Stop Statements"). The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

WhileAll

[RuleSet Control Structure]

This is a cyclic version of **DoAll**. If the while-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the while condition is satisfied or until a **Stop** statement is executed. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

The "while-condition" is specified in terms of the variables and constants accessible from the RuleSet. The constant **T** can be used to specify a RuleSet that iterates forever (or until a **Stop** statement or transfer is executed). The special variable **ruleApplied** is used to specify a RuleSet that continues as long as some rule was executed in the last iteration. Figure 3 illustrates a simple use of the **WhileAll** control structure to specify a sensing/acting feedback loop for controlling the filling of a washing machine tub with water.

```

RuleSet Name: FillTub;
Workspace Class: WashingMachine;
Control Structure: WhileAll ;
Temp Vars: waterLimit;
WhileCond: T;

(* Rules for controlling the filling of a washing tub with
water.)

{1!} IF loadSetting = 'Small THEN waterLimit_10;
{1!} IF loadSetting = 'Meduim THEN waterLimit_13.5;
{1!} IF loadSetting = 'Large THEN waterLimit_17;
{1!} IF loadSetting = 'ExtraLarge THEN waterLimit_20;

(* Respond to a change of temperature setting at any time.)

IF termperatureSetting = 'Hot
THEN HotWaterValve.Open ColdWaterValve.Close;

IF termperatureSetting = 'Warm
THEN HotWaterValve.Open ColdWaterValve.Open;

IF termperatureSetting = 'Cold
THEN HotWaterValve.Close ColdWaterValve.Open;

(* Stop when the water reaches its limit.)

IF waterLevelSensor.Test >= waterLimit
THEN HotWaterValve.Close ColdWaterValve.Close
(Stop T);

```

Figure 3. RuleSet with WhileAll

There are two control structures in Xerox LOOPS that specify iteration over a set of elements in the execution of a RuleSet. These control structures use an explicit while-condition associated with the RuleSet. They are direct extensions of the two primitive control structures above.

FOR1

[RuleSet Control Structure]

This is a cyclic version of **Do1**. If the iteration-condition (or while-condition) is satisfied, the first rule is executed whose conditions are satisfied or until a **Stop** statement is executed. This is repeated as long as the iteration condition is satisfied. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

FORALL

[RuleSet Control Structure]

This is a cyclic version of **DoAll**. If the iteration-condition is satisfied, every rule is executed whose conditions are satisfied. This is repeated as long as the iteration condition is satisfied or until a **Stop** statement is executed. The value of the RuleSet is the value of the last rule that was executed, or **NIL** if no rule was executed.

The "iteration-condition" is specified in terms of the variables and constants accessible from the RuleSet. The simplest condition is

(FOR <iterVar> IN <setExpr> DO ruleSet) ;

The **setExpr** will be parsed with the RuleSet parser. The symbol **ruleSet** is a reserved word, and must be spelled as shown (no changes in capitalization).

Here is an example of iteration:

Control Structure: FORALL;

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO ruleSet) ;

For each buyer in the list produced by RoadStops, the ruleSet will be run. In a **FOR1**, the iteration will go on to the next buyer as soon as one rule executes. In a **FORALL**, all rules in the RuleSet will be tried.

For nested iteration one can use a slightly more complicated form, as illustrated by the following example:

**Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)) DO
(FOR seller in (RoadStops (\$ Producer)) DO ruleSet)) ;**

An experienced Lisp user can see that this resembles the CLISP iteration construct. In fact, except that you can (must) use the RuleSet syntax in the construct, it is the CLISP construct, and any such construct can be used. A DO1 or DOALL ruleSet will be substituted for the occurrence of the atom ruleSet, depending on whether the Control Structure is a FOR1 or FORALL.

As an abbreviation, if the construct does not contain the atom ruleSet, then (DO ruleSet) is appended to the Iteration Condition for a **FOR1** or **FORALL**. Thus one could write the first example as:

Iteration Condition: (FOR buyer IN (RoadStops (\$ Consumer)))

1.5 One-Shot Rules

One of the design objectives of Xerox LOOPS is to clarify the rules by factoring out control information whenever possible. This objective is met in part by the declaration of a control structure for RuleSets.

Another important case arises in cyclic control structures in which some of the rules should be executed only once. This was illustrated in the Washing Machine example in Figure 1 where we wanted to prevent the RuleSet from going into an infinite loop of resetting the breaker, when there was a short circuit in the Washing Machine. Such rules are also useful for initializing data for RuleSets as in the example in Figure 3.

In the absence of special syntax, it would be possible to encode the information that a rule is to be executed only once as follows:

Control Structure: While1
Temporary Vars: triedRule3;

...

IF ~triedRule3 condition condition THEN triedRule3_T action ;

In this example, the variable **triedRule3** is used to control the rule so that it will be executed at most once in an invocation of a RuleSet. However, the prolific use of rules with such control clauses in large systems has led to the common complaint that control clauses in rule languages defeat the expressiveness and conciseness of the rules. For the case above, Xerox LOOPS provides a shorthand notation as follows:

{1} IF condition condition THEN action ;

The brace notation means exactly the same thing in the example above, but it more concisely and clearly indicates that the rule executes only once. These rules are called "one shot" or "execute-once" rules.

In some cases, it is desired not only that a rule be executed at most once, but that it be tested at most once. This corresponds to the following:

Control Structure: While1
Temporary Vars: triedRule3;

...

IF ~triedRule3 triedRule3_T condition condition THEN action ;

In this case, the rule will not be tried more than once even if some of the conditions fail the first time that it is tested. The Xerox LOOPS shorthand for these rules (pronounced "one shot bang") is

{1!} **IF** *condition* *condition* **THEN** *action* ;

These rules are called "try-once" rules.

The two kinds of one-shot rules are our first examples of the use of meta-descriptions preceding the rule body in braces. See Section 1.7, "Saving an Audit Trail of Rule Invocation," for information on using meta-descriptions for describing the creation of audit trails.

1.6 First/Last Rules

It is sometimes useful to have rules which fire before or after the ordinary part of the RuleSet is invoked, independent of the form of the control structure. For example, in a DO1, such "FIRST " rules could be used for initialization. These now exist, and are notated by putting a {F} for a first rule in the MetaDescription field, and a {L} for a last rule. If a RuleSet has L rules which execute, the value of the RuleSet is the value of the last rule which executed.

1.7 Saving an Audit Trail of Rule Invocation

A basic property of knowledge-based systems is that they use knowledge to infer new facts from older ones. (Here we use the word "facts" as a neutral term, meaning any information derived or given, that is used by a reasoning system.) Over the past few years, it has become evident that reasoning systems need to keep track not only of their conclusions, but also of their reasoning steps. Consequently, the design of such systems has become an active research area in AI. The audit trail facilities of Xerox LOOPS support experimentation with systems that can not only use rules to make inferences, but also keep records of the inferential process itself.

1.7.1 Motivations and Applications

Debugging. In most expert systems, knowledge bases are developed over time and are the major investment. This places a premium on the use of tools and methods for identifying and correcting bugs in knowledge bases. By connecting a system's conclusions with the knowledge that it uses to derive them, audit trails can provide a substantial debugging aid. Audit trails provide a focused means of identifying potentially errorful knowledge in a problem solving context.

Explanation Facilities. Expert systems are often intended for use by people other than their creators, or by a group of people *pooling* their knowledge. An important consideration in validating expert systems is that reasoning should be *transparent*, that is, that a system should be able to give an account of its reasoning process. Facilities for doing this are sometimes called *explanation systems*.

and the creation of powerful explanation systems is an active research area in AI and cognitive science. The audit trail mechanism provides an essential computational prerequisite for building such systems.

Belief Revision. Another active research area is the development of systems that can "change their minds". This characteristic is critical for systems that must reason from incomplete or errorful information. Such systems get leverage from their ability to make assumptions, and then to recover from bad assumptions by efficiently reorganizing their beliefs as new information is obtained. Research in this area ranges from work on non-monotonic logics, to a variety of approaches to belief revision. The facilities in the rule language make it convenient to use a user-defined calculus of belief revision, at whatever level of abstraction is appropriate for an application.

1.7.2 Overview of Audit Trail Implementation

When *audit mode* is specified for a RuleSet, the compilation of assignment statements on the right-hand sides of rules is altered so that audit records are created as a side-effect of the assignment of values to instance variables. Audit records are Xerox LOOPS objects, whose class is specified in RuleSet declarations. The audit records are connected with associated instance variables through the value of the **reason** properties of the variables.

Audit descriptions can be associated with a RuleSet as a whole, or with specific rules. Rule-specific audit information is specified in a property-list format in the meta-description associated with a rule. For example, this can include *certainty factor* information, categories of inference, or categories of support. Rule-specific information overrides RuleSet information.

During rule execution in audit mode, the audit information is evaluated after the rule's LHS has been satisfied and before the rule's RHS is applied. For each rule applied, a single audit record is created and then the audit information from the property list in the rule's meta-description is put into the corresponding instance variables of the audit record. The audit record is then linked to each of the instance variables that have been set on the RHS of the rule by way of the **reason** property of the instance variable.

Additional computations can be triggered by associating active values with either the audit record class or with the instance variables. For example, active values can be specified in the audit record classes in order to define a uniform set of side-effects for rules of the same category. In the following example, such an active value is used to carry out a "certainty factor" calculation.

1.7.3 An Example of Using Audit Trails

The following example illustrates one way to use the audit trail facilities. Figure 4 illustrates a RuleSet which is intended to capture the decisions for evaluating the potential purchase of a washing machine. As with any purchasing situation, this one includes the difficulty of incomplete information about the product. For example in this RuleSet, the reliability of the washing machine is estimated to be 0.5 in the absence of specific information from *Consumer Reports*. The meta-descriptions for the rules, which appear in braces, categorize them in terms of the *basis of belief* (the category *basis* is either a fact or estimate) and a *certainty factor* (*cf*) that is supposed to measure the "implication power" of the

rule. Within the braces, the variable on the left of the assignment statement is always interpreted as meaning a variable in the audit record, and the variables on the right are always interpreted as variables accessible within the RuleSet. This makes it straightforward to experiment with user-defined audit trails and experimental methods of belief revision. (Realistic belief revision systems are usually more sophisticated than this example.)

The result of running the RuleSet is an evaluation report for each candidate machine. Since the RuleSet was run in audit mode, each entry in the evaluation report is tagged with a reason that points to an audit record. Figure 5 illustrates the evaluation report for one machine and one of its audit records. In this example, each of the entries in the report has a reason and a cumulative certainty (cc) property in addition to the value. The value of the reason properties are audit records created as a side effect of running the RuleSet. The auditing process records the meta-description information of each rule in its audit record. This information can be used later for generating explanations or as a basis for belief revision. The auditing process can have side effects. For example, the active in the **cf** variable or the audit record performs a computation to maintain a calculated cumulative certainty in the reliability variable of the evaluation report.

The meta-descriptions for **basis** and **cf** are saved directly in the audit record. The *certainty factor* calculation in this combines information from the audit description with other information already associated with the object. To do this, the **cf** description triggers an active value inherited by the audit record from its class. This active value computes a *cumulative certainty* in the evaluation report. (Other variations on this idea would include certainty information descriptive of the premises of the rule.)

```
RuleSet Name: EvaluateWashingMachine;
Workspace Class: EvaluationReport;
Control Structure: doAll ;
Audit Class: CFAuditRecord ;
Compiler Options: A;

(* Rules for evaluating a potential washing machine for a
purchase.)

.

1.8 Comparison with Other Rule Languages

This section considers the rationale behind the design of the Xerox LOOPS rule language, focusing on ways that it diverges from other rule languages. In general, this divergence was driven by the following observation:

When a rule is heavy with control information, it obscures the domain knowledge that the rule is intended to convey.

Rules are harder to create, understand, and modify when they contain too much control information. This observation led us to find ways to factor control information out of the rules.

1.8.1 The Rationale for Factoring Meta-Level Syntax

One of the most striking features of the syntax of the Xerox LOOPS rule language is the factored syntax for meta-descriptions, which provides information about the rules themselves. Traditional rule languages only factor rules into conditions on the left hand side (LHS) and actions on the right hand side (RHS), without general provisions for meta-descriptions.

Decision knowledge expressed in rules is most perspicuous when it is not mixed with other kinds knowledge, such as control knowledge. For example, the following rule:

```

IF ~triedRule4 pluggedInTo:voltage=0
THEN triedRule4_T breaker.Reset;

```

is more obscure than the corresponding one-shot rule from Figure 1:

```

{1} IF pluggedInTo:voltage=0 THEN breaker.Reset;

```

which factors the control information (that the rule is to be applied at most once) from the domain knowledge (about voltages and breakers). In the Xerox LOOPS rule language, a meta-description (MD) is specified in braces in front of the LHS of a rule. For another example, the following rule from Figure 4:

```
{{(basis_Fact cf_8)}  
IF buyer:familySize>2 machine:capacity<20  
THEN suitability_ 'Poor;
```

uses an MD to indicate that the rule has a particular **cf** ("certainty factor") and **basis** category for belief support. The MD in this example factors the description of the inference category of the rule from the action knowledge in the rule.

In a large knowledge-based system, a substantial amount of control information must be specified in order to preclude combinatorial explosions. Since earlier rule languages fail to provide a means for factoring meta-information, they must either mix it with the domain knowledge or express it outside the rule language. In the first option, intelligibility is degraded. In the second option, the transparency of the system is degraded because the knowledge is hidden.

1.8.2 The Rationale for RuleSet Hierarchy

Some advocates of production systems have praised the flatness of traditional production systems, and have resisted the imposition of any organization to the rules. The flat organization is sometimes touted as making it *easy to add rules*. The argument is that other organizations diminish the power of pattern-directed invocation and make it more complicated to add a rule.

In designing Xerox LOOPS, we have tended to discount these arguments. We observe that there is no inherent property of production systems that can make rules additive. Rather, *additivity* is a consequence of the independence of particular sets of rules. Such independence is seldom achieved in large sets of rules. When rules are dependent, rule invocation needs to be carefully ordered.

Advocates of a flat organization tend to organize large programs as a single very large production system. In practice, most builders of production systems have found it essential to create groups of rules.

Grouping of rules in flat systems can be achieved in part by using *context* clauses in the rules. Context clauses are clauses inserted into the rules which are used to alter the flow of control by naming the context explicitly. Rules in the same "context" all contain an extra clause in their conditions that compares the context of the rules with a current context. Other rules redirect control by switching the current context. Unfortunately, this approach does not conveniently lend itself to the reuse of groups of rules by different parts of a program. Although context clauses admit the creation of "subroutine contexts", they require you to explicitly program a stack of return locations in cases where contexts are invoked from more than one place. The decision to use an implicit calling stack for RuleSet invocation in Xerox LOOPS is another example of the our desire to simplify the rules by factoring out control information.

1.8.3 The Rationale for RuleSet Control Structures

Production languages are sometimes described as having a *recognize-act cycle*, which specifies how rules are selected for execution. An important part of this cycle is the *conflict resolution strategy*, which specifies how to choose a production rule when several rules have conditions that are satisfied. For

example, the **OPS5** production language has a conflict resolution strategy (**MEA**) which prevents rules from being invoked more than once, prioritizes rules according to the recency of a change to the data, and gives preference to production rules with the most specific conditions.

In designing the rule language for Xerox LOOPS, we have favored the use of a small number of specialized control structures to the use of a single complex conflict resolution strategy. In so doing, we have drawn on some control structures in common use in familiar programming languages. For example, **Do1** is like Lisp's **COND**, **DoAll** is like Lisp's **PROG**, **WhileAll** is similar to **WHILE** statements in many programming languages.

The specialized control structures are intended for concisely representing programs with different control relationships among the rules. For example, the **DoAll** control structure is useful for rules whose effects are intended to be additive and the **Do1** control structure is appropriate for specifying mutually exclusive actions. Without some kind of iterative control structure that allows rules to be executed more than once, it would be impossible to write a simulation program such as the washing machine simulation in Figure 1.

We have resisted a reductionist argument for having only one control structure for all programming. For example, it could be argued that the control structure **Do1** is not strictly necessary because any RuleSet that uses **Do1** could be rewritten using **DoAll**. For example, the rules

Control Structure: Do1;

```
IF a b c THEN d e ;
IF a b c THEN d e ;
IF a b c THEN d e ;
```

could be written alternatively as

Control Structure: DoAll;
Task Vars: firedSomeRule;

```
IF a b c THEN firedSomeRule_T d e ;
IF ~firedSomeRule a b c THEN firedSomeRule_T d e ;
IF ~firedSomeRule a b c THEN firedSomeRule_T d e ;
```

However, the **Do1** control structure admits a much more concise expression of mutually exclusive actions. In the example above, the **Do1** control structure makes it possible to abbreviate the rule conditions to reflect the assumption that earlier rules in the RuleSet were not satisfied.

For some particular sets of rules the conditions are naturally mutually exclusive. Even for these rules **Do1** can yield additional conciseness. For example, the rules:

Control Structure: Do1;

```
IF a b c THEN d e ;
IF ~a b c THEN d e ;
IF ~a ~b c THEN d e ;
```

can be written as

Control Structure: Do1;

```
IF a b c THEN d e ;  
IF  b c THEN d e ;  
IF   c THEN d e ;
```

Similarly it could be argued that the **Do1** and **DoAll** control structures are not strictly necessary because such RuleSets can always be written in terms of **While1** and **WhileAll**. Following this reductionism to its end, we can observe that every RuleSet could be re-written in terms of **WhileAll**.

1.8.4 The Rationale for an Integrated Programming Environment

RuleSets in Xerox LOOPS are integrated with procedure-oriented, object-oriented, and data-oriented programming paradigms. In contrast to single-paradigm rule systems, this integration has two major benefits. It facilitates the construction of programs which don't entirely fit the rule-oriented paradigm. Rule-oriented programming can be used selectively for representing just the appropriate decision-making knowledge in a large program. Integration also makes it convenient to use the other paradigms to help organize the interactions between RuleSets.

Using the object-oriented paradigm, RuleSets can be invoked as methods for Xerox LOOPS objects. Figure 6 illustrates the installation of the RuleSet **SimulateWashingMachineRules** to carry out the **Simulate** method for instances of the class **WashingMachine**. This definition of the class **WashingMachine** specifies that Lisp functions are to be invoked for Fill and Wash messages. For example, the Lisp function **WashingMachine.Fill** is to be applied when a Fill message is received. When a Simulate message is received, the RuleSet **SimulateWashingMachineRules** is to be invoked with the washing machine as its work space. Simulate message to invoke the RuleSet may be sent by any Xerox LOOPS program, including other RuleSets.

The use of object-oriented paradigm is facilitated by special RuleSet syntax for sending messages to objects, and for manipulating the data in Xerox LOOPS objects. In addition, RuleSets, work spaces, and tasks are implemented as Xerox LOOPS objects.

```

    (Wash WashingMachine.Wash doc (* Perofrm the wash cycle.))
    (Simulate UseRuleSet RuleSet SimulateWashingMachineRules)
    .
    .
    .
  ]

```

Figure 6. RuleSet Invoked as a Method

Using the data-oriented paradigm, RuleSets can be installed in active values so that they are triggered by side-effect when Xerox LOOPS programs get or put data in objects. For example:

```

[DEFINST WashingMachine (StefiksMaytagWasher "uid2")
  (controlSetting RegularFabric)
  (loadSetting #(Medium NIL RSPut) RSPutFn CheckOverLoadRules)
  (waterLevelSensor "uid3")
]

```

The above code illustrates a RuleSet named **CheckOverLoadRules** which is triggered whenever a program changes the **loadSetting** variable in the **WashingMachine** instance in the figure. This data-oriented triggering can be caused by any Xerox LOOPS program when it changes the variable, whether or not that program is written in the rules language.

2. THE RULE LANGUAGE

This chapter describes the syntax and semantics of the rule language.

2.1 Language Introduction

A rule in Xerox LOOPS describes actions to be taken when specified conditions are satisfied. A rule has three major parts called the *left hand side* (LHS) for describing the conditions, the *right hand side* (RHS) for describing the actions, and the *meta-description* (MD) for describing the rule itself. In the simplest case without a meta-description, there are two equivalent syntactic forms:

LHS -> *RHS*;

IF *LHS* **THEN** *RHS*;

The **If** and **Then** tokens are recognized in several combinations of upper and lower case letters. The syntax for LHSs and RHSs is given below. In addition, a rule can have no conditions (meaning always perform the actions) as follows:

-> *RHS*;

if *T* **then** *RHS*;

Rules can be preceded by a meta-description in braces as in:

{*MD*} *LHS* -> *RHS*;

{*MD*} **If** *LHS* **Then** *RHS*;

{*MD*} *RHS*;

Examples of meta-information include rule-specific control information, rule descriptions, audit instructions, and debugging instructions. For example, the syntax for one-shot rules shown in Section 1.5, "One-Shot Rules:"

{**1**} **IF** *condition* *condition* **THEN** *action* ;

is an example of a meta-description. Another example is the use of meta-assignment statements for describing audit trails and rules. These statements are discussed in Section 1.7, "Saving an Audit Trail of Rule Invocation."

LHS Syntax: The clauses on the LHS of a rule are evaluated in order from left to right to determine whether the LHS is satisfied. If they are all satisfied, then the rule is satisfied. For example:

A B C+D (Prime D) -> RHS;

In this rule, there are four clauses on the LHS. If the values of some of the clauses are **NIL** during evaluation, the remaining clauses are not evaluated. For example, if **A** is non-**NIL** but **B** is **NIL**, then the LHS is not satisfied and **C+D** will not be evaluated.

RHS Syntax: The RHS of a rule consists of actions to be performed if the LHS of the rule is satisfied. These actions are evaluated in order from left to right. Actions can be the invocation of RuleSets, the sending of Xerox LOOPS messages, Interlisp function calls, variables, or special termination actions.

RuleSets always return a value. The value returned by a RuleSet is the value of the last rule that was executed. Rules can have multiple actions on the right hand side. Unless there is a **Stop** statement or transfer call as described later, the value of a rule is the value of the last action. When a rule has no actions on its RHS, it returns **NIL** as its value.

Comments: Comments can be inserted between rules in the RuleSet. They are enclosed in parentheses with an asterisk for the first character as follows:

(* This is a comment)

2.2 Kinds of Variables

Xerox LOOPS distinguishes the following kinds of variables:

RuleSet arguments: All RuleSets have the variable **self** as their workspace. References to **self** can often be elided in the RuleSet syntax. For example, the expression **self.Print** means to send a **Print** message to **self**. This expression can be shortened to **.Print**. Other arguments can be defined for RuleSets. These are declared in an **Args:** declaration.

Instance variables: All RuleSets use a Xerox LOOPS object for their workSpace. In the LHS and RHS of a rule, the first interpretation tried for an undeclared literal is as an instance variable in the work space. Instance variables can be indicated unambiguously by preceding them with a colon, (e.g., **:varName** or **obj:varName**).

Class variables: Literals can be used to refer to class variables of Xerox LOOPS objects. These variables must be preceded by a double colon in the rule language, (e.g., **::classVarName** or **obj::classVarName**).

Temporary variables: Literals can also be used to refer to temporary variables allocated for a specific invocation of a RuleSet. These variables are initialized to **NIL** when a RuleSet is invoked. Temporary variables are declared in the **Temporary Vars** declaration in a RuleSet.

Audit record variables: Literals can also be used to refer to instance variables of audit records created by rules. These literals are used only in *meta-assignment* statements in the MD part of a rule. They are used to describe the information saved in audit records, which can be created as a side-effect of rule execution. These variables are ignored if a RuleSet is not compiled in *audit* mode. Undeclared variables appearing on the left side of assignment statements in the MD part of a rule are treated as

audit record variables by default. These variables are declared indirectly -- they are the instance variables of the class declared as the *Audit Class* of the RuleSet.

Interlisp variables: Literals can also be used to refer to Interlisp variables during the invocation of a RuleSet. These variables can be global to the Interlisp environment, or are bound in some calling function. Interlisp variables can be used when procedure-oriented and rule-oriented programs are intermixed. Interlisp variables must be preceded by a backSlash in the syntax of the rule language (e.g., *VispVarName*).

Reserved Words: The following literals are treated as *read-only* variables with special interpretations:

self	[Variable]
The current work space.	
rs	[Variable]
The current RuleSet.	
caller	[Variable]
The RuleSet that invoked the current RuleSet, or NIL if invoked otherwise.	
ruleApplied	[Variable]
Set to T if some rule was applied in this cycle. (For use only in while-conditions).	

The following reserved words are intended mainly for use in creating audit trails:

ruleObject	[Variable]
Variable bound to the object representing the rule itself.	
ruleNumber	[Variable]
Variable bound to the sequence number of the rule in a RuleSet.	
ruleLabel	[Variable]
Variable bound to the label of a rule or NIL .	
reasons	[Variable]
Variable bound a list of audit records supporting the instance variables mentioned on the LHS of the rule. (Computed at run time.)	

auditObject [Variable]

Variable bound to the object to which the reason record will be attached. (Computed at run time.)

auditVarName [Variable]

Variable bound to the name of the variable on which the reason will be attached as a property.

Other Literals: As described later, literals can also refer to Interlisp functions, Xerox LOOPS objects, and message selectors. They can also be used in strings and quoted constants.

The determination of the meaning of a literal is done at compile time using the declarations and syntax of RuleSets. The characters used in literals are limited to alphabetic characters and numbers. The first character of a literal must be alphabetic.

The syntax of literals also includes a compact notation for sending unary messages and for accessing instance variables of Xerox LOOPS objects. This notation uses *compound literals*. A compound literal is a literal composed of multiple parts separated by a periods, colons, and commas.

2.3 Rule Forms

Quoted Constants: The quote sign is used to indicate constant literals:

a b=3 c='open d=f e='(This is a quoted expression) -> ...

In this example, the LHS is satisfied if **a** is non-NIL, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** is the list **(This is a quoted expression)**.

Strings: The double quote sign is used to indicate string constants:

IF a b=3 c='open d=f e=="This is a string"
THEN (WRITE "Begin configuration task") ... ;

In this example, the LHS is satisfied if **a** is non-NIL, and the value of **b** is 3, and the value of **c** is exactly the atom **open**, the value of **d** is the same as the value of **f**, and the value of **e** equal to the string **"This is a string"**.

Interlisp Constants: The literals **T** and **NIL** are interpreted as the Interlisp constants of the same name.

a (Foo x NIL b) -> x_T ...;

In this example, the function **Foo** is called with the arguments **x**, **NIL**, and **b**. Then the variable **x** is set to **T**.

2.4 Infix Operators and Brackets

To enhance the readability of rules, a few infix operators are provided. The following are infix binary operators in the rule syntax:

+	[Rule Infix Operator]
Addition.	
++	[Rule Infix Operator]
Addition modulo 4.	
-	[Rule Infix Operator]
Subtraction.	
--	[Rule Infix Operator]
Subtraction modulo 4.	
*	[Rule Infix Operator]
Multiplication.	
/	[Rule Infix Operator]
Division.	
>	[Rule Infix Operator]
Greater than.	
<	[Rule Infix Operator]
Less than.	
>=	[Rule Infix Operator]
Greater than or equal.	
<=	[Rule Infix Operator]
Less than or equal.	
=	[Rule Infix Operator]
EQ -- simple form of equals. Works for atoms, objects, and small integers.	
~=	[Rule Infix Operator]
NEQ . (Not EQ .)	

== [Rule Infix Operator]

EQUAL -- long form of equals.

<< [Rule Infix Operator]

Member of a list. (**FMEMB**)

In addition, the rule syntax provides two unary operators as follows:

- [Rule Unary Operator]

Minus.

~ [Rule Unary Operator]

Not.

The precedence of operators in rule syntax follows the usual convention of programming languages. For example

1+5*3 = 16

and

[3 < 2 + 4] = T

Brackets can be used to control the order of evaluation:

[1+5]*3 = 18

Ambiguity of the minus sign: Whenever there is an ambiguity about the interpretation of a minus sign as a unary or binary operator, the rule syntax interprets it as a binary minus. For example

a-b c d -e [-f] (g -h) (_ (\$ Foo) Move -j) -> ...

In this example, the first and second minus signs are both treated as binary subtraction statements. That is, the first three clauses are (1) **a-b**, (2) **c** and (3) **d-e**. Because the rule syntax allows arbitrary spacing between symbols and there is no syntax to separate clauses on the LHS of a rule, the interpretation of "**d -e**" is as a single clause (with the subtraction) instead of two clauses. To force the interpretation as a unary minus operator, one must use brackets as illustrated in the next clause. In this clause, the minus sign in the clause **[-f]** is treated as a unary minus because of the brackets. The minus sign in the function call **(g -h)** is treated as unary because there is no preceding argument. Similarly, the **-j** in the message expression is treated as unary because there is no preceding argument.

2.5 Interlisp Functions and Message Sending

Calls to Interlisp functions are parenthesized with the function name as the first literal after the left parenthesis. Each expression after the function name is treated as an argument to the function. For example:

a (Prime b) [a -b] -> c (Display b c+4 (Cursor x y) 2) ;

In this example, **Prime**, **Display**, and **Cursor** are interpreted as the names of Interlisp functions. Since the expression **[a -b]** is surrounded by brackets instead of parentheses, it is recognized as meaning **a** minus **b** as opposed to a call to the function **a** with the argument minus **b**. In the example above, the call to the Interlisp function **Display** has four arguments: **b**, **c+4**, the value of the function call **(Cursor x y)**, and **2**.

The use of Interlisp functions is usually outside the spirit of the rule language. However, it enables the use of Boolean expressions on the LHS beyond simple conjunctions. For example:

a (OR (NOT b) x y) z -> ... ;

Xerox LOOPS Objects and Message Sending: Xerox LOOPS classes and other named objects can be referenced by using the dollar notation. The sending of Xerox LOOPS messages is indicated by using a left arrow. For example:

**IF cell_ ((\$ LowCell) Occupied? 'Heavy)
THEN (_ cell Move 3 'North);**

In the LHS, an **Occupied?** message is sent to the object named **LowCell**. In the message expression on the RHS, there is no dollar sign preceding **cell**. Hence, the message is sent to the object that is the value of the variable **cell**.

For unary messages (i.e., messages with only the selector specified and the implicit argument **self**), a more compact notation is available as described below.

Unary Message Sending: When a period is used as the separator in a compound literal, it indicates that a unary message is to be sent to an object. (We will alternatively refer to a period as a *dot*.) For example:

tile.Type='BlueGreenCross command.Type='Slide4 -> ... ;

In this example, the object to receive the unary message **Type** is referenced indirectly through the **tile** instance variable in the work space. The left literal is the variable **tile** and its value must be a Xerox LOOPS object at execution time. The right literal must be a method selector for that object.

The dot notation can be combined with the dollar notation to send unary messages to named Xerox LOOPS objects. For example,

\$Tile.Type='BlueGreenCross ...

In this example, a unary **Type** message is sent to the Xerox LOOPS object whose name is **Tile**.

The dot notation can also be used to send a message to the work space of the RuleSet, that is, **self**. For example, the rule

IF scale>7 THEN .DisplayLarge;

would cause a **DisplayLarge** message to be sent to **self**. This is an abbreviation for

IF scale>7 THEN self.DisplayLarge;

2.6 Variables and Properties

When a single colon (:) is used in a literal, it indicates access to an instance variable of an object. For example:

tile:type='BlueGreenCross command:type=Slide4 -> ... ;

In this example, access to the Xerox LOOPS object is indirect in that it is referenced through an instance variable of the work space. The left literal is the variable **tile**, and its value must be a Xerox LOOPS object when the rule is executed. The right literal **type** must be the name of an instance variable of that object. The compound literal **tile:type** refers to the value of the **type** instance variable of the object in the instance variable **tile**.

The colon notation can be combined with the dollar notation to access a variable in a named Xerox LOOPS object. For example,

\$TopTile:type='BlueGreenCross ...

refers to the **type** variable of the object whose Xerox LOOPS name is **TopTile**.

A double colon notation (::) is provided for accessing class variables. For example

truck::MaxGas<45 ::ValueAdded>600 -> ... ;

In this example, **MaxGas** is a class variable of the object bound to **truck**. **ValueAdded** is a class variable of **self**.

A colon-comma notation (:,) is provided for accessing property values of class and instance variables. For example

wire:,capacitance>5 wire:voltage:,support='simulation -> ...

In the first clause, **wire** is an instance variable of the work space and **capacitance** is a property of that variable. The interpretation of the second clause is left to right as usual: (1) the object that is the value of the variable **wire** is retrieved, and (2) the **support** property of the **voltage** variable of that object is retrieved. For properties of class variables

::Wire:,capacitance>5 node::Voltage:,support='simulation -> ...

In the first clause, **wire** is a class variable of the work space and **capacitance** is a property of that variable. In the second clause, **node** is an instance variable bound to some object. **Voltage** is a class variable of that object, and **Support** is a property of that class variable.

The property notation is illegal for ruleVars and lispVars since those variables cannot have properties.

2.7 Computing Selectors and Variable Names

The short notations for instance variables, properties, and unary messages all show the selector and variable names *as they actually appear* in the object.

```
object.selector
object:ivName
object::cvName
object:varname:,propName
```

```
(_ object selector arg arg )
```

For example,

apple:flavor

refers to the **flavor** instance variable of the object bound to the variable **apple**. In Interlisp terminology, this implies implicit quoting of the name of the instance variable (**flavor**).

In some applications it is desired to be able to compute the names. For this, the Xerox LOOPS rule language provides analogous notations with an added exclamation sign (!). After the exclamation sign, the interpretation of the variable being evaluated starts over again. For example

apple:!x

refers to the same thing as **apple:flavor** if the Interlisp variable **x** is bound to **flavor**. The fact that **x** is a Lisp variable is indicated by the backslash. If **x** is an instance variable of **self** or a temporary variable, we could use the notation:

apple:!x

If **x** is a class variable of **self**, we could use the notation:

apple!:::x

All combinations are possible, including:

```
object.!selector
object.!selector
object!:::selector
object:!ivName
object!:cvName
object:!varname:,propName
```

```
(_! object selector arg arg )
```

2.8 Recursive Compound Literals

Multiple colons or periods can be used in a literal, For example:

a:b:c

means to (1) get the object that is the value of **a**, (2) get the object that is the value of the **b** instance variable of **a**, and finally (3) get the value of the **c** instance variable of that object.

Similarly, the notation

a.b:c

means to get the **c** variable of the object returned after sending a **b** message to the object that is the value of the variable **a**. Again, the operations are carried out left to right: (1) the object that is the value of the variable **a** is retrieved, (2) it is sent a **b** message which must return an object, and then (3) the value of the **c** variable of that object is retrieved.

Compound literal notation can be nested arbitrarily deeply.

2.9 Assignment Statements

An assignment statement using a left arrow can be used for setting all kinds of variables. For example,

x_a;

sets the value of the variable **x** to the value of **a**. The same notation works if **x** is a task variable, rule variable, class variable, temporary variable, or work space variable. The right side of an assignment statement can be an expression as in:

x_a*b + 17*(LOG d);

The assignment statement can also be used with the colon notation to set values of instance variables of objects. For example:

y:b_0 ;

In this example, first the object that is the value of **y** is computed, then the value of its instance variable **b** is set to **0**.

Properties: Assignment statements can also be used to set property values as in:

box:x:,origin_47 fact:,reason_currentSupport;

Nesting: Assignment statements can be nested as in

a_b_c:d_3;

This statement sets the values of **a**, **b**, and the **d** instance variable of **c** to **3**. The value of an assignment statement itself is the new assigned value.

2.10 Meta-Assignment Statements

Meta-assignment statements are assignment statements used for specifying rule descriptions and audit trails. These statements appear in the MD part of rules.

Audit Trails: The default interpretation of meta-assignment statements for undeclared variables is as audit trail specifications. Each meta-assignment statement specifies information to be saved in audit records when a rule is applied. In the following example from Figure 4, the audit record must have variables named **basis** and **cf**:

```
{{(basis_Fact cf_1.)}  
IF buyer:familySize>2 machine:capacity<20  
THEN suitability_ 'Poor;
```

In this example, the RHS of the rule assigns the value of the work space instance variable **suitability** to **'Poor** if the conditions of the rule are satisfied. In addition, if the RuleSet was compiled in *audit* mode, then during RuleSet execution an audit record is created as a side-effect of the assignment. The audit record is attached to the **reason** property of the suitability variable. It has instance variables **basis** and **cf**.

In general, an audit description consists of a sequence of meta-assignment statements. The assignment variable on the left must be an instance variable of the audit record. The class of the audit record is declared in the *Audit Class* declaration of the RuleSet. The expression on the right is in terms of the variables accessible by the RuleSet. If the conditions of a rule are satisfied, an audit record is instantiated. Then the meta-assignment statements are evaluated in the execution context of the RuleSet and their values are put into the audit record. A separate audit record is created for each of the object variables that are set by the rule.

2.11 Push and Pop Statements

A compact notation is provided for pushing and popping values from lists. To push a new value onto a list, the notation **_+** is used:

```
myList_+newItem;
```

```
focus:goals_+newGoal;
```

To pop an item from a list, the **_-** notation is used:

```
item_-myList;
```

nextGoal_-focus:goals;

As with the assignment operator, the push and pop notation works for all kinds of variables and properties. They can be used in conjunction with infix operator << for membership testing.

2.12 Invoking RuleSets

One of the ways to cause RuleSets to be executed is to invoke them from rules. This is used on the LHS of rules to express predicates in terms of RuleSets, and on the RHS of rules to express actions in terms of RuleSets. A short double-dot syntax(..) for this is provided that invokes a RuleSet on a work space:

Rs1..ws1

In this example, the RuleSet bound to the variable **Rs1** is invoked with the value of the variable **ws1** as its work space. The value of the invocation expression is the value returned by the RuleSet. The double-dot syntax can be combined with the dollar notation (\$) to invoke a RuleSet by its Xerox LOOPS name, as in

\$MyRules..ws1

which invokes the RuleSet object that has the Xerox LOOPS name **MyRules**.

This form of RuleSet invocation is like subroutine calling, in that it creates an implicit stack of arguments and return addresses. This feature can be used as a mechanism for *meta-control* of RuleSets as in:

IF breaker:status='Open
THEN source_\$OverLoadRules..washingMachine;

IF source='NotFound
THEN \$ShortCircuitRules..washingMachine;

In this example, two "meta-rules" are used to control the invocation of specialized RuleSets for diagnosing overloads or short circuits.

2.13 Transfer Calls

An important optimization in many recursive programs is the elimination of tail recursion. For example, suppose that the RuleSet A calls B, B calls C, and C calls A recursively. If the first invocation of A must do some more work after returning from B, then it is useful to save the intermediate states of each of the procedures in frames on the calling stack. For such programs, the space allocation for the stack must be enough to accommodate the maximum depth of the calls.

There is a common and special case, however, in which it is unnecessary to save more than one frame on the stack. In this case each RuleSet has no more work to do after invoking the other RuleSets, and the value of each RuleSet is the value returned by the RuleSet that it invokes. RuleSet invocation in this case amounts to the evaluation of arguments followed by a direct transfer of control. We call such invocations transfer calls.

The Xerox LOOPS rule language extends the syntax for RuleSet invocation and message sending to provide this as follows:

RS..*ws

The RuleSet **RS** is invoked on the work space **ws**. With transfer calls, RuleSet invocations can be arbitrarily deep without using proportional stack space.

2.14 Stop Statements

To provide premature terminations in the execution of a RuleSet, the Stop statement is provided.

(Stop *value*)

[RuleSet Statement]

value is the value to be returned by the RuleSet.

[This page intentionally left blank]

3. USING RULES IN LOOPS

The Xerox LOOPS rules language is supported by an integrated programming environment for creating, editing, compiling, and debugging RuleSets. This section describes how to use that environment.

3.1 Creating RuleSets

RuleSets are named Xerox LOOPS objects and are created by sending the class **RuleSet** a **New** message as follows:

```
(_ ($ RuleSet) New)
```

After entering this form, the user will be prompted for a Xerox LOOPS name as

RuleSet name: *RuleSetName*

Afterwards, the RuleSet can be referenced using Xerox LOOPS dollar sign notation as usual. It is also possible to include the RuleSet name in the **New** message as follows:

```
(_ ($ RuleSet) New NIL RuleSetName)
```

3.2 Editing RuleSets

A RuleSet is created empty of rules. The RuleSet editor is used to enter and modify rules. The editor can be invoked with an **EditRules** message (or **ER** shorthand message) as follows:

```
(_ RuleSet EditRules)
```

```
(_ RuleSet ER)
```

If a RuleSet is installed as a method of a class, it can be edited conveniently by selecting the **EditMethod** option from a browser containing the class. Alternatively, the **EditMethod** message can be used:

```
(_ ClassName EditMethod selector) [Message]
```

Both approaches to editing retrieve the source of the RuleSet and put the user into the TTYIN or TEdit editor, treating the rule source as text.

Initially, the source is a template for RuleSets as shown in Figure 7. The rules are entered after the comment at the bottom. The declarations at the beginning are filled in as needed and superfluous declarations can be discarded.

```
RuleSet Name: RuleSetName;
WorkSpace Class:  ClassName;
Control Structure:  doAll;
While Condition:  ;
Audit Class:  StandardAuditRecord;
Rule Class:  Rule;
Task Class:  ;
Meta Assignments:  ;
Temporary Vars:  ;
Lisp Vars:  ;
Debug Vars:  ;
Compiler Options:  ;

(* Rules for whatever.  Comment goes here.)
```

Figure 7. Initial Template for a RuleSet

You can then edit this template to enter rules and set the declarations at the beginning. In the current version of the rule editor, most of these declarations are left out. If you choose the **EditAllDecls** option in the RuleSet editor menu, the declarations and default values will be printed in full.

The template is only a guide. Declarations that are not needed can be deleted. For example, if there are no temporary variables for this RuleSet, the **Temporary Vars** declaration can be deleted. If the control structure is not one of the **while** control structures, then the **While Condition** declaration can be deleted. If the compiler option **A** is not chosen, then the **Audit Class** declaration can be deleted.

When you leave the editor, the RuleSet is compiled automatically into a Lisp function.

If a syntax error is detected during compilation, an error message is printed and you are given another opportunity to edit the RuleSet.

3.3 Copying RuleSets

Sometimes it is convenient to create new RuleSets by editing a copy of an existing RuleSet. For this purpose, the method **CopyRules** is provided as follows:

```
(_ oldRuleSet CopyRules newRuleSetName) [Message]
```

This creates a new RuleSet by some of the information from the perspectives of the old RuleSet. It also updates the source text of the new RuleSet to contain the new name.

3.4 Saving RuleSets on Lisp Files

RuleSets can be saved on Lisp files just like other Xerox LOOPS objects. In addition, it is usually useful to save the Lisp functions that result from RuleSet compilation. In the current implementation, these functions have the same names as the RuleSets themselves. To save RuleSets on a file, it is necessary to add two statements to the file commands for the file as follows:

```
(FNS * MyRuleSetNames)
(INSTANCES * MyRuleSetNames)
```

where **MyRuleSetNames** is a Lisp variable whose value is a list of the names of the RuleSets to be saved.

If RuleSets are methods associated with a class, and they are saved by using (FILES?), then the file package saves the appropriate entries. The user does not have to be concerned with editing the filecoms of the file being made.

3.5 Printing RuleSets

To print a RuleSet without editing it, one can send a **PPRules** or **PPR** message as follows:

```
( _ RuleSet PPRules) [Message]
( _ RuleSet PPR) [Message]
```

A convenient way to make hardcopy listings of RuleSets is to use the function **ListRuleSets**. The files will be printed on the **DEFAULTPRINTINGHOST** as is standard in Interlisp-D. **ListRuleSets** can be given four kinds of arguments as follows:

```
(ListRuleSets RuleSetName)
(ListRuleSets ListOfRuleSetNames)
(ListRuleSets ClassName)
(ListRuleSets FileName)
```

In the *ClassName* case, all of the RuleSets that have been installed as methods of the class will be printed. In the last case, all of the RuleSets stored in the file will be printed.

3.6 Running RuleSets from Xerox LOOPS

RuleSets can be invoked from Xerox LOOPS using any of the usual protocols.

Procedure-oriented Protocol: The way to invoke a RuleSet from Xerox LOOPS is to use the **RunRS** function:

(RunRS RuleSet workSpace arg2 ... argN) [Function]

workSpace is the Xerox LOOPS object to be used as the work space. This is "procedural" in the sense that the RuleSet is invoked by its name. *RuleSet* can be either a RuleSet object or its name.

Object-oriented Protocol: When RuleSets are installed as methods in Xerox LOOPS classes, they can be invoked in the usual way by sending a message to an instance of the class. For example, if **WashingMachine** is a class with a RuleSet installed for its **Simulate** method, the RuleSet is invoked as follows:

(_ washingMachineInstance Simulate)

Data-oriented Protocol: When RuleSets are installed in active values, they are invoked by side-effect as a result of accessing the variable on which they are installed.

3.7 Installing RuleSets as Methods

RuleSets can also be used as methods for classes. This is done by installing automatically-generated invocation functions that invoke the RuleSets. For example:

```
[DEFCLASS WashingMachine
  (MetaClass Class doc (* comment) ...)
  ...
  (InstanceVariables (owner ...))
  (Methods
    (Simulate RunSimulateWMRules)
    (Check RunCheckWMRules
      doc (* Rules to Check a washing machine.))
  ...]
```

When an instance of the class **WashingMachine** receives a **Simulate** message, the RuleSet **SimulateWMRules** will be invoked with the instance as its work space.

To simplify the definition of RuleSets intended to be used as Methods, the function **DefRSM** (for "Define Rule Set as a Method") is provided:

(DefRSM ClassName Selector RuleSetName) [Function]

If the optional argument *RuleSetName* is given, **DefRSM** installs that RuleSet as a method using the *ClassName* and *Selector*. It does this by automatically generating an installation function as a method to invoke the RuleSet. **DefRSM** automatically documents the installation function and the method.

If the argument *RuleSetName* is **NIL**, then **DefRSM** creates the RuleSet object, puts the user into an Editor to enter the rules,

compiles the rules into a Lisp function, and installs the RuleSet as before.

DefRSM can be invoked with the browser as follows:

- Position the cursor over a class in a browser.
- Press the middle mouse button. A menu pops up.
- Select the Add option in this menu, and drag the mouse to the right to display the submenu that includes the "DefRSM" option. You are prompted to enter a selector name.

After a RuleSet has been installed as a method by using **DefRSM**, you can then edit that RuleSet by selecting the "EditMethod" option from the browser editing menu.

3.8 Installing RuleSets in Active Values

Note: The following section and any other references to active values within the rule documentation refer to active values as they were implemented in the Buttruss release. The functionality of triggering rules from active values has not been tested using the current implementation of active values. It should work to use the **ExplicitFnActiveValue** class to implement this behavior.

RuleSets can also be used in data-oriented programming so that they are invoked when data is accessed. To use a RuleSet as a *getFn*, the function **RSGetFn** is used with the property **RSGet** as follows:

```
...
(InstanceVariables
  (myVar #(myVal RSGetFn NIL) RSGet RuleSetName))
...
```

RSGetFn is a Xerox LOOPS system function that can be used in an active value to invoke a RuleSet in response to a Xerox LOOPS get operation (e.g., **GetValue**) is performed. It requires that the name of the RuleSet be found on the **RSGet** property of the item. **RSGetFn** activates the RuleSet using the local state as the work space. The value returned by the RuleSet is returned as the value of the get operation.

To use a RuleSet as a *putFn*, the function **RSPutFn** is used with the property **RSPut** as follows:

```
...
(InstanceVariables
  (myVar #(myVal NIL RSPutFn) RSPut RuleSetName))
...
```

RSPutFn is a function that can be used in an active value to invoke a RuleSet in response to a Xerox LOOPS put operation (e.g., **PutValue**). It requires that the name of the RuleSet be found on the **RSPut** property of the item. **RSGetFn** activates the RuleSet using the *newValue* from the put

operation as the work space. The value returned by the RuleSet is put into the local state of the active value.

3.9 Tracing and Breaking RuleSets

Xerox LOOPS provides breaking and tracing facilities to aid in debugging RuleSets. These can be used in conjunction with the auditing facilities and the rule executive for debugging RuleSets. The following summarizes the compiler options for breaking and tracing:

T	Trace if rule is satisfied. Useful for creating a running display of executed rules.
TT	Trace if rule is tested.
B	Break if rule is satisfied.
BT	Break if rule is tested. Useful for stepping through the execution of a RuleSet.

Specifying the declaration **Compiler Options: T;** in a RuleSet indicates that tracing information should be displayed when a rule is satisfied. To specify the tracing of just an individual rule in the RuleSet, the **T** meta-descriptions should be used as follows:

{T} IF *cond* THEN *action*;

This tracing specification causes Xerox LOOPS to print a message whenever the LHS of the rule is tested, or the RHS of the rule is executed. It is also possible to specify that the values of some variables (and compound literals) are to be printed when a rule is traced. This is done by listing the variables in the **Debug Vars** declaration in the RuleSet:

Debug Vars: a a:b a:b.c;

This will print the values of **a**, **a:b**, and **a:b.c** when any rule is traced or broken.

Analogous specifications are provided for breaking rules. For example, the declaration **Compiler Options: B;** indicates that Xerox LOOPS is to enter the rule executive (see Section 3.10, "The Rule Exec") after the LHS is satisfied and before the RHS is executed. The rule-specific form:

{B} IF *cond* THEN *action*;

indicates that Xerox LOOPS is to break before the execution of a particular rule.

Sometimes it is convenient in debugging to display the source code of a rule when it is traced or broken. This can be effected by using the **PR** compiler option as in

Compiler Options: T PR;

which prints out the source of a rule when the LHS of the rule is tested and

Compiler Options: B PR;

which prints out the source of a rule when the LHS of a rule is satisfied, and before entering the break.

3.10 The Rule Exec

A Read-Compile-Evaluate-Print loop, called the rule Executive, is provided for the rule language. The rule Executive can be entered during a break by invoking the Lisp function **RE**. During RuleSet execution, the rule executive can be entered by typing **^f** (<control>-f) on the keyboard.

On the first invocation, **RE** prompts the user for a window. It then displays a stack of RuleSet invocations in a menu to the left of this window in a manner similar to the Interlisp-D Break Package. Using the left mouse button in this window creates an Inspector window for the work space for the RuleSet. Using the middle mouse button pretty prints the RuleSet in the default prettyprint window.

In the main rule Executive window, **RE** prompts the user with "**re:**". Anything in the rule language (other than declarations) that is typed to this Executive will be compiled and executed immediately and its value printed out. For example, you may type rules to see whether they execute or variable names to determine their values. For example:

re: trafficLight:color

Red

re:

this example shows how to get the value of the **color** variable of the **trafficLight** object. If the value of a variable was set by a RuleSet running with auditing, then a **why** question can be typed to the rule executive as follows:

re: why trafficLight:color

IF highLight:color = 'Green farmRoadSensor:cars timer.TL
THEN highLight:color _ 'Yellow timer.Start;

Rule 3 of RuleSet LightRules

Edited: Conway "13-Oct-82"

re:

The rule executive may be exited by typing **OK**.

3.11 Auditing RuleSets

Two declarations at the beginning of a RuleSet affect the auditing. Auditing is turned on by the compiler option **A**. The simplest form of this is

Compiler Options: A;

The **Audit Class** declaration indicates the class of the audit record to be used with this RuleSet if it is compiled in *audit* mode.

Audit Class: StandardAuditRecord;

A **Meta Assignments** declaration can be used to indicate the audit description to be used for the rules unless overridden by a rule-specific meta-assignment statement in a meta-descriptor.

Meta Assignments: cf_.5 support_ 'GroundWff;

3.12 Loading Rules

Set the variable LOOPSUSERSDIRECTORIES to include the directory where the Rules files are stored.

Load the file LOOPSRULES-ROOT.LCOM, which will load the following files from LOOPSUSERSDIRECTORIES:

- LOOPSBACKWARDS.LCOM
- LOOPSMIXIN
- LOOPSRULES.LCOM
- LOOPSRULESP.LCOM
- LOOPSRULESC.LCOM
- LOOPSRULESD.LCOM, which will load the file TTY.LCOM from LISPUSERSDIRECTORIES.

Editing rules will be easier if TEdit is loaded. Loading the Rules does not automatically load TEdit.

3.13 Known Problems

In a rule, the expression \$pipe.ri..\$p compiles to (RunRS (QUOTE (\$ pipe)) (\$ p)), which fails.

Meta-assignment statements cannot handle expressions. This means that statements like {cf _ .5} work fine, but {validity _ 'fact} fails.

A value of 1 in a meta-descriptor statement is always taken to be a one-shot designator. You cannot have a meta-descriptor statement like {cf_1}. However, the number 1.0 can be used; the meta-descriptor statement, {cf_1.0}, works.

Rules have not been tested without loading TEdit in order to edit RuleSets.

A. CONVERTING FROM BUTTRESS RULES

The primary change to rules was the removal of the **VarLength** mixin as a super class of **RuleSetSource**. Rules are now stored on the IV **ruleList** of **RuleSetSource**. If any user had added properties to a rule with a construct similar to the following expression, these will need to be reimplemented in some fashion:

```
(PutNthValue ($ some-Instance-Of-A-RuleSetSource) ruleNumber prop)
```

A number of other changes were made to account for changes from Buttress LOOPS to the product release. These should not be noticeable to the general user.

A utility was built to allow rules that were saved in Buttress to be loaded into the product release of LOOPS. In order to convert from Buttress, follow this procedure.

- Load the necessary files for Rules as described in the Section 3.12, "Loading Rules."
- Load the file `LOOPSRULESBACKWARDS`. This redefines `ConvertLoopsFiles` to add functionality for converting rules.
- Do not load the Buttress files that need to be converted. Instead call:

```
(ConvertLoopsFiles files-to-convert T T)
```

This will load, convert, remake, and recompile the files specified by *files-to-convert*.

Any rules that were saved with auditing turned on will need to run through the rule compiler. The old rule compiler output a form that was `(_ ($ StandardAuditRecord) NewTemp)`. The message **NewTemp** no longer exists. The rule compiler now puts out the form `(_ ($ StandardAuditRecord) New)`.

If rules were saved with auditing turned on, then call `(ConvertLoopsFiles files-to-convert T)`. Deleting the final "T", will not enable the cleanup. After recompiling the rules to eliminate the message **NewTemp**, remake your files.

10436 MASTERSCOPE fix to MSANALYZE for CLASSES, into Medley

CACHEOBJECT

By: sML (Lanning.pa@Xerox.com)

4-Sep-86

INTRODUCTION

The file CACHEOBJECT defines a Loops mixin that defines a protocol for instances that cache computed values.

CLASSES

ObjectWithCache [Class]

Instance of the class ObjectWithCache follow a standard protocol for manipulating a dynamic cache. The cache is not stored when an ObjectWithCache is saved on a file.

(← *self* ClearCache) [Method of ObjectWithCache]

Clears the entire cache of *self*.

(← *self* ClearCacheEntry *name*) [Method of ObjectWithCache]

Removes the cache entry for *name* on *self*.

(← *self* GetCache *name*) [Function]

Returns the value of the cache entry for *name* on *self*. If there is no cached value, returns NIL.

(← *self* PutCache *name datum*) [Function]

Stores *datum* as the value of the cache entry for *name* on *self*. Returns *datum*.

LOOPS-FB

By: sML (Lanning.pa@Xerox.com)

INTRODUCTION

LOOPS-FB adds a command to the Lisp File Browsers for opening Loops browsers on files.

Loading the file will automatically add a "Browse" command to all new Lisp File Browsers. Selecting the "Browse" item will open a Loops FileBrowser on each of the currently selected files. The files will be loaded first if they are not currently loaded.

LOOPSIDLE

By: sML (Lanning.pa@Xerox.com)

4-Sep-86

INTRODUCTION

LOOPSIDLE make IDLE "bouncing box" function bounce a Loops icon about about the screen.

VARIABLES

BouncingLoopsIcon [Variable]

The (value of the) variable BouncingLoopsIcon is an expanded copy of the Loops icon. LOOPSIDLE sets IDLE.BOUNDING.BOX to (the value of) BouncingLoopsIcon.

Loops Image Objects

Unknown IMAGEOBJ GETFN: LoopsImageObjectGetFn	Unknown IMAGEOBJ GETFN: LoopsImageObjectGetFn

Interlisp IMAGEOBJS are "objects" that know how to display themselves on IMAGESTREAMs. IMAGEOBJS are most often used to insert non-character items into a TEdit document. Standard Interlisp IMAGEOBJS are available for displaying bitmaps, graphs, and horizontal bars.

Interlisp IMAGEOBJS are not objects in the sense of Loops: there is no provision for specialization of existing IMAGEOBJS and no default behavior is provided. Creation of a new type of IMAGEOBJS requires some effort. Functions must be specified for printing, reading, displaying, and handling button events for the new IMAGEOBJ type.

Loops image objects are Loops objects that can be used as Interlisp IMAGEOBJS. They let the programmer use the full power of the Loops environment in the creation of new IMAGEOBJS.

The LoopsImageObjects file defines a number of classes that can be used to create Interlisp IMAGEOBJS, and an interface that makes it easy to insert these Loops image objects into a TEdit document. Section `LoopsImageObjects:in` defines how to insert Loops image objects into a TEdit

document; section `LoopsImageObjectGetFn` describes some image object classes; sections `LoopsImageObjectGetFn` and `LoopsImageObjectPutFn` define the image object protocol, for people wishing to define their own Loops image objects.

Unknown IMAGEOBJ GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ GETFN: LoopsImageObjectGetFn

Inserting Loops image objects into a TEdit document is easy.

(LIO)

[Function]

The standard way to insert IMAGEOBJS into a TEdit file is via the CONTROL-O character. Hitting CONTROL-O lets you type in a LISP form, and the value of this form is an IMAGEOBJ that will be inserted into the document at the current location. (LIO) will present you with a menu of all known Loops image object classes. If you select a class from this menu, (LIO) will return the IMAGEOBJ that points to a new Loops image object of the specified class. If the instance has IVs that can be edited, you will be given a chance to edit the instance first.

LIOInsertCharCodes

[Variable]

When the Loops image object package is loaded, it redefines the interpretation in TEdit of the characters specified by the variable LIOInsertCharCodes. Hitting one of these characters is equivalent to hitting CONTROL-O and then typing in the form (LIO). The default value of LIOInsertCharCodes is (the value of) (LIST (CHARCODE #W) (CHARCODE #w)). This is an INITVAR, so you override the default before you load the package.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Many of these objects display themselves as text. This can be confusing for the user, who can easily mistake the object for a sequence of characters. To avoid this possibility for confusion, these objects appear boxed when displayed in a TEdit window. The box will not appear in a printed document.

The character looks of these objects can be set from TEdit in the same way that normal characters can have their looks set: select the object and use TEdit's Character Looks Menu, or the Looks item on the title bar pop-up menu. Note that the object can have only a single character looks--all the characters in the object will be displayed with the same looks. There is no way to change the looks of single characters displayed by a Loops image object.

These objects often violate the principle of WYSIWYG (What You See Is What You Get) in that they display more text in a TEdit window than they do when printed. They let you know what text will appear in print by displaying all non-printing text inverted. Thus, the object that displays in a TEdit

window as **Index: IndexEntry** will print up as the string "IndexEntry" when printed. (Note the interaction of this inversion with the boxing mentioned in the previous paragraph: the inversion is performed after the boxing, so that the entire object will still appear boxed if displayed inverted (as in TEdit's highlighting to indicate pending-delete).)

These objects respond to a button event by presenting a menu of options to the user. The items in the menu depend on the class of the object. All objects include a menu item for storing the Loops instance in (SavedValue), and for inspecting the instance. If the instance has IVs that can be set by the user, the menu will include an "Edit" item. The "Edit" item will bring up the standard Loops instance editor on the object. If the instance has a textual IV, the menu will include an option to edit the value of this IV in a new TEdit window.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Many people include in a TEdit file the time the file was last edited, or the name of the file that holds the document. The following classes can be used to automate this process.

WhenLastSaved [Class]

A WhenLastSaved image object will display a time stamp indicating the time the TEdit document was last saved. For example, a WhenLastSaved instance in this document might produce the image  (but would appear without the box when hardcopied).

If the document has not been saved since the WhenLastSaved object was inserted, the WhenLastSaved object will display the string "NotYetSaved" instead of the time stamp.

WhereLastSaved [Class]

A WhereLastSaved image object is much like a WhenLastSaved object, except that it displays the name of the file that the TEdit document was last saved in, instead of the time last saved.

WhenLastSaved and WhereLastSaved objects are used in the running footers in this document.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Using image objects, it is easy to build an index table for a TEdit document.

IndexEntry [Class]

An IndexEntry object associates a string with a page number for inclusion in an index. The IV text of an IndexEntry will be added to the accumulated index, together with the number of the page containing the object. If the IV displayText? is non-NIL (the default), then the text string will also appear in the document, otherwise the object will be invisible in the final hardcopy. For example, an IndexEntry that adds a reference to the string "IndexEntry" appears in a TEdit window as

 `displayText?` IV were NIL, it would appear as  it window, but would be invisible when printed.

`InitIndex` [Class]

An `InitIndex` object must appear in a TEdit document before any `IndexEntry` object. The `InitIndex` object initializes the collection of the index table. It will be invisible when printed.

`CollectIndex` [Class]

A `CollectIndex` object should appear after all the `IndexEntry` objects that appear in a TEdit document. It will sort the index and print the index information into a new TEdit window (you will be prompted for the window). You can then format the text, save it away, print it, or discard it. The IVs `looks`, `paraLooks`, `firstPageFormat`, `rectoPageFormat`, and `versoPageFormat` determine the initial formatting of the index. See the TEdit documentation for a discussion of the definition of these fields. The `CollectIndex` object will not be visible in the printed document.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Automatic chapter and section numbering, and generation of a table of contents, is provided by the following classes.

`SectionHeading` [Class]

`SectionHeading` objects have three IVs: `level`, `text`, and `displayText?`. The `level` IV determines the subsection nesting of the object. Each `SectionHeading` object in the document increments the current section number at the given level. Smaller level numbers will not be affected. Larger level numbers are reset to zero. For example, a sequence of `SectionHeading` objects with `level` IVs of 1, 2, 1, 2, 2, 3, 2, and 1 will produce final section numbers of 1., 1.1., 2., 2.1., 2.2., 2.2.1., 2.3., and 3.

The `text` IV determines the section title for inclusion in the table of contents. If the `displayText?` is non-NIL (the default), the `text` will also be displayed in the document.

As an example, when first displayed in a TEdit window the `SectionHeading` for this subsection looked like  `displayText?` IV were NIL, the text would have been inverted to indicate that it will not be present in the final hardcopy:

hardcopied, the object displayed the section number used at hardcopy time instead of the placeholder "n.n.". (Due to a "bug", you have to redisplay the window to see the updated section numbers.)

InitTOC [Class]

An InitTOC object must appear in a TEdit document before any SectionHeading object. The InitTOC object initializes the collection of the table of contents. The IV initialSectionNumbers can be used to initialize the first section numbers to values other than 1. For example, if the initialSectionNumbers IV is (2 1 3), and the first SectionHeading object has a level IV of 3, it will be given the subsection number "2.1.4.". The InitTOC object will be invisible when printed.

CollectTOC [Class]

A CollectTOC object should be placed at the end of a document, after all SectionHeading objects, to collect the table of contents information into a new TEdit stream. When the document is hardcopied, a new TEdit stream will be opened containing the accumulated table of contents. You can then format this TEdit document as you wish. CollectTOC uses the same IVs as does the CollectIndex to determine the initial formatting of the table of contents. The CollectTOC object not be visible in the final hardcopy.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

The following classes provide a somewhat clumsy way of having page and section references included an a document. Because there is no lookahead in the TEdit page formatting, documents containing these objects must be hardcopied twice. The first time will compute the correct page and section numbers, the second time will incorporate them into the document.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

PageNote [Class]

At hardcopy time, a PageNote object remembers the current page number, associating it with the value of its tag IV. See the PageReference class, below.

PageReference [Class]

At hardcopy time, a PageReference object looks up the value of its tag IV to see if a PageNote object has noted a page number for that tag. If there is page number stored, the PageReference object will display the number, otherwise it will display the string "nn". If the PageNote occurs before

the `PageReference` object in the document, this reference will be found the first time the document is printed. If the `PageNote` occurs after the `PageReference` object, a second hardcopy must be generated.

Unknown IMAGEOBJ
GETFN: `LoopsImageObjectGetFn`

`SectionNote` [Class]

At hardcopy time, a `SectionNote` object remembers the current section number, associating it with the value of its tag IV. See the `SectionReference` class, below.

`SectionReference` [Class]

At hardcopy time, a `SectionReference` object looks up the value of its tag IV to see if a `SectionNote` object has noted a section number for that tag. If there is section number stored, the `SectionReference` object will display the number, otherwise it will display the string "n.". If the `SectionNote` occurs before the `SectionReference` object in the document, this reference will be found the first time the document is printed. If the `SectionNote` occurs after the `SectionReference` object, a second hardcopy must be generated.

`SectionReferences` are used in this document in the last paragraph of the first section.

Unknown IMAGEOBJ
GETFN: `LoopsImageObjectGetFn`

The following class illustrates the possibility of nesting image objects inside of other image objects.

`BoxedImageObject` [Class]

IVs: `boxShade` (the shade of the box: either a shade or a form that will be evaluated to a shade; e.g. `GRAYSHADE`), `boxWhiteSpace` (blank space between the boxed object and the box), `boxWidth` (the width of the box), `boxedObject` (a `LoopsImageObject`).

Unknown IMAGEOBJ
GETFN: `LoopsImageObjectGetFn`

A common document form consists of a table of text entries. These are easy to build in TEdit when each entry fits within its row without having to occupy multiple lines.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Example: BoxedImageObjects and TableTextObjects

The following class takes care of the case where the table entries are too large to fit on a single line.

TableTextObject [Class]

describes a (possibly multiple line) table entry. The class `TableTextObject` defines five important IVs.

`text` [IV of TableTextObject]

contains the text that will be displayed in the table entry.

`widthInWs` [IV of TableTextObject]

defines the width of the table entry. This width is measured in "W"s, in the current font. If the `text` is too long, it will be broken at word boundaries and displayed in multiple lines. The default value is 10.

`nLines` [IV of TableTextObject]

defines the maximum number of lines to be used to print the text. If `nLines` is `NIL` (the default), the object will be as tall as it needs to be to display the entire `text` subject to the width constraint specified by the `widthInWs` IV.

`justify` [IV of TableTextObject]

determines the horizontal justification of the individual lines within the table entry. Possible values are `left` (for left-justify), `center` (for centered text), and `right` (for right-justify). The default is `left`.

`verticalJustify` [IV of TableTextObject]

determines the vertical justification of the lines within the table entry. Possible values are `top` (the first line will be flush with the top of the table entry), `center` (the text will be centered vertically), and `bottom` (the last line of text will be at the bottom of the entry). The default is `bottom`. Note that this IV only has an effect if the IV `nLines` is specified.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Image objects can be used to include prettyprinted forms in a document.

PPIImageObject [Class]

prettyprints a form in the image stream. The relevant IVs of PPIImageObject are:

form [IV of PPIImageObject]

~mumble~

minWidth [IV of PPIImageObject]

~mumble~

maxWidth [IV of PPIImageObject]

~mumble~

Due to an unfortunate bug in Interlisp, PPIImageObject work correctly on display devices .

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Example: PPIImageObject

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Loops objects that are wrapped around an Interlisp IMAGEOBJ. The IMAGEOBJ in turn points back to the Lops image object. When Interlisp "sends a message" to the underlying IMAGEOBJ (more correctly, applies one of the IMAGEOBJ's IMAGEFNS to the IMAGEOBJ), the IMAGEOBJ forwards this message on to the Loops image object. The translation from Interlisp IMAGEOBJ protocol to Loops image object protocol is accomplished by a special set of IMAGEFNS and the LoopsImageObject class.

LoopsImageObject [AbstractClass]

~mumble~

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

The following methods implement the IMAGEFNS for the Loops image object. These message are not intended to be sent by the user; they are sent automatically by TEdit and other packages.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

```
(_ self ImageBox imageStream currentX
    rightMargin)
```

[Method of LoopsImageObject]

returns an instance of the record IMAGEBOX with fields XSIZE, YSIZE, XKERN, and YDESC. This is used by TEdit to determine the size of the object for formatting purposes. Specializations of LoopsImageObject should override this method.

```
(_ self Display imageStream)
```

[Method of LoopsImageObject]

should actually display the object on the *imageStream*. Specializations of LoopsImageObject should override this method.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

```
(_ self ButtonEventIn windowStream selection
    relX relY window textStream button)
```

[Method of LoopsImageObject]

~mumble~

```
(_ self CopyButtonEventIn windowStream)
```

[Method of LoopsImageObject]

~mumble~

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

```
(_ self Copy)
```

[Method of LoopsImageObject]

~mumble~

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Due to restrictions imposed by IMAGEOBJets, LoopsImageObjects cannot duplicate the full generality of saving and retoring Loops objects. Specialized subclasses of LoopsImageObjects cannot change how they are stored or read back in. However, the following methods do give the user some control over what extra information is dumped out when a LoopsImageObjects is stored.

(*_ self BeforePutToFile stream*) [Method of LoopsImageObject]

~mumble~

(*_ self AfterPutToFile fileStream*) [Method of LoopsImageObject]

~mumble~

(*_ self AfterGetFromFile textStream*) [Method of LoopsImageObject]

~mumble~

(*_ self PrePrint*) [Method of LoopsImageObject]

~mumble~

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

(*_ self WhenCopied targetWindowStream
sourceTextStream targetTextStream*) [Method of LoopsImageObject]

~mumble~

(*_ self WhenDeleted targetWindowStream
sourceTextStream targetTextStream*) [Method of LoopsImageObject]

~mumble~

(*_ self WhenInserted targetWindowStream
sourceTextStream targetTextStream*) [Method of LoopsImageObject]

~mumble~

(*_ self WhenMoved targetWindowStream
sourceTextStream targetTextStream*) [Method of LoopsImageObject]

~mumble~

```
(_ self WhenOperatedOn windowStream howOperatedOn
    selection textStream)
```

[Method of LoopsImageObject]

~mumble~

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

The class `LoopsImageObject` provides a number of other methods that can be used by specializations of the above methods.

```
(_ self CachedImageBox imageStream)
```

[Method of LoopsImageObject]

returns the image box computed by the last `ImageBox` method. This is often used inside the `Display` method to avoid resending the `ImageBox` message.

```
(_ self DisplayImageStream? imageStream)
```

[Method of LoopsImageObject]

returns `NIL` unless the image stream is a display image stream.

```
(_ self PrintText imageStream text font)
```

[Method of LoopsImageObject]

prints the string *text* in the font *font*, centered in the object's `CachedImageBox`.

Unknown IMAGEOBJ
GETFN: LoopsImageObjectGetFn

Certain subclasses of `LoopsImageObject` capture some commonly desired functionality. These may be useful to anyone interested in building their own Loops image objects.

`TEditImageObject`

[AbstractClass]

The class `TEditImageObject` contains a few methods that are only applicable when the object is being displayed in a `TEdit` stream.

```
(_ self CurrentFont imageStream)
```

[Method of TEditImageObject]

returns the font of the image object in the current `TEdit` stream.

(*_ self* TextStream *imageStream*) [Method of TEditImageObject]

returns the text stream that is being displayed in *imageStream*.

(*_ self* TEditIV *ivName* *textStream*) [Method of TEditImageObject]

edits the text stored in the IV *ivName* of *self* in a new TEdit window. The image object should be part of the TEdit stream *textStream*. The *textStream* argument is used to update the display when the IV has been edited.

(*_ self* AllObjects *textStream*) [Method of TEditImageObject]

returns a list of all imageobjects contained in *textStream*, in order.

LOOPSINDEX

By: sML (Lanning.pa@Xerox.com)

4-Sep-86

INTRODUCTION

LOOPSINDEX sets up the SINGLEFILEINDEX package to dump out classes, methods, and instances in an intelligible way. LOOPSINDEX can be loaded into any Interlisp sysout: you do not need to have Loops loaded to load LOOPSINDEX.

LOOPSINDEX adds appropriate entries to the lists SINGLEFILEINDEX.TYPES and SINGLEFILEINDEX.FILTERS to cause SINGLEFILEINDEX to index all classes, methods, and instances defined on a file. See the documentation of SINGLEFILEINDEX for a detailed description of these variables.

LOOPSINDEX will load SINGLEFILEINDEX if it is not already loaded.

HOW TO SET UP FOR TESTING LOOPS

Start with a fresh LISP.SYSOUT from {erinyes}<lisp>lyric>basics>, dated 27-Apr-87.

Give no INIT file

Log in.

Type into the exec:

```
(SETQ IL:DISPLAYFONTDIRECTORIES '("{ERINYES}<lisp>LYRIC>FONTS>"))
CONN {ERINYES}<lisp>Lyric>library>
(il:load 'TEDIT.lcom)
(il:tedit '{erinyes}<cate3>loops>LOOPS-setup.tedit)
```

This should bring up this document.

Shift selected all lines below here into the EXEC:

```
(il:load 'FILEBROWSER.lcom)
CONN {erinyes}<lisp>lyric>lispusers>
(il:load 'WHO-LINE.dfasl)
(il:load 'filewatch.lcom)

CONN {erinyes}<lispusers>lyric>
(il:load 'CROCK.lcom)

CONN {erinyes}<test>lisp>lyric>internal>library>
(il:load 'do-test.dfasl)

(setq il:*DEFAULT-CLEANUP-COMPILER* 'cl:COMPILE-FILE)

(setq il:ch.default.domain "AISNORTH")
(SETQ IL:CH.DEFAULT.ORGANIZATION "XEROX")
CONN |{PELE:AISNorth:Xerox}<CATE3>|

(il:closew il:logow)
(IL:CHANGEBACKGROUND 42405)
(il:crock)
```

Follow the instructions for loading loops from the release notes manual.

As long as the workstation can get the font files from the network, steps 1-3 can be ignored in the Installation of Loops (4.3 of Release Notes)

For step 4:

The modified network version:

```
CONN {ERINYES}<lisp>Lyric>library>
(il:load 'grapher.lcom)
```

For steps 5-6:

Insert Lyric LOOPS System #1 floppy, then type:

```
(il:fb '{floppy})
```

and copy all files to {dsk}<lispfiles>loops>

Do the same for the Lyric LOOPS System #2 floppy

Then type or shift select in an Interlisp window:

```
CONN "{DSK}<lispfiles>loops>"
(LOAD 'LOOPS)
```

Stuff the following lines into a temp file in core then shift select out the sysout command.

```
(il:sysout '{erinyes}<cate3>loops>test-loops.sysout)
(il:login)
(il:fb '{erinyes}<cate3>loops>)
; Make sure the Loops stuff is copied to <lispfiles>loops>
load the right software, and change to loops stuff
```

The basic loop is (TIMEALL *form* 10000).

[[Timing old SmallLoops, on an 1132]]

Test name	Time (secs)	Time in test (less var lookup)
Global variable lookup	0.05	0.00

Inspecting and Repairing Notefiles

Xerox Corporation

Randy Trigg

[First written: 8/9/85 Randy Trigg]
[Last updated: 8/26/85 Randy Trigg]

This document describes the Notefile inspector facility available via the Inspect&Repair option on the Notefile Ops menu in NoteCards Release1.2i.

The old Repair Notefile facility rebuilt the links in a Notefile from the contents of card substances. This was used whenever a notefile was thought to have inconsistent links. The problem was that notefiles with inconsistent links often had other problems that caused Repair to break. Thus the motivation for developing the notefile inspector documented here was to verify a notefile's readability before invoking the link rebuild. As it turns out, this inspector is useful generally for checking the health of a notefile, deleting cards and backing up other cards (or more precisely, card parts) to previous versions. Thus, you may want to use the inspector even if your notefile is healthy and doesn't need its links rebuilt.

The notefile inspector has three separate phases: reading the notefile's data area searching for healthy card parts, allowing the user to make modifications, and rebuilding the links. The process can be aborted after phase 1 or 2 if desired. This document begins with a brief discussion of the organization of a notefile. Then follows sections describing each of the three phases. Finally, I outline some tips, strategies and pitfalls to watch for.

1. What you need to know about a notefile's innards.

1.1 Notefile structure.

A notefile consists of two parts, the index and the data area. Each card in the notefile has an entry in the index. An index entry has 5 parts, a status field and 4 pointers. The status field specifies whether the index entry is free or occupied by an active or deleted card. There is one pointer in the index entry to each of the 4 parts of a card: substance, title, links and property list. These point into the data area. Whenever you change, say, the title of a card, the new title is written to the end of the data area and the index entry title pointer for that card is updated to point to the new location in the data area. Thus, in general, a notefile's data area grows every time any part of any card is changed. To throw away the old versions of card parts, it is necessary to compact the notefile.

1.2 Card IDs.

Every card in the notefile has a unique ID, e.g. NC00023. The top level fileboxes; **Contents**, **Orphans**, and **To Be Filed** have IDs NC00001, NC00002, and NC00003, respectively. Note that these boxes cannot be deleted. The IDs from NC00004 through NC00020 are unused. Currently, an old ID is never reused, even if its card is deleted and the notefile is compacted. Thus, if the inspector shows no entry in the card inspector menu for some ID, it is because that card has been deleted. If you've asked to show deleted cards and it still doesn't appear, it's because the notefile has been compacted since that card was deleted.

1.3 Card parts.

Of the four parts of a card, the title and property list are simplest. The title is simply a string while the property list is a list of attribute value pairs. If you have not been attaching properties to your cards, then the inspector will only show those properties that the system maintains. Currently the only such property is "Updates" with value equal to a list of dates on which the card was updated going chronologically backwards from the front of the list to the back.

The substance of the card is simply its contents. Thus a text card's substance is a text stream, a browser card's is its graph, etc. These are stored on the file in a manner appropriate to the substance type. Thus a text substance on the notefile looks like the way TEdit writes out text streams (text followed by "looks" information).

1.4 Links on the notefile.

The links of a card are divided into three groups: **to links**, **from links**, and **global links**, where the global links form a subset of the to links. The to links of a card are those links pointing from this card to some other card. The from links are those links pointing from another card to this one. Finally, the global links are those to links that are global, that is, they point from this card as a whole to another card. (Global links are the ones that aren't anchored in the source card's substance. Source links are an example.)

The confusing thing about links out on the notefile is that they are stored in several places. All links are stored as to links with their source card and as from links with their destination card. Furthermore, links that are not global are also stored within the substance of their source card inside of a link icon. Links that are global are also stored on the global links list of their source card. Thus, all links are stored in three places: as a to link on the source card, as a from link on the destination card and either in the substance of the source card or on its global links list. If these three records of a link don't agree for some reason, then we say that the notefile is **inconsistent** and needs its links rebuilt.

1.5 The links rebuilder.

The third phase of the inspector rebuilds the links of a notefile as follows: First it removes all the to and from links for every card. Then it reads the substances for each card and recreates to links and from links by looking at the links found inside the link icons in the substance.

The link rebuilder is also able to rebuild bad filebox substances. It does this by looking for all cards in the notefile with from links from the bad box and creating a new substance for the box containing only links to those cards. This process loses any text that the box might have contained as well as scrapping the original ordering of links. Nonetheless, in some cases this may be preferred to backing up the substance to a previous version or to deleting the box altogether.

The links rebuilder can rebuild the notefile's list of link types in a similar manner. That is, it records the set of link types seen on valid links and replaces the old links types with the new set. Note that this throws away any link types for which there are no links in the notefile.

Finally, the links rebuilder can rebuild bad global links for a card. It does this by looking for any cards with from links from the bad card that are global. This assumes that the card at the destination end has good links. Thus, if the cards at both ends of a global link have unreadable links, then there is no way to recover that link.

The inspector provides the option of having the links rebuilder phase rebuild bad filebox substances, bad link types, and bad global links. See Section ?? below.

2. Running the Notefile inspector: Phase 1: Scouring the data area

To start the inspector, first be sure that there is no open notefile. Then select the item **Inspect&Repair** from the NoteFile Ops menu. There is one option available at this level by "pulling to the side" called **ReadSubstances**. This ensures that substances of all cards pronounced valid by the inspector are readable. If this option is not invoked, then a check is still run on the length of the substance, but not on its contents. Unfortunately, the ReadSubstances option requires MUCH more work by phase 1. I recommend that you only use this option if Phase 3 (link rebuilding) breaks with some error like "Bad Piece Tbl" from TEdit. In that case, up-arrow out of the break and start the Inspect&Repair process over again, this time using the slower but more comprehensive ReadSubstances option.

Selecting Inspect&Repair will invoke phase 1 of the inspector, wherein the data area of the notefile is scoured for valid card parts. A record of all such parts is kept and statistics printed out at the end. You'll be asked to position the window in which those statistics as well as later inspector communications will be printed. You can monitor the progress of phase 1 by watching the prompt window. It will be printing messages like "Processing byte xxxxx of yyyy."

When phase 1 has completed and you've positioned the interaction window, statistics on your notefile will be provided. You'll be told the total number of card IDs used and the number of those that are currently associated with active and deleted cards. (The rest are free and will never be reused. See Section 1.2 above.) If all seems well with the world, the next line will read "All active cards look okay." If not, there will be various messages outlining the problems. (See Figure 1.)

```

Inspect&Repair Interaction Window
Fileboxes (NC000002 NC000003 NC000033 NC000154) have bad substance(s).
If you don't delete them or back up to a previous version, then phase 3 of Inspect&Repair will rebuild their contents.
Out of 240 card IDs:
there are 176 active cards and 11 deleted cards.
Of the active ones,
1 have improper prop list data.
3 have improper links data.
4 have improper substance data.
  
```

Figure 1: Snapshot of a sample interaction window

Note that several fileboxes have bad substances and that a special message is printed on their behalf. This indicates that if you don't wish to delete or back these up to a previous version, then phase 3 will rebuild them. (See Section 1.5 above.)

If there are cards having user-defined types whose type definition code has not been loaded, then you'll get a message to that effect, something like "<n> cards have unknown card types (FOO BAR)." At this point you should load the lisp files containing the definitions of the unknown card types. If not, then these cards will show up with bad substance in phase 2. If you have a card for which no substance versions could be read, then you'll also get unknown card type messages for it (reading something like "<n> cards have unknown card types (NIL)"). This is because the inspector couldn't find a card type on the notefile for that card.

A menu of options appears attached to the upper right corner of the interaction window. The particular options you get in that menu depend on the state of your notefile and are described below. The first two options appear in all cases. The other two may or may not be present in the menu you get. In any case, you should select one of the options before attempting any other NoteCards-related work.

ABORT: Choosing this option aborts the Inspect&Repair process entirely, throwing away any changes you might have made (such as card deletions or back ups.)

INSPECT CARDS: This brings up a menu of active card IDs with which you can inspect, delete, or back up particular cards. There is a "pull-across" menu item called **INCLUDE DELETED CARDS**, which if selected will include card IDs for deleted cards as well as active ones. Using this option, one can undelete deleted cards and restore some previous version.

END INSPECT&REPAIR: This option is only available if it seems that you don't need to continue to the link rebuilding phase. You will not get this option if you've deleted any cards, or generally if there are problems with the notefile. Choosing this option causes the Inspect&Repair process to end gracefully (via a normal checkpoint and close notefile), thus skipping phase 3, rebuilding links.

CONTINUE INSPECT&REPAIR: This option is only available if the notefile is in fairly good health (i.e. okay except for fileboxes to rebuild or global links to rebuild - see Section 1.5 above). Selecting it causes Inspect&Repair to move to phase 3 and rebuild your notefile's links.

3. Running the Notefile inspector: Phase 2: Your chance to tinker

After selecting **INSPECT CARDS** in the interaction window's attached menu, a menu containing Notecards IDs will pop up and be attached to the interaction window's lower left corner. It will contain IDs for all active cards and possibly deleted cards as well if you selected the submenu item **INCLUDE DELETED CARDS** described above. The menu can hold some 200 card IDs. If your notefile has more than that, then the menu will be composed of several pages each containing around 200 IDs. Rapid switching between pages is possible.

Attached to the upper right corner of the cards inspector menu is a menu containing at least the two options: **ABORT** and **DONE**. If the menu has multiple pages (there are more than 200 active cards in the notefile), then the attached menu will also include the items **NEXT PAGE**, **PREVIOUS PAGE**, and **FIRST PAGE**. Selecting these causes the current menu to be swapped with either the next menu, previous menu, or first menu, respectively.

Clicking **ABORT** causes the entire Inspect&Repair process to quit, throwing away any changes you've made. (This is equivalent to choosing **ABORT** from the inspector window as described in Section 2.)

Choosing **DONE** from this attached menu indicates that you're done tinkering with card parts and wish to return to the main interaction window. Normally, this causes the card inspector

menu to close and the phase 1 process outlined in Section 2 to be performed again. Thus the data area will be rescoured and new statistics on the health of your notefile will be printed. This cycle of scour data area (phase 1) followed by inspect (phase 2) can be repeated as often as desired. Eventually, you must either abort, end the Inspect&Repair process gracefully, or continue to phase 3. Because phase 1 can be quite slow for large uncompact notefiles, there is one optimization: if you've made no changes in phase 2, then the data area scouring is not repeated in phase 1. Rather, the old information from the last scouring is recovered and used instead.

If you've clicked DONE, but there are still cards with bad prop lists, titles, or links (because you haven't either deleted them or backed up their card parts to previous versions), you will be asked up to three questions. The list of card IDs of cards with bad prop lists is printed out and you're asked whether it's okay to set the prop lists of those cards to NIL. Then, the list of card IDs of cards with bad titles is printed out and you're asked whether it's okay to set the titles of those cards to "Untitled." Finally, card IDs for cards with bad links are printed out and you're asked whether it's okay to set the global links to nil. (Global links will be rebuilt as much as possible in phase 3. See Sections 1.5 and 4.) If you want phase 3 to be able to run, it is necessary to either answer yes to these questions or fix each of the bad card parts by hand in phase 2.

3.1 The card inspector menu

In the card inspector menu, those IDs corresponding to deleted cards have a line drawn through them. Those having some sort of problem appear shaded. In addition, an upper-case letter suffix is attached to such IDs indicating the problem. For example, a shaded menu item NC00023SL indicates that ID NC00023 has bad substance and bad links. The letter codes are S, L, P, and T indicating bad substance, links, property list, and title, respectively. If such a letter code appears in lower case, then the indication is that the current version of that card part is beyond the last checkpoint pointer. For example, NC00023t indicates that NC00023's current title was changed since the last checkpoint. (There may have been a crash, for example, thus preventing the notefile from closing normally.)

In addition to menu entries for each card ID, there is also one entry labeled LNTYPES allowing you to inspect (and possibly back up to a previous version) the Link Types for this notefile.

If you button an ID in the card inspector menu, then a popup menu allows up to two choices **Inspect** and/or **Delete**. If the card is currently deleted (has a line drawn through it), then the Delete option is replaced by **Undelete**. Certain card IDs cannot be deleted and thus their popup menus only contain the Inspect option. These are the top level file boxes NC00001, NC00002, NC00003. The link types menu entry LNTYPES also does not allow deletion.

Choosing Delete or Undelete from this popup menu causes the card to be deleted or undeleted, respectively and the line through the menu item either drawn or undrawn. Note, however, that this action (and all others) can be undone by choosing ABORT from either the card inspector menu or the interaction window menu.

Choosing Inspect from the popup menu for a card ID entry brings up a card parts inspector for that card.

3.2 The card parts inspector

Figure 2 below shows an example of a card parts inspector. It is composed of four attached menus arranged vertically and one attached operations menu atop the stack.

Figure 2: A card parts inspector

The four menus contain entries for every valid version of card parts for the card with ID NC00027. The top menu is for version of titles and below that are menus for versions of the card's substance, links, and prop list. For example, the Substance submenu contains entries for three versions of the substance of this card. The current version of each card part is shaded. Each menu entry gives the date that that version was written if available or the string "NO DATE AVAILABLE" if there is no date on the notefile. (The latter is the case for old notefiles prior to the time we began recording card parts write dates.)

If the current version of the card part is bad, then the menu entry will be a string so indicating, for example, "BADSUBSTANCE."

The title of the top menu includes the card's type and ID. In addition, each menu item contains a bit of information, in square brackets, before the date. In the title versions menu, this information is the first few characters of the title. In the substance versions menu, it is the number of bytes in the substance. In the links versions menu, it is a triple of numbers giving the number of to links, from links, and global links for this card. Finally, the proplist versions menu includes the number of entries on the property list for this card (i.e. twice the number of attribute-value pairs).

Atop the stack of menus is an attached menu of operations, described below.

ABORT: This aborts this card parts inspector, throwing away any changes made.

UPDATE: This closes the card parts inspector, effecting any changes (backing up to previous versions of card parts) you might have done.

DELETE: This option closes the card parts inspector and deletes the card. (Again, this can be undone by choosing ABORT from the card inspector menu.)

UNDELETE: For cards that have been deleted, this option appears instead of DELETE. Choosing it causes the card to be undeleted.

RESET: This causes the selections in the submenus to be restored to the values they had when the card parts inspector was first brought up. (Equivalent to doing **ABORT** and then inspecting this ID again from the card inspector menu.)

Note that cards that can't be deleted don't have the **DELETE** option on their card parts inspector.

Buttoning an entry in a submenu of a card parts inspector pops up a short menu unless the entry is for a bad version (e.g. "BADSUBSTANCE"). This menu contains at least the entry **Inspect** and possibly **Change Selection**, if the selected entry is not the same as the current one (i.e. not shaded).

Choosing **Inspect** allows further inspection of the details of the selected card part version. For example, inspecting a title version brings up the Interlisp inspector on a record containing the title, date and card ID. Similarly, inspecting a links or prop list version brings up the Interlisp inspector on a record containing the lists of links (for to links, from links and global links) or the prop list. Note that if you wish to continue inspecting a links version down to the single link level, choose to inspect the link as a **NOTECARDLINK**. This is somewhat more communicative about record field names. Note also that changing values out in the Interlisp inspectors has no affect on the notefile and is ignored.

All substance versions for cards having substance types **TEXT**, **SKETCH** and **GRAPH** can currently be inspected. (This includes all cards except those having user-defined substance types, like the **NCFile** card.) Inspecting a card's substance version will bring up a window showing a copy of the substance. (Note that changes to this copy have no affect on the notefile.) Any links in the substance of the card will show up as bracketed strings describing the link.

Choosing **Change Selection** from the card part version popup menu causes the current selection to be changed, thus backing up the card to the selected version. (This change can be undone by resetting or aborting the card parts inspector as well as by later aborting the card inspector or interaction window.)

4. Running the Notefile inspector: Phase 3: Rebuilding your links

To complete the **Inspect&Repair** process, select the **Continue Inspect&Repair** option from the interaction window menu. This invokes phase 3, the links rebuilder. Normally, this simply rebuilds links from card substances (see Section 1.5). In certain circumstances, it may do extra work as well. If your link types list is bad, and you didn't back it up to a previous version, then phase 3 will rebuild it. If there are fileboxes with bad substances that you haven't either deleted or backed up to previous versions, then phase 3 will rebuild them. Finally, if there are cards with bad links that you haven't backed up or deleted, then phase 3 will rebuild those links as well. (It rebuilds ALL to links and from links anyway. For those cards, it will rebuild global links as well.) Again, for details, see Section 1.5.

5. Tips and hints for using **Inspect&Repair**

This section contains a list of strategies and tips for using **Inspect&Repair**. For the most part, they are ordered from the useful and obvious to the esoteric. Several of these are implicit in the first four sections of the document, but are repeated here for emphasis and completeness.

When in doubt, abort! All your changes will be lost, but then if you're uncertain about what's happened this is the safe course. Often, in fact, you may simply want to check the health of your notefile and abort without tinkering.

Fixing versus tinkering. There are two main ways to use the inspector, either for fixing a broken notefile, or tinkering with a healthy one. The latter case occurs when you wish to recover some card that you inadvertently deleted. Or back up a card that you inadvertently changed to a previous version.

Compacting. Old versions of card parts have always been stored in notefiles, but up till now have been inaccessible. Thus, there was little reason not to compact your notefile often. Now there is a tradeoff between the need to save space by compacting versus the need to be able to back up using Inspect&Repair. Probably the safest course is to keep a backed up copy of the pre-compacted notefile around until you have confidence that the compacted one is healthy and that you have no need for previous versions of any of its cards.

Inspect&Repair can't run when notefile is open. This means that if you are working in your notefile and notice a card you'd like to inspect a previous version of, you must record the card's ID and close the notefile. Then, run Inspect&Repair, find the card ID in the inspector menu and tinker with it as desired.

Fixing enough problems to allow phase 3 to run. You can't run phase 3 unless Inspect&Repair thinks your notefile is above a certain threshold of health. There are certain problems it can handle (e.g. bad filebox substances, see Sections 1.5 and 4), and others that it can't (e.g. bad title). You have to decide either to fix these sorts of problems yourself in phase 2, let phase 3 attempt to rebuild them, or just abort the whole thing (always an option).

Sometimes these decisions can be tricky. For example, suppose a filebox's substance is bad. Call it BadBox. Should you (a) delete BadBox altogether, (b) back its substance up to a previous version, or (c) allow phase 3 to rebuild it by looking for from links in other cards from BadBox? Option (c) may not be advisable if there was important text in BadBox or if the order of cards in BadBox was important. On the other hand, option (b) may be of little use if the last good version is too out of date (or if there is no good version at all).

NoteCards Programmer's Interface

Release 1.2i

Randy Trigg

Xerox PARC

Updated version: 18-Mar-85

Modified: 26-Aug-85 by Randy Trigg

Modified: 1-Aug-85 by Lissa Monty

Introduction

This document describes a facility whereby users with some programming know-how can obtain a lisp interface to NoteCards. In this way, they can create and modify Notefiles, cards and links under program control.

The functions described below are divided into 7 groups:

1. NoteFile Creation and Access
2. Creating and Accessing NoteCard Types
3. Creating NoteCards and FileBoxes
4. Accessing NoteCards and FileBoxes
5. Creating and Accessing Links
6. Creating and Accessing Link Labels
7. Handy Miscellaneous Functions

1. NoteFile Creation and Access

For each of the following functions (except NCP.CloseNoteFile), the argument is a filename. The suffix ".NoteFile" is added if not already present. In any case, the filename used by NoteCards always has this suffix.

(NCP.CreateNoteFile <filename>)

If <filename> is not already a notefile, then create a notefile <filename>.NoteFile, and return this filename which can later be passed to NCP.OpenNoteFile.

(NCP.OpenNoteFile <filename> <don'tCreateFlg> <convertw/oConfirmFlg>)

If there is no currently open notefile, then open <filename> and make it the currently active NoteFile. Returns resultant stream if successful, else nil. If <don'tCreateFlg> is non-nil, then a new file will not be created if the given one doesn't exist. If <convertw/oConfirmFlg> is non-nil, then if needed, the file will be converted to release1.1 format without user confirmation.

(NCP.CloseNoteFile [<stream>])

Closes <stream> if it corresponds to a currently open Notefile. Returns its filename if successful. If <stream> is nil, then closes current open notefile.

(NCP.CheckpointSession)

Checkpoint the current Notecards session, first writing out any dirty cards. In case of a system crash or abort, the notefile can be recovered to the last checkpoint. Note that closing a notefile does a checkpoint.

(NCP.AbortSession)

Abort the current Notecards session, losing all work since last checkpoint or successful close.

(NCP.RepairNoteFile <filename>)

Rebuilds the link structure of <filename>. It must *not* be currently open.

(NCP.CompactNoteFile <filename>)

Copies <filename> to a later version, recovering space. Must not be open.

(NCP.CompactNoteFileInPlace <filename>)

Compacts <filename> in place, replacing the old version. Must not be open.

(NCP.DeleteNoteFile <filename>)

Removes the <filename> notefile. Must not be open.

(NCP.CurrentNoteFileStream)

Returns the currently open notefile stream if there is one, else nil.

(NCP.CurrentNoteFile)

Returns the full name of the currently active notefile if there is one, else nil.

(NCP.CheckOutNoteFile <fromFilename> <toFilename>)

Copies <fromFilename> to <toFilename> unless <fromFilename> is locked. If successful, creates a lock file in <fromFilename>'s directory. The name of the lock file is formed by concatenating the atom LOCKFILE onto <fromFilename>.

(NCP.CheckInNoteFile <fromFilename> <toFilename>)

Check lock file for <toFilename>. If none, then just copy <fromFilename> to <toFilename>. If there is one and it's owned by us, then do the copy and remove the lock file. If there is a lock file owned by someone else or if date of <toFilename> is more recent than date of lock file, then print a message and do nothing.

2. Creating and Accessing NoteCard Types

These functions give the user access to the NoteCard user-defined types facility. For an explanation of this facility, see the NoteCards Types Mechanism documentation.

(NCP.CardTypes)

(NCP.SubstanceTypes)

Returns lists of all currently defined NoteCard types and substances, respectively.

(NCP.CreateCardType <TypeName> <SuperType> <SubstanceType> <FnsAssocList> <VarsAssocList>)

Makes a new NoteCard type with name <TypeName>, super type <SuperType>, substance <SubstanceType>. Any functions not appearing in <FnsAssocList> will be inherited from <SuperType>. The CardWidth and CardHeight vars fields will be inherited if not specified in <VarsAssocList>. Other vars fields default to nil. Note that, for now, specializing the FileBox card type is not allowed.

(NCP.CreateSubstanceType <SubstanceName> <FnsAssocList> <VarsAssocList>)

Makes a new substance type with name <SubstanceName> and the given functions and vars fields. None of the function fields should be nil (but might conceivably be the function NILL).

(NCP.CardTypeSuper <type>)

Returns the super type of <type>.

(NCP.CardTypeSubstance <type>)

Returns <type>'s substance type.

(NCP.CardTypeLinkDisplayMode <type>)

Returns the link display mode of <type>.

(NCP.CardTypeFn <type> <fn>)

(NCP.CardTypeVar <type> <var>)

Returns the <fn> (<var>) field for <type>.

(NCP.CardTypeInheritedField <type> <field>)

Returns the value of the card type function or variable <field> for <type>. This is possibly different from the value returned by NCP.CardTypeFn or NCP.CardTypeVar in that if the defined value for <field> of <type> is nil, then the super is checked for a non-nil value. This checking continues until either a non-nil <field> is found or we reach the top of the super hierarchy. In that case, the value of <type>'s substance's <field> is used. Note that among the variable fields, only CardDefaultWidth and CardDefaultHeight inherit, so for the other Var fields, the result of NCP.CardTypeVar is valid (even if it's nil).

(NCP.SubstanceTypeFn <substance> <fn>)

(NCP.SubstanceTypeVar <substance> <var>)

Returns the <fn> (<var>) field for the substance <substance>.

(NCP.ValidCardType <type>)

Returns non-nil if <type> is an existing NoteCard type.

(NCP.ValidSubstanceType <substance>)

Returns non-nil if <type> is an existing NoteCard substance type.

(NCP.ValidCardTypeFn <fn>)

(NCP.ValidCardTypeVar <var>)

Returns non-nil if <fn> (<var>) is a valid function (variable) field for NoteCard types, for example, the litatom MakeCardFn (CardDefaultWidth). In other words, <fn> (<var>) can serve as the <fn> (<var>) arg to NCP.CardTypeFn (NCP.CardTypeVar).

(NCP.ValidSubstanceTypeFn <fn>)

(NCP.ValidSubstanceTypeVar <var>)

These return non-nil if <fn> (<var>) is a valid function (variable) field for substance types. In other words, <fn> (<var>) can serve as the <fn> (<var>) arg to NCP.SubstanceTypeFn (NCP.SubstanceTypeVar).

(NCP.CardTypeFns)

(NCP.CardTypeVars)

(NCP.SubstanceTypeFns)

(NCP.SubstanceTypeVars)

These return lists of all valid Fn (Var) fields for NoteCard types and substances respectively.

3. Creating NoteCards and FileBoxes

The following functions create various sorts of cards and boxes within the currently open notefile.

(NCP.CreateTextCard <title> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns a new notecard having type Text. If <title> is non-nil, it is installed as the Notecard's title, otherwise the title is "Untitled." <props>, if non-nil, should be a prop-list of properties and values to be placed on the user property list of the Notecard. If <parentfileboxes> is non-nil, then it should be a list of FileBoxes in which to initially file this card.

(NCP.CreateFileBox <title> <nodisplayflg> <props> <childcardsboxes> <parentfileboxes>)

Creates and returns a new Filebox with title <title> (or a gensym'ed name if <title> is nil). It will initially contain child cards and boxes from the list <childcardsboxes> (if that arg is non-nil). If <parentfileboxes> is nil, then the new filebox will be filed in the value of (NCP.GetToBeFiledFileBox). The <props> arg is handled as it was for NCP.CreateNoteCard.

(NCP.CreateBrowserCard <title> <paramList> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns a new browser card with given title, props and parents. <paramList> should be a prop list of browser parameters. The properties currently recognized are:

ROOTCARDS: A list of Notecards to serve as roots of the forest or lattice generated by the browser. If omitted or NIL then user is asked to choose root cards.

LINKTYPES: A list of link types to follow when creating the browser. Any label present in the list having the backarrow prefix ("_") represents that link type but in the reverse direction. This list can also contain the atoms ALL or _ALL in which case browsing will be done on all links in either the forward or reverse direction. If both ALL and _ALL are specified, then links in both directions will be used (generally making a mess).

DEPTH: The depth at which to cut off the browser. This should be a non-negative integer. If NIL or omitted, then will assume no limit. (Currently integers greater than 9 are assumed equivalent to infinity.)

FORMAT: This should be a list of one, two or three elements. The first should be an atom indicating grapher format. The choices are FAST (laid out as a forest, sacrificing screen space for speed), COMPACT (laid out as a forest, using minimal screen space), LATTICE (laid out as a directed acyclic graph, the default), *GRAPH* (laid out as a graph, i.e. virtual nodes are eliminated). The second element of the FORMAT list, if present, should be either HORIZONTAL (the default) or VERTICAL specifying whether the graph is laid on its side or up and down. The third element, if present, should be the atom REVERSE. This indicates that horizontal graphs should be laid out from right to left instead of left to right and that vertical graphs should be laid out from bottom to top rather than vice versa.

(NCP.CreateSketchCard <title> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns an initially empty sketch/map card having given title, props, and parents.

(NCP.CreateGraphCard <title> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns an initially empty graph card having given title, props, and parents.

(NCP.CreateCard <type> <title> <nodisplayflg> <props> <parentfileboxes> <otherargs>)

Creates and returns a card of the given (possibly user-defined) type, with given title, props, and parents. <otherargs> is a possibly nil list of args that will be passed to the MakeCardFn of <type>. Card is initially displayed or not according to value of <nodisplayflg>.

(NCP.MakeDocument <rootcard> <parametersProplist> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns a Document card starting from <rootcard>. The default set of parameters for making documents can be accessed via NCP.DocumentParameters, but some of these can be given new values just for the duration of this MakeDocument by specifying a non-nil <parametersProplist>. For example, a value of '(TitlesFromNoteCards Bold ExpandEmbeddedLinks ALL)' for <parametersProplist> would cause temporary changes to the values of the parameters TitlesFromNoteCards and ExpandEmbeddedLinks. As usual, the resulting card will have the given props and parents.

(NCP.MakeLinkIndex <linktypes> <backpointersP> <nodisplayflg> <props> <parentfileboxes>)

Creates and returns a LinkIndex text card consisting of a sorted record of all instances of links in the current notefile having one of the given link types. <linktypes> can contain the litatoms ALL and/or _ALL as well as any particular backwards links. (See the above description of NCP.MakeDocument.) Backpointer links are inserted in the text if <backpointersP> is non-nil. Resulting card will have given props and parents.

4. Accessing NoteCards and FileBoxes

The following functions provide access to the cards and boxes present in the current notefile. Note that whether a card's window has been brought up on the screen has little or no effect on the following functions. If the user changes some field of a card while that card is visible on the screen, then the field will update itself automatically. Thus, users can switch between program-driven and screen-interface-driven modes at will.

Cards can be active or inactive. An active card has its information cached (on its property list) thus saving time at the expense of memory. All cards visible on the screen are active. Most of the following functions leave the card in the same state as it was when they started (except NCP.BringUpCard, which makes it active). Thus, users needing to do several consecutive operations to the same card should consider temporarily caching the card's information via NCP.ActivateCards (and then uncache with NCP.DeactivateCards).

Most of the following functions take as first argument a card or filebox. If this does not in fact correspond to an existing card or box, then an error message is printed and nil is returned.

(NCP.BringUpCard <card> <region/position>)

Brings up on the screen the given card in the given region or at the given position. If <region/position> is nil, then user is asked to specify position with mouse.

(NCP.ActiveCardP <card>)

Returns non-nil if given card or box is currently active (i.e. information is currently cached in memory).

(NCP.ActivateCards <cardList>)

For each card or box in <cardList> (or just the one, if the argument is atomic), make it active (i.e. cache its information in memory).

(NCP.DeactivateCards <cardList>)

For each card or box in <cardList> (or just the one, if the argument is atomic), make it inactive (i.e. uncache its information back into the file). If any cards in <cardList> were on the screen then this will close their windows.

(NCP.CardType <card>)

Returns the type of <card> or NIL if the card does not exist.

(NCP.ValidCard <card>)

Returns non-nil if <card> exists (hasn't been deleted). (This is currently a synonym for NCP.CardType.)

(NCP.CardTitle <card> [<newtitle>])

Returns old title of <card>. If <newtitle> is present, then set <card>'s title to <newtitle>. <newtitle> can be an atom or string. Note, however, that all titles are converted internally to strings by NoteCards.

(NCP.FileCards <cards> <fileboxes>)

Every card or box in <cards> is filed in every box in <fileboxes>. Either arg may be an atom or a list.

(NCP.UnfileCards <cards> <fileboxes>)

Every card or box in <cards> is unfiled from every box in <fileboxes>. Furthermore if <cards> is the litatom ALL, then the boxes in <fileboxes> will be cleared of all children. Similarly, if <fileboxes> is the litatom ALL, then the cards and boxes in <cards> will be unfiled from all their parent boxes. Either arg may be an atom or a list.

(NCP.CardParents <card>)

Returns list of fileboxes in which <card> has been filed.

(NCP.FileBoxChildren <filebox>)

Returns list of children of <filebox> in the order in which they appear in the box's textstream.

(NCP.GetLinks <cards> <destinationCards> <labels>)

Returns list of all links from any of <cards> to any of <destinationCards> having any label in <labels>. Any of these arguments can be nil. For example, if <destinationCards> is nil, then all links pointing from <cards> to anywhere with a label in <labels> are returned. If both <cards> and <destinationCards> are nil, then this returns all links having a label in <labels>. If all three args are nil, then this is a slow synonym for NCP.AllLinks.

(NCP.CardPropList <card>)

Returns the prop list of the given card.

(NCP.CardProp <card> <propname> [<newvalue>])

Returns old value of property <propname> on <card>'s prop list. If <newvalue> is present, then set <card>'s <propname> property to <newvalue>. (Semantics are analogous to the Interlisp function WINDOWPROP.)

(NCP.CardAddProp <card> <propname> <newitem>)

Adds <newitem> to the list present on the <propname> property of <card>. Returns old value of property. (Semantics are analogous to WINDOWADDPROP.)

(NCP.CardDelProp <card> <propname> <itemToDelete>)

Deletes <itemToDelete> from the <propname> property of <card> if it is there, returning the previous value of that property. If not there, return nil. (Semantics are analogous to WINDOWDELPROP.)

(NCP.CardSubstance <card>)

Returns the substance of <card>. This is a textstream in the case that the type of <card> has TEXT substance. Otherwise, it is the appropriate underlying structure if <card> has GRAPH or SKETCH substance.

(NCP.CardRegion <card>)

Returns the region of <card>. This works even if <card> is not currently up on the screen, since the region information is stored on the notefile.

(NCP.CardAddText <card> <textstr> <loc>)

Adds the text within the string <textstr> to the text card <card>. If <loc> is the litatom START or END, then the text will be placed at the start or end of the card respectively. If <loc> is a number, then it is assumed to be a character count within the card at which to place the new text. If <loc> is NIL, then the text is placed at the current cursor location.

(NCP.ChangeLoc <card> <loc>)

Changes the cursor's location in <card>'s textstream to <loc>. Possible values for <loc> are as described for NCP.CardAddText.

(NCP.DeleteCards <cards>)

Deletes the given cards and fileboxes from the current notefile, or deletes just the one if <cards> is atomic.

(NCP.FileBoxP <card>)

Returns non-nil if <card> is a filebox.

(NCP.AllCards)

Returns a list of all extant cards for the current notefile.

(NCP.AllBoxes)

Returns a list of all fileboxes in the current notefile.

(NCP.MapCards <fn>)

Maps down the set of all cards in the current notefile, applying <fn> to each.

(NCP.MapBoxes <fn>)

Maps down the set of all fileboxes in the current notefile, applying <fn> to each.

(NCP.GetContentsFileBox)

(NCP.GetOrphansFileBox)

(NCP.GetToBeFiledFileBox)

These functions retrieve the three predefined FileBoxes for the currently open NoteFile. These boxes can be modified (but not deleted) by the user in the same way as any other filebox.

5. Creating and Accessing Links

Links can be connected to points within a card or to the card as a whole, thus the following four link creation functions are provided. Those that connect to points within a card specify at least one of <fromloc> or <to loc>. If nil, then the link icon is placed at the current cursor location in the card. If the arg is the litatom START or END, then it is placed at the front or end of the text respectively. If the loc arg is a number, then it is assumed to be a character count at which to place the link icon.

(NCP.GlobalGlobalLink <label> <sourceCard> <destinationCard>)

Creates and returns a new link with label <label>, connecting <sourceCard> to <destinationCard>.

(NCP.LocalGlobalLink <label> <sourceCard> <destinationCard> <fromloc> <displaymode>)

Creates and returns a new link with label <label>, connecting from <fromloc> of <sourceCard> card to <destinationCard>. If <displaymode> is non-nil, then the new link is displayed in the given mode. Otherwise the default displaymode for the source card's type is used.

(NCP.GlobalLocalLink <label> <sourceCard> <destinationCard> <toloc>)

Not implemented at this time.

(NCP.LocalLocalLink <label> <sourceCard> <destinationCard> <fromloc> <toloc>)

Not implemented at this time.

(NCP.LinkDesc <link>)

Returns list of three items (<label> <sourceDesc> <destinationDesc>) where <label> is the link type and <sourceDesc> and <destinationDesc> have the form (<anchor mode> <card> <loc>). <anchor mode> is either LOCAL or GLOBAL, <card> is the card at this end of the link, and <loc> gives a position in the text of <card> if <anchor type> is LOCAL and <card>'s substance's type is TEXT.

(NCP.LinkDisplayMode <link> [<newdisplaymode>])

Returns old display mode of <link>. If <newdisplaymode> is present, then set <link>'s displaymode accordingly. If non-nil, it can be one of the litatoms Icon, Title, Label, or Both. Or it can be an instance of the LINKDISPLAYMODE record. This has the 3 fields SHOWTITLEFLG, SHOWLINKTYPEFLG, and ATTACHBITMAPFLG. Each field can have one of the three values T, NIL, or FLOAT. If a field, say SHOWTITLEFLG, has value FLOAT then the corresponding global parameter (DefaultLinkIconShowTitle, in this case) will be consulted to decide whether or not to display the destination card's title in this icon. (See Section 7 for a description of the global parameters.)

(NCP.LinkLabel <link> [<newlabel>])

Returns old label of <link>. If <newlabel> is present, set <link>'s label to <newlabel>.

(NCP.GetLinkSource <link>)

Returns the card at the source end of <link>.

(NCP.GetLinkDestination <link>)

Returns the card at the destination end of <link>.

(NCP.DeleteLinks <links>)

Removes all links in <links> (or the single one if <links> is atomic).

(NCP.ValidLink <link>)

Returns non-nil if <link> is a link in the current notefile.

(NCP.AllLinks)

Returns a list of all existing links in the current notefile. (This is equivalent to but faster than (NCP.GetLinks NIL NIL NIL).)

(NCP.MapLinks <fn>)

Maps down the set of all links in the current notefile, applying <fn> to each one.

6. Creating and Accessing Link Labels

The following functions allow the user to manipulate link labels.

(NCP.CreateLinkLabel <label>)

Creates a new link label with name <label> for current notefile unless there is already one defined by that name.

(NCP.DeleteLinkLabel <label>)

Deletes the link label <label> from the current notefile. The label must exist and must not be the label of any existing link, and it must not be a system-defined link label (e.g. SubBox or FiledCard).

(NCP.RenameLinkLabel <label> <newlabel>)

Changes any links having label <label> to have label <newlabel>. <label> must exist and neither <label> nor <newlabel> should be a system-defined label.

(NCP.GetLinkLabels)

Returns a list of all existing link labels including system-defined ones.

(NCP.GetReverseLinkLabels)

Returns a list of the reverse labels for every existing link label. Thus, whereas SubBox would appear in the list returned by NCP.GetLinkLabels, _SubBox would appear in the list returned by NCP.GetReverseLinkLabels.

(NCP.GetUserLinkLabels)

Returns a list of all existing user-defined link labels.

(NCP.ValidLinkLabel <label>)

Returns non-nil if <label> is a defined link label for current notefile.

7. Handy Miscellaneous Functions

(NCP.TitleSearch <key> <key> ...)

Returns a list of all cards having all of the <key>s (can be atoms, numbers or strings) within their titles.

(NCP.PropSearch <propOrPair> <propOrPair> ...)

Returns a list of all cards such that for every <propOrPair> arg, if it is atomic, then the card must contain that property. If it is a list of two elements, then the card must have a property EQ to the first element with value EQ to the second element.

(NCP.WhichCard <x> <y>)

Returns the card currently displayed on the screen whose window contains the position in screen coordinates of <x> if <x> is a POSITION, the position (<x>,<y>) if <x> and <y> are numbers, or the position of the cursor if <x> is NIL. Returns NIL if the coordinates are not in the window of any card. If they are in the window of more than one card, then returns the uppermost. If <x> is a window, then NCP.WhichCard will return the card associated with that window.

(NCP.CardFromWindow <window>)

Returns the card associated with <window>, or NIL if not a notecards window.

(NCP.CardWindow <card>)

Returns <card>'s window if <card> is currently displayed somewhere on the screen.

(NCP.SelectCards)

Returns a list of those cards selected from the screen. A menu appears near the top of the screen with buttons for "DONE" and "CANCEL". Selections are made by left buttoning in the title bars of the desired cards.

(NCP.DocumentParameters <parametersProplist>)

Returns the old value of the document parameters in the form of a proplist. If <parametersProplist> is non-nil then it should be a proplist whose properties are (some of the) valid document parameter names and whose values are permissible values for those parameters. The valid parameters and possible values are as follows:

HeadingsFromFileboxes: NumberedBold, UnnumberedBold, NONE.

TitlesFromNoteCards: Bold, NotBold, NONE.

BuildBackpointers: ToCardsBoxes, ToCards, ToBoxes, NONE.

CopyEmbeddedLinks: ALL, NONE, <listOfLinkLabels>.

ExpandEmbeddedLinks: ALL, NONE, <listOfLinkLabels>.

[See the Notecards user's manual for an explanation of these parameters and how their values affect the document created.]

(NCP.NoteCardsParameters <parametersProplist>)

Returns the old value of the global Notecards parameters in the form of a proplist. If <parametersProplist> is non-nil then it should be a proplist whose properties are (some of the) valid document parameter names and whose values are permissible values for those parameters. The valid parameters and possible values are as follows:

DefaultCardType: <legalCardType>

FixedTopLevelMenu: T or NIL

ShortWindowMenus: T or NIL

ForceSources: T or NIL

ForceFiling: T or NIL

ForceTitles: T or NIL

CloseCardsOffScreen: T or NIL

MarkersInFileBoxes: T or NIL

AlphabetizedFileBoxChildren: T or NIL

DefaultLinkIconAttachBitmap: T or NIL

DefaultLinkIconShowTitle: T or NIL

DefaultLinkIconShowLinkType: T or NIL

LinkDashingInBrowsers: T or NIL

ArrowHeadsInBrowsers: one of the litatoms {AtEndpoint, AtMidpoint, None}

SpecialBrowserSpecs: T or NIL

AnnoAccessible: T or NIL

EnableBravoToTEditConversion: T or NIL

DefaultFont: a font

LinkIconFont: a font

Here, <legalCardType> should be an existing Notecard type, i.e. one that appears in the list returned by NCP.CardTypes.

(NCP.PrintMsg <window> <clearFirstFlg> <arg1> <arg2> ...)

Prints a message in the prompt window of <window>. If <window> is NIL, then prints message in the Lisp prompt window. If <clearFirstFlg> is non-nil, then clears the prompt window first. The args are PRIN1'ed one at a time.

(NCP.ClearMsg <window> <closePromptWinFlg>)

Clears the prompt window associated with <window> (or with the main Lisp prompt window if <window> is NIL) and closes it if <closePromptWinFlg> is non-nil.

**(NCP.AskUser <Msg> <prompt> <FirstTry> <ClearFirstFlg> <MainWindow>
<DontCloseAtEndFlg> <DontClearAtEndFlg> <PROMPTFORWORDFlg>)**

This function can be used to ask questions of the user in a window's prompt window. The <Msg> and <prompt> are printed along with <FirstTry> (if non-nil). The value returned is whatever the user types. If <ClearFirstFlg> is non-nil, then the prompt window is cleared first. If <MainWindow> is nil, then the top level prompt window is used. If <DontCloseAtEndFlg> is non-nil, then the prompt window won't be closed after the question is answered and if <DontClearAtEndFlg> is non-nil, then the prompt window won't be cleared at the end. If <PROMPTFORWORDFlg> is non-nil, then the PROMPTFORWORD typein protocol will be used rather than TTYIN. The former doesn't allow mouse editing of the string typed in. On the other hand, typing automatically overwrites the prompt when PROMPTFORWORD is used.

(NCP.AddTitleBarMenuItems <Win> <NewMenuItems>)

Adds the given menu items to the left button title bar menu of <Win>. <Win> should be the window of a visible notecard.

(NCP.GetDates <Card>)

Returns a NOTECARDDATES record structure containing the dates of last modification of each of the four card parts of <Card>. The fields of the record are SUBSTANCEDATE, TITLEDATE, LINKSDATE and PROPLISTDATE.

Notice of release of Notecards 1.2i

The 1.2i Intermezzo release of Notecards is hereby officially released.

To run NoteCards, load onto an Intermezzo sysout the file {qv}<notecards>release1.2i>notecards.dcom. As usual, send bug reports by choosing "NoteCards Report" from the Lafite middle button send mail menu. Mail of more general interest to the NoteCards community should be sent to NoteCards↑.pa.

Even if you have been using 1.2i for some time and feel comfortable with Notecards, please take a look at the release notes in {qv}<notecards>release1.2i>doc>ReleaseNotes.ted.

The release notes describe in detail the changes since 1.1. These include incorporation of the latest version of sketch, new functionality in the browser, a new notefile inspect and repair facility, several new library packages, and many other feature additions and bug fixes.

Also on {qv}<notecards>release1.2i>doc> you can find updated documentation on the programmer's interface, ProgIntFace.ted, and a new document describing the inspect and repair facility, NoteFileInspector.ted.

The library packages and accompanying documentation can be found in {qv}<notecards>release1.2i>library>.

Enjoy!

- Randy

NoteCards Release1.2i Announcement

Xerox Corporation

Randy Trigg
Frank Halasz

[Location: {qv}<notecards>release1.2i>notecards.dcom]
[First written: 3/27/85 Randy Trigg]
[Last updated: 8/26/85 Randy Trigg]

This document updates the NoteCards Release1.1 User's Manual, describing changes and new features for Release1.2i. As usual, send bug reports to NoteCardsSupport.pa (or use the Lafite SendMail middle button menu) and matters of more global interest to Notecards↑.pa.

You must be in Intermezzo to run NoteCards Release1.2i. From now on, you can depend on the letter suffix following the release number to indicate the appropriate version of Interlisp.

Changes from 1.1 are mostly in the following areas: the NoteCards browser, notefiles interface, link icon display and user interface. In addition, there are various miscellaneous changes, a couple of new card types, and fixes of several outstanding 1.1 bugs.

1. Operating on a Notefile.

Checkpointing and aborting a session:

A fundamental change was made to the way Notecards updates its working notefile that allows 1.2i users to checkpoint their work, abort a session (losing work since the last checkpoint), and recover more gracefully from crashes. First, a word about the way Notecards notefiles are structured.

A notefile consists of two parts, an index area and a data area. The index includes for each notecard, several pointers into the data area. There are separate pointers for the notecard's substance, title, prop list, and links. When, say, a notecard's title is changed, the new title is written at the end of the data area (in fact the end of the file) and the index pointer is changed. In Release1.1 (and earlier), the index modifications happened out on the file as they occurred. Now, in Release1.2i they happen in an in-core array and are not written to the file till checkpoint (or close) time. In addition, there is a checkpoint pointer that points to the end of file at the time of the last checkpoint or close. New data (such as a new title) is still written to the file, but always at the end of the file. Thus if a crash occurs and later the notefile is reopened, Notecards can notice the extra data beyond the checkpoint pointer and truncate the file at that point (if you confirm).

More concretely, there are now two new NoteFile Ops menu entries: "Checkpoint Session" and "Abort Session." Checkpointing causes any active cards to have their contents saved to the notefile (but not closed), the index array to be written back out to the file, and the checkpoint pointer to be reset to the end of the file. (Note that closing a notefile automatically does a CheckpointSession.) Aborting a session causes Notecards to close down, discarding all work since the last checkpoint or close.

When a notefile is opened, the checkpoint pointer is compared with the end of file pointer. If they don't agree, then you're asked whether the file should be truncated. You're also given the option of saving the extra work since the last checkpoint to a file. If valuable cards were created (or modifications made) since the last checkpoint, then you should answer yes and provide the name of a file in which to store the truncated information.

Next, you should open the truncated notefile and bring up a separate TEdit window on the file containing the truncated information. Though TEdit formatting information is lost, you can recover a card's text by browsing this file. (Note that scrolling from back to front will retrieve the most recent version of each card.)

[Note that closing (or saving without closing) a card writes it out to the file, but does not force the index to be updated. Thus, if crashes are anticipated, do CheckpointSession often.]

Compacting a Notefile:

Because Notecards never actually overwrites any information in the data area of a notefile, it is necessary to periodically compact the notefile. This facility has been improved in Release1.2i in two ways. It is now possible to specify a target file name for the compaction (rather than always going to the same name), and it is now possible to compact a notefile in place. These two choices form a submenu of the CompactNotefile entry in the Notefile Ops menu.

Copying, restoring, and backing up notefiles:

The menu entries for RestoreFromFloppy and BackupToFloppy have been removed from the NotefileOps menu. In their place is a general CopyNotefile option. It prompts you for source and target file names for the copy.

There is a new facility for checking in and out notefiles using locks for multiple users sharing a notefile. Still in the experimental stages, it must be called via the programmer's interface. See the programmer's interface documentation.

Inspecting and healing broken notefiles:

The old Repair option on the Notefile Ops menu is now called Inspect&Repair and has been improved considerably. Before rebuilding the links of your notefile, it reads the entire data area looking for good card parts (including outdated and deleted versions). It then allows you to delete and/or back up card parts to previous versions. All this is done interactively through a menu driven interface. Only when the notefile is deemed healthy are you allowed to perform the link rebuilding. For details on the operation of Inspect&Repair, see the document titled NotefileInspector.ted.

2. Changes to the Notecards user interface.

Stylesheets:

Several places in Notecards now use Tayloe Stansbury's stylesheet package for user interaction, in particular, changing a link's display mode, a browser's specs, or the default text and link icon fonts from the global parameters menu. Stylesheets allow packaging of several menus together with "buttons" governing individual menus and the stylesheet as a whole. Menus within a stylesheet can optionally allow multiple selections. All stylesheets have three global buttons "Done," "Reset," and "Abort." "Done" causes the new values to be accepted. "Reset" causes the

original values (when the stylesheet was entered) to be recovered. "Abort" causes the stylesheet to be exited without changing any values. Menus allowing multiple selections also have the buttons "All" and "Clear" attached. "All" causes all values in the menu to be selected while "Clear" unselects the entire menu. Toggling of menu entries is accomplished by left clicking the entry.

New global parameters:

The top level global parameters menu has several new additions. These (as well as some old 1.1 ones) are described below. To change the value of a global parameter, click on the variable name. The value will toggle between "Yes" and "No" if binary, and allow selection from an appropriate menu otherwise.

ForceSources, ForceFiling, ForceTitles: These dictate whether to bother you at card closing time about incomplete information for the card. If ForceFiling is set, for example, then you are asked to designate parent fileboxes of the card before closing. Similarly, for sources and titles. If ForceFiling is off (value is "No"), then cards without parents will be filed automatically in the ToBeFiled filebox at closing time. If ForceTitles is off, then an untitled card will be left with the title "Untitled." ForceTitles and ForceFiling default to "Yes," while ForceSources defaults to "No."

CloseCardsOffScreen: If "Yes," then when a card is closed, it is first dragged off screen so that the close happens invisibly.

MarkersInFileBoxes: If "Yes," then new fileboxes will contain the markers "FILE BOXES" and "NOTE CARDS." New child boxes are inserted under the FILE BOXES marker and new child cards under the NOTE CARDS marker. If "No," then new fileboxes come up without markers and new children are inserted at the current cursor position. Note that regardless of the MarkersInFileBoxes setting, if a filebox has no markers (because you've deleted them) then new children are inserted at the cursor position.

AlphabetizedFileBoxChildren: If "Yes," then new fileboxes will have the property OrderingFn set to NC.IDAlphaOrder. This will cause any new cards put into such a filebox to be inserted in alphabetical order. For further details on OrderingFn's for fileboxes see Section 4.

DefaultLinkIconAttachBitmap, DefaultLinkIconShowTitle, DefaultLinkIconShowLinkType: These dictate the manner in which link icons are displayed if not currently specified in the icon. There are three fields of a link's display mode that can be set, unset, or floated independently. If a field is floated, then the global parameter for that field is consulted. For example, if a link icon's display mode has value FLOAT for the ShowTitle field, then whether the title gets shown inside the link icon depends on the value of DefaultLinkIconShowTitle. See below for a further description of a link's display mode.

LinkDashingInBrowsers: If "Yes," then browser links are drawn with dashed lines with the dashing style corresponding to the link's type. See Section 3 for further details on browser changes. Defaults to "No."

ArrowHeadsInBrowsers: This dictates whether arrow heads are drawn on browser links. The variable can be set to either "AtMidpoint," "AtEndpoint," or "None." See Section 3 for details. Defaults to "None."

EnableBravoToTEditConversion: If "Yes" then TEdit checks when getting a file whether that file is in Bravo format and if so, converts. This defaults to "No" for efficiency.

DefaultFont: This dictates the font that new text cards default to.

LinkIconFont: This dictates the font for text appearing in link icons.

Link icon display mode:

The display mode of a link icon can be changed by middle buttoning in the icon and selecting from the three menus in the resulting stylesheet. These are: AttachBitmap, ShowTitle, and ShowLinkType. AttachBitmap, if "Yes," causes link icons to be shown with a bitmap representing the type of the destination card attached at the left. ShowTitle and ShowLinkType, if "Yes," cause the link icon to contain the title of the destination card and/or the link type. Any of the three fields can have the value FLOAT, in which case the appropriate global parameter will be consulted. (See description of global parameters above.) If all fields are set to "No" (or the floating ones inherit No from the global parameters), then a small, uninformative icon is used to display the link.

"Pushing" and "Pulling" link icons:

There are now two ways to move or copy a link icon between cards or within a card. "Pulling" works like TEdit shift-select. That is, to move an icon, put the cursor where you want to move to and hold down the shift key (or shift and ctrl keys) while left clicking in the left or right quarter of the icon. The new style is called "pushing" and is done by holding down the shift key while left clicking in the middle part of the icon. Then move the cross-hairs cursor to the icon's new home and left-click. To abort a "push," just left click in the background. Note that "pushing" currently only works for copying, not moving.

Specifying notefile names and card titles:

A different editor has been incorporated into Notecards for obtaining card titles, file names, etc. This editor is the same one used in the top level lisp exec window (TTYIN). Thus you can change the title (or file name) given as prompt via mouse edits.

3. Changes to the Notecards browser.

Multiple roots:

Browsers can now contain multiple roots, in which case the graph will be laid out as a forest.

Dashed links:

Dashed browser links was a rarely used option in Release1.1, largely because of speed considerations. The speed of drawing dashed links has improved in Release1.2i by taking advantage of improvements in Grapher. There are currently nine different dashing styles possible. If a browser contains instances of more than nine different link types, then the last dashing style will be used repeatedly for each link type beyond the ninth. As before, link dashing is a user-settable option in the GlobalParameters menu (see Section 2).

Arrowheads:

Arrowheads can now be drawn on browser links. These show the direction of the notecards link being represented in the browser. This is a user-settable parameter in the GlobalParameters

menu with possible values AtMidpoint, AtEndpoint, or None. If AtMidpoint or AtEndpoint is specified, then arrowheads will be drawn at link midpoints or endpoints, respectively. However, in either case, if two browser nodes are connected by more than one link, then any arrowheads for those links will appear at the midpoints (so as not to overlap).

Browser specs:

Whereas in Release1.1 only the link types to traverse could be specified, in Release1.2i, link types is one of a number of browser specs. Also included are browser depth, format, and orientation. These are accessible through a BrowserSpecs stylesheet, a collection of 5 menus. For general details on the stylesheet interface see Section 2. In this case, the forward and backward link types menus are multi-selectable, that is, more than one entry can be chosen. The other three menus are used to make single selections.

Forward and backward link types function as in Release1.1. That is, the browser will contain only nodes for cards reachable from the root cards by following forward links in "line of direction" or backward links in "reverse line of direction."

Browser depth is chosen from a menu containing entries for the integers 0 through 9 and INF (or infinite depth). The default is INF, meaning that the browser will not be cut off until there are no more links to follow from leaf nodes. Choosing depth 0 means that only the root nodes will appear (and no links).

Browser format is one of *GRAPH*, LATTICE, COMPACT, or FAST. The latter three are provided by the grapher package and correspond to lattice, compact forest and fast forest, respectively. COMPACT and FAST generate virtual nodes (in double boxes) whenever two or more links would be drawn to the same node. LATTICE only generates virtual nodes when a cycle exists in the graph. *GRAPH* is a new format that never generates virtual nodes. The drawback to using *GRAPH* is that a cycle can cause lines to be drawn that cross boxes or overlap other lines. Thus you may have to move nodes around for legibility after computing the browser. The default is LATTICE.

Browser orientation is one of Horizontal, Vertical, Reverse/Horizontal, or Reverse/Vertical. These specify whether the graph is layed out left-to-right, top-to-bottom, right-to-left, or bottom-to-top, respectively. The default is Horizontal.

New middle button title bar menu options:

Several new entries have been added to the middle button menu invoked from a browser's title bar. The options are now RecomputeBrowser, RelayGraph, ReconnectNodes, UnconnectNodes, ExpandBrowserNode, GraphEditMenu, and ChangeBrowserSpecs.

RecomputeBrowser causes the current contents of the browser to be thrown away and recomputed as in Release1.1. However, in Release1.2i, you can optionally specify a new set of root nodes.

RelayGraph does not rebuild the graph, but rather causes the nodes and links of the graph to be repositioned on the screen (using Grapher's LAYOUTGRAPH). This will destroy any work you have done moving nodes within the graph.

ReconnectNodes first causes any link edges in the graph to be erased. (Note, however, that non-link edges, those created by "AddEdge" as described below, are ignored.) Then, each node in the

graph is connected to every other node in the graph for which there is a link between them having one of the currently selected link types. This can be useful for several reasons:

1. when the linking structure between cards has changed, but the current browser layout needs to be preserved.
2. when some browser nodes need to be moved, but dragging the connected links is too slow. In this case, do `UnconnectNodes` followed by `ReconnectNodes` (after you've moved the nodes around).
3. when special browser layouts are desired. For example, suppose you like the layout that Grapher gives you when certain links are left out or when you limit the depth. Then calling `ReconnectNodes` will fill in the missing links without affecting the graph's layout.

UnconnectNodes simply erases all edges in the browser. This is useful for positioning a browser's nodes before invoking `ReconnectNodes`.

ExpandBrowserNode allows you to enlarge the graph under a given node. After selecting a node, you're asked for a depth (defaults to 1). The graph is then expanded under the selected node to the given depth, following any currently selected links. Note that `ExpandBrowserNode` calls `LAYOUTGRAPH` so any existing special node arrangements will be lost.

GraphEditMenu brings up the graph editing menu. See the description below.

ChangeBrowserSpecs brings up the `BrowserSpecs` stylesheet to allow you to change any of the browser specs. These changes will be noticed at the next `RecomputeBrowser`, `ExpandBrowserNode`, etc.

Editing the browser manually and "structure editing":

The browser can be edited through the use of the `GraphEditMenu`. This menu can be obtained either by right-buttoning in the browser window or by choosing `GraphEditMenu` from the title bar middle button menu. The `GraphEditMenu` includes options for "structure editing"; that is, changing underlying `NoteCards` structure by editing the browser. The old options for editing without changing structure are also present. Given below are the menu items in `GraphEditMenu` and the actions they engender.

CreateCard&Node causes a new card to be created in the current Notefile and a corresponding node for it to be included in the browser. You're asked for the type of the new card, its title, and where to position the node representing it.

CreateLink&Edge causes a new link to be created between two existing cards and a corresponding edge to be drawn in the browser. (We call such an edge representing a Notecards link, a "link edge." See `AddEdge` below for creating non-link edges.) You're asked for the "From" and "To" nodes in the browser corresponding to the cards to be linked as well as a link type. The link icon for the new link is positioned at the cursor point in the From card if the card has text substance and an open window. Text cards with closed windows have links inserted at the start of the text stream. Otherwise, the new link is a global link. You can have multiple link edges between pairs of cards. In this case the edges are displayed in a spline or "flower" arrangement.

DeleteCard&Node causes a card to be deleted and its corresponding node in the browser to be removed. You are asked first to choose the node representing the card to be deleted and then to confirm the removal of the node (type "y" to confirm) and the deletion of the card. If the selected node is one of a set of virtual nodes (double boxed), then all nodes in the set (i.e. representing the given card) are removed.

DeleteLink&Edge causes a link in the Notefile to be deleted and the corresponding edge in the browser to be removed. You first pick the "From" and "To" nodes corresponding to the source and destination ends of the link respectively. Then, if there is only one link between those two cards, the link is deleted after user confirms. If there are multiple links between the two cards, then the user chooses from a menu of link types.

AddLabel puts a "label node" into the browser that does not represent a Notecard. You are prompted for a string forming the node's label and then must position the label node. This node is not boxed. (But note that "virtual" label nodes can be boxed and thus can be confused with non-virtual regular nodes.)

AddNode adds a node into the browser corresponding to some existing card. You are asked to point to a card (title bar or link icon) on the screen that this node is to represent and then to position the node.

AddEdge draws a line between two nodes in the browser. This edge does not correspond to a real link in the Notefile. To avoid confusion, it is best to have the arrowheads option on (see Section ??) in this case, since edges formed by AddEdge do not have arrowheads (or dashing). Only one such edge is allowed between any two nodes and none if there are already link edges between the nodes. Thus doing CreateLink&Edge will remove any existing non-link edge.

RemoveNode removes a node from the browser. It does not delete the card (if any) that the node represents. Edges into and out of the node are also removed. If the selected node is one of a set of virtual nodes representing the same card, then you will be told how many nodes will be removed with this one and will be asked to confirm. The only way to remove only one node of a set of virtual nodes, is to first manually remove edges into and out of it using RemoveEdge. Then RemoveNode can be used to remove only the one virtual node.

RemoveEdge removes an edge from the browser. It does not delete the link (if any) that the edge represents. The user is asked to select the "From" and "To" nodes of the edge.

MoveNode allows you to change the position of any node, rubber banding any edges pointing to it. You're asked to point to the node by left-buttoning, and holding down the left button, drag the node to its new position.

LabelSmaller is used to decrease the font size of label nodes. Note that it does not work for regular non-label nodes.

LabelLarger is used to increase the font size of label nodes.

<->Shade toggles the shade of a node between black-on-white and white-on-black. This can only be performed on label nodes (not on nodes representing Notecards).

FIX MENU causes the GraphEditMenu to be affixed to the lower right edge of the browser window. Note that this does not prevent you from obtaining the menu via right button inside the window.

[Note that the above editing commands do not work on old 1.1 browsers. Such browsers should either be recomputed (via `RecomputeBrowser`) or unconnected and reconnected.]

4. Miscellaneous changes.

Links ordering within text cards:

The internal list of outgoing links in a text card is now kept in the same order that the links appear in the card's text. This means, for example, that the daughters of a browser node for a filebox will appear in the correct order.

Link insertion:

The title bar menu entry for "InsertLinks" now has an attached submenu containing entries for adding single links, multiple links, and global links. When inserting multiple links (or adding multiple global links) you're only asked for one link type which is used to label all the new links and all are inserted at the same place in the text.

Show links:

This is now a normal entry in the left button title bar menu of a card (rather than a subentry under Edit Properties). The format of the ShowLinks display has been changed slightly. The prefix is now either TO, FROM, or Global TO. The link type is shown in the icon. Also, for text cards, the TO links should appear in the correct order.

Sketch changes and fixes:

Notecards now uses the latest version of sketch. See the sketch documentation for details on changes. Several long-standing bugs having to do with link icons in sketch cards have been fixed.

Sketches and graphs in text cards:

It is possible to shift-copy the contents of sketch and graph/browser cards into text cards. In addition, the Document card is now able to include the contents of sketch and graph cards if encountering them during card gathering. (It is still not possible for Document to include the contents of cards having user-defined substance types such as NCFFile cards.)

Data saved at card closing:

When a card is closed, only those parts that are dirty are written out to the notefile. A message indicating which parts are being saved is now printed to the card's prompt window during closing. Furthermore, certain card types (in particular, browsers) were saving their substance even if no changes were made. This source of space inefficiency has been fixed in Release1.2i.

Ordering cards in a filebox:

It is now possible to dictate the relative placement of new cards in a filebox. If the `OrderingFn` property of a card has a value, it should be a lisp function that takes two card ID arguments and returns T if the first should appear before the second and NIL otherwise. You can make such a function appear automatically on new boxes for the case of alphabetizing by using the global parameter `AlphabetizeFileBoxChildren`. See section 2.

Programmer's interface:

The Programmer's interface has been updated. Thus users with existing programmer's interface code should read the revised PI documentation. The changes are not all forward compatible.

Notecards system date:

You can find the date of your Notecards system in the variable NC.SystemDate. The 'NewestFile' property on the NC.SystemDate atom contains the name of the last modified Notecards file.

The Notecards library packages:

The old Release1.1 library packages have been converted to 1.2i and documented and several new ones have been added. These can be found on {qv}<notecards>release1.2>library> and include NCScreen, NCCluster, NCChain, NCFileCard, NCKeys, NCHacks, and ARIDemo. Documentation can be found in <filename>.ted.

NCScreen defines several handy functions for arranging cards on the screen callable from the programmer's interface. NCCluster defines several new card types, most notably CaseCluster, a cluster of cards for use in the sample domain of legal case analysis. NCChain defines the Chain card type, useful for breaking up a large text card into a linked chain of cards. NCFileCard defines the new File card type and FILE substance allowing a notefile to link to external files via standard Notecards links. NCKeys provides a shorthand language for invoking various handy programmer's interface functions. NCHacks contains several handy functions written using the programmer's interface. Two of these allow global text searches and replaces throughout a notefile. In addition there is a function that searches by last card modification date and one that links cards to form chains. Finally, ARIDemo is an example of how the programmer's interface can be used to construct notefiles that demo themselves.

Loading NoteCards from different directories:

NoteCards now uses the values of four directories variables to decide from whence to load the code. These are NOTECARDSDIRECTORIES, NOTECARDSMAPDIRECTORIES, QUADTREEDIRECTORY, and MAPFILEDIRECTORY. They default to ({QV}<NOTECARDS>RELEASE1.2I>), ({QV}<NOTECARDS>MAPS>NEW>), {QV}<NOTECARDS>MAPS>, and {QV}<NOTECARDS>MAPS> respectively.

5. Known bugs and plans for future improvements:

- o The compactor should check first for available space.
- o There are major speed problems in redrawing large browsers. Changing link display mode could also use some streamlining.
- o Integrate the document compiler and the types mechanism so that instances of new card types can be sucked into TEdit documents.
- o Make links into full-fledged objects having properties and type hierarchies.

The NoteCards Types Mechanism

Release 1.2

Frank G. Halasz

Xerox PARC

First Written: 22-Mar-85

Modified: 26-Mar-85 by Frank G. Halasz

Modified: 1-Aug-85 by Lissa Monty

1. Introduction

The NoteCards types mechanism allows a user with some knowledge of Interlisp to add new types of note cards to the system. The types mechanism is built around an inheritance hierarchy of note card types. If the user needs to create a new card type that is a small change from an already existing card type, he or she need only define the few functions or parameters that account for the differences between the new card and the existing card. However, if the user wishes to create a totally new type of card, then he or she must define the 20-odd functions and parameters that make up a note card type.

Every note card has a substance. A substance is essentially a data structure that contains the information in the note card. Different types of note cards have different types of substances. Associated with every substance type is an editor that can be used to create and/or modify the data structure of that substance type. For example, the substance of a Text card is a TEXTSTREAM that can be edited using TEdit. Similarly, the substance of a Browser card is a GRAPH record that can be edited using GRAPHER. Defining a new note card type involves specifying the functions necessary to handle the card's substance and its editor.

1.1 The Inheritance Hierarchy

The inheritance hierarchy in NoteCards has two parts: a tree of NoteCardTypes and a list of SubstanceTypes. Every NoteCardType has a super-type and a substance type. The super-type is an already existing NoteCardType from which the NoteCardType will inherit fields. Thus, the set of NoteCardTypes forms a tree structure based on the super-type field. The substance type of a NoteCardType is an already existing SubstanceType.

The inheritance process for a given field of a NoteCardType works as follows: if the field has a non-NIL value in the NoteCardType then this value is used, otherwise the field value is inherited from its super-type. If there are no non-NIL values anywhere in the inheritance path for the NoteCardType, then the field value is taken from the corresponding field in the substance type for the NoteCardType. Substance types are guaranteed to have values in all of their fields.

Example: ProtectedText is a card with super-type Text. Text in turn has super-type NoteCard (the null root of the NoteCardType tree). In addition, Text has substance type TEXT. If an EditCardFn is not defined in ProtectedText, then it will be inherited from Text. If Text doesn't have an EditCardFn then the EditSubstanceFn from the TEXT SubstanceType will be used (since NoteCard by definition does not have an EditCardFn).

Functions are inherited all or none. Often, however, a new NoteCardType will require only a minor addition to the corresponding function of its super-type. In this case, the new card type should define a new function, but this function can call the corresponding function of its super-type to do the bulk of the work. The following construction will accomplish this goal:

```
(APPLY* (NCP.CardTypeInheritedField (NCP.CardTypeSuper <type>) <fn>) <arg1>
<arg2> ...)
```

where <type> is the TypeName of the card type in question, <fn> is the name of the function in question, and <arg1> <arg2> ... are the arguments to that function. For example the following might be the definition of the EditCardFn for the passworded Text card called ProtectedText:

```
(DEFINEQ
(NC.EditProtectedTextCard
  (LAMBDA (ID Substance Region/Position)
    (* * Edit a Protected Text card, asking for the password first.)
    (PROG (Password Result)
      (* * Get this card's password from the prop list)
      (SETQ Password (NCP.CardProp ID (QUOTE Password)))
      (COND
        ((EQUAL Password (NC.GetPassword ID))
          (* Password is okay.
            Call the EditCardFn of my super-type)
          (SETQ Result (APPLY*
            (NCP.CardTypeInheritedField
              (NCP.CardTypeSuper (QUOTE ProtectedText))
              (QUOTE EditCardFn))
            ID Substance Region/Position)))
        (T (* Password is bad. Express condolences)
          (NCP.PrintMsg Window T "Sorry." (CHARACTER 13)
            "You do not know the password!!"
            (CHARACTER 13)
            "Bye."
            (CHARACTER 13))
          (DISMISS 2000)))
      (RETURN Result))))
```

1.2 Links and Link Icons

An integral part of NoteCards is the ability to create a link between two note cards. Presently, there are two kinds of links: *GlobalToGlobal* links and *LocalToGlobal* links. GlobalToGlobal links connect one entire card with another entire card and are stored separately from either card's substance.

GlobalToGlobal links are maintained (almost) entirely by the NoteCards system code and therefore do not vary across note card types.

LocalToGlobal links connect a particular position within the substance of one card (the *source* card) to the entirety of the other card (the *destination* card). Within the source card, the link is represented by an image object called a link icon that must be contained by the card's substance. Since substances vary across note card types, the handling of link icons varies across note card types. The destination (or Global) end of a LocalToGlobal links is maintained by the NoteCards system code.

Not all note cards can be the source of LocalToGlobal links. Card types that support LocalToGlobalLinks must have their LinkAnchorModesSupported parameter set to T. If a this parameter has any other value, then cards of this type can be the source of only GlobalToGlobal links. These Global-links-only card types need to provide only one piece of functionality in support of the linking mechanism. In particular, they must provide user access to the function **NCP.GlobalGlobalLink** from the editor that runs when the card is being displayed. For example, the editor's command menu might include an "Insert Global Link" command. All other link maintenance is carried out by the NoteCards system.

If a card type supports LocalToGlobal links, then it must contain the necessary mechanisms for supporting link icons in its substance. Link icons are instances of standard Interlisp-D image objects (See documentation of Image Objects in Interlisp-D). The mechanisms supporting link icons include functions for inserting, deleting, updating, and collecting the link icons contained in a card's substance. These functions are described in detail below. In addition to these functions, a note card type supporting LocalToGlobal links must provide user access to the function **NCP.LocalGlobalLink** from the editor that runs when the card is being displayed. In addition the editor must provide user access to the function **NCP.GlobalGlobalLink**.

Inside the link icon image object is a link record containing all of the information about the link. These link records can be manipulated using the link manipulation functions provided by NoteCards' programmer's interface (e.g., **NCP.GetLinkDestination** returns the destination field of a link record). The functions required to define a note card or substance type deal in both link records and link icons. You can translate between these two representations using the functions **NC.MakeLinkIcon** and **NC.FetchLinkFromLinkIcon**; **NC.MakeLinkIcon** will create a link icon image object from a link record, while **NC.FetchLinkFromLinkIcon** will return the link record contained in a link icon.

1.3 Using the Types Mechanism

Most uses of the types mechanism involve defining new NoteCardTypes. Usually, these new NoteCardTypes involve specifying a TypeName, a SuperType, a SubstanceType, and one or two functions that differ from the SuperType. The most commonly defined functions are the MakeCardFn, the EditCardFn and the QuitCardFn.

Definition of new substance types occurs only when a new kind of substance (e.g., a spreadsheet) and its corresponding editor are to be added to the system. When defining a substance, all of its fields must be fully defined since there is no inheritance among SubstanceTypes.

2. The NoteCardType

Each note card type in the system is defined by a record structure (i.e., a NoteCardType) containing about 20 names, functions and parameters. The functions implement behaviors that are required by the NoteCards system but vary across the different card types. For example, one function is responsible for writing the card's substance to the NoteFile. The parameters represent specifications that inform NoteCards about the specific properties of each card type, e.g., whether it handles local links or not.

The NoteCardTypes are organized into an inheritance hierarchy. Each NoteCardType has a super-type. If any of the functions or parameters is not specified for a given NoteCardType, that function or parameter is inherited from its super-type (or its super-type's super-type, if the function or parameter is not specified for the super-type either). Each NoteCardType also has a SubstanceType. If any of the functions or parameters cannot be found along the super-type chain of the NoteCardType, then the card type inherits the function or parameter from its SubstanceType.

Overall, a card type is a data structure with the following 21 fields:

Inheritance Hierarchy Specifications

- 1) TypeName
- 2) SuperType
- 3) SubstanceType

Functions

- 4) MakeCardFn
- 5) EditCardFn
- 6) QuitCardFn
- 7) GetCardFn
- 8) PutCardFn
- 9) CopyCardFn
- 10) MarkCardDirtyFn
- 11) CardDirtyPFn
- 12) CollectLinksInCardFn
- 13) DeleteLinksInCardFn
- 14) UpdateLinkIconsInCardFn
- 15) InsertLinkInCardFn
- 16) TranslateWindowPositionToCardPositionFn

Parameters

- 17) LinkDisplayMode
- 18) CardDefaultWidth
- 19) CardDefaultHeight
- 20) CardLinkAnchorModesSupported
- 21) CardDisplayedInMenuFlg

These fields are defined as follows:

- 1. TypeName:** The atom that is the name of this card type. TypeNames must be unique among the NoteCardTypes tree, though they may overlap with SubstanceNames. The convention is that NoteCardType TypeNames have only the first letter capitalized. This is to set them apart from SubstanceNames which are by convention all caps.
- 2. SuperType:** The TypeName of the NoteCardType that is the super-type for this NoteCardType. When a new NoteCardType is created, its SuperType must be an existing NoteCardType.
- 3. SubstanceType:** The SubstanceName for the substance of this card type. When a new card is created, its SubstanceType must be the name of an existing SubstanceType (see Section 3.0 below). The basic NoteCards system includes the following substance types: TEXT, SKETCH, GRAPH which represent the substances handled by the TEdit, Sketch, and Grapher packages respectively.
- 4. MakeCardFn:** The name of a function to be applied to an ID, a Title, and a NoDisplayFlg. The function should create a new card of this type. The ID is the note card ID that will be assigned to the newly created card. It should be used to set the various properties of the new card. The title is a string specifying the title of the new card. It can be used in messages to the user or to set the title of any windows created. NoDisplayFlg determines whether the new card is to be displayed on the screen or not. If NoDisplayFlg is non-NIL, then the card is to be displayed in a window on the screen. If NoDisplayFlg is NIL, then the card is to be created but not displayed on the screen.

The MakeCardFn should return the window of the new card if NoDisplayFlg is non-NIL and the ID if NoDisplayFlg is NIL.

Before returning, every MakeCardFn is required to set the substance property of ID by calling (**NC.SetSubstance** ID *Substance*) where *Substance* is whatever is considered a substance for this card type. For example, a TextStream for Text cards, a Graph record for Graph cards, or a Sketch record for Sketch cards.

By convention, every MakeCardFn sets the SHRINKFN of any window it creates to the function **NC.ShrinkFn** using WINDOWPROP.

- 5. EditCardFn:** The name of a function to be applied to ID, Substance, and Region/Position. The function should start an editor for the given card. ID is the note card ID of the card. Substance is the substance of the card; it will be a thing of whatever type is considered a substance for this card type, e.g., a TextStream or Sketch record. Region/Position is a Region or a Position on the screen that specifies where the card is to be placed. (**NC.DetermineDisplayRegion** ID Region/Position) is a function that will determine the exact region for the card's window given the ID and the Region/Position.

The EditCardFn should return the editor window.

The EditCardFn is responsible for checking to make there is not already an editor for card ID already on the screen. If there is, the EditCardFn should just flash the previous editor window.

By convention an EditCardFn sets the SHRINKFN of any window it creates to the function **NC.ShrinkFn** using WINDOWPROP. Also by convention, an EditCardFn should set the title of the editor window to be the value of (**NCP.CardTitle** ID).

6. QuitCardFn: The name of a function to be applied to WindowOrSubstanceOrID which is either the editor window for a card or the substance of a card or a note card ID. QuitCardFn should quit out of the editor currently operative on the specified card and close the window containing the card.

The value returned by QuitCardFn is unspecified.

Before returning the QuitCardFn should apply the function **NC.DeactivateCard** to the ID of the card. Note that the ID may have to be computed from the Window or Substance passed to the QuitCardFn. The function **NC.CoerceToID** will do this computation.

The QuitCardFn should also insure that all processes related to this card are completed (or guaranteed to eventually complete) before returning.

7. GetCardFn: The name of a function to be applied to the DatabaseStream, a card ID, and a screen Region. The GetCardFn should read the substance of the note card specified by ID from the DatabaseStream. The format of the data to be read is determined by the PutCardFn (see below). When the GetCardFn is called, the file pointer for DatabaseStream is positioned on the first byte of the data to be read.

The GetCardFn should return a pointer to the substance read from the DatabaseStream.

GetCardFn need produce no side-effects. The ID and the Region are for reference purposes only.

Note that the GetCardFn need only read the substance of the card, i.e., that information about the card which is specific to its card type. General information about a card such as its title, its property list, its list of links, etc. is read from the DatabaseStream by the system.

8. PutCardFn: The name of a function to be applied to a note card ID and the DatabaseStream. The PutCardFn should write the substance of the note card specified by ID to the DatabaseStream. When the PutCardFn is called, the file pointer for DatabaseStream is positioned at the first byte assigned to the card. When the PutCardFn returns, the file pointer should be positioned immediately after the last byte written.

The format for writing the card's substance is fairly unrestricted. The data written on the DatabaseStream can take up any number of bytes, but the bytes must be contiguous. It must be written so that it can be recovered by reading from the DatabaseStream using the GetCardFn. The only other restriction is that the first 6 bytes of the substance must contain the file position of the start and the end of the substance: 3 bytes for the start file pointer and 3 bytes for the end file pointer. These pointers are for use by the CopyCardFn.

The value returned by the PutCardFn is unspecified.

Note that the PutCardFn need only write out the substance of the card, i.e., that information about the card which is specific to its card type. General information about a card such as its title, its property list, its list of links, etc. is written to the DatabaseStream by the system.

9. CopyCardFn: The name of a function to be applied to a note card ID, a "from" DatabaseStream, and a "to" DatabaseStream. The CopyCardFn should copy the substance for the note card specified by ID from the "from" DatabaseStream to the "to" DatabaseStream. When the CopyCardFn is called the file pointer for the "from" DatabaseStream is positioned on the first byte of the data to be copied. The file pointer for the "to" DatabaseStream is positioned at the first byte of the space assigned to the card on the "to" DatabaseStream.

The format for writing the substance on the "to" DatabaseStream has the same restrictions as for the PutCardFn.

Most often the CopyCardFn is a simple COPYBYTES that uses the start and end pointers written by PutCardFn in the first 6 bytes of the substance. Note, however, that all file absolute pointers (including the start and end pointers) must be updated; the file location on the "to" DatabaseStream is almost never the same as the original file location on the "from" DatabaseStream.

The value returned by the CopyCardFn is unspecified.

The CopyCardFn is used primarily by the compactor that eliminates "dead" space in the database. Thus, it is important that the CopyCardFn be as time efficient as possible.

10. MarkCardDirtyFn: The name of a function to be applied to a note card ID and a ResetFlg. If the ResetFlg is non-NIL, the function should mark the card specified by ID as being dirty (i.e., changed since it was last written to the DatabaseStream). If the ResetFlg is NIL, the function should reset the "dirtiness" of the card.

The MarkCardDirtyFn is called by NoteCards system functions that change the card. It is not necessarily called by user operations inside the editor on the card. Therefore, it is best if the mechanism used by the MarkCardDirtyFn is somehow coordinated with the corresponding mechanism used by the editor on the card. (See the CardDirtyPFn below.)

The value returned by the MarkCardDirtyFn is unspecified.

The card specified by ID is guaranteed to be active.

11. CardDirtyPFn: The name of a function to be applied to a note card ID. The function should return a non-NIL value if the card specified by ID is dirty, i.e., if it was changed since it was last written to the DatabaseStream. NIL should be returned otherwise.

Note that a "dirty" card is one that has been changed in any way. Only NoteCards specific changes to a card will result in a call to the card's MarkCardDirtyFn. Changes made through the editor on the card will use the editors "mark dirty" mechanism and will not call the MarkCardDirtyFn. Therefore, the CardDirtyPFn should check all dirty flags, i.e., the dirty flag set by the MarkCardDirtyFn as well as any set by the card's editor.

The card specified by ID is guaranteed to be active.

12. CollectLinksInCardFn: The name of a function to be applied to a note card ID, a CheckAndDeleteFlg, a DatabaseStream, a ReturnLinkIconsFlg, and a ReturnLocationsFlg. The function should examine the substance of the card specified by ID and produce a list of the links (or link icons) contained by the substance. The ReturnLinkIconsFlg and the ReturnLocationsFlg determine the contents of the list to be returned as follows:

ReturnLinkIconsFlg and ReturnLocationsFlg both NIL: the list to be returned should be a list of link records.

ReturnLinkIconsFlg is non-NIL, ReturnLocationsFlg is NIL: the list to be returned should be a list of link icons.

ReturnLinkIconsFlg is NIL, ReturnLocationsFlg is non-NIL: the list to be returned should be a list of pairs where the first member of the pair is a link record and the second member of the pair is the "location" of the link icon for that link inside the substance.

ReturnLinkIconsFlg and ReturnLocationsFlg both non-NIL: the list to be returned should be a list of pairs where the first member of the pair is a link icon and the second member of the pair is the "location" of that link icon.

If CheckAndDeleteFlg is non-NIL, then the list produced by CollectLinksInCardFn should contain valid links only. Any links found to be invalid should be deleted. To check the validity of a link, the function **NC.ValidLinkP** should be applied to the link record and the DatabaseStream. To delete a link, apply the function **NC.MakeInvalidLink** to the link icon.

The CollectLinksInCardFn should return the list produced CONSed to a dirty flag. The dirty flag should be non-NIL if any links were deleted, NIL otherwise.

The card specified by ID is guaranteed to be active.

13. DeleteLinksInCardFn: The name of a function to be applied to a "source" note card ID and a link record or "destination" note card ID. If the second argument is a link, the function should

remove from the substance of the card specified by "source" ID the link icon corresponding to link. If the second argument is a "destination" note card ID, the function should remove from the substance of the card specified by "source" ID all link icons corresponding to links pointing to the card specified by "destination" ID.

To "remove" a link icon, the link icon should be replaced in the substance by the image object that is the value of **NC.DeletedLinkImageObject**. Note that before deleting the link icon, it is best to replace the IMAGEOBJFNS of the link icon with the value of **NC.NoDeleteImageFns**. This will prevent the link icon's WHENDELETEDFN from being activated when the deletion takes place.

The value returned by the DeleteLinksInCardFn is unspecified.

The card specified by "source" ID is guaranteed to be active.

14. UpdateLinkIconsInCardFn: The name of a function to be applied to a "source" note card ID or window and a "destination" note card ID. The function should update (i.e., force a redisplay of) all link icons in the "source" card that represent links pointing to the "destination" card. This function is called when some property of the link is changed by the NoteCards code. It is also called when certain properties of the destination card (e.g., its title) are changed.

The value returned by the UpdateLinkIconsInCardFn is unspecified.

The "source" card is guaranteed to be active.

15. InsertLinkInCardFn: The name of a function to be applied to a window, a link, and a position. The function should insert a link icon containing the link into the card being edited in the window at the position specified. The position is whatever object is returned by the TranslateWindowPositionToCardPositionFn.

The value returned by the InsertLinkInCardFn is unspecified.

The ID of the card being edited by the window is guaranteed to be the SOURCEID of the link.

16. TranslateWindowPositionToCardPositionFn: The name of a function to be applied to a window, an X-coordinate in that window, and a Y-coordinate in that window. The window is an editor window on the substance of some card. The function should return a position object that describes the position in the card substance that is currently located at the given X-Y position in the window. The format of the position object is undefined. It will be passed to the InsertLinkInCardFn and used as the position at which to insert a links in the card being edited in the window.

17. LinkDisplayMode: determines the default display mode for link icons inserted into cards of this type. It must be a record of type LINKDISPLAYMODE. LINKDISPLAYMODE describes what information will be displayed in a link icon. It consists of three flags: SHOWTITLEFLG, SHOWLINKTYPEFLG, and ATTACHBITMAPFLG. If SHOWTITLEFLG is non-NIL, the link icon will display the destination card's title. If SHOWLINKTYPEFLG is non-NIL, the link icon will

display the type of the link. If ATTACHBITMAPFLG is non-NIL, a bit map describing the type of the destination card will be attached to the right of the link icon.

Note: This property is NOT inherited.

18. CardDefaultWidth: The default width for editor windows on cards of this type.

19. CardDefaultHeight: The default height for editor windows on cards of this type.

20. CardLinkAnchorModesSupported: an atom that determines the kind of links this card type will support (i.e., the kind of links for which cards of this type can be a source). If NIL, then this card type does not support links of any type. If Global, this card supports only Global links. If Local, this card supports only local links. If T, this card supports both Global and Local links.

Note: This property is NOT inherited.

21. CardDisplayedInMenuFlg: if non-NIL then this card type will appear in the choice of card types in the menu used during card creation using the "Create" entry in the main NoteCards menu. If NIL, then this card type will not appear in this menu.

3. The SubstanceType

The SubstanceType is a record structure whose fields are virtually identical to those of the NoteCardType record. In particular, the SubstanceType has the following 17 fields:

- 1) SubstanceName
- 2) CreateSubstanceFn
- 3) EditSubstanceFn
- 4) QuitSubstanceFn
- 5) GetSubstanceFn
- 6) PutSubstanceFn
- 7) CopySubstanceFn
- 8) MarkSubstanceDirtyFn
- 9) SubstanceDirtyPFn
- 10) CollectLinksInSubstanceFn
- 11) DeleteLinksInSubstanceFn
- 12) UpdateLinkIconsInSubstanceFn
- 13) InsertLinkInSubstanceFn

14) TranslateWindowPositionToSubstancePositionFn

15) SubstanceDefaultWidth

16) SubstanceDefaultHeight

17) SubstanceLinkAnchorModesSupported

These fields are defined as follows:

1. SubstanceName: The atom that is the name of this substance type. SubstanceNames must be unique among the substance types, though they may overlap with card TypeNames. The convention is that SubstanceNames are all in caps. This is to set them apart from card TypeNames which by convention have only their first letter capitalized.

2 Thru 14. Functions: All of the functions are identical to the corresponding functions in the NoteCardType record structure. Note the (arbitrary) use of "create" instead of "make" in the name of the CreateSubstanceFn.

15 Thru 17. Parameters: The parameters are identical to the corresponding parameters in the NoteCardType data structure. There are no parameters for the LinkDisplayMode and the DisplayInMenuFlg because these two parameters are not inherited. They must be specified separately for each card type.

4. Adding a New NoteCardType or SubstanceType to the System

The functions **NCP.CreateCardType** and **NCP.CreateSubstanceType** can be used to add new Types to the system.

NCP.CreateCardType takes 5 arguments: the TypeName, its SuperType, its SubstanceType, a functions list, and a parameters list. The functions list is an ASSOC list where the CAR of each sub-list is one of the function field names given above (e.g., EditCardFn, MakeCardFn, etc.). The CDR of the sublist should contain the name of the required function. Any function field name for which there is no entry will be set to NIL and will thus be inherited. The parameters list is analogous to the functions list, except that it applies to the parameter field names (i.e., LinkDisplayMode, CardDefaultWidth, CardDefaultHeight, and CardLinkAnchorModesSupported).

NC.CreateSubstanceType takes 3 arguments: the SubstanceName, a functions list, and a parameters list. The functions and parameters list are analogous to those for **NCP.CreateCardType** except that all of the function and parameter fields specified above MUST have an entry in the ASSOC lists.

Both **NCP.CreateCardType** and **NC.CreateSubstanceType** will overwrite existing types (NoteCard and Substance, respectively) of the same name.

5. Example: Defining the ProtectedText NoteCardType

The following is an example of defining a new card type called the ProtectedText card. The card type is created by specifying new MakeCardFn and EditCardFn functions. All other functions are inherited from the super-type, i.e., the Text card. All of the parameters are specified directly for this card.

- The function that creates the new ProtectedText card type:

```
(NC.AddProtectedTextCardType
  (LAMBDA NIL (* fgh: "26-Mar-85 15:48")
    (* * Create the ProtectedText card type)
    (NCP.CreateCardType (QUOTE ProtectedText)
      (QUOTE Text)
      (QUOTE TEXT)
      (QUOTE ((MakeCardFn NC.MakeProtectedTextCard)
        (EditCardFn NC.EditProtectedTextCard)))
      (QUOTE ((LinkDisplayMode (T NIL NIL))
        (CardDefaultHeight 300)
        (CardDefaultWidth 400)
        (CardLinkAnchorModesSupported T)
        (CardDisplayInMenuFlg T))))))
```

- The MakeCardFn for the ProtectedText card type:

```
(NC.MakeProtectedTextCard
  (LAMBDA (ID Title NoDisplayFlg) (* fgh: "26-Mar-85 15:23")
    (* * Make a protected Text card
      by calling the make card fn for a Text card
      and then attaching a password to the card)
    (PROG (Window WindowOrID)
      (* * Create the Text card)
      (SETQ WindowOrID (APPLY*
        (NCP.CardTypeFn (NCP.CardTypeSuper
          (QUOTE ProtectedText))
            (QUOTE MakeCardFn))
          ID Title NoDisplayFlg))
      (* * Get the window for the card, if there is one)
      (SETQ Window (WINDOWP WindowOrID))
      (* * Get the password from the user
        and add it to the cards prop list)
      (NCP.CardProp ID (QUOTE Password)
        (NC.GetPassword Window))
      (* * Return whatever the super-type's MakeCardFn returned)
      (RETURN WindowOrID)))
```

- The EditCardFn for the ProtectedText card type:

```

(NC.EditProtectedTextCard
  (LAMBDA (ID Substance Region/Position)
    (* fgh: "26-Mar-85 17:21")
    (* * Edit a Protected Text card, asking for the password first.)
    (PROG (ExactRegion Window Password Result)
      (* * Open a window for this card)
      (SETQ ExactRegion (NC.DetermineDisplayRegion ID
        Region/Position))
      (SETQ Window (CREATEW ExactRegion))
      (* * Get this card's password from the prop list)
      (SETQ Password (NCP.CardProp ID (QUOTE Password)))
      (COND
        ((EQUAL Password (NC.GetPassword Window))
          (* Password is okay.
            Call the EditCardFn of my super-type)
          (SETQ Result (APPLY*
            (NCP.CardTypeInheritedField
              (NCP.CardTypeSuper (QUOTE ProtectedText))
              (QUOTE EditCardFn))
            ID Substance ExactRegion)))
        (T (* Password is bad. Express condolences)
          (NCP.PrintMsg Window T "Sorry." (CHARACTER
            13)
            "You do not know the password!!"
            (CHARACTER 13)
            "Bye."
            (CHARACTER 13))
          (DISMISS 2000)))
      (* * Close the window you created.

Copyright protection includes material generated from the software programs displayed on the screen, such as icons, screen display looks, and the like.

The information in this document is subject to change without notice and should not be construed as a commitment by Envos Corporation. While every effort has been made to ensure the accuracy of this document, Envos Corporation assumes no responsibility for any errors that may appear.

Text was written and produced with Envos text formatting tools; Xerox printers were used to produce text masters. The typeface is Modern.

NoteCards

NoteCards is a computer environment designed to help people work with ideas. Its users are authors, researchers, designers, and other intellectual laborers engaged in analyzing information, constructing models, formulating arguments, designing artifacts, and generally processing ideas. The system provides these users with a variety of tools for collecting, representing, managing, interrelating, and communicating ideas. NoteCards is based on the notion that creative intellectual work is a hand-craft, a uniquely human skill that cannot be easily automated.

Notecards provides the user with a "semantic network" of electronic notecards interconnected by typed links. This network serves as a medium in which the user can represent collections of related ideas. It also functions as a structure for organizing, storing, and retrieving information. The system provides the user with tools for displaying, modifying, manipulating, and navigating through this network.

From: *NoteCards in a Nutshell*, by Frank G. Halasz, Thomas P. Moran, Randall H. Trigg of the Intelligent Systems Laboratory in the Xerox Palo Alto Research Center, Preceedings of the ACM CHI+GI '87 Conference, Toronto, Canada April 1987

System Overview

	Functionally, the NoteCards system for the Sun Workstation consists of the following parts:
<i>emulator</i>	A SunOS executable program which executes the NoteCards system contained in the sysout and provides access to the Sun host's hardware.
<i>sysout</i>	A virtual memory image (the <i>sysout</i>) containing both the NoteCards program and its data structures. The sysout provided can be used both on the Sun Workstations and on the Xerox 1100 series workstations.
<i>notefiles</i>	A file containing your cards on a particular topic and all their links. This is your data and its organizational structure.
<i>fonts</i>	Data describing the "looks" of printed characters used by NoteCards' graphics, windowing, and hardcopying subsystems. Font directories are in four groups, display fonts, PostScript printer fonts, Interpress printer fonts, and Press printer fonts.

Useful SunOS and UNIX Conventions

SunOS is Sun Microsystems' version of the UNIX operating system. For users unfamiliar with the Sun Workstation, the following SunOS (and UNIX) conventions, are used in the manual.

For complete information on UNIX and SunOS, refer to your Sun documentation set.

case, filenames

Type-in to UNIX is case sensitive. Typically, input is in lower case. When UNIX searches for a name, it is case sensitive; it distinguishes between lower and upper case characters. By convention, most names are lower case characters.

shell

Command interpreter; the commands shown are in the C-Shell, unless otherwise noted.

NoteCards Device Conventions

NoteCards allows users to interact with SunOS file systems (including file systems mounted from other machines) by using host device names. The device names are

{DSK}

A host name which gives you access to the SunOS file system using Xerox workstation local disk conventions.

{UNIX}

A host name which gives you access to the file system using normal SunOS conventions.

The {DSK} device name provides an interface to the Sun Workstation for users who want to maintain compatibility with existing development tools and applications originally developed on a Xerox workstation. The {UNIX} device name provides a way for new applications to interact naturally with UNIX. Chapter 4, System Use Issues, explains, in greater detail, some important exceptions and restrictions to the {DSK} and {UNIX} device name.

Stylistic Conventions

Text marked by a revision bar in the right margin contains information that was added or modified since the last release.

Prompts

All examples which include SunOS dialogues use the following conventions for the SunOS prompt:

A number sign (#), as part of the system prompt, indicates that the user is logged on as root or is running su; e.g.,

prompt #

A percentage sign (%), as part of the system prompt, indicates that a user other than root is logged on; e.g.,

prompt %

Font Usage

Bold text in TITAN font indicates text you should type in exactly as printed.

Regular text in TITAN font indicates what the system prints on your workstation screen. UNIX files and programs are shown in TITAN FONT.

Italic text in Titan font indicates variables or parameters that you should replace with the appropriate word or string.

Bold text in Modern font is used to indicate menu commands and NoteCards parameters.

Italic text in Modern font is used to indicate emphasis.

Quote marks are used to indicate window titles, parameter values, and when referring to the names of section headings within chapters; e.g., The "Stylistic Conventions" section in Chapter 1, Introduction.

Keyboard Conventions

Keys that you press are in uppercase (e.g., COPY, for the Copy key). A carriage return is displayed as <RETURN>. Instructions that ask you to press two or three keys simultaneously are indicated as follows:

"Press CONTROL-E"

Note that on some Xerox machines, the CONTROL key is labeled PROPS or EDIT, but has the same function as the CONTROL key.

[This page intentionally left blank]

Welcome to NoteCards, an idea manipulation tool for the modern intellectual. NoteCards provides you with a new way to organize and manage your ideas on your computer desk top.

This guide explains in detail how to install NoteCards on your Sun 3 or Sun 4 workstation, provides a basic tutorial for the NoteCards environment, and contains the reference manual for NoteCards.

Audience

The *Envos NoteCards Users's Guide* was written for users of NoteCards on Sun workstations. The *Guide* assumes that you are already familiar with UNIX and SunOS concepts.

Section I of this manual, Introduction and Installation, should be read by the System Administrator or person installing the NoteCards system. The NoteCards user should also read this section, in particular, Chapters 1 and 4, Introduction and System Use Issues. The user who wishes to remain safely ignorant of system-level aspects of UNIX and NoteCards can skip over Chapters 2 and 3, System Requirements and Software Installation. (The system installer should also read Appendices C and D.)

Section II, NoteCards Tutorial, provides an introduction to NoteCards and the system which underlies it. Chapter 5, NoteCards Basics, is the place for all new users of NoteCards to start once they have their system up and running.

Section III, Reference Manual, is a compilation of all the necessary background information on NoteCards new and old users will need to learn to fully exploit the NoteCards system.

The final section contains the Appendices, Glossary, and Index for the *Envos NoteCards User's Guide*.

Included with the NoteCards Guide are the manuals for TEdit and Sketch, *A User's Guide to TEdit* and *A User's Guide to Sketch*.

What's in the Manual

Here is what you will find in this manual, chapter by chapter, accompanied by a brief description of when you will want to read each chapter.

Chapter 1, Introduction, gives a brief introduction to and some background on NoteCards as well as explaining the stylistic conventions used in the *Guide*. Read this chapter before you install NoteCards.

Chapter 2, System Requirements, goes over the hardware requirements of the system. Read this chapter before you install NoteCards on a particular machine to verify that it will run acceptably on that machine.

Chapter 3, Software Installation, gives you step by step directions for installing NoteCards. Read this chapter before and during system installation.

Chapter 4, System Use Issues, discusses some of the basic ins and outs of using the system, Initialization, Starting, and Exiting NoteCards, as well as file access. Read this chapter after you have installed NoteCards. In particular, read the sections "Starting NoteCards" and "Exiting NoteCards and Saving State" when you are modifying your .cshrc and .login UNIX files for ideas on how to simplify the NoteCards booting process. In order to allow it to run on two different file systems NoteCards differs slightly from the standard SunOS and UNIX file systems. Read the section "Using SunOS Files from NoteCards" when you are learning how to access files from NoteCards.

Chapter 5, NoteCards Basics, takes you by the hand and leads you step by step through the basics of using the NoteCards system. This is the place for new users to start once you have NoteCards up and running. Once you get going, this is also a good chapter to review as it brings together ideas scattered through the users's guides whose importance many not be obvious from their context in the user's guides.

Chapter 6, Building NoteCards Structures, tries to give you some insights on how to use the NoteCards systems to its best advantage. NoteCards has been around as a PARC research prototype for several years. In this chapter we try to present some of what they have learned about using this system. Read this chapter after you have become somewhat familiar with NoteCards.

Chapter 7, The User Interface, covers some of the more basic aspects of using the system, the mouse, the keyboard, menus, etc. Read this chapter to understand more of the lower level capabilities of the system.

Chapter 8, Links, describes the link icon in all of its manifestations. Links and their physical representation, link icons, live at the core of NoteCards. Read and understand this chapter as soon as possible to make the most effective use of the system.

Chapter 9, Cards and Banners, discusses the user interface to individual notefiles and those aspects that all cards have in common. This is also an important chapter. The section "The Card Menu" is particularly important as it explains the functionality all cards have in common.

Chapter 10, User Cards, discusses cards where you are responsible for creating the contents. Read the sections "Text Cards" and "FileBox Cards" right away. The "Text Cards" section points you to the TEdit manual *A User's Guide to TEdit*. As TEdit forms the core of the system. We suggest that you make an effort to gradually learn more about TEdit all the time. Read the remaining sections as you explore the other card types. Note that the Bit Map Editor is discussed at the end of this chapter even though there is no bit-map card type

Chapter 11, System Cards, covers those cards where the system creates the contents for you. The section "Browser Cards" is the

most important one to read for a beginner. The others can be read as you need them.

Chapter 12, The MenuBox Icon, discusses the functionality on the three menus available from the MenuBox. The important commands for a new users are on the "Notefile Ops" menu. When just getting used to NoteCards, focus on the commands: **Open**, **Checkpoint**, **Close**, and **Abort**.

Chapter 13, System Parameters, explains how to change the global defaults for the system. New users can safely ignore this chapter. Most users will find that the default settings will suit all their needs.

Chapter 14, The FileBrowser, explains how to use the FileBrowser.

Chapter 15, Other Tools, explains how to use the Directory Connector, and the clocks.

Chapter 16, Printing, covers setting up print capabilities and printing to PostScript and Interpress printers. Read this chapter when you have the machine on a network and are ready to set up your print capability.

Chapter 17, Known Problems, Error Conditions and Recovery, covers those problems we know about as of this writing and how to cope with and avoid them. A quick reading of the sections "Known Problems" and "Break Windows" are all that most users will ever need.

Appendix A, Notefile Concepts, explains the inner workings and structure of notefiles. Read this if you want to understand how information is stored in the notefile and why you have to perform operations like compacting occasionally. This is essential background material if you are about to inspect or fix a damaged notefile.

Appendix B, Notefile Inspector, explains how to fix notefiles damaged by power failed, broken net connections and other unforeseeable calamities. Read this before you attempt to fix a damaged notefile.

Appendix C, Initialization Files, collects a lot of information on how to write a file which will automatically set site specific values for parameters like printer names and font locations. Read this appendix when you are first setting up your system.

Appendix D, Checksum Control, covers what to do if you believe the files loaded from the distribution tape are damaged.

Acknowledgements

NoteCards has a long history. Its gestation began in October 1982 when the U.S. Government funded XSIS (Xerox Special Information Systems) and Xerox PARC (Palo Alto Research Center) to prototype a Problem-Structuring-Aids system to allow users to build "semantic networks of textual information." The first successful prototype was completed by Frank Halasz, at PARC, in

November 1983. The first real user of the NoteCards system was Ken Allen, a history graduate student at Stanford University, in the spring of 1984. The birth came in June 1984 when NoteCards was released to the government, in fulfillment of the Problem-Structuring-Aids contract. Since then, XSIS and PARC have released three unsupported versions of NoteCards on Xerox D-machines. In November 1988, the Envos NoteCards product team started work on a supported, productized version of NoteCards. Envos NoteCards Release 1.1 for the Sun Workstation was completed in April 1989.

NoteCards is based on the work of many people.

From Xerox, Frank Halasz, Tomas Moran, Randall Trigg, Richard Burton, Ronald Kaplan, Peggy Irish, Catherine Marshall, and many others.

From Envos, Robert Krivacic, Keith Mountford, Craig Sweat, Karin Sye, Daniel Sagalowicz, Larry Harada, John Sybalsky, and others.

BUILDING

6. NOTECARDS STRUCTURES

NoteCards has been around for some time and people have developed different ways of using it. In this chapter we have recorded some of the different approaches people have taken towards using NoteCards in the hopes that these notes will help you discover the best way of using NoteCards for you.

If you have ideas about ways of using NoteCards which you would like to share with others please send them to us.

Introduction

By its very design, NoteCards encourages you to use it in specific ways. However, some users have found that they make the best use of NoteCards by not following the intended path but by branching off and forcing NoteCards to conform to their own idea of what a hypertext system should look like.

A Standard View of Building NoteCards Structures

NoteCards was intended to support two parallel modes of organization, a hierarchial one, implemented with FileBoxes, and a relational one, implemented with links.

One possible scenario is that you would collect a body of material and break it up into logical bits which would then be placed into Text, Sketch, Graph, and other card types. Ideally, the material would be scanned in, or collected from electronic sources. You would then build a hierarchial structure with FileBoxes inserting the data cards in their appropriate place in the FileBox hierarchy. Once you had established the structure you would then read through the document building links between related ideas, and constructing other non-hierarchial structures keeping these several lines of thought apart by using different link types. The different lines of thought in the material could then be collected by using document cards to follow the different link types.

This is a stereotypical view of how you might generate a structure in NoteCards however, it is not the only view.

A Non-Standard View of Building NoteCards Structures

FileBoxes and Hierarchies

One frequent comment from long time users is that people have a tendency to use FileBoxes too soon. They try to organize their data into a structure before the best structure is apparent and wind up reorganizing their ideas, wasting much time and energy. These users suggest that you build your structures only after you have worked with your data for awhile.

Other users simply do not use FileBoxes at all or use them to build only very shallow structures. Note that you could use links directly to build the equivalent hierarchial structure as with FileBoxes.

The Flat System

In the flat system, all cards are filed in the "Table of Contents", the "To Be Filed" or some user-specified FileBox card. These users may specify one or several start points for the reader, but aside from that the system is flat.

The Almost Flat System

In this organization the cards are grouped into large bunches which can be based on source, topic or some other broad category. One FileBox is used for each source, topic, or whatever the divisions are. One user likens his use of FileBoxes to library shelves where each FileBox is a different shelf. He then uses Sketch cards as an organization and integration tool, to help him navigate through his system.

Link Types

The system is built with the idea that you will classify each link type so that later you can build documents or browsers based on link types. However, some users make all their link types "Unspecified."

One of the dangers with links is that new users tend to link everything to everything else and end up with spaghetti.

Multiple Users

NoteCards was not designed with collaboration in mind. One way users have gotten around the problem of tracking what each user has done is to assign each collaborator a different font. Each contributor's work can then be recognized by font face.

Cards and Information Chunk Size

Because cards come up on the screen a particular size, able to display a small amount of information, the perception grows among new users that the information chunks have to be small. It is important to recognize that cards can hold any amount of information, and that they can be scrolled or resized to display all the information they hold.

There are trade offs, however. If you work with large cards, the size of your notefile grows much more rapidly. This is not serious. It only means that you need to compact your notefile more frequently than people who work with smaller information chunks do.

A second trade off is that links always point to the beginning of a card never into the body of a card. If your cards are very large, it may not be immediately clear what the relationship is between the source card and the destination card.

Types of Structures People Have Built with NoteCards

One user working on a design project used a notefile structured with design goals as roots moving down to the component level at leaf nodes. This structure allowed him to see the design history, subgoals, and goals which were retracted.

Other users use NoteCards to maintain indices of where to find sources of information. This is fairly common. Users frequently implement on-line rolodexes, customer-support or customer-tracking notefiles, and other types of text databases, such as project tracking.

The most common use is in writing large reports. NoteCards is used to collect, organize, and cross-reference information until the writer has a firm grasp of the material and how various pieces of it interact.

Specializing NoteCards

It is possible to specialize NoteCards to specific tasks.

One user has created an interface to the Lexis legal database. To do this he created a new text-card type which receives retrieved data from Lexis. He is also working on an interface to videodisk and other sources.

At Xerox PARC there is a group working on an Instructional Design Environment for designing, developing, and presenting instruction. These people are extensively modifying the NoteCards environment

If you have a need for a particular extension to NoteCards there is a programmers interface which you or your company's developers can use to extend the NoteCards environment, or Envos Consulting Services group can provide you with specialized extensions to NoteCards.

[This page intentionally left blank]

7. THE USER INTERFACE

This chapter covers the basics of using the window system NoteCards is built on top of. Read this chapter if you are a new user of the system or you need to understand how to manipulate windows, icons, and use the functions on the background menu. For a lower-level introduction to mouse-button and keyboard use, read Chapter 5, NoteCards Basics.

This chapter explains:

- Where to find system menus.

- What these menus do.

The Window Menu

The NoteCards window system allows you to interactively manipulate the windows on the screen, moving them around, changing their shape, etc. by selecting various operations from the window menu.

Figure 7-1. The window menu.

When you press and hold down the right mouse button in a window's title bar, as shown in Figure 7-2, that window will come to the top and a menu of window operations will appear. In some cases, you can hold down the right mouse button anywhere in the window to access the window menu.

Figure 7-2. The window menu being accessed from a TEdit-window title bar. Note how the TEdit window has been brought to the top of all the windows.

Close

Closes a window, i.e., removes it from the screen. If you have modified the contents of the window, the system may ask you to confirm, by pressing the left mouse button, that you want to close the window and lose your changes. Pressing the right or middle mouse button cancels the close operation.

Figure 7-3. A TEdit window requesting you to confirm the **Close** command.

Snap

Prompts for a region on the screen and makes a new window whose image is a snapshot of the image currently in that region. Useful for saving some particularly choice image before the window image changes.

Figure 7-4. The mouse cursor prompting you to sweep out a new size and shape for a window.

Most of the images presented as figures in this manual are screen snaps.

When making a snap, it is possible to change corners and change the snap shape from a different side of the ghost frame. In the middle of a snap process, while you still have the left mouse button down, simultaneously press and hold down the right mouse button.

When you do this, the forceps cursor () will appear. Move this cursor to the corner of the ghost frame you want to move and still holding the left mouse button down, release the right mouse button. You will now be able to adjust the snap from the corner you just selected.

Paint

Switches to a mode in which the cursor can be used like a paint brush to draw in a window. This can be useful for making notes on a window or touching up snaps. While the left key is down, pixels are blackened. While the middle key is down, they are erased. The right button pops up a command menu that allows you to change the brush size, shape, shade, mode, and to quit the paint utility.

Figure 7-5. Paint command menu.

Set Mode

Brings up the menu shown in Figure 7-6.

Figure 7-6. The Mode menu for Paint.

Changing the paint mode changes the way the bits in the brush combine with the existing bits in the snap.

Figure 7-7. The vertical bars show a sample bit map pattern from a snap. The horizontal bars are the pattern in the example brush.

Figure 7-8. The snap and brush patterns shown in Figure 7-7 combine as shown here.

Set Shade

Pops up a menu which allows you to choose one of a preexisting set of shades or specify your own 4x4 shade. New shades are added to the "Choose shade" menu.

Figure 7-9. The "Choose shade" menu.

Figure 7-10. The 4x4 shade tool.

Set Shape

Pops up the menu below which allows you to set the shape of the mouse cursor.

Figure 7-11. The shape menu.

Set Size

Brings up the following menu which sets the cursor brush size.

Figure 7-12. The size menu.

Quit

Quits the paint program.

Clear

Clears the window. Sets all pixels in the window to white.

Bury

Places the window under all other windows which it covers or overlaps, thereby exposing any windows that it was hiding.

Redisplay

Clears the window and rewrites the window contents to the window.

Hardcopy

Sends the contents of the window to the printer. If the window is associated with a text, sketch, or graph editor the editor's contents are printed. In the case of TEdit and Sketch, this means that the associated TEdit file, if there is one, is printed. If the window is not associated with an editor a bit-map image of the window is sent to the printer.

To save the image in a PostScript, Interpress, or Press formatted file, or to send it to a non-default printer, use the submenu of the **Hardcopy** command. When the mouse is moved off to the right of the **Hardcopy** menu item, a second pop-up menu appears giving the choices **To a file** or **To a printer**.

Figure 7-13. The Hardcopy submenu.

If **To a file** is selected, you are prompted to supply a file name, and the format of the file (PostScript or Interpress) from the "File type?" menu and the contents of the window is stored in that file, formatted for the printer type you specified.

Figure 7-14. The "File type?" menu.

The system provides the suffixes for these files. PostScript files have a "ps" suffix. Interpress files have an "ip" suffix. For example, given a file name of "Letter," the system stores a file with the name "Letter.ps" for a PostScript formatted file and "Letter.ip" for an Interpress formatted file. If you change the suffix for a formatted file from "ps" or "ip" to some other name, the system will prompt you to let it know the file type when you try to print the file. For a formatted file, select the **BINARY** response. For an unformatted file, select the **TEXT** response. You print a formatted file the same way you print an unformatted file, by using the **Hardcopy** option on the FileBrowser menu.

Figure 7-15. The "File Type?" menu requesting the file type of a file formatted for a particular printer type.

If you select **To a printer**, you are prompted to select a printer from the list of known printers, or to type the name of another printer.

Figure 7-16. The "Which printer?" menu asking which printer you want to send to.

The topmost printer in the "Which printer?" menu is the default printer. If the printer selected is not the topmost printer on the list, indicating that it is not the default printer, you will be asked whether to make the printer you selected the new default printer.

Figure 7-17. The "Make this the new default?" menu asking you whether you want to make the printer you selected the default printer.

Note, unless you are using only fully specified Interpress printer names or you have set the DEFAULTPRINTERTYPE variable from your initialization file, it is unadvisable to use the **Other...** option on the "Which printer?" menu shown in Figure 7-16, as using this option does not allow you to specify the printer type.

Move

Moves the window to a new screen location. When you select **Move** you are presented with a ghost frame which is the size and shape of the original of the window you are moving. You move the mouse to position the ghost frame where you want the window to appear and then you plant the window by clicking the left mouse button.

Figure 7-18. A TEdit window and its ghost frame.

Shape

Allows the user to specify a new size and shape for an existing window. You can use either the left or middle mouse buttons to shape a window.

Using the left mouse button allows you to change the size, shape, and location of a window. Once you have selected **Shape** from the window menu, position the cursor where you want the upper left corner of the window to be located, press and hold down the left mouse button, sweep out a new region for the window, and release the mouse button when the window has the size and shape you want.

Using the middle mouse button allows you to change the size and shape of a window by moving just one corner of the window. Select **Shape** from the window menu and position the mouse cursor at the corner you want to move. Press and hold down the middle mouse button and move the mouse cursor to the location you want that corner of the window to be at. A ghost frame will appear to indicate the new size and shape of the window.

When reshaping a window with either the left or middle mouse button it is possible to change corners and change the window shape from a different side of the window. In the middle of a shape process, while you still have the left or middle mouse button down, simultaneously press and hold the right mouse button down. When

you do this, the forceps cursor (0) will appear. Move this cursor to the window corner you want to move and still holding the left or middle mouse button down, release the right mouse button. You will now be able to reshape the window from the corner you just selected.

If you have too many windows on the screen and you are having problems accessing them, you probably want to try shrinking some windows.

Shrink

Removes the window from the screen and brings up its icon. The window can be restored by clicking the middle mouse button inside the window's icon, or by selecting **Expand** from the right button icon menu. Some icons are shown below.

Figure 7-19. TEdit-window shrink icons look like books.

Figure 7-20. Sketch-window shrink icons look like sketch pads.

Figure 7-21. FileBrowser-window shrink icons look like filing cabinet drawers.

Figure 7-22. The NoteCards MenuBox shrink icon looks like a recipe file box.

Figure 7-23. Notecard shrink icons look like link icons with an extra border.

The Icon Menu

Icons are a variant of windows and have a menu similar in form and function to the window menu.

Figure 7-24. The icon menu.

For the options Close, Snap, Paint, Bury, Move, and Shape see the discussion above under the "Window Menu" heading.

Expand

Restores the window associated with the icon accessed and removes the icon image from the screen. You can also expand an icon by clicking the middle mouse button inside the icon.

The Background Menu

If the right button is pressed while the cursor is not in any window, the background menu appears.

Figure 7-25. The background menu.

TEdit

Opens a new TEdit window and starts a new TEdit session.

Sketch

Opens a new Sketch window and starts a new Sketch session.

Figure 7-26. The Sketch submenu options.

Page sized sketch

Allows you to start a sketch which will fit exactly on an 8 1/2 x 11 inch sheet of paper when held in the normal vertical or portrait position.

Landscape sketch

Allows you to start a sketch which will fit exactly on an 8 1/2 x 11 inch sheet of paper when held in a horizontal or portrait position.

Sketch, from a file

Allows you to start a preexisting sketch which is stored in a file.

NoteCards

Opens the NoteCards MenuBox Icon which is the interface for a NoteCards session.

Snap

The same as the window menu command Snap described above.

Also, TEdit, Sketch, and NoteCards allow information to be shift-inserted at the current cursor position by selecting an area of the screen with the SHIFT key held down. To shift-insert the bitmap of a snap into an editor, position the cursor where you want the image to appear, hold the SHIFT key down, press and hold down the right mouse button in the background, and select **Snap** from the single item menu which appears. Finally, sweep out the area for the snap and release the mouse button and the SHIFT key. The snap will appear in the editor where the cursor was positioned. Note, sometimes it is necessary to scroll or redisplay the window for the snap to appear.

Hardcopy

Prompts for a region on the screen, and sends the bit map image to the default printer. Note that the region can cross window boundaries.

Like the window menu **Hardcopy** command discussed above, you can print to a file or specify a different printer than the default by using the **Hardcopy** submenu. See the discussion of the Hardcopy command under the "Window Menu" section above, for more detail.

Clocks

Starts an analog clock and places it on the screen. The Clocks submenu gives you access to a digital clock.

Figure 7-27. The Clocks option on the background menu.

For a complete discussion of this menu option, see Chapter 15, Other Tools.

FileBrowser

Opens a FileBrowser window which prompts you for a directory to browse.

For a complete discussion of this menu option, see Chapter 14, The FileBrowser.

Directory Connector

Opens a window which displays your currently connected directory, and allows you to change directories.

For a complete discussion of this menu option, see Chapter 15, Other Tools.

Idle

Enters idle mode, which blacks out the display screen to save the phosphor. Idle mode can be exited by pressing any key on the keyboard or mouse. This menu command has subitems that allow the user to interactively set idle options to erase the password cache (for security), to request a password before exiting idle mode, to change the timeout before idle mode is entered automatically, etc.

Figure 7-28. The Idle submenu.

If either shift key is pressed while NoteCards is in idle mode, the current user name and the amount of time spent idling are displayed in the prompt window. This information appears as long as the shift key is held down.

Show Profile

Displays the current idle profile in the system prompt window.

Set Timeout

Sets the amount of time that the machine will wait for a key stroke or mouse click before automatically going into idle mode.

When you select this option the system brings up a number pad on which you can enter the new idle time out. An idle time out of zero sets the machine so that it will never go into idle mode.

Figure 7-29. The number pad menu requesting a new idle timeout duration.

The submenu option **Never**, will set the machine so that it never goes into idle mode. We counsel against using this option as it can result in the phosphor on your screen being damaged.

Choose Display

Allows you to select what will be displayed on the blacked out screen when the machine is in idle mode. Selecting this option brings up the two-choice menu shown below.

Figure 7-30. The idle display menu.

Bouncing Box

Chooses the Envos logo as the idle display.

Figure 7-31. The **Bouncing Box** Envos logo.

Bouncing Username

Chooses the your username as the item to bounce around on the screen while in idle mode.

Forget

If set to "Don't" (or NIL), your password is not erased when idle mode is entered. Default is "Do" (or T(rue)) erase password. The initialization file distributed with the NoteCards system resets **Forget** to "Don't."

Figure 7-32. The **Forget** submenu.

Note: If the password is erased, any programs left running when idle mode is entered will fail if they try doing anything requiring passwords, such as accessing file servers.

Allowed Logins

Determines who can exit idle mode.

Figure 7-33. The "Allowed Logins" submenus.

- Unlocked** Sets the system such that login is not required to exit idle mode. Initialization file value is "NIL."
- Locked** Lets only the previous user exit idle mode. Initialization file value is "(T)."
- Any Login** Require login, but let anyone exit idle mode. Login overwrites the previous user's user name and password each time idle mode is exited. Initialization file value is "(*)."
- Group** Allow any members of a specified group to exit idle mode. Figure 7-33 shows the **Group** submenu which allows you to add and delete group members.

Authenticate

The value of this property determines what mechanism the system uses to check passwords.

Figure 7-34. The Authenticate submenu.

If the value of this property is "Do" or "T(rue)," the Xerox network system protocol is used to do the authentication.

If the property value is "UNIX," the Sun Operating System is used to do the authentication. This option is set in the standard initialization file. See Appendix C for a complete discussion.

If the value of this property is "Don't" or NIL, the password is not checked. Any password is accepted.

Logout

Saves the NoteCards virtual memory working image to a file and returns the system to UNIX. This is the normal way to return to UNIX.

Figure 7-35. The Logout option and its submenu on the background menu.

Save image & Exit

The same as Logout.

Flush image & Exit.

Returns the system to UNIX without saving the working image. Use this option when you have saved all your work to files and you do not care if the system comes up in the same state it was in when you left it.

Save VM

Saves the NoteCards virtual memory working image to a file but does not return the system to UNIX. Use this option frequently if you are concerned about power failures or other problems which may cause your machine to crash.

Suspend & Exit

Suspends the NoteCards session and returns control to UNIX. You restart the NoteCards session by entering the command `fg` (foreground), at the UNIX prompt.

Low Level Tools

This menu option provides people extending the NoteCards system access to the Lisp executives, the process status window, and allows them to set the **Show TEdit Props** flag. The NoteCards user should never access these options except under the instruction of a developer or support person.

Set Default Printer

Allows you to specify which printers you want to print to and which one is the default.

For a complete discussion of this menu option, see Chapter 16, Printing.

Postscript Parameters

Allows you to control the way PostScript documents are printed.

For a complete discussion of this menu option, see Chapter 16, Printing.

Set Default Display Font

Brings up a series of menus which allow you to specify what fonts will be used on the screen. This is a particularly useful option if you are using a high resolution screen and want to increase font size or for people who are vision impaired.

Figure 7-36. The "Choose Font Profile to Update" menu.

To change a display font, select the **Set Default Display Font** background menu option and choose the font you want to change from the "Choose Font Profile to Update" menu. Each of the font options is discussed below. Once you have selected the font you want to modify, the "Please select a font:" menu will appear. Select the font family, size, and face you want then select **DONE**. **RESET** makes the menu display the current setting for the default display font you are modifying. **ABORT** terminates this operation and closed the "Please select a font:" menu.

Figure 7-37. The "Please select a font:" menu.

If you choose a font which does not exist or the system is unable to find, the old font specification remains unchanged.

If the system is unable to find a font which you know to exist, check the setting of the display font directory list. This is done with the **Show Font Directories** subsubmenu option off the **Set Default Printer** background menu option. See Chapter 16, Printing, for a complete description of how to use this option.

FileBrowser Display Font

The font in which the information in the main display window is printed, initially 10-point Gacha.

FileBrowser Prompt Font

The font in which FileBrowser prompt messages are printed. Initially 8-point Gacha. Changing this value only affects new FileBrowsers created from the background menu. Existing FileBrowsers are unaffected.

Prompt Window Font

The font used to print information in the black system-prompt window.

Default Font

The starting font used in TEdit and Sketch windows as well as all other windows which do not have an explicitly specified font associated with them.

Note that the default font for NoteCards cards is specified from the "NoteCards System Parameters" menu. See Chapter 13, System Parameters for a complete discussion of how to specify this default font.

Menu Font

The font used in all system menus. The menu font is used in the window, icon, background, and other menus.

[This page intentionally left blank]

A link is a connection between a source card and a destination card. A link icon represents the link.

Figure 8-1. A link-icon image.

By clicking on the link icon, you can display the destination card. Links are the glue which holds together the relationships and conceptual structures represented in a notefile.

This chapter explains:

- What links and link types are.

- How links are accessed and used.

- How to create links.

- How to delete and undelete links.

- How to tailor links to your taste.

- What cross-file links are.

Links and Link Types

Link types specify the nature of the relationship between the source and destination cards. Some typical link types are Question, Answer, and Explanation.

Two groups of link types exist in the NoteCards system; one group is system-reserved, the other is user-specified. Some of the system-reserved links support the FileBox hierarchy that NoteCards helps you to create. The user-specified links add a relational dimension to information structuring. Here you can link cards together to form networks. These networks allow you to represent the interconnections between various ideas or pieces of information, independent of any categorization into topic areas. In contrast, the set of FileBoxes forms a strict hierarchy typically representing a breakdown of information into subtopics or subcategories. By strict hierarchy, we mean that you are not allowed to create circular lists of FileBoxes. Circular lists of other card types are allowed, however.

System-Reserved Link Types

SubBox	A link pointing to a FileBox from another FileBox.
FiledCard	A link pointing from a FileBox card to any non-FileBox card. Text, Sketch, Graph, Browser, Search, LinkIndex, and Document cards are non-FileBox cards.

BrowserContents	A link pointing to a card or box from a Browser card. This type of link is traversed when you bring up any of the cards or boxes represented as link icons in a Browser card.
ListContents	A link pointing to a card or box from a Search card, enabling you to bring up any of the cards or boxes found during the search process.
LinkIndexBackPtr	A link pointing to a card or box from a LinkIndex card. This type of link is built when you specify that a LinkIndex card should have back pointers to the cards and boxes being indexed, i.e., link icons should be included in the LinkIndex card.
DocBackPtr	A link pointing to a card or box from a Document card. This type of link is built when you specify that a Document card should include back pointers to each card and/or box used to build the document.

User-Specified Link Types

User-specified links indicate the logical relationships between cards. The system comes with three predefined user-specified link types, Comment, See, and Unspecified. However, the system allows you to create new link types as you need them. Typical link types users create include Explanation, Example, Question, Answer, Next, and Source. Choose your link types carefully as they determine the lines along which you will be able to extract information from your notefiles with Document cards.

Randy Trigg, one of the developers of the NoteCards prototype at Xerox PARC, proposed a long list of standard link types for users to follow in categorizing the relationships between their notes. A partial list is included here to give you some idea of the possibilities.

Note that some long-time users of the system use only one link type. NoteCards gives you a great deal of flexibility. Just because some functionality is there does not mean you should feel obligated to use it if it is not helpful to your task.

Link Directions and Link Ends

Links have a single start point and a single end point. However, whenever you create a link from one card to another, the system automatically builds a backwards link so that it is possible to traverse a linked sequence of cards in either direction. The result is that all cards are linked bidirectionally.

A link's start point is either the card itself or somewhere in the card's contents. In the case of a text card, this would be somewhere within the body of the card's text. A link's end point is always another card. Thus, there are three distinct link categories. There are also a few terms which refer to different groupings of these categories.

Link Categories

To-Links	Refer to links whose start point is in a card's contents and whose end point is another card. These links are represented as link icons in a card's body.
Global To-Links	Refer to links whose start point is a card itself and whose end point is another card. These links are not represented by link icons in a card's body. To see and access these link icons you must choose the Show Links option from a card's left-button title-bar menu.
From-Links	For every to-link and global to-link there is a corresponding from-link which points from the destination card to the source card. All from-links are global.

Other Link Terminology

Local Links	Links whose start point is somewhere in the contents of a card.
Global Links	Links whose start point is the card itself and not some point in the card's contents. These links are not represented by link icons in a card's body. To see and access these link icons, you must choose the Show Links option from a card's left-button title-bar menu.
Forward Links	Include both to-links and global to-links. This term is used when setting Browser and LinkIndex card parameters.
Backward Links	The same as from-links. This term is used when setting Browser and LinkIndex card parameters.
Back Links	System-generated to-links. These links point from a Document or LinkIndex card <i>back</i> to the source cards from which the Document or LinkIndex was built. Hence the name back link.

Link Types vs. Card Types

Link types and card types are frequently confused but they are totally independent of each other.

Link types classify the assigned relationship between two cards. Link types frequently include Explanation, Question, Answer, and Citation.

A card's type specifies the functional capabilities of that card and is associated with a text or graphics editor. The eight card types are Text, FileBox, Search, LinkIndex, Document, Sketch, Graph, and Browser. The Text, FileBox, Search, LinkIndex, and Document cards are all based on the text editor TEdit. The Sketch card is based on the Sketch editor and the Graph, and Browser cards are based on the graph editor Grapher.

Link Access and Use

Link Icon Functionality

A link icon is an active region with an associated menu and four functions. The most frequently used functionality is to click the left mouse button in the body of the link icon to traverse the link to the destination card. The middle mouse button brings up a menu which allows you to traverse the link, change the link type, change the card title and change the link display mode.

Active Regions of Link Icons

The entire link icon except for 10 pixels at the left edge and 10 pixels at the right edge responds to mouse clicks by carrying out a NoteCards action.

Figure 8-2. Link icon active and inactive regions.

Clicking in the "inactive" 10-pixel strips at the left and right edges of the link icon selects the link icon, in text-based cards (Text, FileBox, Search, LinkIndex, and Document cards), for delete, copy, and move operations, without traversing the link. This region does not exist on sketch- and graph-based cards (Sketch, Graph, and Browser cards).

The inactive area can be somewhat difficult to access without touching the active region of the card. One way to access it is to hold the left or middle mouse button down and slide into the link icon's inactive region. You have selected the link icon when it appears underlined.

Figure 8-3. A selected icon

If you go too far and the card redisplay in reverse video, simply slide the mouse cursor out to the edge of the link icon and watch for it to underline again. Once the icon appears underlined release the mouse button.

If a link icon is so narrow that its active region would be less than 10 pixels wide, the active region is set to the middle 50% of the link icon width, with 25% at left and 25% at the right being the inactive strips. If the link icon is less than 10 pixels in width altogether, then the link icon will have no inactive strips. Its entire area will be active.

Mouse-Button Actions in Link Icons

The exact response to a mouse click in the active region of a link icon varies depending on a number of conditions. For more general mouse button behaviors, see Chapter 7, *The User Interface*, as well as the *User's Guide to TEdit* and the *User's Guide to Sketch*.

Left Button	Brings up the destination card represented by the link icon.
Middle Button	Brings up the link icon menu which allows you to change the link type, title, and display mode.
Right Button	Following a left- or middle-button click elsewhere in a TEdit-based card, selects a region of the window for moving, copying, or deletion which can include link icons.

Copy/Shift or Move/Shift-Control key plus mouse-button operations are three-step operations. First, you specify the destination window by clicking the left mouse button to position the flashing cursor in the window. Second, hold the appropriate keyboard key down. Third, while still holding the key down, use the mouse to select the piece of text/graphics to be operated on. Once you have completed your selection, release the keyboard key and what you have selected will be copied or moved to the destination window.

Link icons should only be copied or moved to NoteCards windows. TEdit and Sketch, when used outside of NoteCards text-based and sketch-based cards, will not understand link icons.

Copy/Shift key + Left Button	This operation is frequently referred to as a shift-select, occasionally as a copy-select. This operation copies a link icon, or link-icon name and link, to another card. If the flashing cursor is in the body of a card, holding the SHIFT or COPY key down and clicking the left mouse button on a link icon copies the link icon and the link it represents to the position of the caret cursor in the destination card.

If the flashing cursor is a crosshairs and is in a "Selecting cards to file" prompt window, holding the SHIFT or COPY key down and clicking the left mouse button on a link icon will copy the link icon name and link to the select-card prompt window. This operation is used when you are inserting links in cards or filing cards in a FileBox card.

Figure 8-4. A select card prompt window.

Copy/Shift key+ Middle Button

Same as left button.

Copy/Shift key + Right Button

Holding the COPY or SHIFT key down and pressing the right mouse button following a left- or middle-button click elsewhere in a text-based card, selects a region of the window for copying which can include link icons.

Move/Shift-Control + Left Button

Moves a link and link icon from one card to another card by deleting the link in the first card and inserting it into the second. To move a link, position the caret cursor in the destination window where you want the link to appear and, holding the MOVE key down or holding the CONTROL and SHIFT keys down simultaneously, select the link icon you want to move with the left mouse button. When you release the key or keys you are holding down, the link icon will move to its new position.

Move/Shift-Control + Middle Button

Same as left button.

Move/Shift-Control + Right Button

Holding the MOVE key or SHIFT and CONTROL keys down and pressing the right mouse button following a left- or middle-button click elsewhere in a text-based card, selects a region of the window to be moved which can include link icons.

CONTROL key plus mouse button operations are two-step operations. First, hold the CONTROL key down. Second, while still holding the key down, use the mouse to select the piece of text/graphics to be deleted. Once you have completed your selection, release the CONTROL key and what you have selected will be deleted.

Control key+ Left Button

Deletes a link and link icon from a card. Holding the CONTROL key down and pressing the left mouse button on a link icon will select the link icon for deletion. This is shown by displaying the link icon in reverse video.

Figure 8-5. A selected link icon.

The link icon and the link it represents are deleted when you release the CONTROL key. You can cancel this operation before you release the CONTROL key by clicking elsewhere in the window to deselect the link icon.

Figure 8-6. An unselected link icon.

You can undo this operation, after you have released the control key, by hitting the UNDO key.

Control key + Middle Button

Same as left button.

Control key + Right Button

Holding the CONTROL key down and pressing the right mouse button following a left- or middle-button click elsewhere in a text-based card, selects a region of the window for deletion which can include link icons.

It is also possible to just backspace over a link icon or to select it and then hit the DELETE key. Note that on some Sun keyboards, the backspace key has the word "Delete" printed on it and that the NoteCards DELETE key is one of the function keys, usually the key labeled "L10."

Viewing Local and Global Links

All links are stored in three places.

- 1) as a to-link on a source card
- 2) as a from-link on a destination card

and either

- 3a) for local to-links, in the card's contents as a link icon
- 3b) for global to-links, in the card's global links list

Only the local to-links, the links in a card's contents, are immediately visible.

To see all of the links to and from a card, hold the left mouse button down in the card's title bar and select the **Show Links** option.

Figure 8-7. The card menu with the **Show Links** option selected.

This will open a window titled: "List of Links". This window always opens with the same initial height. If the list of links is longer than three or four, you will need to scroll or reshape the window to see

the rest of the links. The link icons in this window have the standard left-button functionality, you can traverse links, but no middle-button functionality. Links can also be copied, moved, and deleted from this window.

Figure 8-8. A "List of Links" window showing links to and from the "Earth" and "Moon" cards.

The headings to the left of the links are active but have no operations associated with them.

You can close the "List of Links" window by holding down the left or middle mouse button in the window title bar and selecting **Quit** from the single-option menu, or by pressing the right mouse button in the title bar and selecting the **Close** option from the standard window menu.

Figure 8-9. The "List of Links" left button menu.

Unfiled and Lost Cards

All cards, including FileBox cards, must be filed in at least one FileBox. This assures that you will have a pointer to your information and helps to remind you to hierarchically organize your information in addition to specifying other types of relationships. When you close a card without linking it to a FileBox card, the closed card is placed in the "To Be Filed" FileBox. You can access this FileBox card by holding the middle mouse button down on the notefile-banner **Special Cards** menu option and selecting the **To Be Filed** option from the menu which appears.

Figure 8-10. The **To Be Filed** option on the "Special Cards" menu.

From this FileBox all "unfiled" cards are accessible. It is possible to force yourself to file cards in a FileBox by setting the **Force Filing**

Edit Parameter. See Chapter 13, System Parameters, for a complete explanation.

You can remove all FileBox links to a card by accident or by design. When you do this, the following message is displayed in the System Prompt Window. "You have just unfiled *card name* from its last filebox. It is being filed in the Orphan FileBox." You can access this FileBox card by holding the middle mouse button down on the notefile-banner **Special Cards** menu option and selecting the **Orphans** option from the menu which appears.

Finally, you can delete card links from the "Orphans" FileBox. When you do this the following message is displayed in the card's prompt window. "You have just deleted the last filing link to *card name*. The Search operation can be used to find it." At this point, if there are no other cards with links to this card, it becomes a lost card and there is no simple way to access the card even though it still exists. As the message says, though, you can retrieve lost cards by building new links to them with a Search card. However, unless you remember some fragment of the card's name, using a Search card to find lost cards can be a time consuming task in a large notefile.

Creating Links

The links you create always run from a source card to a destination card. References to the source card refer to the card with the link icon. References to the destination card refer to the card which opens, or flashes if already open, when you click on the link icon.

Figure 8-11. An illustration of a link icon pointing to its destination card.

Creating Links in Text Cards

The procedures for creating links are basically the same for all cards. We will use Text cards as the model, and then discuss the differences between Text cards and other cards.

Insert Link

You use the **Insert Link** command to create a link originating in the source card's contents and terminating at another card. This is a multi-step process. First, you place the caret cursor in the card at the position where you want the link to appear by clicking in the source card's window. If the type-in process belongs to another card or window this usually takes two mouse clicks, one to make the card the active card and one to position the mouse cursor. Once you have established the location for the link icon in the

source card, you hold the left mouse button down in the source card's title bar and select the **Insert Link** option.

Figure 8-12. The card menu with the **Insert Link** option selected.

At this point the "Link Type" menu will open, asking you to specify the link type.

Figure 8-13. The "Link Type" menu with the **--New Link Type--** option selected.

Choosing appropriate link types is important as they will determine the ways you will be able to extract information from your notefiles. For more information on link types see the section User-Specified Link Types in this chapter and the section on Document cards in Chapter 12, System Cards. You can create new link types as you need them by selecting the **--New Link Type--** option and typing the name of the new link type into the prompt window which will appear above the source card. When you type a carriage return to this prompt window, without defining a new link type, the system assigns the link type the value "Unspecified."

Figure 8-14. A note card prompt window requesting a new link type.

After you have selected an existing link type or defined a new one, the system opens a "Selecting Note Card" window and prompts you to shift-select the card UID from the destination card.

Figure 8-15. A "Selecting Note Card" window prompting the user to shift-select a card ID from the destination card's title bar.

A card UID is shift-selectable from three locations,

When shift-selecting the card UID, there are two distinct behaviors. From the link icon, it is necessary to lift the Shift or Copy key after each selection. This is the expected behavior when shift-selecting anything from an edit window. From the title bar and shrink icon, it is not necessary to lift the Shift key. The transfer happens immediately.

What you see transferred is the destination card's title, but NoteCards also maintains an identifier for each card which is unique across all cards and notefiles. This is what you are really shift-selecting from one card to another. And this is also the reason why it is not possible to shift-select or type text into this window.

Figure 8-16. A link icon to a destination card as it appears in a source card.

At this point, the new link icon will appear in the source card. From now on, when you click on this link icon, it will open the destination card, or flash the destination card if it is already open.

Selecting **New Card** from the menu on top of the "Selecting Note Card" prompt window will bring up a menu allowing you to create a new card, of any type, which will be the destination card.

Selecting **Cancel** from this menu, cancels the entire **Insert Link** operation.

At any point in this process, it is possible to transfer the type-in process from a prompt window to some other window by clicking in the window you want to use. The prompt window will stay open waiting for you to complete the operation. When you are ready to finish inserting the link, simply click in the prompt window to make it the active window, shown by the flashing crosshairs, and continue where you left off.

Insert Links

If you need to insert multiple links of the same link type at the same location in a source card, **Insert Links** will save you from inserting each link individually.

Figure 8-17. The card menu with the **Insert Links** option on the **Insert Link** submenu selected.

Insert Links works exactly as **Insert Link** except you will be allowed to select multiple destination cards. It is possible to shift-select a mixture of text and link icons from a card. In this case, the source card's prompt window will ignore all the extraneous text. To complete the insert operation, either type a carriage return or select the **Done** menu option.

Figure 8-18. A "Selecting Note Cards" prompt window.

The **Cancel** option terminates the entire link insertion operation.

Undo allows you to remove the last item from the list. You can select **Undo** until you have removed all the items from the list.

Add Global Link

Global links are not rooted in a card's contents. For this reason we draw the contrast between *inserting* a link into a card's contents and *adding* a global link to a card.

A second result of this difference is that the procedure for **Add Global Link** is somewhat different from that for **Insert Link**. To add a global link, hold the left mouse button down on the card's title bar and slide off **Insert Link** to access the submenu and select the **Add Global Link** option.

Figure 8-19. The card menu with the **Add Global Links** option on the **Insert Link** submenu selected.

Because you are adding a link to a card itself and not inserting a link into a card's contents, it is not necessary to first position the caret cursor to select the link icon's insertion point. Note that the link will not be visible unless you use the **Show Links** option to show the links to and from that card. Aside from these few minor differences the procedure is exactly the same as that for **Insert Link**.

Add Global Links

Add Global Links functions just like a combination of **Add Global Link** and **Insert Links**. It allows you to add multiple global links of the same link type to a source card without adding each link individually. If you want the global links to have different link types, they must be added one by one using **Add Global Link**.

Creating Links in Other Card Types

There are three basic card types in NoteCards, text-based, sketch-based and graph-based cards.

Text-Based Cards

Text-based cards are based on the TEdit editor and can contain the output from sketch-based and graph-based cards. Text-based cards include Text, FileBox, Search, LinkIndex, and Document cards. The link creation procedure for all text-based cards is the same as for Text cards.

Sketch-Based Cards

Sketch-based cards are based on the Sketch editor. There is only one sketch-based card and it is the Sketch card.

The link icon insertion procedure differs from that for text-based cards only concerning *when* the new link icon is positioned in the card. For text-based cards, the cursor is positioned where you want the link to appear and then one of the link insertion options is selected. For sketch-based cards, the order is reversed. The

menu option is selected first and then, after you have indicated which card you want to link to, you move the cursor into the Sketch card and position the link icon.

Graph-Based Cards

Graph-based cards are based on the graph editor. Graph and Browser cards are graph-based cards.

As with sketch-based cards, the link icon position is selected after the card you are linking to.

Deleting Links

When you delete a link icon you are deleting the to-link that points from the source card to the destination card and also the from-link which points from the destination card back to the source card.

To understand what happens when you delete a link, create a Source Card and a Destination Card. Next insert a link from the Source Card to the Destination Card, and open the "List of Links" windows on each card by selecting the **Show Links** option from the left-button title-bar menu. When you delete one link, all the links will be deleted.

Figure 8-20. A "List of Links" window showing a to-link to a destination card.

Figure 8-21. A "List of Links" window showing a from-link pointing back to a source card.

The delete procedure for links depends on where you are accessing the link and the card type you are deleting the link from.

Deleting Links from Card Contents

Text-Based Cards

Link icons in the body of text-based cards can be deleted in several ways.

You can select the link icon with the mouse by clicking in the *inactive* region of the link icon and hitting the delete key. Also, you can select a region of text in a text-base card with a sequence of left+right or middle+right mouse buttons and hit the delete key to delete the selected region which can include a mixture of text and link icons.

You can also hold the control key down and select the link icon by pressing the left or middle mouse button in the link icon active region, when you release the control key, the link icon will be deleted.

Finally, you can simply backspace over a link to delete it.

All of these operations can be undone by hitting the Undo key.

For more detail on inactive regions of link icons and coordinated keyboard-plus-mouse operations, see the Link Access and Use section above and as well as the TEdit documentation.

Sketch-Based Cards

You can delete link icons in the body of sketch-based cards by bringing up the sketch menu, if it is not permanently attached to the right side of the sketch window, and selecting the delete option. Next, click in the link icons control point which is the small box attached to one corner of the link icon.

Figure 8-22. A selected link icon in a Sketch card.

This operation can be undone by hitting the Undo key.

For more detail on this and other Sketch operations see the Sketch documentation.

Graph-Based Cards

To delete a link from a Graph card, hold the right mouse button down in the Graph card window, select the **Delete Node** option, and then click on the card you want to delete. When you confirm, the link will be deleted.

Note, this operation cannot be undone.

Because a Browser card is an overview of a link network in addition to being a member of that network, the meanings of delete operations in Browser cards is not straightforward. Please turn to the section on Browser cards in Chapter 11, System Cards, for a detailed explanation of links in Browser cards.

Deleting Links from the Show Links Display

Deleting links from the show links display is very similar to deleting links from text-based cards.

You select the link icon with the mouse by clicking in the inactive region of the link icon and hitting the delete or backspace key.

You can also hold the control key down and select the link icon with the mouse by pressing the left- or middle-mouse button in the link-icon active region, when you release the control key, the link icon will be deleted. This second way is frequently the easier of the two, as it does not require you to access the narrow inactive regions on either end of the link icon.

Note, this delete operation cannot be undone.

Tailoring Links

It is possible to modify the appearance of links to suit your personal tastes and the task at hand. Links can be modified using the middle-button icon menu and the NoteCards "System Parameters" menu.

Link Ops Menu

You bring up the "LinkOps" menu by holding the middle mouse button down in the active region of the link icon.

Figure 8-23. The "Link Ops" menu.

Bring Up Card/Box

Performs the same function as clicking the left mouse button in the link icon's active region. It traverses the link to the destination card and opens it, or flashes it if it is already open.

Change Link Type

Allows you to choose a different link type for the link you select.

Change Card Title

Changes the title of the card the link points to and the titles shown in all the link icons pointing to that card. The one exception to this statement is when you have created one-way cross-file links. These links update only when you access the link icon which points to the changed card.

Change Display Mode

Selecting **Change Display Mode** brings up the "Display Mode?" menu. This menu allows you to override the display mode defaults for the individual link icon you have selected.

Display Mode?			
Title?	LinkType?	AttachBitmap?	
Yes	Yes	Yes	DONE RESET ABORT
No	No	No	
System Defaults	System Defaults	System Defaults	

Figure 8-24. The "Display Mode?" menu.

There are two levels of defaults for link icon display modes. Each card defined in the NoteCards system sets how links will be displayed in its contents. This is the first level of defaults and you have no control over them. These defaults can be set to three values, "Yes," "No" and "System Defaults." These are the values which appear in the "Display Mode?" menu shown above. If the value is set to "System Defaults," NoteCards consults the System Parameters to determine whether or not to display that particular attribute. See Chapter 13, System Parameters for how to set link default display modes.

With all the values set to "No," the link appears as a small rectangular box.

Figure 8-25. A link icon with all display mode values set to "No."

With all the values set to "yes," the links have the following appearance.

Figure 8-26. A link icon with all display mode values set to "Yes."

The link type is shown in angled brackets and the card title is to the right of the link type. The card-type bitmap is the square piece on the left of the link icon and varies in design depending on the card type.

Represents Search cards.
The image is a stylized eye.

Represents LinkIndex cards.
The image is a stylized list of link icons.

Represents Document cards.
The image is a stylized linear list of note cards.

Represents cards for which the type is unknown occurs with cross-file links.

System Parameters for Links

There are nine system parameters to enable you to customize the appearance of links. They are **Link Icon Font**, **Link Icon Border Width**, **Link Icon Multi Line Mode**, **Cross File Link Mode**, **Link Icon Max Width in Pixels**, **Link Icon Show Title Default**, **Link Icon Attach Bitmap Default**, **Link Icon Show Link Type Default**, and **Use Deleted Link Icon Indicators**. For a complete discussion of these parameters, see Chapter 13, System Parameters.

Cross-File Links

The NoteCards system allows you to have links from one notefile that point to cards in another notefile. These types of links are known as cross-file links. See also Chapter 13, System Parameters for how to set the cross-file link mode.

Appearance

Cross-file links are indicated by an arrow bitmap on the right-hand side of the link icon.

Figure 8-27. A cross-file link indicated by an arrow bitmap on the right-hand side of the link icon.

It is also possible to cross-file cards. This is to say that you can file a card from one notefile in the FileBox of another notefile. Note that this is only possible after you have first filed it in its origin notefile. This is, in effect, just another way of creating a cross-file link. Cards are always physically filed in their origin notefiles.

When a cross-file link is displayed, and the notefile the link points to is closed, then the link can have the following form.

Figure 8-28. A cross-file link to a closed notefile. The question-mark bitmap indicates that the card cannot be accessed to determine its card type.

The card-type bitmap on the left of the link icon is a question mark because the card type is stored on the card and this link has no access to the card because the notefile is closed. As a result, the

link cannot display the appropriate card-type link. When you click on the cross-file link the system will ask you if you want to open the corresponding notefile. At this point, if you redisplay the card, by selecting the **Redisplay** option on the window menu, the link will be shown with its appropriate card-type bitmap.

Missing Notefiles

If you rename or delete a notefile which has cross-file links pointing to it, the system will try to open the notefile by its original name. When it cannot find the notefile under its original name, it will ask you which notefile to look in. You cannot give a name with wild card characters like "*" or "?." You must give actual notefile names. The system will continue to prompt you for new notefiles to search until you give up.

[This page intentionally left blank]

9. CARDS AND BANNERS

Cards are the basic units of information in the NoteCards system. This information can be a mixture of text and graphics. The cards can contain as much or as little information as you deem necessary. You can link each card to any number of other cards to create an information network which you can randomly browse or systematically read. You access cards through the notefile Banner.

This chapter explains:

- What you can do from the notefile Banner.

- How to access old cards.

- How to create new cards.

- What card types there are.

- What the card menu does.

The Notefile Banner

Each notefile which you have opened is represented on the screen by a notefile Banner. The notefile name appears across the top of the Banner in the region called the title bar. The semi-colon after the name is followed by the notefile version number.

Figure 9-1. The Banner for the Solar System notefile.

The Banner has three active regions, the title bar, the **New Cards** option and the **Special Cards** option.

The Banner Title Bar

From the title bar you can access three notefile menus.

Notefile Ops Menus

There are two "Notefile Ops" Menus. One displays only those options which work on open notefiles. The other displays only those options which work on closed notefiles.

Holding the left mouse button down in the Banner title bar when the notefile is *closed* brings up the following "Notefile Ops" menu. Note that the **New Cards** and **Special Cards** options are grayed over when the notefile is closed.

Figure 9-2. "Notefile Ops" menu from the Banner of a closed notefile.

Holding the left mouse button down in the Banner title bar when the notefile is *open* brings up the following "Notefile Ops" menu.

Figure 9-3. "Notefile Ops" menu from the Banner of an open notefile.

These two sets of options are a subset of those found on the "Notefile Ops" menu accessed by holding the left mouse button down on the MenuBox Icon's **Notefile** option.

Figure 9-4. The MenuBox Icon's "Notefile Ops" menu.

All of these commands are discussed in Chapter 12, The MenuBox Icon.

Middle-Mouse-Button Title-Bar Menu

Holding the middle mouse button down in a notefile Banner's title bar brings up the following menu.

Figure 9-5. Middle-button menu in notefile Banner title bar.

Full File Name

Selecting the **Full File Name** option will bring up a window containing the full name of a file, including its directory path.

Figure 9-6. The full file name of the Solar System notefile.

Press any mouse button to continue. The window will close and you will be allowed to continue your work. This option is useful when you have two files with the same name, but different directories, on the screen and you need to be able to differentiate their Banners.

File Capacity

When the notefile is open, selecting the **File Capacity** option will attach a window to the top of the notefile Banner which will display the percentage and ratio of used cards in the notefile.

Figure 9-7. Notefile Banner with file capacity window open.

To close the file capacity window, hold the right button down in the file capacity window, not in the Banner title bar, and select the **Close** option off the window menu.

When 90% of the cards in a notefile have been used, the file capacity window will automatically open and warn you that the file is almost full and that it needs to be compacted. You must close a notefile before you can compact it. See Chapter 12, The MenuBox Icon, for instructions on compacting notefiles.

Figure 9-8. Notefile Banner with file capacity window warning to compact notefile.

If you try to create a new card when the notefile is 100% full, the system will display a message that the notefile is full and you will be asked if it is ok to checkpoint the notefile and make room for some number of new cards.

Figure 9-9. "Expand notefile index?" menu and prompt window.

If you select **Yes**, the system will save all the open cards, close the notefile, expand the notefile index by the amount you indicated, reopen the notefile, and create the card you requested. Note that the notefile is not compacted in this operation.

Cancel stops the operation. **Change Num** allows you to change the number of cards to expand the notefile by, after which you can choose the **Yes** option from the "Expand notefile index?" menu and proceed to save and expand the notefile.

Special Cards

Old notecards are accessed from the notefile Banner under the option **Special Cards**, (see Figure 9-1). Clicking the left mouse button in the **Special Cards** option brings up the "Table of Contents" FileBox card for the named notefile.

Figure 9-10. "Table of Contents" FileBox card for the "Solar System" notefile.

Holding down the middle mouse button in the **Special Cards** option brings up the "Special Cards" menu.

Figure 9-11. The "Special Cards" menu.

This menu allows you to access all of the top-level FileBoxes. Ultimately, all accessible cards are linked to one of these three FileBoxes.

Table of Contents FileBox

This is the top-level FileBox of each notefile. It is intended for storage of links to FileBoxes and other cards at the highest level of the information hierarchy.

To Be Filed FileBox

A temporary FileBox for cards that are not filed in any FileBoxes. If you close a card without specifying its FileBox, or if you close a notefile, without having specified the FileBoxes for every card, the system will place the cards without assigned FileBoxes in the "To Be Filed" FileBox.

If you later designate a FileBox for an unfiled card using the **Designate FileBoxes** or **Title/FileBoxes** commands from the card menu, this does not remove the card from the "To Be Filed" FileBox. To remove a card from the "To Be Filed" FileBox either delete its link or use the **Unfile From FileBoxes** suboption on the card menu of the newly filed card.

Figure 9-12. A card menu showing the **Unfile from FileBoxes** suboption selected.

As a general rule, it is a good idea to check the "To Be Filed" FileBox at the end of every session to verify that you have properly filed every card where you want it. You might also keep a copy of this FileBox on the screen so that you can tell at a glance if any cards have been filed there.

Orphans FileBox

A FileBox for cards whose last link from another FileBox has been removed.

Removing a link icon from the "Orphans" FileBox severs the card from the FileBox hierarchy but does not delete it from the notefile. Cards in this state are lost cards. The only means of retrieving a lost card is with a search card.

As a general rule, it is a good idea to check the "Orphans" FileBox at the end of every session to verify that you have properly filed every card where you want it. You might also keep a copy of this FileBox on the screen so that you can tell at a glance if any cards have been filed there.

New Cards

New cards are created from the notefile Banner under the option **NewCards**, (see Figure 9-1).

Clicking the left mouse button on the **NewCards** option immediately creates a specific type of card. The type of card created is determined by the value of the **Default Card Type** System Parameter. See Chapter 12, The MenuBox Icon, which describes how to set this parameter. The default value is "Text."

Pressing the middle mouse button over the **NewCards** option brings up the "Card Types" menu.

Figure 9-13. The "Card Types" menu.

Selecting one of these options creates a card of that type.

Figure 9-14 graphically represents the notecard types and their range of use. Text, Graph, and Sketch cards help you to collect and express your ideas. FileBoxes allow you to express the relationships between your ideas and organize them into coherent structures. Browser cards provide a broad range of functionality, and are a means of representing as well as retrieving information. LinkIndex cards build sorted lists of cards. Search cards perform searches on card titles. And, Document cards create a linear document from your linked cards.

Figure 9-14. Card types and their range of use.

User Cards and System Cards

Cards can be broadly divided into two categories. User cards are those cards for which you create the contents. System cards are cards where the contents are built by the system for you. Chapter 10 discusses user cards; Chapter 11, system cards.

In Figure 9-13, the top four card types (Text, FileBox, Sketch, and Graph) are user notecards. The bottom four card types (Browser, Search, LinkIndex, and Document) are system notecards.

Text-, Sketch-, and Graph-Based Cards

All cards are based on one of three editors, the text editor TEdit, the Sketch editor Sketch, or the Graph editor Grapher.

Text, FileBox, Search, LinkIndex, and Document cards are all based on the text editor TEdit. Hence they all behave in essentially the same way and are referred to as text-based cards.

The Sketch card is the only card based on the Sketch editor. This card is referred to as a sketch-based card.

Graph and Browser cards are both based on the graph editor Grapher. These cards behave in basically the same way and are referred to as graph-based cards.

The Card Menu

All cards have a left-button title-bar menu called the card menu. This menu is the same for all cards except FileBox cards. Each card also has a middle-button title-bar menu which is frequently card-specific. These menus are discussed under their respective card types in Chapter 10, User Cards, and Chapter 11, System Cards.

The Standard Card Menu

Figure 9-15. The note card menu

This menu is found on all cards except the FileBox card which has a slightly different version.

Edit Property List

The property list editor allows you to associate property-value pairs with cards. For example, you might want to attach a Certainty Value property (and value) to every card. The value of this property

would indicate the degree to which you believe the information contained on the card is true.

You bring up the "Edit Property List" window by selecting the **Edit property List** option off the card menu.

Figure 9-16. "Edit Property List Window"

You can only change the property list of a card interactively, from the menu shown in Figure 9-17. Holding down the left or middle mouse button in the "Edit Property List" window's title bar brings up the following edit menu for property lists. Select commands from this menu before releasing the button.

Figure 9-17. Menu from "Edit Property List" window title bar.

Add New Property

Adds user-defined properties to the property list of this card. Type in the property name and the value when prompted. Next, select one of the properties already in the list. The new property will be inserted in front of the selected property. Properties are displayed in bold type and values are displayed between brackets in regular type. You can abort the add process by hitting the Stop key.

In Figure 9-16, **Source** and **Certainty Factor** are the properties and "John Smith" and ".9" are the values. You can edit the values directly with the mouse and keyboard as you would any text string.

Delete Selected Property

Deletes a property from the property list of this card. After choosing this option click on the property to be deleted with the left mouse button. Properties are displayed in bold type. Once you have started the delete process there is no way to abort it, but you can hit the Undo key to undo the deletion.

Quit w/o Saving Changes

Closes the display without saving any of the current changes made using **Add New Property** or **Delete Selected Property**.

Quit - Saving Changes

Closes the display saving all current changes made using **Add New Property** or **Delete Selected Property**.

Show Links

Displays, in the "List of Links" window above the card, a list of all links to and from other cards. Links are represented by link icons. Selecting an icon in this window with the left mouse button displays the card referenced by that link icon.

To close this display, place the cursor in the title bar of the "List of Links" window, depress the left button, and select **Quit** from the single item menu.

For more on the **Show Links** option, see the section "Viewing Local and Global Links" in Chapter 8, Links.

Show Info

Brings up the "Card Attributes" window. This window displays the card's type, the dates each of the card parts was last changed, and a list of dates chronicling when the card was updated.

Card attributes	
Type	Text
ItemDate	" 5-Jan-89 18:00:19"
TitleDate	" 4-Jan-89 09:55:45"
LinksDate	" 6-Jan-89 18:04:26"
PropsDate	" 5-Jan-89 18:00:20"
Updates	((MOUNTFORD,ENVOS " 5-

Figure 9-18. The "Card attributes" window.

The **Show Info** option also automatically brings up the notefile indicator on the card.

Indicate NoteFile

This pull-across subitem on the **Show Info** option brings up the notefile indicator without bringing up the "Card Attributes" window.

Figure 9-19. The **Indicate Notefile** submenu off **Show Info**.

Solar System;1 {DSK}/usr/users/kmount/NC	
Table of Contents	
FILE BOXES	
	Sun
	Planets
NOTE CARDS	

Figure 9-20 A card with its notefile indicator window open on the top of the card.

To close the "Card Attributes" window, just choose the **Close** item on the standard window title bar menu of the "Card Attributes" window. Closing the "Card Attributes" window does not close the notefile indicator window, which must be closed separately using its standard window title bar menu.

Designate FileBoxes

Pops up a prompt window above the card asking the user to file the card in one or more FileBox cards.

Figure 9-21. The "Selecting FileBox(es)" prompt window.

Associated with the prompt window is a three-item menu. Select **Done** from this menu or type a carriage return after shift-selecting the FileBoxes to file the card in. Select **Cancel** to abort the filing operation. Choose **Undo** to remove the last selected FileBox from the list of new parent FileBoxes.

Figure 9-22. A card menu showing the **Unfile from FileBoxes** suboption selected.

Unfile from FileBoxes

Unfiles the card from the FileBoxes you select. You unfile the card by shift-selecting the FileBox card IDs from their title bars. The system tells you when you have made an invalid selection. The prompt window menu options are the same as those for **Designate FileBoxes**, shown in Figure 9-21.

Assign Title

Assign Title allows you to assign a title to a card or edit an existing title.

You can reposition the cursor in the edit string with the mouse. You can also use the mouse to delete pieces of the string by using the left mouse button to position the cursor at the beginning of the piece you want to delete and sweeping out the portion to delete while holding down the right mouse button. When you release the right mouse button the selected text will be deleted.

To cancel the delete operation, still holding the right mouse button down, move the mouse cursor outside the prompt window and release the right mouse button.

You can undo the delete operation by hitting the Undo key.

Title/FileBoxes

Selecting **Title/FileBoxes** is identical to selecting **Assign Title** and **Designate FileBoxes** in sequence.

Insert Link

Insert Link inserts a user-specified link to another card inside the body of the current card. The link is represented by a link icon.

Before execution of this command, select the point, in the body of the card, where you want the link icon to appear.

When you select this menu option, a menu pops up displaying a list of link types currently available in the notefile. Link types are notefile specific. Specify the type of link by selecting one from this list or select **--New Link Type--** to create a new type. This new type of link is added to the notefile and becomes a choice in its list of link types. It is not possible to assign a system-reserved type of link to a user-specified link. Select ****CANCEL**** from the menu to abort the **Insert Link** command or just click outside the menu.

After a type has been designated, a prompt window and menu pops up above the card asking the user to choose the destination card for the link. The user has the option of selecting an existing card or of creating a new card as the destination card by selecting **New Card** from the menu with the left mouse button. If this option is chosen, a menu of card types pops up from which the user selects the desired type of card. Again, selecting **Cancel** from the "Selecting Note Card" menu aborts this command.

At this point, the link icon will be inserted at the flashing caret in the body of the source card.

For more on **Insert Link** and its submenu options **Insert Links**, **Add Global Link**, and **Add Global Links**, see Chapter 8, Links.

Close and Save

Figure 9-23. The submenu off the **Close and Save** option

Close and Save

Saves the card in the notefile before closing the card. If the **Force Titles** and **Force Filing** system parameters are set to "Yes," NoteCards will request that you provide a title and a FileBox for the card before closing it. If you do not wish to provide this information,

simply type a carriage return to both requests. In this case, the card will be titled "Untitled," and be filed in the "To Be Filed" FileBox.

Close w/o Saving

Closes the card without saving it, in the notefile. Any changes you have made to the card since the last save are lost. This option is useful if the card contents are mistakenly lost or scrambled while you are editing. This command may ask for confirmation. Type a carriage return or click on the **Yes** option to confirm. Type "n" or "N" and a carriage return or click on the **No** option to cancel.

Save w/o Closing

Saves, to the notefile, all changes you have made to the card without closing the card. Saving updates the card in the notefile but does not update the notefile index. If there is a system crash you will have to perform an **Inspect & Repair** operation to recover the card contents.

Delete Card

Permanently deletes the card from the notefile and all its links to and from other cards. Because this deletion is irreversible, the user is asked to confirm before the delete command is executed. Type a carriage return or click on the **Yes** option to confirm. Type "n" or "N" and a carriage return or click on the **No** option to cancel. Note that a deleted card cannot be retrieved with a search card as a lost card can.

The FileBox Card Menu

The FileBox card menu differs in only two items, **Add Global Link**, and **Put Cards Here**.

Add Global Link

The **Add Global Link** and **Add Global Links** options are the same global link options found on the submenu of the **Insert Link** option. **Insert Link** appears in this position on this menu for all other cards. These two options are discussed extensively in Chapter 8, Links.

Figure 9-24. The FileBox card menu with the **Add Global Link** submenu.

Put Cards Here

The **Put Cards Here** menu option is a specialization of the **Insert Links** option for FileBox cards. It allows you to file more than one card in a FileBox in a single operation. Selecting this option brings up the "Selecting cards to file" prompt window into which you can shift select the card IDs from the title bars of all the cards you want to file in this FileBox card.

Figure 9-25. The "Selecting cards to file" prompt window.

[This page intentionally left blank]

Cards can be broadly divided into two categories. User cards are those cards for which you create the contents. System cards are cards where the contents are built by the system for you. This chapter discusses user cards.

This chapter explains :

How to use Text cards.

How to use FileBox cards.

How to use Sketch cards.

How to use Graph cards and the graph editor.

How to use the bit map editor.

Text Cards

The Text card is based on TEdit, a versatile editor and text formatter. This entire document was produced using TEdit. For a detailed discussion of how this editor works, see *A User's Guide to TEdit*. Text cards allow you to include sketches, graphs, and bit maps. To learn how to manipulate sketches, see *A User's Guide to Sketch*. For graphs and bit maps see the sections below on the Graph card and the bit map editor.

The Text-Card Menu

The text-card menu is the same as the TEdit menu with one additional option separated from the others by a dashed line.

Figure 10-1. The text-card menu.

You use the **Restart Editor** command when the contents of the Text card are incorrectly displayed on the screen.

For all the other menu items, see *A User's Guide to TEdit*.

FileBox Cards

The FileBox card, like the Text card, is based on TEdit. For a detailed discussion of how this editor works, see *A User's Guide to TEdit*. Text-based cards allow you to include sketches, graphs, and bit maps. To learn how to manipulate sketches, see *A User's Guide to Sketch*. For graphs and bit maps see the sections below on the Graph card and the bit map editor.

A FileBox is a card that contains links to other cards including other FileBox cards. All cards, including FileBox cards, can be filed in one or more FileBoxes. Every card, including FileBox cards, except the top level Special FileBox Cards, is contained in at least one other FileBox. Whereas other cards may be linked together to form an arbitrary network, the set of FileBoxes forms a strict hierarchy. This is to say that no child FileBox is allowed to have its parent FileBox as a child. In short, no circular linkages.

FileBoxes are meant to hold all cards relating to some given topic. A FileBox typically contains both links to subFileBoxes, which contain any cards relevant to the subtopics of the main topic, and links to other card types, which contain information relevant to the main topic. For example, the screen image below shows a FileBox containing both FileBoxes and other note cards.

Figure 10-2. The Solar System FileBox containing subFileBoxes for its subtopics and a Sketch card dealing with the main topic, the Solar System.

The FileBox structure provides a way of keeping track of sets of cards on a common topic. In contrast, the links between individual cards allow you to represent the interconnections between various ideas or pieces of information, independent of any categorization into topic areas.

The markers FILE BOXES and NOTE CARDS help differentiate what kinds of cards are filed in the FileBox. In addition, since FileBoxes are text-based cards, anything you can do with a text card, you can also do with a FileBox. This means that you can, for example, insert your own labels or short lines of commentary to break up the links into subgroups.

Suggested FileBoxes and Note Cards

You may find it helpful to create the following types of general FileBoxes

Bibliography

A FileBox for the collection of sources used in the notefile.

Index

A FileBox listing keywords from the notefile, may be helpful when using Search cards.

Read Me

A note card in the top level FileBox giving global information about the notefile for first time browsers.

Active Cards

A FileBox kept at the top level of the FileBox hierarchy containing FileBoxes and note cards that represent work in progress and are thus frequently accessed. A Sketch card containing links to these FileBoxes and note cards is another method of organizing active cards, using spatial cues as a way of representing structure.

The FileBox-Card Menu

This menu is the same as the Text-card menu. See the section immediately above on Text cards as well as *A User's Guide to TEdit*.

System Parameters Affecting FileBoxes

FileBoxes have two system parameters associated with them, **Markers In FileBoxes** and **Alphabetized FileBox Children**. For a complete discussion of these parameters see Chapter 13, System Parameters.

Sketch Cards

The Sketch card is based on Sketch, a sophisticated graphics package. For a detailed discussion of how Sketch works, see *A User's Guide to Sketch*. Sketch cards allow you to include graphs, and bit maps. To learn how to manipulate graphs and bit maps see the sections below on the Graph card and the bit map editor.

The Sketch-Card Menu

This menu is the same as the Sketch editor menu. For a detailed discussion of this menu's functionality, see *A User's Guide to Sketch*.

Figure 10-3. The Sketch card menu.

System Parameters Affecting Sketch Cards

Sketch cards have one system parameter associated with them, **Attach Sketch Menu**. For a complete discussion of this parameter see Chapter 13, System Parameters.

Graph Cards

The Graph card is designed to allow you to construct a layout of user-defined words or phrases, called nodes, which may be connected together with lines to indicate some structure. Each node may be easily moved about the card without losing its connections.

The Graph-Card Menu

The Graph card, like the Browser card, is based on the graph editor Grapher. To make the graph-card menu and terminology more consistent with the browser-card menu and terminology the

Graph card presents a slightly different menu to you than Grapher does. However, since the functionalities are virtually identical, both the graph-card and Grapher menus are discussed in parallel below. The graph-card menu-option titles are left justified while the Grapher menu-option titles are right justified.

You display the graph-card menu by depressing the right mouse button in the body of the card. Select the desired command before releasing the button.

Figure 10-4. The graph-card menu.

The Grapher Menu

You will probably encounter the Grapher menu only if you save your document cards to TEdit files and edit a graph-card graph from within the TEdit document. You can safely skip over this section and still understand the Graph card.

To edit a graph from a TEdit document you must first select the **Edit graph** option from the one-item menu which appears when you hold any mouse button down in the graph region.

Figure 10-5. The "Edit graph" menu.

When you select this option, Grapher opens a window containing the graph. Hold the middle mouse button down in this window to make the menu shown in Figure 10-6 appear. Use the left mouse button to move nodes. When you are done editing the graph, select the **STOP** option.

While you are editing a graph, Grapher captures the type-in process and does not allow you to do anything other than mouse operations. To free the type-in process, select the **STOP** option.

There is no simple way to abort out of the Grapher editor and throw away all the changes you have made to the graph. For this reason, if you are going to edit the graph extensively, we recommend that you use shift-select to copy the original graph in place and call the Grapher editor on the copy. In a worst case scenario, you can try hitting the STOP key or typing CONTROL-E.

Figure 10-6. The Grapher menu.

Prompts for information or confirmation are given in the card prompt window for Graph cards and appear in the system prompt window for Grapher. General information is printed to the system prompt window for both Graph cards and Grapher.

The Graph-Card and Grapher Menu Options

Move Node

Move Node

Moves a node and connections to a new position. After selecting this option, point to the node you want to move, press and hold the left mouse button, move the node to its new position, and release the mouse button.

Move Node has three options on a submenu. These same three options appear on the Grapher **Move Node** submenu.

Figure 10-7. The **Move Node** submenu.

Move Single Node

Functions exactly as **Move Node** does.

Move Node & SubTree

Moves a selected node and all subnodes which it is connected to. This operation does not move any super nodes of the selected node. That is, nodes which are connected to the selected node as opposed to nodes which the selected node is connected to.

Figure 10-8. A node and subtree selected to be moved.

Figure 10-8 shows what happens, when you select **Move Node & SubTree** and then hold the left mouse button down on node B. Nodes B, C, and D are selected to be moved, but not node A. Grapher keeps track of the nodes where each connection starts and ends, and in this case the connections run from A to B to C to D. So node A is not in the subtree of node B and hence is not moved. See the **Directed/Undirected** option below for more information.

Move Region

Allows you to sketch out a region of the graph which you want to move. **Move Region** does not pay attention to the graph hierarchy, it only pays attention to the area you sweep out in the Graph card.

Remove Node

Delete Node

Removes a node from the graph. Select the node to be deleted with the left mouse button. The card prompt window will prompt you for confirmation.

Connect Nodes

Add Link

Draws a connection between two nodes. Select the "from" node and then the "to" node with the left mouse button when prompted. If a second overlapping connection is made running in the opposite direction between the same two nodes, the lines representing the connections, between those two nodes, will not be visible. You can make them visible by choosing the directed display option.

Figure 10-9. A graph, with connections from A to B to C and a third connection from C to B, displayed using the **Undirected** option.

Figure 10-10. A graph, with connections from A to B to C and a third connection from C to B, displayed using the **Directed** option.

Disconnect Nodes

Delete Link

Removes a connection from between two nodes. Select the "from" node and then the "to" node with the left mouse button when prompted.

Add Label**Add Node**

Pops up a window prompting you to type in a label name followed by a carriage return. The label will appear next to the cursor within the graph card. Position the new label by moving the cursor to where you want the label to appear. Plant the label by clicking any mouse button. This operation can be cancelled by typing a carriage return before typing any other characters to the prompt window.

Change Label**Change Label**

Allows you to change a label. **Change Label** first waits for you to select, with the left mouse button, the label you want to change. It then pops open a window prompting you to type in a new label name followed by a carriage return. The new label immediately replaces the old label, preserving font, position, and connections. You can cancel this operation by clicking outside a node, or by typing a carriage return before typing any other characters to the prompt window.

Smaller Label**label smaller**

Decreases the font size of the selected node. Repeat this command as many times as necessary to achieve the font size you want.

Larger Label**label larger**

Increases the font size of the selected node. Repeat this command as many times as necessary to achieve the font size you want.

Toggle Shade**<-> Shade**

Inverts the shade around the selected node. For example, a black label on a white background becomes a white label on a black rectangular background. Select the node to be inverted with the left mouse button. To change the shade back, re-apply this option.

Toggle Border**<-> Border**

Draws a rectangular border around the selected node. Select the node to have a border drawn around it with the left mouse button. To remove a border, re-apply this option.

Directed/Undirected**<-> Directed**

A graph is stored as a directed lattice. Connections always run from one node to some other node.

The **Directed** option makes the flow of the connections explicit in the presentation of the graph. When you select the **Directed** option, connections prefer to run from the left side of the parent node to the right side of the child node when you have **Sides** selected. When you have the **Centers** option selected, connections prefer to run from the bottom center of the parent node to the top center of the child node.

Figure 10-11. A **Directed** graph which explicitly shows the flow of connections from A to B to C to D, with the **Sides** option selected.

Figure 10-12. A **Directed** graph which explicitly shows the flow of connections from A to B to C to D, with the **Centers** option selected.

The **Undirected** option draws the graph without regard to the flow of connections. The lines are drawn starting and ending on the sides of the nodes closest to each other.

Figure 10-13. An **Undirected** version of Figure 10-11.

Figure 10-14. An **Undirected** version of Figure 10-12.

Sides/Centers

<-> Sides

The sides mode predisposes the graph editor to make the left and right sides of the nodes the connection points for lines.

Figure 10-15. A graph drawn favoring sides.

The centers mode predisposes the graph editor to make the top and bottom centers of the nodes the connection points for lines.

Figure 10-16. A graph drawn favoring centers.

FIX MENU

Attaches the graph-card menu to the right side of the Graph card.

STOP

Only appears on the Grapher menu, not on the Graph card menu.
STOP exits the Grapher editor saving all your changes.

The Bit Map Editor

The bit map editor allows you to manipulate bit maps that have been inserted in Text or Sketch cards as well as TEdit and Sketch files. It is automatically invoked when the bit map area is selected.

Inserting Bit Maps into Cards

The method for inserting bit maps into text-based cards differs slightly from that for inserting them into sketch-based cards. Each procedure is discussed below.

You cannot insert bit maps into graph-based cards.

Text-based Cards

Inserting a bit map into a text-based card involves several steps. First, position the caret cursor where you want the bit map to appear in the destination card, or TEdit window, by clicking at that position with the left mouse button. Second, depressing the Copy key or either of the Shift keys, hold the right mouse button down somewhere in the background and select the **Snap** option from the single item menu which will appear.

Figure 10-17. The single-item "Snap" menu.

At this point the mouse cursor changes to look like this,  This is the prompt asking you to sweep out an area of the screen to be made into a bit map. Third, press and hold the left mouse button while you sweep out a region of the screen. When you release the left mouse button, the bit map will be transferred to the designated card or edit window.

If you need to adjust the area you are sweeping out, do the following. Hold down the right mouse button, in addition to the left mouse button, to bring up the forceps prompt,  This prompt

allows you to change corners so that you can adjust the size of your bit map in all directions.

Sketch-based Cards

The procedure for inserting bit maps into sketch-based cards differs in only one respect from that for text-based cards. The sketch-based card must be the active card, which is to say you must click in it so that it has the type-in process to mark it as the destination for the bit map. However, when you do this, you are not indicating the insertion point for the bit map. In sketch-based cards, positioning the bit map is done last. After you have swept out a region of the screen to include as a bit map in the sketch, move the mouse cursor back into the Sketch card. When you enter the Sketch card, the snapped bit map will appear attached to your mouse cursor, and you can position it by clicking the left mouse button.

Bit Map Operations

Moving the mouse cursor into a bit map and holding down the left or middle mouse button brings up the "Operations on bitmaps" menu.

Figure 10-18. The "Operations on bitmaps" menu.

Change Scale

Changes the scale or size of the bit map. Giving a scale of 2 doubles the size of the bit map; a scale of .5 halves the size of the bit map. You achieve the best results shrinking or enlarging a bit map when you change the scale by evenly divisible amounts. For example, 4, 2, 1, .5, or .25.

Hand Edit

Invokes the bit map editor on the bit map. The bit map editor is described in detail below.

10. USER CARDS

Trim

Trims the white columns and rows from all four edges of the bitmap. This is a very useful operation to remove any extraneous white space from around the bit map. Position the image that you are taking a snap of on a white background to take the greatest advantage of this option.

Reflect Left-to-right

Flips the bitmap about its vertical centerline.

Reflect Top-to-bottom

Flips the bitmap about its horizontal centerline.

Reflect Diagonally

Flips the bitmap about its X=Y diagonal so that the resulting bit map is reversed and lying on its right side. The same effect can be achieved by performing a **Reflect Left-to-Right** followed by a **Rotate Right**.

Rotate Left

Rotates the bit map by 90 degrees in a counterclockwise direction so that the resulting bit map is lying on its left side.

Rotate Right

Rotates the bit map by 90 degrees in a clockwise direction so that the resulting bit map is lying on its right side.

Expand on Right

Adds white space to the right of the bit map. You specify the width of the white space in pixels using the number pad. Select **ok** when you are done.

Figure 10-19. The number pad.

The number pad is used much like a simple calculator to enter numbers. The **ok** button returns the number to the system. **bs** deletes the last digit you entered. **clr** resets the input to "0." You abort the operation by setting the input value to "0" and selecting **ok**.

You enter a negative number by first entering the digits and then selecting the minus sign. Entering a negative number removes that many pixels from the right side of the bit map.

Expand on Left

Adds white space to the left of the bit map. You specify the width of the white space in pixels using the number pad. Select **ok** when you are done. See the **Expand on Right** option for more detail.

Expand on Bottom

Adds white space to the bottom of the bit map. You specify the width of the white space in pixels using the number pad. Select **ok** when you are done. See the **Expand on Right** option for more detail.

Expand on Top

Adds white space to the top of the bit map. You specify the width of the white space in pixels using the number pad. Select **ok** when you are done. See the **Expand on Right** option for more detail.

Switch Black & White

Inverts all of the pixels in the bit map; exchanges black for white and white for black.

Add Border

Adds a border to the bit map. The system prompts you for the width of the border using the number pad described above. It then prompts you for the texture of the border with the texture bit map editor.

Figure 10-20 The texture bit map editor.

The area at the top of the window shows what the texture looks like in true screen scale and the bottom area contains a four-by-four

edit array. Clicking the left mouse button in the edit grid turns a pixel on; clicking the middle button turns a pixel off. Select the **Quit** option when the texture looks the way you want it to. The texture will then appear as the border around the bit map.

To abort this operation, select **clr** followed by **ok**, on the number pad.

There is no simple way to abort this operation once you have brought up the texture bit map editor. However, you can turn all the pixels off (set them to white space) and select **Quit**. Then selecting **Trim** from the "Operations on bitmaps" menu should return the bit map to its previous condition.

The Bitmap Editor

The editing window has three active areas, a grid edit area in the lower part of the window, a display area in the upper left part, and a gray bar in the upper right.

Figure 10-21. The "Bitmap Editor" display.

In the edit area, the left button adds points and the middle button erases points. The display area shows the actual size and form of the bit map. The gray bar provides access to the "Bitmap Editor" menu.

The right mouse button brings up the normal window menu in all areas of the window.

If the bit map is too large to fit in the edit area, you can change the portion which can be edited by scrolling up and down in the left margin, and left and right in the bottom margin. Pressing the middle mouse button while in the display area brings up a menu that allows you to make a global placement of the portion of the bit map which can be edited. If you want to see more of the bit map

you are editing, you can reshape the window to make it larger, or you can use the **GridSize** command, described below, to reduce the bit size in the edit area.

Whenever you press the left or middle mouse button down with the cursor inside the display area or the gray bar, the section of the bit map that is currently in the edit area is shown in reverse video. Pressing the left button while in the gray bar puts the lower left 16 x 16 bit section of the bit map into the mouse cursor for as long as the left button is held down.

Pressing the middle button while in the grey bar or in the title bar brings up the "Bitmap Editor" menu.

Figure 10-22. The "Bitmap Editor" menu.

Holding the middle button down over a command results in an explanatory message being printed in the system prompt window.

Paint

Puts the current bit map into a window and calls the paint command on the bit map. You use the left mouse button for drawing and the right for erasing. The paint command implements drawing with various brush sizes and shapes but only on an actual sized bit map. You set brush characteristics and exit paint by pressing the right mouse button and selecting the appropriate command from the paint command menu. When you exit, you will be asked whether or not the changes you made while in Paint mode should be placed in the current bit map. **Paint** is particularly useful for erasing or filling in large regions in bit maps. See the section "The Window Menu" in Chapter 7, The User Interface for a detailed discussion of all the paint menu options.

Figure 10-23. Paint command menu.

ShowAsTile

Tesselates the current bit map in the gray bar. This is useful for determining how a bit map will look if it were made the display background. The tiled display does not automatically change as

the bit map changes. To update it, use the ShowAsTile command again.

Grid On/Off

Turns the editing grid display on or off.

GridSize

Allows you to specify the size of the editing grid. When you select this option, a number menu appears, giving you a choice of several point sizes for the grid.

Figure 10-24. The number menu.

When you select a size, the editing portion of the bit map editor is redrawn. A smaller size allows you to edit more of the bit map without scrolling, while a larger size makes it easier for you to turn individual bits on and off. The original size is chosen heuristically. It is typically about 8. Clicking outside the number menu aborts this operation.

Reset

Sets all or part of the bit map to the contents it had when you originally called the bit map editor. When you select this option, a second menu appears giving you a choice between resetting the entire bit map or just the portion that is in the edit area.

Figure 10-25. The "RESET how much?" menu.

This second menu also acts as a confirmation, since clicking outside of this menu results in no action being taken. Note that if the entire bit map appears in the edit area the menu only has the **WholeBitmap** option.

Clear

Sets all or part of the bit map to white space. As with the Reset command, a second menu gives you a choice between clearing the entire bit map or just the portion that is in the edit area.

Figure 10-26. The "CLEAR how much?" menu.

Cursor

Sets the cursor to the contents of the lower left part of the bit map. This operation next prompts you to specify the new cursor's active pixel. You do this by clicking somewhere in the lower left 16 x 16 portion of the grid. Cursors created this way are typically very short lived. This option is intended for people extending the NoteCards environment. We recommend that non-programmers do not use this option.

OK

Copies the edited bit map image into the original bit map, exits the bit map editor, and closes its edit window. The image you modify using the editor is a copy of the original bit map. Unless you exit the bit map editor via **OK**, no changes are made to the original bit map.

Abort

Exits the bit map editor without making any changes to the original bit map. Contrast with **OK**.

[This page intentionally left blank]

12. THE MENUBOX ICON

The MenuBox Icon is the main interface to NoteCards. Through this icon you access all the system NoteCards menus.

This Chapter explains:

How to create notefiles.

How to perform basic operations on notefiles.

How to recover notefiles when they are damaged.

How to perform structure operations on notefiles.

Figure 12-1. The MenuBox Icon.

Notefile Options

It is through the Notefile-Operations menu that you interact with notefiles. The word "Operations" is usually abbreviated as "Ops" and, as a result, this menu is usually referred to as the "Notefile Ops" menu.

You access the "Notefile Ops" menu by holding the left mouse button down in the **NoteFile** option of the MenuBox Icon. The menu has three regions, separated by dashed lines. The top region contains operations you can only apply to closed notefiles. The middle region contains commands you can only apply to open notefiles. The bottom item, NC FileBrowser, does not share these limitations. It provides you with a notefile interface.

Figure 12-2. The MenuBox Icon's "notefile Ops" menu.

Open

Opens an existing notefile. If you have not previously opened any files, the system prompts you to type in a file name. The file name is not case sensitive. If you provide just a file name with no path, the system looks in the connected directory for the notefile. If NoteCards does not find the file there, it asks you if you want to create the file.

The system maintains a list of all notefiles you open. Subsequently, when you select **Open**, these files will be presented to you in menu format. If the file you want to open is not on the menu, select the **--Other Notefile--** option.

There are two submenu options for Open, **Open Read/Write** and **Open Read-only**.

Figure 12-3. The **Open** submenu.

Open Read/Write

Is the same as selecting **Open** from the top-level menu.

Open Read-only

Opens the file but does not allow you to make any changes to the file. When you open a file read-only, the file name appears in its Banner with a read-only prefix (RO:).

Figure 12-4. A notefile opened read-only with its Banner showing the read-only prefix "RO:"

If the notefile is damaged the following menu appears.

Figure 12-5. The menu which appears when you open a damaged notefile.

Cancel causes the open notefile operation to be aborted.

Truncate File deletes everything after the checkpoint pointer.

Inspect & Repair causes the notefile inspector to be called on your notefile. This is an easy, but slow, way to incorporate these post-checkpoint changes into the notefile. For more details, see the

Inspect & Repair and Appendix A, Notefile Concepts and Appendix B, The Notefile Inspector.

Compact

Compresses a notefile by deleting old information. NoteCards never actually overwrites any information in the data area of a notefile. When cards are revised, old information remains in the notefile. Compacting creates a new, compressed version of the notefile by copying into the new version only the latest information from the old version. To understand the structure of notefiles and compacting, see Appendix A, Notefile Concepts.

Compacting can take 5 to 20 minutes, depending on the size of the notefile.

There are two submenu options off **Compact**, **Compact To New File** and **Compact in Place**.

Figure 12-6. The **Compact** submenu.

Compact To New File

Is the same as selecting **Compact** from the main menu. NoteCards prompts you to type in a new file name. The default is the same file name with a higher version number.

Figure 12-7. NoteCards prompting for the output file name for the compact operation.

Figure 12-8. The notefile Banner after compacting to the same file name. The old version is "Solar System;1." The new version is "Solar System;2."

Compact In Place

Does not build a new copy of your notefile, rather the contents of the old file are rearranged in such a way that old versions of cards are written over. This is useful when your notefile is large and there isn't room to store another version. However, be aware that when you use this option you are not able to back up cards to previous versions by using the **Inspect & Repair** utility. We recommend

compacting to a target file and saving the uncompact version until you are sure that the older versions of cards are not needed.

Inspect & Repair

Reads the data area of your notefile, looking for good card parts, including outdated and deleted versions. It then allows you to delete or back up card parts to earlier versions through its menu interface. Only when the notefile is considered healthy are you allowed to perform the link rebuilding.

Inspect & Repair has two submenu options, **From Links** and **From Contents**.

Figure 12-9. The **Inspect & Repair** submenu.

From Links

Rebuilds the notefile index using only the links part of the notefile.

From Contents

Rebuilds the notefile index using the links part of the notefile as well as the links stored in the bodies of individual note cards. **From Contents** takes longer to rebuild a notefile index.

For a detailed explanation of the **Inspect & Repair** utility, see Appendix B, The Notefile Inspector.

Copy

Allows you to copy a notefile.

Prompts you for a new name and path for the notefile to be copied and copies it. This is the same as doing a file copy.

Rename

Allows you to rename a notefile.

Prompts you for a new name and path for the notefile to be renamed and renames it. This is the same as executing a file rename.

Delete

Deletes a notefile.

NoteCards asks you to confirm the deletion by typing a carriage return for "No" or a **Y** and a carriage return for "Yes." If your response is "Yes," a second confirmation is required a second time to insure against unintentional deletion.

Create

Creates a new empty notefile. When you use **Create**, it is possible to assign an already existing name to the new notefile, thereby creating more than one version of the notefile.

Create has two submenu options, **Create without Open** and **Create and Open**.

Figure 12-10. The **Create** submenu.

Create without Open

Is the default action. It prompts you for a new notefile name, creates a new notefile, and place the new notefile's Banner on the screen. If you supply only a name and no path, the notefile is created in your connected directory.

Create and Open

Does all of the above, and opens the new notefile.

Checkpoint

Saves the contents of any active cards to the notefile without closing the cards or the notefile. The index array is written out to the file and the checkpoint pointer is reset to the end of the file.

A notefile consists of two parts, an index area and a data area. For each card, the index contains four pointers into the data area. There are pointers for the notecard's contents, title, property list, and list of links. When, for example, you change a card's title, NoteCards writes the new title at the end of the file, and the card's title pointer is changed to point to the new title. To increase access speed, index modifications are written in memory and are not written to the file till checkpoint, or close time. There is a checkpoint pointer that is updated to point to the end of file at checkpoint or close. New data, such as a new title, is still written to the file, but always at the end of the file. Thus if a crash occurs, due to a power failure or some other mishap, and later you reopen the notefile, NoteCards can notice the extra data beyond the checkpoint pointer. Each time a notefile is opened, the checkpoint pointer is compared with the end of file pointer. If they don't agree, then a message that something is wrong is printed out. At this point, you must choose one of three options from a menu: **Cancel**, **Truncate File**, or **Inspect & Repair**.

Figure 12-11. The menu which appears when you open a damaged notefile.

Cancel causes the open notefile operation to be aborted.

Truncate File deletes everything after the checkpoint pointer.

Inspect & Repair causes the notefile inspector to be called on your notefile. This is an easy, but slow, way to incorporate these post-checkpoint changes into the notefile. For more details, see Appendix A, Notefile Concepts and Appendix B, The Notefile Inspector.

Figure 12-12. The **Checkpoint** submenu.

Checkpoint and **Checkpoint Notefile** pop up a menu of known notefiles which you can checkpoint.

NoteFiles	
Solar System;2	{dsk}/usr/users/kmount/nc/nf/solar system,notefile;2
o Solar System;4	{dsk}/usr/users/kmount/nc/nf/solar system,notefile;4
o demo;1	{dsk}/usr/users/kmount/nc/nf/demo,notefile;1
test;1	{dsk}/usr/users/kmount/nc/nf/test,notefile;1

Figure 12-13. A menu of the list on known notefiles.

The grayed over notefiles are closed and cannot be checkpointed. Selecting one of the open notefiles causes that notefile to be checkpointed.

Checkpoint All checkpoints all open notefiles.

Figure 12-14. The card menu with the **Close w/o Saving** menu option selected.

In contrast to **Checkpoint**, when you choose **Close and Save** or **Save w/o Closing** from the card menu, the card's contents are written to the notefile but the notefile index is not written to the notefile. If you are anticipating a crash, you should checkpoint you notefile frequently.

Close

Allows you to close a notefile.

Figure 12-15. The **Close** submenu.

Close and Close Notefile

Pop up a menu of known notefiles like that shown in Figure 12-13. Selecting one of these notefiles closes that notefile. The grayed over notefiles are already closed. Selecting one of these has no effect.

Close w/o confirm

Closes a notefile without asking you about open cards on the screen. Open cards are closed and saved to either their designated FileBox or the "To Be Filed" FileBox.

Close All

Closes all open notefiles.

Close All w/o confirm

Closes all open notefiles without asking you about open cards on the screen. Open cards are closed and saved to either their designated FileBox or the "To Be Filed" FileBox.

Abort

Truncates and closes a notefile.

If you discover that you have made changes to a notefile that you don't want to keep, choose this option to truncate your file. This should only be done if you feel that the post-checkpoint work is not worth saving.

Figure 12-16. The **Abort** submenu.

Abort and Abort Notefile

Pop up a menu of known notefiles like that shown in Figure 12-13. Selecting one of these notefiles aborts that notefile. The grayed over notefiles are already closed. Selecting one of these has no effect.

Abort All

Aborts all open notefiles.

NC FileBrowser

Opens up a FileBrowser specialized for NoteCards.

Figure 12-17. The NC FileBrowser.

The commands: **Open**, **Checkpoint**, **Close**, **Abort**, **Compact**, and **Inspect & Repair** can be looked up in this chapter.

The commands: **Copy**, **Rename**, **Delete**, **Undelete**, **Recompute**, **Sort**, and **Expunge** should be looked up in Chapter 14, The FileBrowser.

Card Options

The Card options allow you to perform a **Close**, **Delete**, **Copy**, or **Move**, on a series of cards or a card structure.

Figure 12-18. The "Card Ops" menu.

Close

Enables you to close any number of currently open cards by simply shift-selecting each one's card-ID into the "Selecting Cards" prompt window.

After you have specified your choices, select **Done** from the menu on top of the "Selecting Cards" prompt window, or type a carriage return. **Cancel** aborts this command. **Undo** removes the last selected card from the list.

Figure 12-19. The "Selecting Cards" prompt window and menu.

The **Close** option has two submenu options.

Close and Close NoteCards

Perform the same action as **Close**.

Close Structure

Closes a linked list of cards. This operation follows both local and global links.

Figure 12-20. The **Close** submenu.

Once you have selected the cards from which to start the **Close Structure** operation, a menu opens asking you what types of links you want to follow. When you are done, select **Done**. **Reset** sets the menu to the values it had when it came up. **Abort**, terminates the operation.

Figure 12-21. The "Include cards at:" menu.

For an explanation of Forward and Backward links see Chapter 8, Links. The **Depth** variable determines how many link levels are traversed in carrying out the operation. If set to a depth of 2, only cards two levels down are closed. For example, if you had cards 1,

2, 3, and 4 on the screen, each forming a sequence (card 1 only pointing to card 2, and card 2 only pointing to card 3, etc.), then if the depth were set to two and you started the close operation from card 1, only cards 1, 2, and 3 would be closed, because only two levels of links would be traversed. Card 4 would remain open on the screen after the **Close Structure** operation.

Delete

Works just like **Close**.

Figure 12-22. The **Delete** submenu.

We caution you to be very careful with the **Delete Structure** command as it is very easy to unintentionally delete large numbers of cards. This command is most useful in conjunction with **Copy Structure** as a way of performing a safe **Move Structure**. First you copy the structure you think you want and then once you have verified that you have gotten the structure you wanted, you use **Delete Structure** to remove it.

Copy

Works just like **Close**. Allows you to copy a group of cards or a card structure to another FileBox which may be in a different notefile.

Figure 12-23. The **Copy** submenu.

Move

Works just like **Close**. Allows you to move a group of cards or a card structure to another FileBox which may be in a different notefile.

Figure 12-24. The **Move** submenu.

Other Options

Figure 12-25. The "Other Ops" menu.

Edit Parameters

The **Edit Parameters** option brings up the System Parameters menu. This menu is discussed in detail in Chapter 13, System Parameters.

NF Indicators On

NF Indicators On and the submenu option **Indicators On** turn on notefile indicators for all the cards on the screen.

Indicators Off

Turns off all notefile indicator windows for all the cards on the screen. Note that whether or not cards come up with notefile indicators is determined by the system parameter **Show Notefile On Cards**. To learn more about this parameter and changing system parameters, see Chapter 13, System Parameters.

Figure 12-26. The "NF Indicators On" submenu.

Notefile indicators are small windows on the tops of cards which show the name and path of the card's notefile.

Figure 12-27. A notefile indicator window attached to the "Table of Contents" card from the Solar System notefile.

TEdit Killer On

Kills TEdit processes after they have been around for a specified period of time.

Figure 12-28. The "TEdit Killer On" submenu.

Since every text-based card and every TEdit window, including TEdit command menus, is a separate TEdit process it is very easy to get twenty or thirty TEdit processes all vying for machine time. This can greatly slow down your machine's response time. If you like to work with many cards and windows open on the screen at one time turning the TEdit killer on will help improve your machine's response time. Note that TEdit killer only affects text-based cards. The processes for sketch-based cards are unaffected. To restart a TEdit process that has been killed in this manner, you only have to click in the TEdit window.

TEdit Killer On

Turns on the TEdit killer process.

TEdit Killer Off

Turns off the TEdit killer process.

New Process Limit

Sets the number of TEdit process which are allowed to exist. Selecting this option brings up the following menu.

```

Old TEdit
process limit: 5

  0

  - AB CLE
    OR AR
  1 2 3
  4 5 6
  7 8 9
bs 0 ok
  
```

Figure 12-29. The TEdit process limit number pad.

A response of "0" allows you to have one TEdit process running and not none.

The default value is "5."

New Wait Time

Sets the number of second which a TEdit process can be idle before it will be killed. Selecting this option brings up the following menu.

Figure 12-30. The TEdit killer wait time number pad.

Note: If both the TEdit process limit and the TEdit killer wait time are set to "0," it can freeze your system.

The default value is "100."

Load Patches

Forces the loading of any patches which were distributed with the NoteCards sysout.

[This page intentionally left blank]

13. SYSTEM PARAMETERS

System parameters allow you to customize the NoteCards environment to your particular needs and tastes.

This chapter explains:

- How to set system parameters.

- What each system parameter does.

Accessing System Parameters

System parameters are set from the "NoteCards Parameters" menu. To access this menu, hold the left mouse button down on the **Other** option on the MenuBox Icon. When the "Other Ops" menu comes up, still holding the mouse button down, slide off and select the **Edit Parameters** option. At this point, you release the mouse button. You can also execute a single rapid left-button click on the Other menu option and the "Other Ops" menu will come up and stay up. To select the option you want click on it.

Figure 13-1. The MenuBox Icon with the **Edit Parameters** option on the **Other** menu option selected.

This action brings up the "NoteCards Parameters" permanent menu, shown below in Figure 13-2.

Each parameter is preset to a default value. Placing the cursor over the name of the parameter and depressing the left mouse button will toggle the value, listed to the right, between "Yes" and "No" if binary, and allow selection from an appropriate menu otherwise.

NoteCards Parameters	
NoteCards System Parameters	
Extra TEdit Props	None
Include Card Object In ShowInfo	No
Del TEdit Process When Shrinking	No

Link Icon Show Title Default	Yes
Link Icon Attach Bitmap Default	Yes
Link Icon Show Link Type Default	No
Use Deleted Link Icon Indicators	Yes

Figure 13-2. The "NoteCards Parameters" menu.

NoteCards System Parameters

Extra TEdit Props

Does not initially appear on the list of parameters for the user version of NoteCards. It is obtained by going into the **Low Level Tools** option on the background menu. This parameter is to be used by people extending the NoteCards environment. Users of NoteCards should not add this parameter to their "NoteCards Parameters" menu.

The value of this parameter is a property list that is appended to the property list passed as the PROPS argument to every call to TEdit. This parameter allows you to set up the initial TEdit props for all new text-based cards.

Selecting this property brings up a type-in window above the parameter editor window. To set the parameter value, type in a sequence of zero or more attribute/value pairs followed by carriage return. The possibilities for attributes and values are described in *A User's Guide to TEdit*, Chapter 8, The Programmer's Interface to Tedit, in the section "Using the Top-level TEdit function".

For example, to set the default line leading to 2 you would type:

PARALOOKS (LINELEADING 2)

You should be very careful when setting other than LOOKS-related properties. In particular, NoteCards sets properties like QUITFN and PROMPTWINDOW itself, overriding any alternative values for these properties that you may have typed in.

Special note: If for some reason, you need to have an expression EVAL'ed in the typein window, precede it with ctrl-y.

The default value is "None."

Include Card Object In ShowInfo

When the value of this parameter is Yes, the Show Info inspector will include the Card Object. This option is for people extending or modifying the NoteCards system.

The default value is "No."

Del TEdit Process When Shrinking

If the value of this parameter is "Yes," when you shrink any text-based card, NoteCards will kill the TEdit process behind it. If the value is "No," the TEdit process remains running even when the card is shrunk to an icon.

Expanding an icon for a card whose TEdit process has been killed will not automatically restart the TEdit process. Instead, the user has to click the MIDDLE button in the substance of the card, and select the **New Edit Process** item from the singleton menu that appears.

Running TEdit processes use up limited resources. As a result, only about 25 to 30 TEdit processes can be active simultaneously. Setting the value of this parameter to "Yes," eliminates

unnecessary use of these limited resources when text-based cards are shrunk to icons. The cost is the extra effort needed to restart the process when the card is expanded.

The default value is "No."

Font Parameters

When you select any of the parameters in the Fonts section the system displays the "Please select a font:" menu.

Family	Size	Face	
TIMESROMAN	8	STANDARD	DONE RESET ABORT
HELVETICA	9	BOLD	
GACHA	10	ITALIC	
CLASSIC	11	BOLDITALIC	
MODERN	12		
TERMINAL	14		
TITAN	18		
CREAM	24		
OLDENGLISH	30		
	36		

Figure 13-3. The "Please select a font" menu.

To change the link icon font, select the values you want for each of the parameters with the mouse and click on **DONE**. **RESET** returns the values to their original settings. **ABORT** returns the values to their original settings and exits.

The value for each font parameter is three-element list which includes the font family, the font size in points and the font face.

Menu Font

The value of this parameter is a description of the font in which the text in all menus will be printed.

The default value is "(HELVETICA 10 BOLD)."

Default Font

This parameter controls the font all new text-based cards will use.

The default value is "(HELVETICA 12 STANDARD)."

Link Icon Font

The value of this parameter is a description of the font which is used to print the card name and link type that appear inside the links.

The default value is "(HELVETICA 10 BOLD)."

Notefile Parameters

Show Notefile On Cards

In order to associate a card with its notefile, NoteCards provides a notefile indicator window which attaches to the top of the card's title bar.

Figure 13-4. A card with its notefile indicator window attached to the top of the card.

The notefile indicator is constructed by concatenating the root file name, the version number, and the full file name. The indicator is left justified. If the card is too narrow to show the entire Indicator string, the full file name is truncated before the root name and version number as shown.

Figure 13-5. A card with its notefile indicator window attached to the top of the card, showing a truncated full file name.

If the NoteCards system parameter **Show Notefile On Cards** has the value "Yes," then a notefile indicator is attached to every card as it is brought up on the screen.

Occasionally, after you have reshaped a card, a piece of the text in the notefile indicator window will be garbled or broken. To redisplay the text in this window, place the point of the mouse cursor in the notefile indicator window, hold down the right mouse button, and select the **Redisplay** option from the window menu which pops up.

The default value is "No."

New Notefile Initial Size

When you create a new notefile, the system consults the value of this parameter to determine the initial size of the notefile index. The notefile-index size is equal to the number of cards the notefile can hold. Larger notefiles take a little longer to create. Notefiles can be enlarged later on, using the **Inspect & Repair** option.

The default value is "1000."

Menu Lingers After Notefile Close

If the value of this parameter is "No," the notefile Banner is removed from the screen when the notefile is closed. If the value is set to "Yes," then the Banner remains on the screen with its menu items greyed.

The default value is "Yes."

Card Parameters

Force Filing

If you set **Force Filing** to "Yes," the system will require you to file every card in a FileBox before the card can be closed. Setting the value to "No" eliminates this forced filing, but the system will file the card in the "To Be Filed" FileBox if the card has no parent FileBox when you close it.

The default value is "Yes."

Force Titles

If you set **Force Titles** to "Yes," this parameter will require you to title a card before it can be closed. Setting the value to "No" eliminates forced titling. When a card is not titled, it is named "Untitled" by default. This may cause confusion if several cards are left untitled. The system, however, has a unique identifier for each card and will continue to regard them as unambiguous entities.

The default value is "Yes."

Default Card Type

When you select **the New Cards** option from the notefile Banner with the left mouse button, a card of the default type is immediately created and displayed. This parameter allows you to change this default to suit your needs. Select the new default card type from the list of choices provided.

The default value is "Text."

Close Cards Off Screen

If set to "Yes," then when a card is closed, it is first moved off the screen so that the close happens invisibly.

The default value is "No."

Bring Up Cards At Previous Pos

If set to "Yes," cards are brought up on the screen in the position they occupied when you last closed them. You are not asked to position a frame image.

The default value is "No."

FileBox Card Parameters

Markers In FileBoxes

If set to "Yes," then new fileboxes will contain the markers "FILE BOXES" and "NOTE CARDS." New child boxes are inserted under the FILE BOXES marker and new child cards under the NOTE CARDS marker. If set to "No," then new fileboxes come up without markers and new children are inserted at the current cursor position . Note that regardless of the **Markers In FileBoxes** setting, if a filebox has no markers (because you've deleted them) then new children are inserted at the cursor position.

Figure 13-6. A FileBox card showing the markers "FILE BOXES" and "NOTE CARDS."

The default value is "Yes."

Alphabetized FileBox Children

If set to "Yes," then FileBoxes created while this parameter is set to "Yes" will automatically alphabetize any new cards filed in them.

The default value is "No."

Browser Card Parameters

Special Browser Specs

If set to "Yes", this parameter causes a sequence of five prompts to appear above the Browser NoteCard during the Browser creation process. These prompts mainly concern the node-link graph properties documented in the "Browser Cards" section of Chapter 11, System Cards.

For example, this option may be used to create a vertical browser instead of the default horizontal presentation. Note that a carriage return given as a response to any of the prompts will cause the Special Browser Spec to retain its default value.

The default value is "No."

Arrow Heads In Browsers

This dictates whether arrow heads are drawn on browser links. The variable can be set to either AtMidpoint, AtEndpoint, or None. See the Browser card section of Chapter 11, System Cards for details.

The default value is "None."

Link Dashing In Browser

If set to "Yes", this parameter builds a Browser with dashed links. Each link in a Browser refers to the type of link being followed. With link dashing, each link included in the Browser is assigned a different style of dashing (up to six styles). A "No" setting means links will be presented as solid lines in a Browser. A Browser with link dashing will take a little longer to create than one with solid lines.

There may be problems printing Browsers with dashed lines.

The default value is "No."

Sketch Card Parameters

Attach Sketch Menu

If set to "Yes," the Sketch menu is automatically attached to the right-hand side of each Sketch card when it is opened.

The default value is "No."

Link Parameters

Link Icon Border Width

Changes the border size of a link icon.

Figure 13-7. A link icon with a border size of 3.

The link icon border width can also be set to zero for link icons that blend more smoothly with text.

This is a  **Link Icon** with no border.

Figure 13-8. A link icon with a border size of 0.

The default value is "1."

Link Icon Multi Line Mode

This parameter works in conjunction with **Link Icon Max Width in Pixels**. Multi line mode determines whether the link icon will allow multiple text lines or whether all the text will be forced to appear on a single line. If **Link Icon Multi Line Mode** is set to "Yes," all link icons will display in multiple lines, with each line fitting within the width specified by **Link Icon Max Width in Pixels**. Line breaks occur at word boundaries.

Figure 13-9. A link icon in multi line mode.

The default value is "No."

Cross File Link Mode

All links in NoteCards are bidirectional or two-way with one possible exception. When you are creating cross-file links, these links can be unidirectional or one-way. A one-way link means that a source card contains a to-link pointing to the destination card, but the destination card does not contain a corresponding from-link pointing back to the source card. This allows you to update a source-card file without being forced to open any corresponding destination-card files.

One-Way	Creates unidirectional links between cards in different notefiles.
Two-Way	Creates the usual bidirectional links between cards in different notefiles.
Ask	The system asks you whether you want One-Way or Two-Way links each time you create a cross-file link. The default value is "Ask."

Link Icon Max Width in Pixels

Sets the maximum width in pixels of a link icon. This value includes the card-type bitmap, if it is displayed. All links are truncated at the width specified by this parameter.

Figure 13-10. A truncated link icon in single line mode.

The default value is "1024" pixels.

Link Icon Show Title Default

This parameter and the following two determine the manner in which link icons are displayed if these parameters are not currently specified in the icon. Which is to say, if the link icon display mode values are set to "System Default."

If the title field in a link icon is set to "System Default" then the **Link Icon Show Title Default** parameter is consulted to determine whether the title will be shown inside the link icon. If it is set to "Yes" then the title will be shown.

The default value is "Yes."

Link Icon Attach Bitmap Default

If the bitmap field in a link icon is set to "System Default" then the **Link Icon Attach Bitmap Default** parameter is consulted to determine whether the card-type bitmap is shown next to the link icon. If it is set to "Yes" then the card-type bitmap is shown.

The default value is "Yes."

Link Icon Show Link Type Default

If the link type field in a link icon is set to "System Default" then the **Link Icon Show Link Type Default** parameter is consulted to determine whether the link type will be shown inside the link icon. If it is set to "Yes" then the link type will be shown.

The default value is "No."

Use Deleted Link Icon Indicators

If the value of this parameter is "Yes," when you delete a card, all link icons which point to that card are replaced with a deleted icon.

Figure 13-11. A deleted icon.

If the value of this parameter is "No," the links to the card are simply removed, leaving no trace behind.

Delete icons are useful when you may be deleting cards where you have link icons pointing to them and these link icons are referred to in the text.

Eg. "This link  takes you to the next card in the sequence." If the "Next" card were subsequently deleted with this parameter set to "Yes," this would become, "This link  takes you to the next card in the sequence." If this parameter were set to "No," the sentence would become the following more obscure version, "This link takes you to the next card in the sequence." with no visible link.

The default value is "Yes."

[This page intentionally left blank]

The FileBrowser provides a convenient user interface for manipulating files stored on a workstation or file server. It enables you to see, edit, delete, print, load, copy, move, rename, compile, sort, and get several types of information about groups of files.

User Interface

Starting FileBrowser

To open a browser on a set of files select the FileBrowser command from the background menu.

FileBrowser will prompt you to create a window by presenting you with a dashed rectangle with the mouse cursor and a small geometric design at the lower right corner.

1. Move your mouse until the upper left corner of the rectangle is where you want it on the screen.
2. Hold down the left mouse button and move your mouse down and to the right, thus expanding the window diagonally, until the window is the right size.
3. Release the mouse button. This creates a window group on your screen in the outlined area.

Next, FileBrowser prompts you for a file pattern. Type a pattern, as described in the section "Specifying What Files to Browse," below.

FileBrowser enumerates the set of files matching the pattern you requested to see. While the enumeration is in progress, the **Recompute** command is grayed out. When the enumeration is finished, you may select files and issue commands. You can scroll the window at any time, even while the browser is busy.

If FileBrowser can't find any files matching the pattern you specified, or you decide you specified the wrong pattern and want to try again, you can specify a new file name pattern from within the browser using the **New Pattern** command; see **Recompute** in the section "FileBrowser Commands," below.

You can have as many active FileBrowsers open at once as you like.

Specifying What Files to Browse

A full file name in NoteCards consists of a device or host (such as your local disk, a file server), a principal directory and zero or more subdirectories, a file name (possibly including an extension), and a version number. These fields are put together in the form

```
{HOST}<DIRECTORY>SUBDIRECTORY>FILENAME.EXTENSION;VERSION
```

A file name pattern, as specified to FileBrowser, consists of a file name with one or more pieces omitted or filled with wild cards (*).

All the files matching the pattern are listed by FileBrowser. Thus, you can browse all the files in a particular directory, all the files in a subdirectory of that directory, all the files in a directory with a particular extension, and so forth. The wild card `*` can be used to stand for zero or more consecutive characters in the file name. You can use as many wild cards in a pattern as you wish.

If you leave out some of the fields in a file name pattern, the missing fields are defaulted by the system. Omitted fields in the front of the pattern, i.e., the host, device, or directory fields, are filled in by consulting your connected directory. Other omitted fields are filled in with wild cards unless they are explicitly omitted; i.e., the field is empty, but the preceding punctuation is still present. In more detail, some of the cases are as follows:

If you leave out the name of the host/device, specifying `<DIRECTORY>FILENAME`, FileBrowser will use the name of the host/device for the directory to which you are currently connected.

If you leave out both the device and directory names, specifying `FILENAME`, FileBrowser will use the device and directory to which you are currently connected.

If you do not specify a file name, FileBrowser lists all the files in the specified directory (or the connected directory if you also omitted the host and directory).

If you leave out the extension of a file name, FileBrowser lists all the files with the specified file name and any extension. If you omit the extension but include the period that usually precedes the extension, FileBrowser lists only the files with the specified name and *no* extension.

If you omit the version number of the file name, FileBrowser lists all versions of the matching files. If you omit the version number but include the semicolon that usually precedes the version, FileBrowser lists only the highest version of the matching files.

Thus, the minimal pattern you can type is `*` (asterisk—enumerate all files in the connected directory) or `;` (semicolon—enumerate just the highest version of all files). If you press the RETURN key without giving a pattern, FileBrowser aborts the prompt for a pattern, leaving you with an empty browser in which the only things you can do are change some FileBrowser parameters (see the subcommands of **Recompute** in the section "FileBrowser Commands," below) and then use the **Recompute** command to be prompted for a pattern again.

Examples

The pattern `*` specifies all files in the connected directory. It is equivalent to `*.*` or `*.*.*`.

The pattern `<NoteCards>Demo` specifies all files in directory NoteCards with name Demo and any extension. It is equivalent to `<NoteCards>Demo.*.*`.

The pattern `<NoteCards>Demo.` specifies all files in directory NoteCards with name Demo and *no* extension. It is equivalent to `<NoteCards>Demo.*`.

The pattern *.TEdit specifies all files in the connected directory with the extension TEdit. It is equivalent to *.TEdit;.*.

The pattern *.TEdit; specifies only the newest version of all files in the connected directory with the extension .TEdit.

The pattern <NoteCards>A*E specifies all files in directory NoteCards whose names begin with A and end with E and have any extension.

The pattern {DSK}<NoteCards>*MY* specifies all files in directory {DSK}<NoteCards> whose names contain the substring MY and any extension.

Using the FileBrowser Window

The FileBrowser window has six major subwindows, which from top to bottom are as follows.

Enumerating {DSK}/usr/users/kmount/NC/DOC/ENVOS/1.1/WORKING/*.*;* ...done			
{DSK}/usr/users/kmount/NC/DOC/ENVOS/1.1/WORKING/*.*;* at 12:26

Figure 14-1. The FileBrowser display.

Prompt window This topmost subwindow is where FileBrowser prints messages about what it is doing and receives input from you. Its contents are cleared before every command.

Tally window This subwindow immediately below the prompt window keeps a running tally of the total number of files listed in the window and the number of files that you have marked for deletion. In addition, if one of the attributes you are displaying is a size attribute (Pages or Length, as in the INFO menu, described below), this window maintains a tally of the total number of pages in the files listed and the files marked for deletion.

This window also has a title bar across the top identifying the pattern you specified and the time at which the directory enumeration was performed.

The window is blank while the files are being enumerated.

Browser window This is the principal subwindow, in which the files matching the specified pattern are listed. Each file's name appears at the left, and various attributes of the file are displayed in columns to the right. A title bar across the top of the browser window identifies the contents of each column (e.g., Name, Pages, Created). The files are listed in alphabetical order, with multiple versions of the same

file listed in decreasing version order; i.e., the newest version appears first. The width of the column listing the file names is initially chosen to be appropriate for average-sized file names. If the files you asked to browse have particularly long names, then when FileBrowser has finished listing all the files it may choose to redraw the browser window with the attribute columns moved farther to the right to accommodate the longer file names.

Command menu

This menu appears vertically along the right side of FileBrowser window (under a title bar "FB Commands") and lists the commands that you may select to perform operations on the files in the browser, or to change the appearance of the browser. Most of the commands operate on the set of currently selected files (see the section "Selecting Files" below). Some commands have subcommands, as indicated by the small triangle alongside them, which can be selected by holding down the left mouse button and sliding the mouse to the right over the triangle.

Info menu

An additional subwindow, the Info menu, is not normally displayed. It is used to change the set of file information (attributes) displayed in the browser (see the section "Getting Information About Files," below).

Scroll bar

If there are more files in the listing than fit at one time in the browser window, you can scroll the browser window to view more files. Slide the mouse cursor out the left side of the browser window to get the scroll bar and press the left mouse button to scroll the region up and the right mouse button to scroll it down. Pressing a mouse button when the cursor is near the bottom of the scroll bar will scroll the region by larger increments than when the cursor is at the top.

You can also press the middle mouse button in the scroll bar to move the listing to the place that corresponds to that position in the scroll bar. For example, pressing the middle mouse button when the cursor is at the bottom of the scroll bar will display the end of the listing. This quick-scrolling technique is called thumbing. The gray box in the scroll region indicates where the currently displayed contents are, relative to the entire contents of the browser.

Similarly, if there is more attribute information than fits in the browser window, you can scroll the browser window horizontally to view the rest of the attribute information. To do this, slide the mouse out the bottom of the browser window to get the horizontal scroll bar. The left button scrolls to the left, the right button to the right.

Selecting Files

Most FileBrowser operations are performed by selecting a single file or set of files, then giving a command that specifies what you want to do with the selected files. The current selection is indicated by a small triangle in the left margin of the browser next to each selected file.

```

| ▶05-NOTECARDS-BASICS.TEDIT;48  
| 06-BUILDING-NC-STRUCTURES.TEDIT;13
```

Figure 14-2. Four selected files marked by triangles.

To select one file, point to any part of the line (which lists the file name and its attributes) and press the left mouse button. If other files are already selected, this unselects them; thus, a file selected with the left mouse button is always the only selection.

To add a single file to the current selection, press the middle mouse button at any place in the line. The file is selected without unselecting any other file.

To remove a single file from the current selection, hold down the control key and press the middle mouse button at any place in the line. The file is unselected without affecting any other file.

To extend the selection to include a group of contiguous files, that is, to select all the files between a file and the nearest already selected file, press the right mouse button on any part of the line. You can only extend the selection from the first selected file upward, or the last selected file downward. In addition, files marked for deletion are not normally selected when you extend.

If you want to include all files, both deleted and undeleted, hold down the control key while extending the selection.

Some lines in a FileBrowser display are directory-only lines. These lines are slightly indented and name the directory and subdirectory to which the files listed below that line belong. You cannot select in these lines, though you can copy-select them (see the section "Copy-Selecting Files," below).

Commands that Require Input

Some FileBrowser commands require input from you. For example, the **Copy** command requires that you supply a destination file name. When a command requires input, FileBrowser prints a prompt message in its prompt window. This is usually followed by a default answer. If you want the default answer, you can just press the carriage return to finish the input. If you want to specify a different answer, simply start typing it; the default answer is erased and your answer replaces it.

Alternatively, you can modify the default answer by backspacing over individual letters, or typing control-W to back up over complete words. Typing CONTROL-Q erases the entire answer. You can also use the mouse to edit your answer, using the same rules as followed by the Executive (see the documentation of TTYIN). Briefly, the left mouse button positions the caret at a character boundary; the middle mouse button positions the caret at the nearest word boundary; and the right mouse button deletes the characters between the caret and the mouse.

When you have finished, position the caret at the end of your answer, if it isn't there already, and press the carriage return. You can also type CONTROL-X to finish your answer even if the caret isn't at the end.

If you change your mind and want to abort the command, supply an empty input; i.e., if there is an answer in progress, backspace over it or type CONTROL-Q to erase it, then press <RETURN>. FileBrowser prints "aborted" and aborts the command. In most situations, the CONTROL-E interrupt can also be used to abort your answer.

While you are typing an answer, you can copy-select file names out of the browser (or any other browser), as described below in the section "Copy-Selecting Files". This can be useful, for example, if you wish to rename a file to a similar name in the same directory, or move a file into a subdirectory listed in the browser.

Aborting Commands

During commands of indefinite duration, such as **Recompute** or **Copy**, FileBrowser adds another command to the browser, **Abort**.

Figure 14-3. The FileBrowser menu with the Abort option attached.

Clicking on the **Abort** command will immediately abort the current operation. Aborting some commands can take a little while, as FileBrowser may need to do some cleaning up, so the **Abort** command is greyed out during this time to show you that it is doing something.

Quitting the FileBrowser

To quit a FileBrowser, simply close the browser window. If any files have been deleted but not expunged, a small menu will pop up listing two options: **Expunge deleted files** and **Don't Expunge**. If you choose **Expunge deleted files**, the files will be expunged before the window closes. If you choose **Don't Expunge**, your deletions are ignored. If you click outside the menu, no action is taken, and the **Close** command is aborted.

Figure 14-4. The "Do what with deleted files?" menu.

If you have finished with FileBrowser only temporarily and want to put it aside to work on later, you can shrink the browser by selecting the **Shrink** command from the right-button background menu. The browser shrinks to an icon which displays the file pattern inside the browser. If any files are marked for deletion, you will be prompted with the same menu of expunge options as when you close a browser.

Figure 14-5. A FileBrowser shrink icon.

Copy-Selecting Files

You can copy-select file names from a FileBrowser into other windows, such as TEdit windows, by holding down the COPY or SHIFT key while selecting a name in the window. The full name of the file is inserted as if you had typed it where the input caret is flashing. You can also copy-select in a directory-only line, in which case the full directory name is inserted in your type-in.

Getting Hardcopy Directory Listings

You can get a hardcopy listing of the directory displayed in a FileBrowser by using the regular window **Hardcopy** command. Press the right button in FileBrowser's prompt window or tally window and select **Hardcopy** from the menu. FileBrowser will produce a hardcopy listing of the files and the attributes displayed in the browser.

If the browser displays a large number of attributes, or your default printer font is too large, the listing may not accommodate all the attributes on one line, making the listing less readable. You may want to make the listing with fewer attributes, or use a smaller font for the listing.

FileBrowser Commands

Delete, Undelete

Removing a file from the file system using FileBrowser is a two-step process. First, you mark the file or files for deletion. Then you issue the **Expunge** command. Any time between the deletion and the expunge you can change your mind and undelete any of the files.

To mark a file or files for deletion, select them, then choose the **Delete** command. FileBrowser draws a line through the deleted files. It also adjusts the numbers in the tally window to show how many files are marked deleted and how many pages they contain. It is thus easy to see how much file space you will regain when you issue the **Expunge** command.

```

16-PRINTING.TEDIT;52

```

Figure 14.6 Two files marked for deletion.

To undelete a file or files (i.e., to remove the deletion mark), select them, then choose the **Undelete** command. The lines through the files are removed, and the tally of deleted files is updated. The **Undelete** command has a single subcommand, **Undelete ALL Files**, which undeletes all the files in the browser, independently of whether they are selected. This is useful if you completely change your mind about deleting any files.

Figure 14-7. The **Undelete** submenu.

The **Delete** command has a useful subcommand, **Delete Old Versions**. When you have been editing a file in the text editor and performing repeated **Put** commands, multiple versions of the file accumulate, each more recent version denoted by a higher version number. The **Delete Old Versions** command is used to delete excess versions of the files displayed in the browser.

Figure 14-8. The **Delete** submenu.

To use this command, press the mouse down on the **Delete** command and slide the cursor out to the right, choosing the **Delete Old Versions** command. Unlike the **Delete** command (or **Delete Selected Files**, the equivalent subcommand), the **Delete Old Versions** command operates on all the files in the browser. FileBrowser prompts you for the number of versions of each file that you wish to retain. It offers the default of one version. You can accept the default or you can type a different number of your choosing, followed by a carriage return. FileBrowser then marks for deletion all but the most recent *n* versions of all the files in the browser, where *n* is the number you specified. Before issuing the **Expunge** command, you can, if you wish, scroll through the browser, undeleting any particular files for which you wish to retain more versions than you specified.

The **Delete Old Versions** command is sometimes useful even when you are not planning to actually expunge the files. This is because of the way extending the selection avoids deleted files (see the section "Selecting Files," above).

For example, if you wanted to copy only the most recent version of all the files in the browser to another location, you could do the following:

1. Use the **Delete Old Versions** command, retaining just one version. This marks deleted all files but the newest version of each.
2. Go to the start of the browser and select the first file, then scroll to the end of the browser and press the right mouse button to extend the selection to the end of the browser. You have selected exactly the newest version of each file.
3. Use the **Copy** command to copy those files.
4. Finally, use the **Undelete ALL Files** command to undelete all the old versions.

Copy

The **Copy** command is used to copy an entire file or set of files to another file system location; for example, from your disk to a file

server. Select the file(s) you wish to copy, then select the **Copy** command. FileBrowser prompts you to supply a destination.

If you selected just one file, FileBrowser prints the old name and offers a default, which consists of the same file name and either the same directory that was last used in a **Copy** or **Rename** in this FileBrowser, or the connected directory if this is the first use of **Copy** in this FileBrowser. You can accept the default or supply your own destination file name. If you supply just a directory specification, e.g., `{SERVER}<DIRECTORY>`, the file is copied to that directory under its current name. If you supply a complete name, the file is copied to that exact name.

Copy file {DSK}/usr/users/kmount/NC/DOC/ENVOS/1.1/WORKING/14-FILEBROWSER.TEDIT;10 to new file name: {Eris}<NoteCards>Doc>ENVOS>1.1>WORKING>14-FILEBROWSER.TEDIT

Figure 14-9. The Copy command confirming the name of the file to copy to.

Note: Unless you specify a version number in the destination file name, the version number of the new file will be 1, or one higher than the highest existing version of the file in the destination directory, independent of the version number of the old name.

Even files marked for deletion can be copied.

If you selected several files, FileBrowser notes how many files you wish to copy and offers as a default destination the connected directory. You can accept the default or supply a different directory. All the files are copied to that directory under the names they currently have.

You must supply a directory specification, e.g., `{SERVER}<YOURDIRECTORY>`, rather than a complete file name, since you can't copy multiple files to the same name. If you mistakenly type a file name, rather than a directory specification, FileBrowser will complain and abort the command.

If you want to copy files from different subdirectories, FileBrowser will ask, via a message in its prompt window, if you want to preserve the subdirectory structure at the destination. If you answer **Yes**, then the names at the destination will include not just the root name of each source file, but also all the subdirectory names below the greatest subdirectory prefix common to all the selected files (this common prefix is displayed as part of the question). If you answer **No**, then the names at the destination are formed solely from the root name of each file (the name displayed in the browser), ignoring any directory information each name might have. This can cause multiple files with the same root name to be copied into the same destination name (but with different version numbers, of course).

When copying (or renaming) multiple versions of the same file, FileBrowser does the copying in order of increasing version number, so that the versions at the destination are in the same relative order as at the source.

As each file is copied, FileBrowser prints a message giving the full name of the new file. If a file with the chosen name already exists, the new file's version number will be one higher; otherwise it will be version 1 (one). The new file will have the same creation date as the original file. If the destination file happens to be one that matches the pattern of the files in the browser, the new file is inserted in the appropriate place in the browser display. However, if it matches the pattern of some other FileBrowser, it is not inserted in that other browser's display (in other words, FileBrowsers do not know about each other). You would have to **Recompute** the destination FileBrowser to see that the file was copied into it.

Rename

The **Rename** command is used for changing the name of a file or group of files, or for moving a file or group of files to a different directory.

The **Rename** command is used in exactly the same way as the **Copy** command. If you rename a single file, you can supply a complete new name or just a directory; if you rename several files, you must specify a directory. As each file is renamed, FileBrowser prints a message giving the file's new name and removes the file from the browser display. If the new name belongs in the same browser, it is inserted in the appropriate place. If for some reason a file could not be renamed, this is noted in the FileBrowser prompt window. The reasons for the failure of a renaming operation are roughly the same as for the failure of an **Expunge**; the file is open, or you do not have the access rights needed to rename the file.

Note: If the destination of the rename is on a different file system than the original file, changing its name is equivalent to copying the file to its new name and then deleting the original file.

Hardcopy

You can print text files, TEdit, Sketch, Interpress, and PostScript files from FileBrowser. Select the appropriate file or files, then select the **Hardcopy** command. The **Hardcopy** command will determine what type of file you are printing and call the appropriate function for printing that file. Then the files will be printed one at a time on your default printer. The prompt window will display status messages telling you when files are being printed and when they are done (if your printer is one that provides this status service).

Figure 14-10. The **Hardcopy** submenu.

You may specify printing to a file or to a printer other than the default printer by means of a submenu from the **Hardcopy** command. This menu is the same as the one on the **Hardcopy** command in the background menu. Selecting **To a printer** presents you with a choice of printers from a menu. Selecting **To a file** prompts you to supply a file name. If you selected a single file, you must specify a single hardcopy file name (or accept the offered default). If you selected multiple files, then you must specify a pattern with a single asterisk somewhere in the "name" field, for example, *.INTERPRESS or Hardcopy-*.IP. The output file names are constructed by merging the pattern with each selected file name. If the name includes an extension that implies the type of print format (e.g., .IP or .INTERPRESS implies the Interpress print format), then a file of the specified type is made automatically. Otherwise, you are prompted to supply a print format type.

Note: For files stored on servers not supporting random access, FileBrowser is currently unable to determine that a file is in TEdit format unless the file has the extension .TEDIT. Therefore you should use TEdit to hardcopy TEdit files with other extensions. Use FileBrowser's **Edit** command (to call TEdit), then the **Hardcopy** command either from the TEdit Expanded Menu or from the right-button menu.

Note: To obtain a hardcopy of the directory itself, use the **Hardcopy** command from the right-button window menu. See the section "Getting Hardcopy Directory Listings".

See

When you browse a directory you sometimes want to see a file before printing or performing some other operation on it. To do this, select the file, then select the **See** command from the command menu. FileBrowser will prompt you to open a window by presenting you with a dashed rectangle and printing a message in the system prompt window. The window will be blank until FileBrowser starts printing the contents of the file in it.

There are actually four different **See** commands, as shown in the submenu for **See**. The **Fast SEE Pretty** and **Fast SEE Unformatted** commands are provided to let you quickly see the contents of a file, but not do anything fancy, such as scroll around

at random in the file. The slower **Scrollable & Pretty** command does let you scroll, and if the file contains formatting information of a kind that FileBrowser knows about (via the editors you have loaded), you will see the file formatted. However, this command does much more work, and may take a bit longer to show you even the first line of the file. The **Filebrowse** command is for use on files that are directories; it is described in the next section.

Figure 14-11. The **See** submenu.

The **Fast SEE Pretty** and **Fast SEE Unformatted** commands display the selected file in the display window one windowfull at a time. When the file fills the window, a small menu appears at the bottom-left corner of the window (or top-left if your display window is at the bottom of the screen) giving you the option of seeing more of the file or aborting the **See** command. If you issued the command with more than one file selected, you also have the choice of aborting just the display of this file or the entire **See** command.

Figure 14-12. The **See** window control menu.

If you select **More**, the **See** command displays another windowful of the file. If you select **Next File**, the **See** command closes this file and goes on to display the next file in the current selection. If you select **Abort**, the entire **See** command is aborted. You can also abort the **See** command by closing the display window.

The next time you give a **Fast See Pretty** or **Fast SEE Unformatted** command, the same window will be reused.

The only difference between the **Fast See Pretty** and the **Fast SEE Unformatted** commands is the manner in which the characters of the file are processed as they are displayed.

The pretty (formatted) version interprets certain control characters found in source files to be font change commands, and interprets certain multibyte sequences as representing characters in the Xerox extended character set. It also squeezes out blank lines and shrinks the indentation of indented lines in order to better fit the text in a window that is generally much narrower than the standard file width. The formatted version is thus most appropriate for viewing source files and files containing plain text.

The unformatted version of the **See** command does no special processing on the characters whatsoever. It simply displays each eight-bit byte as a single character, uninterpreted. This means that bytes that do not represent normal printing characters may be displayed as black boxes, in the form ^x or #x, or as a flashing of the window (for the byte that represents the ASCII "bell" character). The Unformatted version is thus most appropriate for viewing binary files that also contain text portions that might be worth seeing; e.g., compiled files (those with extension .LCOM) or Interpress masters (extension .IP or .INTERPRESS).

The **Scrollable & Pretty** command views a file in a different way. This command brings up a new read-only TEdit window for viewing a file (only if TEdit is loaded in your system; otherwise, **Scrollable & Pretty** reverts to fast format). You can scroll and copy-select the file's contents at will, as with any TEdit window. If the file is a NoteCards source file, its contents are first formatted into a TEdit document, so that all the font information is retained. This formatting, however, can take a long time for a large file. For other kinds of files, the **Scrollable & Pretty** command is exactly like viewing the file in a regular TEdit window, except that you can't edit it. If you want to edit a file, use the Edit command instead of the See command.

You can keep the display window used by the **Scrollable & Pretty** command open as long as you like. The command uses a different window for each file you select. Simply close the window with the standard right-button window menu when you are finished with it.

Filebrowse

The **Filebrowse** command is a subcommand of **See** used to view a subdirectory in its own FileBrowser window. The selected file must be a (sub)directory. Subdirectory files appear in browsers on XNS file servers when the depth is finite (see the **Set Depth** command), and their names always end in ">". On Sun servers subdirectory file names end in "/".

```
medley/  
►nc/  
NOTES/  
PROGS/  
setup/  
sysouts/
```

Figure 14-13. Some subdirectories on a Sun server, indicated by trailing slashes.

The **Filebrowse** command prompts you for a region for a new FileBrowser window group, in which it proceeds to enumerate the contents of the selected subdirectory, to the same depth as the main browser used, if any.

Edit

The **Edit** command invokes an editor on the selected file. To specify an editor explicitly, use one of the commands on the submenu.

Figure 14-14. The **Edit** submenu.

To start up a TEdit editor on a selected text file, select **Edit** with the left mouse button. If you have recently closed a TEdit window, then TEdit will probably reuse that window; otherwise, you will be prompted to create an editor window. TEdit only remembers the most recently abandoned window, however, so if you issue the **Edit** command when you have several files selected, you will be prompted to create windows for all but the first file.

The subcommand **Lisp Edit** is for people extending the NoteCards environment. Do not use this command unless you are extending the NoteCards system.

If you select the main **Edit** command, without sliding off to the submenu, then FileBrowser's default editor, TEdit, is called.

Load

The **Load** command is for people extending the NoteCards system. Do not use this command unless you are extending the NoteCards system.

Compile

The **Compile** command is for people extending the NoteCards system. Do not use this command unless you are extending the NoteCards system.

Expunge

If you are sure you want to delete files permanently, choose the **Expunge** command. The **Expunge** command is grayed while FileBrowser expunges the files that were marked for deletion by the

Delete command. As each file is removed from the system, it is removed as well from the browser display, and the tally of total number of files and number of deleted files is updated, so you can see the progress of the command.

If for some reason a file can not be expunged, FileBrowser prints a message saying so in its prompt window, but continues to expunge the other files. The main reasons that prevent a file from being expunged are its being opened, either by you or some other user, or your not having the access rights required to delete it (if it is on a file server). See the section "Troubleshooting Problems with FileBrowser," below.

Note: The **Expunge** command is not affected by the current selection; it operates only on files marked for deletion, whether currently selected or not.

Recompute

FileBrowser's display shows those files that existed and matched the specified pattern at the time you created the browser. If you want the browser to reflect the latest state of the file system, use the **Recompute** command.

For example, if you open a FileBrowser on your directory, then save several versions of a TEdit file on that directory, the file listing will not display the new versions until you **Recompute**.

The **Recompute** command operates exactly as when you started up FileBrowser initially: it clears the display and tally windows, then enumerates the files matching the pattern. The **Recompute** command in the menu is grayed until the enumeration is finished. During this time you cannot scroll or perform any other operations on the browser. However, you can close the window if you want to abort the command and throw away the browser.

If any files are marked for deletion at the time you request a **Recompute**, FileBrowser will present the choice of expunging or undeleting the files, just as it does when you want to quit the browser (see the section "Quitting the FileBrowser," above).

The **Recompute** command also has a menu of subcommands that allow you to list different files or different information for the same set of files.

Figure 14-15. The **Recompute** submenu.

Same Pattern	Is the same as the main Recompute command, i.e., it enumerates the files matching the same pattern as before.
New Pattern	Lets you change the pattern, i.e., browse a new set of files. FileBrowser prompts you to supply a new file name pattern and offers the old pattern as an initial default. You can either type an entirely new pattern, replacing the one offered, or delete the old pattern one character at a time by backspacing. Press the carriage return when you have finished specifying the pattern. FileBrowser then enumerates the files matching this pattern, just as with the Recompute command. You can abort the command with the Abort button, or by erasing the whole pattern (by backspacing or using CONTROL-Q) and then pressing the <RETURN>.
New Info	Lets you change which attributes the browser displays. It is described in the next section.
Set Depth	Lets you change the depth to which FileBrowser enumerates a directory on an XNS file server. It is described in the section "Set Depth."
Shape to Fit	Reshapes the FileBrowser window so that all the attributes in the display are visible at once, eliminating the need to horizontally scroll the window to get at all the information.

New Info

FileBrowser displays some file attributes, or information about the file, alongside each file in the browser display. Ordinarily, the attributes displayed are the size of the file in pages, its creation date, and its author. You can change the attributes displayed in a particular browser window by using the **New Info** command.

To use the **New Info** command, select it from the submenu of the **Recompute** command. FileBrowser opens up an additional subwindow, the "Info Options" window, below the display window. This subwindow contains a menu of attributes, with the current defaults shaded. Selecting a shaded item unshades it; selecting an unshaded item shades it. When you have selected all the attributes you wish to see displayed, issue either the **Recompute** or the **New Pattern** command. The files will be listed with the new information you requested. The "Info Options" window stays open—you can close it at any time.

Figure 14-16. A FileBrowser showing the "Info Options" window.

The Info Options items have the following meanings:

Created	The date and time that the content of the file was created. This date changes whenever the file is modified, but does not change when a file is copied or renamed.
Written	The date and time the file was last written to the file system. This date is never older than the Created date, but it can be newer if the file is copied, unmodified, from one file system to another.
Read	The date and time the file was last read. This attribute may be blank if the file has never been read.
Author	The login name of the person who wrote the file, or last modified it.
Length	The length of the file in (usually eight-bit) bytes.
Pages	The number of 512-byte pages in the file. On some servers, this attribute is blank if the file is empty.
ByteSize	The size (in bits) of the bytes in the file.
Type	A value indicating what kind of data the file contains. The usual values of this attribute are TEXT, meaning the file contains just characters, or BINARY, meaning the file contains arbitrary data. Some servers have additional types, such as INTERPRESS for files in Interpress format.

Set Depth

XNS file servers support a feature that allows enumerating a directory to a user-specifiable depth. The "depth" of a file reflects the number of subdirectories between it and the root of the enumeration, i.e., the directory or subdirectory you gave in the pattern to FileBrowser, not counting any containing wildcards (asterisks). The immediate descendants of the root are at depth 1, files in subdirectories of depth 1 are at depth 2, and so on.

Ordinarily, FileBrowser enumerates a directory to the default depth, which is usually unlimited. To enumerate a directory to a different default, use the FB command with argument :DEPTH *n*, for some positive integer *n*, or T for unlimited depth. To change the depth in an existing FileBrowser, use the **Set Depth** command, a subcommand under the **Recompute** command. The command offers you a menu of choices:

Figure 14-17. The **Set Depth** menu.

Global default means use the default depth, overriding the depth at which this browser was last enumerated. **Infinite** means use no depth limit (same as depth T). **1** and **2** are common depth choices;

to choose some other numeric value, select **Other** and enter the value via the displayed keypad.

The **Set Depth** command does not affect the current display. It takes effect the next time you use the **Recompute** or **FileBrowse** commands from the same browser.

During a **Recompute**, if a subdirectory appears at the specified maximum depth, its descendants are not enumerated; rather, the subdirectory itself appears as an entry in the browser display. This entry can be selected, just like a file, but only a small number of commands can be used on it: you can **Rename** it, you can **Delete** it if it has no descendants, and you can **FileBrowse** it. It has attributes, just as ordinary files do. Its page size is the size of the entire subtree rooted at the subdirectory.

Note: Depth currently affects only XNS servers; all other devices ignore it and enumerate to their own default depths. In addition, due to a bug in XNS Services 10, depth is ignored for nontrivial patterns, i.e., anything but `"*.*"`.

Sort

The **Sort** command allows you to sort the files in the browser by any attribute of the files displayed in the browser. Selecting **Sort** brings up a menu of attributes by which to sort. This menu includes all the attributes currently displayed in the browser (such as Creation Date, Author), plus the choice Name. For some attributes you can sort forward or backwards; the choice is on a submenu, and the default is generally in the order of numerically greatest (e.g., size) or most recent (e.g., creation date) first.

If the attribute you select is not Name, then the file names displayed in the browser will be reformatted to include their directory portion (if there are any subdirectories below the browser's main pattern), as the subdirectory information is no longer implicit in a file's position in the browser.

The sort order Name, Decreasing Version is the default order in which browsers initially are created.

Troubleshooting Problems with FileBrowser

When FileBrowser returns the message: No files in group *FILENAMEPATTERN* when you know those files exist, the file server is probably down or rejecting connections. If this is so, your only option is to wait until the server is functioning again, and then give the **Recompute** command. In the case of an Xerox file server, the enumeration of files can also fail if you do not have sufficient access privileges; this condition is usually noted by a message in the system prompt window.

When you try to expunge a file and FileBrowser displays the message: Can't expunge *FILENAME*, it may be because you

don't have write access to the file, or someone else is reading the file. However, the most common reason is that the file is still open. Be sure to close any TEdit windows in which you may still be viewing the file. If you have recently issued a **Hardcopy** command for the file, a background process may still be working on the file.

[This page intentionally left blank]

Digital Clock

Introduction

The digital clock allows you to keep track of the time in multiple time zones. The clock updates itself once a minute. Clicking the left mouse button inside any of the clock windows will cause the digital clock to update itself.

17 Feb 89 11:39am (Fri)	
Washington DC:	17 Feb 89 2:39pm (Fri)
Tokyo, Japan:	18 Feb 89 5:39am (Sat)

Figure 15-1. The Digital Clock with two auxilliary regional time-zone windows showing the time in Washington and Tokyo.

Starting the Digital Clock

To put a digital clock on the screen, bring up the background menu by holding down the right mouse button, position the mouse over the **Clocks** option and slide off to the right to bring up the Clocks submenu. Slide the mouse cursor over the **Digital Clock** choice and release the right mouse button.

Figure 15-2. The **Digital Clock** option from the **Clocks** submenu from the background menu.

Selecting the digital clock option will delete any existing digital clock and start a new one.

When the clock comes up, it will prompt you for an auxilliary time zone. If you click outside the "Enter Time Zone" menu, the clock will come up with just the local time zone.

Figure 15-3. The "Enter Time Zone" menu.

Stopping the Digital Clock

To remove the clock from your screen and kill the clock process, simply close the clock window using the clock window's right mouse-button **Close** option.

Changing the Digital Clock

You can specialize the digital clock to suit your needs. You modify the digital clock by holding the middle mouse button down in the clock window. Holding this mouse button down in the main clock window brings up the menu shown in Figure 15-4. Holding the middle mouse button down in one of the regional time-zone windows brings up the menu shown in Figure 15-5.

Figure 15-4. The main-window middle-button menu.

Figure 15-5. The auxilliary-window middle-button menu.

Set Font

Brings up a series of menus which allows you to change the font in the main clock window.

Figure 15-6. The font menu.

Figure 15-7. The font size menu.

Figure 15-8. The font face menu.

Select each option you want in sequence. If you want to keep any particular aspect of a font, simply click outside that particular menu. Clicking outside all the menus, leaves the font exactly the way it was to begin with.

While the system is searching for a font in the font files, it displays the message, "Fetching Font."

Not all possible combinations of every font exist. When the clock cannot find a particular font, it displays the message "Font Not Found."

Set Time

Brings up a menu which allows you to set the time.

Figure 15-9. The set-time menu.

Each click on a + advances the counter for that category; each click on a - decreases the counter for that category. Selecting the **Set** option sets the time and closes the menu. Selecting **Esc** (Escape) closes the menu without setting the time.

Set Alarm

Brings up the set-time menu shown in Figure 15-9. The menu functions the same way it does for the **Set Time** option. After you have set the time, the clock will ask you for a message to associate with the alarm time. Type in your message followed by a carriage return.

Figure 15-10. The Digital Clock with the auxilliary window prompting for a message to associate with the alarm time.

Quiet Alarm/Loud Alarm

Toggles the clock back and forth between, a loud/auditory alarm and a quiet/visual alarm.

Figure 15-11. The main window middle-button menu with the **Loud Alarm** option showing instead of the **Quiet Alarm** option.

The loud alarm causes the monitor to beep once a minute when the alarm is ringing. The quiet alarm causes the screen to flash once a minute when the alarm is ringing.

Delete Alarm Setting

Turns the alarm off when it is ringing. This option, shown in Figure 15-11, only appears when the alarm is set.

Shape to Fit

Resizes the window to the minimum size necessary for the font you are using.

The window should resize automatically whenever you change the font. If ever the window and font size get out of synch, you can force the window to resize itself by selecting this option.

12-Hour Clock/24-Hour Clock

Toggles the digital clock back and forth between 12- and 24-hour modes. Compare Figures 15-4 and 15-11 to see how these options appear in the menu.

Set Local Time Zone

Allows you to change the time zone shown in the main digital clock window. Selecting this option brings up the "Enter Time Zone" menu, shown in Figure 15-3, from which you can choose the appropriate time zone. Clicking outside this menu leaves the time zone unchanged.

Add New Regional Time Zone

Allows you to add an additional regional time zone to the digital clock display. Selecting this option opens a new auxiliary window on the bottom of the clock and then pops up the "Enter Time Zone"

menu, shown in Figure 15-3, for you to select a time zone for the auxilliary window.

Delete This Window

Deletes the auxilliary window the mouse cursor was in when you pressed the middle mouse button to bring up the auxilliary-window menu.

Figure 15-12. The auxilliary-window menu.

Set Font for Aux Clocks

Changes the font for all the auxilliary clocks indepent of the main clock. Selecting the option brings up the series of menus shown in Figures 15-6, 15-7, and 15-8. Clicking outside of any menu leaves that aspect of the font the way it was originally.

Set Aux Clock Font In Just This Window

Changes the font for the auxilliary window the mouse cursor was in when you pressed the middle mouse button to bring up the auxilliary-window menu. Selecting the option brings up the series of menus shown in Figures 15-6, 15-7, and 15-8. Clicking outside of any menu leaves that aspect of the font the way it was originally.

Figure 15-13. The submenu for setting the font in just one auxilliary window.

Set Time-Zone Heading

Prompts you for a new heading for the auxilliary window you were in when you pressed the middle mouse button to bring up the auxilliary-window menu. Type in the name followed by a carriage return.

Figure 15-14. An auxilliary window prompting for a new heading.

Occasionally, the window isn't wide enough to display the whole name. In this case choose the option **Shape to Fit** from the main window middle-button menu.

Set Regional Time Zone

Brings up the "Enter Time Zone" menu shown in Figure 15-3, which allows you to change the time zone region. **Set Regional Time Zone** does not allow other than hour increments.

Analog Clock

Introduction

The **Analog Clock** suboption off the **Clock** option on the background menu sets up an analog clock on your screen. The clock is updated once a minute.

Figure 15-15 The analog clock.

Starting the Analog Clock

To put an analog clock on the screen, bring up the background menu by holding down the right mouse button, position the mouse over the **Clocks** option and slide off to the right to bring up the Clock submenu. Slide the mouse cursor over the **Analog Clock** choice and release the right mouse button.

Figure 15-16. The Analog Clock option from the Clock submenu from the background menu.

The first time you bring the analog clock up in a sysout, it will prompt you to sweep out a window. Once you have done this this clock will always appear in its last size. If you want to resize the analog clock, choose the **Shape** option from the right button window menu, and sweep out the new shape for the clock.

Stopping the Analog Clock

To remove the clock from your screen and kill the clock process, simply close the clock window using the clock window's right mouse-button **Close** option.

Changing the Analog Clock

Holding the middle mouse button down inside the analog clock pops up the following menu.

Figure 15-17. The analog clock menu.

There are four independent properties which the user may control: the hands of the clock, time digits printed where the hands end, rings on the clock face, and 12 numbers around the outside of the clock face.

Figure 15-18. An analog clock with no points or numbers, rings, no hands, and times.

NUMBERS

Removes points and adds numbers to the clock face.

POINTS

Removes numbers and adds points to the clock face.

NO.NUMBERS

Removes both numbers and points from the clock face.

RINGS

Adds rings to the clock face.

NO.RINGS

Removes rings from the clock face.

HANDS

Adds hands to the clock face.

NO.HANDS

Removes hands from the clock face.

TIMES

Adds time digits to the clock face.

NO.TIMES

Removes time digits from the clock face.

SHOW.STYLE

Prints the current style to the system prompt window.

SET.TO.DEFAULT

Resets the clock face to the default settings.

CHANGE.DEFAULT

Sets the default to the current style.

SETTIME

Forces the clock to go to the machine to ask it the time.

Known Problems

The clock will occasionally not respond to style changes. To force it to change, close the clock window and restart the clock from the background menu.

Directory Connector

The directory connector allows you to keep track of your currently connected directory and allows you to change the directory. It updates itself about once every ten seconds.

Dir: {DSK}/usr/users/kmount/nc/nf/

Figure 15-19. The directory connector window.

Starting the Directory Connector

To put a directory connector on the screen, bring up the background menu by holding down the right mouse button, position the mouse over the **Directory Connector** option and release the right mouse button.

Stopping the Directory Connector

To remove the directory connector from your screen and kill its process, simply close the directory connector window using the window's right mouse-button **Close** option.

Changing the Directory Connector Fonts

To change the directory connector font, bring up the background menu by holding down the right mouse button, position the mouse over the **Directory Connector** option, slide off the menu to the right, position the mouse over the **Change Font** option, and release the right mouse button.

Directory Connector » **Change Font**

Figure 15-20. The **Directory Connector** option on the background menu showing the **Change Font** submenu option.

When you select the Change Font option you will be presented with a series of two menus asking you for a font and a size.

Figure 15-21. The font menu.

Figure 15-22. The font size menu.

While the directory connector is looking for a font, it prints the message "Fetching Font..." to the system prompt window.

Not all possible combinations of fonts are possible. If a font is not found the directory connector prints the message "Font Not Found." in the system prompt window.

Using the Directory Connector

The directory connector can be used in two ways.

Left Mouse Button

Clicking the left mouse button in the directory connector window causes the window to update itself.

You can shift-select the connected directory name out of the directory connector window with the left mouse button. You do this by pointing to the position in the window where you want the name of the directory to appear and clicking the left mouse button to position the caret cursor there, a FileBrowser prompt window for instance. Next you hold a SHIFT key down and click the left mouse button in the directory connector window. The name of the directory will appear where you positioned the caret cursor.

Middle Mouse Button

Clicking the middle mouse button in the directory connector window brings up a menu of directories to connect to.

Figure 15-23. The "New Directory?" menu.

If the directory you want to connect to is on this list, click the left mouse button on it to connect to it.

If you change your mind and want to abort the operation, click outside the "New Directory?" menu.

If the directory you want to connect to is not on this list, click the left mouse button on * * Connect to Other Directory * * and type the directory name into the prompt window which will appear.

Figure 15-24. The "New Directory?" prompt window.

The prompt window will come up with your currently connected directory. The moment you start typing the system will erase the window and show what you are typing.

If you want to modify the name of your currently connected directory, backspace over as much of the name as you need to and type the name of the new subdirectory. Be sure to end it with a slash.

If you type in an invalid directory name, directory connector will beep and print the message "Not a valid directory name." to the system prompt window.

[This page intentionally left blank]

NoteCards includes facilities for printing in the PostScript language by Adobe, and the Interpress, language by Xerox.

This chapter explains:

How to setup your printers.

How to specify where your font directories are.

How to deal with some common printer problems.

How to customize your postscript printer.

Setting Up Printers

You can set up printers from either the background menu or the initialization file. For how to set up your printers with the initialization file, see Appendix C.

Adding Default Printers

To set up a new default printer from the background menu, press and hold the right mouse button in the background, place the mouse cursor on **Set Default Printer** then slide off to the right and select **Add Default Printer**.

Figure 16-1. The **Set Default Printer** background menu option displaying its submenu.

A prompt window will appear showing you the name of the current default printer and asking for the name of a new default printer.

Figure 16-2. A PostScript printer name being entered as a new default printer.

Figure 16-3. An Interpress printer name being entered as a new default printer.

Enter the name of the new default printer. The moment you type the first character of the new printer name, the old name will be deleted and replaced with what you type. If you don't want to make any changes, strike the carriage return key. If you want to modify the name that is there, you can backspace over the name to erase

part of it. If you type a carriage return without a entering printer name, this operation is aborted.

When you type a carriage return to end the name, a menu will pop up requesting the printer type. Select one of the options with the left mouse button.

Figure 16-4. The system prompting you for the printer type.

If you do not select any option (by clicking outside the menu) and the printer's type was previously defined, it will remain the same. If the printer's type was not previously defined, and you do not select any option, the printer's type will be left undefined which will cause problems when you try to print. If you leave the printer type undefined the system will warn you.

Figure 16-5. The system prompt window giving the new printer status and warning you that the printer type for Oahu is undefined.

Figure 16-6. The system prompt window giving the new printer status.

At this point, if you have already specified the font directories, you should be able to print to any default printer.

Setting the Default Printer

The system maintains a list of printers, one of which is the default printer--the printer that files are sent to when no printer is explicitly specified.

To set the default printer, select the **Set Default Printer** option from the background menu.

Figure 16-7. The **Set Default Printer** option on the background menu.

This will cause the system to open a menu listing all the known printers.

Figure 16-8. The "Choose Default Printer." menu

Selecting one of these options will make that printer the default printer. The current default printer is the topmost option.

Once you have selected a new default printer, the system will confirm your choice by printing the printer name and type to the system prompt window.

Figure 16-9. The system prompt window giving the new printer status.

If the printer type is undefined the system beeps and issues a warning.

Figure 16-10. The system prompt window giving the new printer status and warning you that the printer type for Oahu is undefined.

Removing a Default Printer

If you make a mistake specifying a printer or want to remove a printer for some reason, you can use the **Remove Default Printer** submenu option on the background menu.

Figure 16-11. The **Remove Default Printer** submenu option off the background menu.

Selecting this option brings up a menu of known printers. Selecting one of these deletes it from the known-printers list and makes the topmost remaining printer the default printer.

Figure 16-12. The "Choose Printer to Remove." menu.

Setting Font Directories

As with printers, it is possible to set your font directories from either the background menu or your initialization file. We recommend that you set your directories from the initialization file. There are two reasons for this. Setting the font directories involves a lot of typing, and these directories are set correctly for you by the standard initialization file unless you have moved the font files. See Appendix C for how to set the font directories from the initialization file.

Adding a New Font Directory

To add a font directory from the background menu, press and hold the right mouse button in the background to bring up the background menu. Position the mouse cursor on the **Set Default Printer** option and slide off to bring up the submenu containing **Add Font Directory**.

Figure 16-13. The **Add Font Directory** submenu options on the background menu.

Selecting **Add Font Directory** brings up a menu asking you to specify the font group you want to add a search directory to.

Figure 16-14. The "Add to which directory group?" menu.

The NoteCards system supports one display and three hard copy modes. For each of these there is a specialized set of fonts. The fonts for the screen display are stored in the display font directories, the fonts for PostScript printers are stored in the PostScript font directories, those for Interpress printers are stored in the Interpress font directories, etc. When you add a new directory to one of these groups, you are providing the system with another place to search for fonts. For example, the display font directories typically include the following directories:

```
{DSK}/usr/local/lde/fonts/display/presentation/
{DSK}/usr/local/lde/fonts/display/presentation/
{DSK}/usr/local/lde/fonts/display/publishing/
{DSK}/usr/local/lde/fonts/display/printwheel/
{DSK}/usr/local/lde/fonts/display/miscellaneous/
```

When the system is looking for a new display font, it will search through each of these directories in sequence for the font. The fonts are broken up into separate directories for convenience and efficiency reasons.

Once you have specified the font directory group you want to work with, the system will prompt you for the name of a new directory to search for fonts of that type.

Figure 16-15. The system prompting for a new font directory to search for Interpress fonts.

Enter the name of the new font directory. The moment you type the first character of the font directory name, the old name will be deleted and replaced with what you type. If you don't want to make any changes, strike the carriage return key. If you want to modify the name that is there, you can backspace over the name to erase part of it. If you type a carriage return without a printer name, this operation is aborted.

Note that for Sun machines, the directory name will always start with {DSK}, that subdirectories in the path name are separated by slashes, and that the directory path name must end in a slash (/).

Showing the Font Directories

In order to view a particular set of font directories, use the **Show Font Directories** submenu option shown in Figure 16-13.

Like **Add Font Directory**, this first brings up menu asking you for the directory group you want to show.

Figure 16-16. The "Show which directory group?" menu.

Once you have selected the directory group, the system pops up a window which displays the font directories in that group. You can close this window using the standard window-menu close option or the window will close of its own accord after about two minutes.

Figure 16-17. A window showing the list of display font directories.

Removing a Font Directory

If you make a mistake entering a font directory name or for some other reason want to remove a font directory, use the **Remove Font Directory** option shown in Figure 16-13.

Like the **Add Font Directory** this first brings up menu asking you for the directory group you want to modify.

Figure 16-18. The "Remove from which directory group?" menu.

Once you have selected the directory group, the system pops up a menu of all the directories currently in that group.

Figure 16-19. The "Remove which directory?" menu.

Selecting one of these options deletes that directory. Clicking outside the menu aborts this operation.

Trouble Shooting Common Printer Problems

This section discusses some of the more common breaks which occur when your printers are not properly set up.

Can't determine IMAGETYPE for {LPT}

This break occurs when you do not have any printers specified on the default printer list, or if you have not specified the printer type.

Figure 16-20. A break window indicating that the system cannot find a valid printer.

Type an up-arrow to exit the break and make sure that the printer and its type are properly set.

You can get into this situation by choosing the hardcopy **To a printer** suboption off the standard window menu and then selecting the **Other...** option from the "Which Printer?" menu.

Figure 16-21. The standard right button window menu, showing the hardcopy **To a printer** submenu option selected.

Figure 16-22. The "Which printer?" menu showing the **Other...** option selected.

The **Other...** option does not automatically prompt you for a printer type. Therefore, we recommend that you always add new printers using the background menu **Add Default Printer** submenu option.

Font not Found

This break occurs when you do not have one of your font directories set properly.

```
INTERLISP-ERROR
In ERROR:
FONT NOT FOUND (coerced to)
(TIMESROMAN 14 (BOLD REGULAR
REGULAR) 0 INTERPRESS)

OLDMOUSE/154(debug)↑
```

Figure 16-21. A break window indicating that the system cannot find the appropriate font.

In this particular case, the system was unable to find an Interpress font. Note that the font description contains the word Interpress. This implies that either there are no Interpress font directories set or that the given Interpress font directories do not contain that font.

Type an up-arrow to exit the break and make sure that the appropriate font directory is properly set. You can do this by selecting the **Show Font Directories** suboption off the **Set Default Printer** option on the background menu. If directories are not correctly set use the **Add Font Directory** and **Remove Font Directory** options to correct the errors.

Can't Convert a POSTSCRIPT for a NIL printer

This break can occur if you have incorrectly typed the case of the printer name.

```
INTERLISP-ERROR
In ERROR:
Can't convert a POSTSCRIPT for a NIL printer
{LPT}MAUI.;5

OLDMOUSE/13(debug)\
```

Figure 16-22. A break window indicating that the system cannot find the appropriate printer.

Type an up-arrow to exit the break and if you have entered a printer name in lower case, try entering the same name in upper case by selecting the **Add Default Printer** option off the **Set Default Printer** submenu on the background menu.

Customizing Your PostScript Printer

The PostScript driver allows you to set a number of parameters to modify the output to suit your needs.

Portrait vs. Landscape

There are two terms used to describe how an image is printed on a piece of paper which you need to know.

Figure 16-23. Portrait describes the way we normally hold a piece of paper.

Figure 16-24. Landscape describes a piece of paper held on its side.

Maximum Wild Font Size

Indicates the maximum point size that the system will indicate as available when looking for fonts.

The default value is "72."

Font Association Menu

Maps display font names onto PostScript font names. To change the mapping click the left mouse button on a display font name in the left-hand column then select a PostScript font from the a menu of PostScript fonts names which will appear.

Figure 16-25. The "Postscript Font Association Menu" showing the display fonts on the left and the PostScript printer fonts on the right.

Figure 16-26. The "Postscript Font Association Menu" with the TIMESROMAN display font selected and about to be set to correspond to the COURIER PostScript printer font.

PostScript Short Edge Shift

Is the distance (in points) to shift the image perpendicular to the short edge of the paper. A positive value gives a shift upward in portrait mode, and to the right in landscape mode. A negative value shifts the image down in portrait and to the left in landscaped mode.

The default value is "0."

Figure 16-27. The short edge shift in portrait mode.

Figure 16-28. The short edge shift in landscape mode.

PostScript Short Edge Points

Indicates the printable region of the page, in points, along the short edge of the paper. It should be adjusted to allow for any short edge shifts of the image.

The default value is "576" points or 8 inches.

PostScript Long Edge Shift

Is the corresponding variable for shifts perpendicular to the long edge of the paper. A positive value here gives a shift to the right in portrait mode and downward in landscape mode.

The default value is "0."

Figure 16-29. The long edge shift in portrait mode.

Figure 16-30. The long edge shift in landscape mode.

PostScript Long Edge Points

Indicates the printable region of the page, in points, along the long edge of the paper. It should be adjusted to allow for any long edge shifts of the image.

The default value is "786.24" or "10.92" inches.

Note:

The AST TurboLaser PS has an imageable area on the page which is a different size than that of the Apple LaserWriter. The values of **PostScript Short Edge Points** and **PostScript Long Edge Points** for the AST are "575.76" and "767.76," respectively.

Landscape Mode

Indicates whether the default orientation of output files is landscape.

The default value is "No."

Landscape Text Mode

Indicates if the printing of text files should force the orientation of output files to landscape.

The default value is "No."

Bitmap Scale

Specifies an independent scale factor for display of bit map images, window hardcopies, for example. Values less than 1 reduce the image size, i.e. a value of 0.5 will give a half size bit map image. The position of the scaled bit map will still have the same lower-left

corner, i.e., the scaled bit map is not centered in the region of the full size bit map image.

The default value is "1."

Note:

Setting bit map scale to 0.96, instead of 1, will give cleaner bit map images on a 300 dpi printer. This corrects for the 72 ppi imagestream vs. the 75 dpi printer, using 4x4 device dots per bit map pixel. Also, values of 0.24, 0.48 and 0.72, instead of 0.25, 0.5 and 0.75, will also give cleaner images for reduced size output. In general, use integer multiples of 0.24 for a 300 dpi printer.

Texture Scale

Specifies an independent scale for the display of bit map textures. The value represents the number of printer bits per screen pixel. The default value is 4, which represents each pixel of the texture as a 4x4 block, so that textures are approximately the same resolution as on the screen for 300 dpi output devices, such as the Apple Laserwriter.

The PostScript package extends the allowed representations of a texture, beyond 16-bit integers and 16x16 bit maps, to any square bit map. (If the bit map is not square, its longer edge is truncated from the top or right to make it square.) Use this feature with caution, as large bit map textures, or sizes other than multiples of 16 bits square, require large amounts of storage in the PostScript interpreter, and can cause errors when printing.

Image Size Factor

Specifies an independent factor to change the overall size of the printed image. This resizing affects the entire printed output. Values greater than 1 enlarge the printed image, and values less than 1 reduce it. The **Bitmap Scale** parameter does not consider the **Image Size Factor** when determining the scale factor for a bit map.

17. ERROR RECOVERY AND KNOWN PROBLEMS

NoteCards on the Sun Workstation has an error handling system which includes

- the break window error system,
- a diagnostic program, URAID, which handles emulator errors.

Occasionally, you may encounter SunOS error messages. Refer to your Sun documentation set for recovery procedures when these errors occur.

Known problems with the NoteCards system are discussed at the end of this chapter.

System Status, Aborting Operations, and Spawning a New Mouse

NoteCards provides a number of keyboard combinations for enquiring about system status and aborting operations.

System Status

Typing CONTROL-T prints status information on the type-in process. The type-in process is the process which has the flashing caret cursor. This is of minimal usefulness as the type-in process is usually just sitting waiting for you to type characters in, and the messages are aimed at people extending the NoteCards system. However, if you need to know if the system is still active, typing CONTROL-T will force the system to give you the status on one process.

Aborting Operations

Hitting the STOP key will frequently abort the process you want it to. However, as the system runs multiple processes the process which receives the stop command may not be the one you intended to receive it .

Typing CONTROL-G gives you a list of all the currently running processes, in menu format, as shown in Figure 17-1.

```

Interrupt which process?
[Spawn Mouse]
OLDMOUSE *run
TEdit *tty
MOUSE
TEdit#3
DIGI-CLOCK
DIRECTORY CONNECTOR
TEDIT-KILLER#2
ERIS#LEAF
\10MBWATCHER#2
\NSGATELISTENER
\PUPGATELISTENER
\TIMER.PROCESS
BACKGROUND

```

Figure 17-1. The "Interrupt which process?" menu showing all the currently running processes.

Selecting one of these processes will cause a break to occur in that process. You can then uparrow, ^, out of the break to abort the process. If you decide you have broken the wrong process, you can type **ok** to have the process resume where it left off.

```

INTERRUPT
Interrupt below \TEDIT,HARDCOPY,DISPLAYLINE,
OLDMOUSE/118(debug)ok

```

Figure 17-2. A break caused by a CONTROL-G. The OLDMOUSE process is being resumed with the **ok** command.

Because there can be so many processes, TEdit processes in particular (there is one TEdit process for every TEdit window including the expanded-menu command windows), it is important to know which process you want to break to abort an operation. Generally, if you start an operation with the mouse, it either runs under the MOUSE or OLDMOUSE process, which is deleted the moment the operation finishes. If you see an OLDMOUSE process, this is usually the process you want to break.

There are exceptions to the OLDMOUSE rule. Performing operations from the FileBrowser causes a process with an "FB-" prefix to be spawned. All operations on the TEdit expanded menus are run in the main TEdit process associated with that edit window. If you have one TEdit window open on your screen and one TEdit expanded menu open, you will have two TEdit processes running: TEdit, which is the process associated with the main TEdit window, and TEdit#2, which is the process associated with the expanded menu.

***Killing the wrong process can cause you to lose information.
USE WITH CAUTION!***

Spawning a New Mouse

If by some chance you do manage to kill your mouse process off, it is easy to start a new one. Type CONTROL-G and choose the **[Spawn Mouse]** option on the "Interrupt which process?" menu. **[Spawn Mouse]** will always be the very top option. If you create several new mouse processes, the system will remove all but one mouse process.

Break Windows

Occasionally, when performing certain operations like accessing a file which has been moved to another directory, deleted, or renamed, or trying to create a font which does not exist, NoteCards will enter a break. When this happens, NoteCards provides you with information about what caused the break, and asks you what to do.

Figure 17-3. A break window caused by a font-not-found error.

In cases like this, you should first determine if the cause of the break is a simple error. Here for instance, there is no Helvetica 33 bold font. There is, however, a Helvetica 32. The appropriate action in this case would be to up arrow out of the break window by typing a ^, and reexecuting the operation with the correct font.

Another possibility is that the font directories may have been moved and the system may be looking in the wrong place for the fonts. Here again, you would up arrow out of the break window by typing a ^, edit the initialization file (see Appendix C, Initialization Files) to insert the correct values for DISPLAYFONTDIRECTORIES, load the initialization file, and then retry the operation.

If the break is caused by a missing file, you should up arrow out of the break window by typing a ^, find the current location of the file, and retry the operation with the new path and file name.

If you are unable to uparrow out of a break, or the system is behaving strangely, you should save all your work by closing your notefiles, and saving your TEdit and Sketch files, perform a **Flush**

image & Exit, and reload your system. **Flush image & Exit** is a submenu off **Logout** on the background menu.

Errors While Running NoteCards

The following errors may occur running NoteCards on the Sun Workstation.

ERROR MESSAGE	REASON/FUNCTION RESPONSIBLE
File access timed out	Occurs when you try to access a file on a remotely mounted file system or NFS service that is down.
File too large	Self explanatory.
Too-Many-Files-Open	Occurs when 1) you exceed the SunOS open file limit (see Chapter 4, System Use Issues) 2) you exceed system file resources while writing a sysout (using the Logout command from the background menu.)
Nonexistent directory	Occurs when user tries to connect to a nonexistent directory.
No-Such-Directory	Occurs when user tries to connect to a nonexistent directory.
Connection timed out	Self explanatory.
Bad Host Name	Self explanatory.

I/O Errors

These Xerox workstation-specific errors may occur if certain functions are inadvertently used on the Sun Workstation.

ERROR MESSAGE	REASON/FUNCTION RESPONSIBLE
Floppy: No floppy drive on this machine.	Self-explanatory.
Device error: {FLOPPY}	Occurs when you try to access a floppy device while running on the Sun Workstation.
Wrong machinetype	Occurs when functions controlling Xerox disk drive device-specific behavior are entered when running on a Sun.

Virtual Memory Errors

ERROR MESSAGE	REASON/FUNCTION RESPONSIBLE
File-System-Resources-Exceeded	Logout, Save image & Exit, Save VM
Protection-Violation	Logout, Save image & Exit, Save VM
File-Wont-Open	Logout, Save image & Exit, Save VM

URAI

The NoteCards system normally operates as a self-contained environment. In some unusual circumstances NoteCards may encounter a situation from which it cannot recover. In this case, when an unrecoverable emulator error is encountered, the emulator halts and enters into a small debugger called URAID. URAID allows you to inspect memory, or to look inside the sysout file, and attempt to recover from the error.

If you produce the same type of error condition in NoteCards on a Xerox workstation as you did on a Sun Workstation, you get an MP error instead of a URAID error.

Entering URAID

Normally, the emulator automatically enters URAID when an unrecoverable emulator error occurs. If the system freezes and will not let you regain control, you can throw the system into URAID by simultaneously holding down the SHIFT, CONTROL and DELETE (L10) keys or the SHIFT, CONTROL, and NEXT (ALTERNATE) keys.

URAI Commands

URAI has a few simple commands which you can use to attempt error recovery. All URAID commands are case sensitive.

- h** Hard Reset. Attempts to recover by resetting the Lisp stack. Quits URAID and causes NoteCards to resume execution. This command should not be used unless you are sure that execution can be resumed.
- e** Exit to SunOS. NoteCards will end. If you are going to call Customer Support, call *before* you give this command. After giving this command, nothing is recoverable.
- q** Quits URAID and returns to NoteCards.

Note: An error may occur while the NoteCards system is running uninterruptably. The following message signals this error:

Error in uninterruptable system code -- ^N
to continue into error handler

Disregard the ^N command; it is not supported by URAID.
Use the **q** command to continue.

Other Fatal Error Conditions

Occasionally, other emulator, operating system, or system administration errors may occur from which the URAID program cannot recover. Such error conditions include a process dying, the emulator going into an infinite loop, the keyboard being lost, or the system freezing up.

If any of these emulator errors occur, use the UNIX `kill` command to kill the `lde` process.

System Error Conditions

The following are error messages generated by SunOS. For complete information on these error messages, see the *SunOS Reference Manual*, Intro(2).

ERROR MESSAGE	DESCRIPTION
:0 Unused	
:1 EPERM	Not owner
:2 ENOENT	No such file or directory
:3 ESRCH	No such process
:4 EINTR	Interrupted system call
:5 EIO	I/O error
:6 ENXIO	No such device or address
:7 E2BIG	Arg list too long
:8 ENOEXEC	Exec format error
:9 EBADF	Bad file number
:10 ECHILD	No children
:11 EAGAIN	No more processes
:12 ENOMEM	Not enough core
:13 EACCES	Permission denied
:14 EFAULT	Bad address
:15 ENOTBLK	Block device required
:16 EBUSY	Mount device busy
:17 EEXIST	File exists
:18 EXDEV	Cross-device link
:19 ENODEV	No such device
:20 ENODIR	Not a directory
:21 EISDIR	Is a directory
:22 EINVAL	Invalid argument
:23 ENFILE	File table overflow

:24	EMFILE	Too many open files
:25	ENOTTY	Not a typewriter
:26	Unused	
:27	EFBIG	File too large
:28	ENOSPC	No space left on device
:29	ESPIPE	Illegal seek
:30	EROFS	Read-only file system
:31	EMLINK	Too many links
:32	EPIPE	Broken pipe
:33	EDOM	Math argument
:34	ERANGE	Result too large
:35	EWOULDBLOCK	Operation would block
:36	EINPROGRESS	Operation now in progress
:37	EALREADY	Operation already in progress
:38	ENOTSOCK	Socket operation on non-socket
:39	EDESTADDRREQ	Destination address required
:40	EMSGSIZE	Message too long
:41	EPROTOTYPE	Protocol wrong type for socket
:42	ENOPROTOPT	Bad protocol option
:43	EPROTONOSUPPORT	Protocol not supported
:44	ESOCKNOSUPPORT	Socket not supported
:45	EOPNOTSUPP	Operation not supported on socket
:46	EPFNOSUPPORT	Protocol family not supported
:47	EAFNOSUPPORT	Address family not supported by protocol family

ERROR MESSAGE**DESCRIPTION**

:48	EADDRINUSE	Address already in use
:49	EADDRNOTAVAIL	Can't assign requested address
:50	ENETDOWN	Network is down
:51	ENETUNREACH	Network is unreadable
:52	ENETRESET	Network dropped connection on reset
:53	ECONNABORTED	Software caused connection abort
:54	ECONNRESET	Connection reset by peer
:55	ENOBUFS	No buffer space available
:56	EISCONN	Socket is already connected
:57	ENOTCONN	Socket is not connected
:58	ESHUTDOWN	Can't send after socket shutdown
:59	Unused	
:60	ETIMEDOUT	Connection timed out
:61	ECONNREFUSED	Connection refused
:62	ELOOP	Too many levels of symbolic link
:63	ENAMETOOLONG	File name is too long
:64	EHOSTDOWN	Host is down
:65	EHOSTUNREACH	No route to host
:66	ENOTEMPTY	Directory not empty
:67	Unused	
:68	Unused	
:69	EDQUOT	Disc quota exceeded
:70	ESTALE	Stale NFS file handle
:71	EREMOTE	Too many levels of remote in path
:72	ENOSTR	Not a stream device
:73	ETIME	Timer expired
:74	ENOSR	Out of stream resources
:75	ENOMSG	No message of desired type
:76	EBADMSG	Not a data message

Known Problems

Printing Browsers

Printing Browsers which contain dashed lines may cause your printer to hang.

Notefile Indicator Window

Occasionally, after you have reshaped a card, a piece of the text in the notefile indicator window will be garbled or broken. To redisplay the text in this window, place the point of the mouse cursor in the notefile indicator window, hold down the right mouse button, and select the **Redisplay** option from the window menu which pops up.

Fonts

The PostScript Zapfchancery font does not work at this point in time.

TEdit

When a TEdit window is positioned such that part of the display region of the window is off the screen, TEdit will display some lines of text in a garbled fashion. Simply move the window so that the entire extent of the window is on the screen or redisplay the window using the **Redisplay** option on the title-bar right-button mouse menu.

[This page intentionally left blank]

This document provides a brief explanation of the structure of notefiles. It also describes how checkpointing, aborting, and recovering a notefile after a crash work. Finally, it describes the use of **Inspect & Repair** to repair a notefile with inconsistent links. For additional information see Appendix B, The Notefile Inspector.

Note: The information in this appendix was copied whole from the documentation for a prerelease of NoteCards and has not yet been updated for this release. As such, it may be inaccurate in places.

Background Concepts

Unique identifiers: UIDs

All objects in NoteCards (i.e., cards, links, notefiles) are assigned a unique identifier called a UID. Each UID is a 112-bit number that is guaranteed to be unique across all time and space. UIDs are used in many places in NoteCards as keys for indexing and retrieving cards, links, and notefiles.

Card parts

For storage purposes a note card is decomposed into 4 independent parts: contents, title, property list, and links. Each of these parts is stored separately in the data area of the notefile. This is discussed in the Notefile Structure section below. When a card is saved, only those card parts that have changed are rewritten in the notefile.

The contents of the card are stored on the notefile in a manner appropriate to its type. Thus a Text card's content is a text stream and is written on the notefile exactly the way TEdit writes out text streams (i.e., text followed by "looks" information). In contrast, all titles are stored as strings and all property lists as standard Lisp lists. Storage of Links is described in Section 4 below.

Notefile Structure: index and data areas

A notefile consists of three parts, a header, an index, and a data area. The header and the index are fixed in size for each notefile. The data area follows the index area and grows as cards are added to or modified in the notefile.

The notefile header contains the following information about the notefile: its UID, a number identifying its format, the checkpoint pointer, the size of the index, and a pointer to the next available index entry. If the notefile header is destroyed, it cannot be automatically reconstructed. Careful hand manipulation of the

notefile by a NoteCards wizard is required to recover a notefile with a bad header.

The structure of the index and data area is shown in Figure A-1 .

The index contains a fixed number of index entries. Each index entry that is in use, contains information for one of the cards in the notefile. Specifically, an index entry contains 5 fields: a status character, the card's UID, and 4 pointers. The status character specifies whether the index entry is free (not in use) or contains information for an active or a deleted card. If the index entry is not free, the UID field contains the UID of the card referred to by this index entry and the four pointer fields contain the location in the data area of the 4 parts of its card: contents, title, links and property list.

The number of index entries is fixed at notefile creation time. The default is 1000 entries. The number of index entries is automatically doubled by the notefile compactor if 75% of the entries are used. The compactor also frees (i.e., makes unused) all of the index entries that refer to deleted cards. In normal operation, NoteCards prints a warning whenever more than 90% of the index entries in a notefile are used. At this point, the notefile should be compacted to increase the index size.

The data area contains the actual information about the card. Whenever you change, say, the title of a card, the new title is written at the end of the data area. The title pointer in the card's index entry is then updated to point to this new location in the data area. Thus, in general, a notefile's data area grows every time any part of any card is changed.

The old information, now somewhere in the middle of the data area, is not removed. However, it is no longer directly accessible because there is no index entry that points to it. Thus, for most purposes this old information can be considered "dead space" in the notefile. The notefile compactor rewrites the notefile, eliminating all such dead space.

Figure A-1. The structure of a notefile.

As long as the notefile has not been compacted, all the old information can be accessed (and made to be "current") via the notefile Inspect and Repair facility. Inspect and Repair does this by ignoring the index and parsing the entire data area to produce a listing of all the information (both current and old) about a card that is stored on the data area. See the Inspect and Repair manual for more information.

Notefile Checkpointing

As long as a notefile is open, its index area is cached in memory. When a card part is saved, the card part's information is written to the end of the data area but the card's actual index entry on the notefile is not updated with this new location. Instead, the appropriate pointer in the card's in-memory index entry is updated. Thus, the index in the notefile continues to point to the old information in the data area, while the in-memory index points to the new information.

Thus while a notefile is open, its current state is distributed between the actual notefile and information cached in memory. The current index is cached in memory. For cards open on the screen (or cached in memory from the programmer's interface), the "current" card part information is contained in an in-memory cache. For all

other cards, the current information is contained in the data area of the notefile pointed to by the in-memory index entry.

If a machine crashes while a notefile is open, the information cached in memory is lost. A crash not only discards changes made to cards on the screen, but it also leaves the information stored on the notefile in an inconsistent state. For example, the index on the notefile may point to old information in the data area. This occurs because the new information (e.g., a new title) is written to the data area but only the in-memory index pointers (which are lost in the crash) have been updated to point to the new information.

Checkpointing forces all of the in-memory information to be written onto the notefile. Specifically, checkpointing causes all open cards to be saved and the in-memory index to be written to the notefile's index area. Thus, immediately after checkpointing, the notefile itself contains its current (and consistent) state. If the machine were to crash at this point, no information would be lost and the notefile would be consistent.

Checkpointing also writes a **checkpoint pointer** onto the notefile header. The checkpoint pointer contains the location of the end of the data area (i.e., the end of the notefile) at the time the checkpoint is done.

As the notefile is used after the checkpoint, information is written in the data area past the checkpoint pointer but only the in-memory index entries are updated to point to this information. The on-file index entries still point to the information in the data area *before* the location referenced by the checkpoint pointer. Thus, a consistent notefile can be constructed from the index area and all of the information in the data area located before the checkpoint location. This is essentially the notefile as it was at the time of the last checkpoint. (Note: one small exception is that changes to a card's size on the screen are actually written in the middle of the data area rather than at the end. Thus, truncating a notefile to its checkpoint location cannot "undo" the reshaping of a card.)

When opening a notefile after a crash, the system will insure that the notefile is in a consistent state. It does so by truncating the data area to the last checkpoint location, saving the truncated information if requested by the user. This leaves the notefile in the state it was during the last checkpoint before the crash.

Aborting a notefile does the same thing. It truncates the data area to the last checkpoint location, thereby eliminating all changes made to the notefile since the last checkpoint. It also discards the in-memory index. Thus, the notefile is left in the exact state it was after the last checkpoint.

Finally, note that notefile Close forces a checkpoint. Therefore, aborts and recovery after crashes actually restore the NoteFile to its state as of the last user-initiated checkpoint or close.

Storing links and repairing notefiles with inconsistent links

The links card part is divided into three subcomponents: to-links, from-links, and global links. The to-links is a list of all links whose Source is the given card (i.e., that point from the card to some other card). The from-links is a list of links whose Destination is the given card (i.e., that point from some other card to the given card). Finally, the global links is a subset of the to-links that includes only the Global links originating in the given card.

Given this scheme, every link is stored on the notefile in three different places. First, if the link is Local it is stored inside the link icon which in turn is inside the content part of the link's source card. If the link is global, it is stored in the global links subpart of its source card. Second, the link is stored in the to-links list of its source card. Third, the link is stored in the from-links list of its destination card.

These three records of the same link occasionally get out of synch, resulting in an inconsistent notefile. There are a number of symptoms of such inconsistency. For example, the **ShowLinks** display for card may indicate that the card is a destination for a link from some source card X while the ShowLinks display for X does not include a ToLink to that destination card. Occasionally, inconsistent links will also result in link icons that contain the words "DELETED" or "FREE" when displayed on the screen. This usually means that the card at one end of a link was deleted, but somehow the links of the card at the other end were not updated. Such link icons cause NoteCards to break when you try to follow them.

One function of the NoteCards **Inspect & Repair** facility is to resynchronize the three records for all links in the notefile. The inspector's third phase rebuilds the links as follows. First it removes all to- and from-links for every card. Then it reads the contents for each card and recreates to-links and from-links by looking at the links found inside the link icons in the card's content and in its global links list. In addition, the links rebuilder phase of the notefile inspector can rebuild filebox contents from cards pointed to by the filebox, and the set of all link types from the list of all links.

[This page intentionally left blank]

The main purpose of the notefile inspector is to repair notefiles by rebuilding their links. However, the inspector is generally useful for checking the health of notefiles, deleting cards and backing up cards (or more precisely, card parts) to previous versions. Thus, you may want to use the inspector even if your notefile is healthy and doesn't need its links rebuilt.

The notefile inspector has three separate phases: reading the notefile's data area searching for healthy card parts, allowing the user to make modifications, and rebuilding the links. The process can be aborted after phase 1 or 2 if desired. This document describes each of the three phases in turn and concludes with tips, strategies and pitfalls to watch for.

Using the notefile inspector requires some knowledge of the innards of notefile organization. We recommend that you read Appendix A, Notefile Concepts, before continuing.

Note: The information in this appendix was copied whole from the documentation for a prerelease of NoteCards and has not yet been updated for this release. As such, it may be inaccurate in places.

Running the Notefile Inspector: Phase 1: Scouring the Data Area

To start the inspector on a notefile, first be sure that the notefile is not open. Then select the item **Inspect&Repair** from one of the NoteFile Ops menus (i.e. from the notefile Banner, the MenuBox icon or the notefile FileBrowser). There is one option available at this level by "pulling to the side" called **ReadSubstances**. This ensures that substances of all cards pronounced valid by the inspector are readable. If this option is not invoked, then a check is still run on the length of the substance, but not on its contents. Unfortunately, the ReadSubstances option requires MUCH more work by phase 1. We recommend that you only use this option if Phase 3 (link rebuilding) breaks with some error like "Bad Piece Tbl" from TEdit. In that case, up-arrow out of the break and start the Inspect&Repair process over again, this time using the slower but more comprehensive ReadSubstances option.

Selecting **Inspect&Repair** will invoke phase 1 of the inspector, wherein the data area of the notefile is scoured for valid card parts. A record of all such parts is kept and statistics printed out at the end. You'll be asked to position the window in which those statistics as well as later inspector communications will be printed. (Note that closing this window will abort the Inspect&Repair process if you confirm.) You can monitor the progress of phase 1 by watching the prompt window. It will be printing messages like "Processing byte xxxxx of yyyy."

When phase 1 has completed and you've positioned the interaction window, statistics on your notefile will be provided. You'll be told the total number of cards and the number of deleted ones. If all seems well with the world, the next line will read "All non-deleted

cards look okay." If not, there will be various messages outlining the problems. (See Figure 1.)

Figure B-1: Snapshot of a sample interaction window

Normally, the messages describing problems are of the form shown in Figure 1, namely a count of the number of cards broken in a given way. Some messages are a bit trickier. If you have fileboxes with bad substances (i.e. main card data), then you're told that if you don't wish to delete or back up such fileboxes to previous versions, then phase 3 will rebuild them. If, however, the filebox is one of the top level boxes (Contents, Orphans, ToBeFiled), then deletion is not an option. (See Section 3.)

If there are cards having user-defined types whose type definition code has not been loaded, then you'll get a message to that effect, something like "<n> cards have unknown card types (FOO BAR)." At this point you should load the lisp files containing the definitions of the unknown card types. If not, then these cards will show up with bad substance in phase 2. If you do load the appropriate files, then run **Recheck Bad Cards** to get the bad cards list recomputed before inspecting any cards.

If you have a card for which no substance versions could be read, then you'll also get unknown card type messages for it (reading something like "<n> cards have unknown card types (NIL)"). This is because the inspector couldn't find a card type on the notefile for that card.

A menu of options appears attached to the upper right corner of the interaction window. (See Figure 2.) The particular options you get in that menu depend on the state of your notefile and are described below. The last three options appear in all cases. The other two may or may not be present in the menu you get. In any case, you should select one of the options before attempting any other NoteCards-related work.

Figure B-2: The Phase 1 options menu.

Continue Repair

This option is only available if the notefile is in fairly good health (i.e. okay except for fileboxes to rebuild or global links to rebuild - see Section 3). Selecting it causes Inspect&Repair to move to phase 3 and rebuild your notefile's links.

End Inspect & Repair

This option is only available if it seems that you don't need to continue to the link rebuilding phase. You will not get this option if you've deleted any cards, or generally if there are problems with the notefile. Choosing this option causes the Inspect&Repair process to end gracefully (via a normal checkpoint and close notefile), thus skipping phase 3 of rebuilding links.

Abort

Choosing this option aborts the Inspect&Repair process entirely, throwing away any changes you might have made (such as card deletions or back ups.) It requires your confirmation in the prompt window.

Recheck Bad Cards

Recompute the bad cards list by running the last part of phase 1 again. This is useful if you've loaded files containing definitions of previously undefined card types.

Inspect Cards

This brings up a menu of titles of active cards with which you can inspect, delete, or back up particular cards. There is a "pull-across" menu item called **Include Deleted Cards**, which if selected will include card titles for deleted cards as well as active ones. Using this option, one can undelete deleted cards and restoring them to some previous version.

Running the Notefile Inspector: Phase 2: Your Chance to Tinker

After selecting **Inspect Cards** in the interaction window's attached menu, a menu containing numbered titles of notecards pops up and is attached to the interaction window's lower left corner. It contains the first 10 characters of titles for all active cards and possibly deleted cards as well if you selected the submenu item **Include Deleted Cards** described above. The menu can hold some 100 card titles. If your notefile has more than that, then the menu is composed of several pages each containing around 100 cards. Rapid switching between pages is possible. Figure 3 below shows a sample card inspector menu.

Attached to the upper right corner of the cards inspector menu is a menu containing at least the three options: **Abort**, **Done** and **Search**. If the menu has multiple pages (there are more than 100 active cards in the notefile), then the attached menu will also include the items **Next Page**, **Previous Page**, and **First Page**. Selecting these causes the current menu to be exchanged for either the next menu, previous menu, or first menu, respectively.

Clicking **Abort** causes the entire Inspect&Repair process to quit, throwing away any changes you've made. It requires your confirmation in the prompt window. (This is equivalent to choosing

Abort from the inspector window as described in the previous section.)

Choosing **Done** from this attached menu indicates that you're done tinkering with card parts and wish to return to the main interaction window. This causes the card inspector menu to close and the phase 1 process outlined in the previous section to be performed again (leaving you looking at something like Figure 1). Note, however, that the scanning of the data area is not repeated (it takes way too long). Rather, your changes are made to the in-core index array and the statistics on bad cards are recomputed. This cycle of compute statistics (phase 1) followed by inspect and tinker (phase 2) can be repeated as often as desired. Eventually, you must either abort, end the Inspect&Repair via **End Inspect&Repair**, or continue to phase 3 via **Continue Repair**.

Choosing **Search** from the attached menu allows you to find those cards having titles matching a given string. This works much like the Search card in Notecards. That is, you specify a string and the list of cards whose titles contain that string is printed out. This is handy, for example, if you want to undelete a card, but only know its title. Note that the search is case *ins*sensitive.

The card inspector menu

In the card inspector menu, those titles corresponding to deleted cards have a line drawn through them. Those having some sort of problem appear shaded. In addition, an upper-case letter suffix is attached to such entries indicating the problem. For example, in the card inspector menu shown in Figure 3, the shaded menu item "10: BNF for Li|S" indicates that the card with title beginning "BNF for Li" has bad substance. The letter codes are S, L, P, and T indicating bad substance, links, property list, and title, respectively. If such a letter code appears in lower case, then the meaning is that the current version of that card part is beyond the last checkpoint pointer. (There may have been a crash, for example, thus preventing the notefile from closing normally.)

Figures 3 and 4 show both pages of a two page card inspector including deleted cards. Sometimes deleted cards (e.g. "110: NIL|LSPT" in Figure 4) show up shaded with LSPT suffixes. This is because they were deleted before any data about the card was written to the notefile. Thus there are no valid card parts to back up to for those cards. But often, deleted cards can be backed up to previous versions. (See Figure 6 and discussion below.)

Figure B-4: A card inspector menu: Page 2.

At the top of the first page of any notefile's card inspector, there are entries for the top level boxes and special cards. These are labeled

"1: Contents", "2: Orphans", "3: To Be File", "4: Link Label", and "5: Registry".

Note that if the inspector shows no entry in the card inspector menu for some card, it is because that card has been deleted. If you've asked to show deleted cards and it still doesn't appear, it's because the notefile has been compacted since that card was deleted.

If you button card title entry in the card inspector menu, then a popup menu allows up to two choices **Inspect** and/or **Delete**. If the card is currently deleted (has a line drawn through it), then the Delete option is replaced by **Undelete**. Certain cards cannot be deleted and thus their popup menus only contain the Inspect option. These are the 5 special cards mentioned above.

Choosing Delete or Undelete from this popup menu causes the card to be deleted or undeleted, respectively and the line through the menu item either drawn or undrawn. Note, however, that this action (and all others) can be undone by choosing ABORT from either the card inspector menu or the interaction window menu.

Choosing Inspect from the popup menu for a card entry brings up a card parts inspector for that card.

The card parts inspector

Figures 5 and 6 below show examples of card parts inspectors. A card parts inspector is composed of four attached menus arranged vertically and one attached operations menu atop the stack.

Figure B-5: Card parts inspector for a browser card.

In Figure B-5, the four menus contain entries for every valid version of card parts for the browser card with title "Tailorability". The top menu is for versions of titles and below that are menus for versions of the card's substance, links, and prop list. For example, the Substance submenu contains entries for 6 versions of the substance of this card. The current version of each card part is shaded. Each menu entry gives the date that that version was written. (Very old notefiles may show "NO DATE AVAILABLE" in place of a real date.)

Figure B-6: Card parts inspector for a deleted card.

Figure B-6 shows a card parts inspector for a deleted text card and thus allows the UNDELETE option. By clicking UNDELETE, this card can be backed up to its last version.

If the current version of the card part is bad, then the menu entry will be a string so indicating, for example, "BADSUBSTANCE."

The title of the top menu includes the card's type. In addition, each menu item contains some information, in square brackets, before the date. In the title versions menu, this information is the first few characters of the title. In the substance versions menu, it is the number of bytes in the substance. In the links versions menu, it is a triple of numbers giving the number of to links, from links, and global links for this card. Finally, the proplist versions menu includes the number of entries on the property list for this card (i.e. twice the number of attribute-value pairs).

Atop the stack of menus is an attached menu of operations, described below.

CANCEL

This cancels this card parts inspector, throwing away any changes made.

UPDATE

This closes the card parts inspector, incorporating any changes (backing up to previous versions of card parts) you might have done.

DELETE

This option closes the card parts inspector and deletes the card.

UNDELETE

For cards that have been deleted, this option appears instead of DELETE. Choosing it causes the card to be undeleted.

RESET

This causes the selections in the submenus to be restored to the values they had when the card parts inspector was first brought up. (Equivalent to doing CANCEL and then inspecting this card again from the card inspector menu.)

Note that cards that can't be deleted (like the top level fileboxes) don't have the DELETE option on their card parts inspector.

Buttoning an entry in a submenu of a card parts inspector pops up a short menu unless the entry is for a bad version (e.g. "BADSUBSTANCE"). This menu contains at least the entry **Inspect** and possibly **Change Selection**, if the selected entry is not the same as the current one (i.e. not shaded).

Choosing Inspect allows further inspection of the details of the selected card part version. (See Figure B-7 below.) For example, inspecting a title version brings up the Interlisp inspector on a record containing the title, date and card object. Similarly, inspecting a links or prop list version brings up the Interlisp inspector on a record containing the lists of links (i.e. to links, from links and global links) or the prop list. Note that changing values in these Interlisp inspectors has no affect on the notefile and is ignored.

Figure B-7: Card part version inspectors for title, links and prop list.

All substance versions for card types inheriting from Text, Sketch and Graph can currently be inspected. (This includes most cards except those having user-defined substance types, like the NCFfile card.) Inspecting a card's substance version will bring up a window showing a copy of the substance. (Note that changes to this copy have no affect on the notefile.) Any links in the substance of the card will show up as bracketed strings describing the link.

Choosing **Change Selection** from the card part version popup menu causes the current selection to be changed to the selected one. This changes a card part's current version to another legal one. (This change can be undone by resetting or canceling the card parts inspector as well as by later aborting the card inspector or interaction window.)

Running the Notefile inspector: Phase 3: Rebuilding your links

To complete the Inspect&Repair process, select the **Continue Repair** option from the interaction window menu. This invokes phase 3, the links rebuilder. Normally, this simply rebuilds links from card substances. In certain circumstances, it may do extra work as well. If your link types list is bad, and you didn't back it up to a previous version, then phase 3 will rebuild it. If there are fileboxes with bad substances that you haven't either deleted or backed up to previous versions, then phase 3 will rebuild them. Finally, if there are cards with bad links that you haven't backed up or deleted, then phase 3 will rebuild those links as well. (It rebuilds ALL to links and from links anyway. For those cards, it will rebuild global links as well.)

First the links rebuilder removes all the to and from links for every card. Then it reads the substances for each card and recreates to

links and from links by looking at the links found inside the link icons in the card's substance.

The link rebuilder is also able to rebuild bad filebox substances. It does this by looking for all cards in the notefile with from links from the bad box and creating a new substance for the box containing only links to those cards. This process loses any text that the box might have contained as well as scrapping the original ordering of links. Nonetheless, in some cases this may be preferred to backing up the substance to a previous version or to deleting the box altogether.

The links rebuilder can rebuild the notefile's list of link types in a similar manner. That is, it records the set of link types seen on valid links and replaces the old links types with the new set. Note that this throws away any link types for which there are no links in the notefile.

Finally, the links rebuilder can rebuild bad global links for a card. It does this by looking for any cards with from links from the bad card that are global. This assumes that the card at the destination end has good links. Thus, if the cards at both ends of a global link have unreadable links, then there is no way to recover that link.

Note that the links rebuilder automatically files any unfiled cards in the ToBeFiled box. A message is printed in that case.

Tips and hints for using Inspect & Repair

This section contains a list of strategies and tips for using Inspect&Repair. For the most part, they are ordered from the useful and obvious to the esoteric. Several of these are implicit in the first four sections of the document, but are repeated here for emphasis and completeness.

When in doubt, abort!

All your changes will be lost, but then if you're uncertain about what's happened this is the safe course. Often, in fact, you may simply want to check the health of your notefile and abort without tinkering.

Fixing versus tinkering

There are two main ways to use the inspector, either for fixing a broken notefile, or tinkering with a healthy one. The latter case occurs when you wish to recover some card that was inadvertently deleted. Or back up a card that was accidentally changed to its original version.

Inspect & Repair after a crash

If you try to open a notefile and you get the infamous "Work was done since last checkpoint..." message, then you're given the chance to run Inspect&Repair on the notefile. This is a good idea

whenever you wish to recover that post-checkpoint work. The inspector will integrate the changes you made since that checkpoint. (You do have to continue through phase 3, however.)

Compacting

It used to be the case that old versions of card parts were in the notefile but inaccessible. Thus, there was little reason not to compact a notefile often. Now there is a tradeoff between the need to save space by compacting versus the need to be able to back up using Inspect&Repair. Probably the safest course is to keep a backed up copy of the pre-compacted notefile around until you have confidence that the compacted one is healthy and that you have no need for previous versions of any of its cards.

Inspect & Repair closes the notefile before starting

This means that if you are working in your notefile and notice a card you'd like to inspect a previous version of, you must record the card's title and close the notefile. Then, run Inspect&Repair, find the card's entry in the inspector menu using the Search facility, and tinker with it as desired.

Fixing enough problems to allow phase 3 to run

You can't run phase 3 unless Inspect&Repair thinks your notefile is above a certain threshold of health. There are certain problems it can handle (e.g. bad filebox substances, see Section 3), and others that it can't (e.g. bad substance for non-filebox). You have to decide either to fix these sorts of problems yourself in phase 2, let phase 3 attempt to rebuild them, or just abort the whole thing (always an option).

Sometimes these decisions can be tricky. For example, suppose a filebox's substance is bad. Call it BadBox. Should you (a) delete BadBox altogether, (b) back its substance up to a previous version, or (c) allow phase 3 to rebuild it by looking for from links in other cards from BadBox? Option (c) may not be advisable if there was important text in BadBox or if the order of cards in BadBox was important. On the other hand, option (b) may be of little use if the last good version is too out of date (or if there is no good version at all

Once your system administrator has installed the NoteCards software on your Sun, you can customize your NoteCards environment. The initialization file allows you to specialize your NoteCards environment to the idiosyncracies of your individual site. This file is automatically loaded when you start a fresh sysout.

Site Initialization File

When NoteCards starts, it reads in a site initialization file. This file sets things like the pointer to fonts, printers, and other site-specific parameters.

Locating the Initialization File

When running under SunOS, NoteCards looks for a site initialization file in a number of locations.

LDEINIT

If the UNIX environment variable `LDEINIT` is set to a complete NoteCards file name, NoteCards looks there first for the site initialization file:

```
prompt% setenv LDEINIT /users/smith/site-init.lisp
```

- or -

```
prompt% setenv LDEINIT /users/smith/nc-init
```

/usr/local/lde/site-init.lisp

If `LDEINIT` is not set or there is no file with the name given, NoteCards looks for a site initialization file called `/usr/local/lde/site-init.lisp`. The distribution tape contains a standard site initialization file in the NoteCards lisp directory `/usr/local/lde/lisp/init.NoteCards` which is linked to `/usr/local/lde/site-init.lisp`. You or your system administrator should customize this file for your site. The comments below and in the standard `site-init.lisp` describe the parameters it sets and gives some guidelines for customizing it to your local conditions.

{DSK}INIT.LISP

NoteCards looks for a site initialization file on your NoteCards home directory (`{DSK}`). Chapter 4, System Use Issues, describes the `{DSK}` device.

Finally, to load an initialization file after you have been working in a sysout, FileBrowse the directory the initialization file is in, select the file with the left mouse button, and select the **Load** option. The file will load and reset all of the initialization variables.

Figure C-1. A FileBrowser loading an initialization file.

Initialization File Structure

The structure of each command in the initialization file is as follows:

`(SETQ variable-name value)`

Each command must appear between parentheses. There must always be an even number of parentheses. Every open parenthesis must have a corresponding close parenthesis. SETQ is the assignment command. The variable name is always a single word, and the value is usually either a single word preceded by a single quote mark (') or a list of words enclosed in parentheses preceded by a single quote mark.

The initialization file must always start with two specific lines. The first line must be a comment line, indicated by starting the line with a semicolon (;). The second line must contain the command `(CL:IN-PACKAGE "INTERLISP")`.

Site Variables

The following NoteCards variables should be set in your site initialization file.

LISPUSERSDIRECTORIES

The list of paths to search for library files. Every path in this list should also be in DIRECTORIES.

```
(SETQ LISPUSERSDIRECTORIES
  ' (" {DSK}/usr/local/lde/lispusers/"
    " {DSK}/usr/local/lde/lisplibrary/"))
```

Note that each directory name is a string enclosed in double quotes ("). Unless you are a developer who is modifying NoteCards, there will probably never be any reason to change these values. You only need to change the value for this variable if you move the files in these directories to some other location, such as a central fileserver.

DIRECTORIES

The list of paths to search for files that are not found in the current NoteCards connected directory. The current NoteCards connected

directory is distinct from the current UNIX connected directory, and NoteCards will not necessarily search for files in the UNIX connected directory.

```
(SETQ DIRECTORIES (COPYALL LISPUSERSDIRECTORIES))
```

Note that there is *no* quote mark (') before the parenthesis in front of COPYALL. If you set DIRECTORIES in this fashion, this command must follow the one which sets LISPUSERSDIRECTORIES.

You can also simply copy the directories from LISPUSERSDIRECTORIES, e.g.

```
(SETQ DIRECTORIES
  ' (" {DSK}/usr/local/lde/lispusers/"
    " {DSK}/usr/local/lde/lisplibrary/"))
```

Unless you are a developer who is modifying NoteCards, there will probably never be any reason to change these values.

DISPLAYFONTDIRECTORIES

A list of directories to search when the system is looking for display fonts. The site initialization file should set DISPLAYFONTDIRECTORIES to a list of path names where each path name is represented as a string in double-quotes ("), e.g.,

```
(SETQ DISPLAYFONTDIRECTORIES
  ' (" {DSK}/usr/local/lde/fonts/display/presentation/"
    " {DSK}/usr/local/lde/fonts/display/publishing/"
    " {DSK}/usr/local/lde/fonts/display/printwheel/"
    " {DSK}/usr/local/lde/fonts/display/miscellaneous/"
    " {DSK}/usr/local/lde/fonts/display/jis1/"
    " {DSK}/usr/local/lde/fonts/display/jis2/"
    " {DSK}/usr/local/lde/fonts/display/chinese/"))
```

If you remove the Chinese and Japanese fonts from the font directories it is not necessary to edit this variable to reflect the change.

You only need to change the value for this variable if you move the fonts to some other location, such as a central fileserver. If you do change the value for this variable, note that each location is represented as a double quoted string and that each path name must end with a slash (/).

INTERPRESSFONTDIRECTORIES

A list of directories for the system to search for Interpress font widths files. The site initialization file should set INTERPRESSFONTDIRECTORIES to a list of path names where each path name is represented as a string in double-quotes ("), e.g.,

```
(SETQ INTERPRESSFONTDIRECTORIES
  ' (" {DSK}/usr/local/lde/fonts/interpress/presentation/"
    " {DSK}/usr/local/lde/fonts/interpress/publishing/"
    " {DSK}/usr/local/lde/fonts/interpress/printwheel/"
    " {DSK}/usr/local/lde/fonts/interpress/miscellaneous/"
    " {DSK}/usr/local/lde/fonts/interpress/jis1/"
    " {DSK}/usr/local/lde/fonts/interpress/jis2/"))
```

```
"{DSK}/usr/local/lde/fonts/interpress/chinese/"))
```

If you remove the Chinese and Japanese fonts from the interpress font directories it is not necessary to edit this variable to reflect the change.

You only need to change the value for this variable if you move the interpress fonts to some other location, such as a central fileserver. If you do change the value for this variable, note that each location is represented as a double quoted string and that the lowest subdirectory name in each path must end with a slash (/).

POSTSCRIPTFONTDIRECTORIES

The list containing the name of the PostScript font width files, for PostScript printers.

```
(SETQ POSTSCRIPTFONTDIRECTORIES  
  ' (" {DSK}/usr/local/lde/fonts/postscript/"))
```

You only need to change the value for this variable if you move the PostScript fonts to some other location, such as a central fileserver. If you do change the value for this variable, note that the location is represented as a double quoted string and that the lowest subdirectory name in the path must end with a slash (/).

USERGREETFILES

The list of places to search for personal initialization files. If not set in the site initialization file, no personal initialization file is used. The list should be similar to the following

```
(SETQ USERGREETFILES  
  ' ( (" {DSK}~/lde/INIT.LISP") (" {DSK}~/INIT.LISP") ) )
```

This will search for the file `INIT.LISP` in your home directory and in the subdirectory `lde` immediately under your home directory. The file `INIT.LISP` can be renamed to what ever you want it to be, but it has to be a name which is used by all users of the NoteCards system.

Unless you are a developer who is modifying NoteCards, there will probably never be any reason to change these values or use user greet files.

DEFAULTOSTYPE

Specifies the default operating system type for file servers.

```
(SETQ DEFAULTOSTYPE 'UNIX)
```

Unless you are using other than Sun NFS (Network File System) servers there is no reason to change the value of this variable.

DEFAULTPRINTINGHOST

A list of names of default printers.

```
(SETQ DEFAULTPRINTINGHOST NIL)
```

`NIL` is the default setting and signifies that there are no default printers specified. This variable can also be set from the **Set Default Printer** background menu option, (see Chapter 16, Printing).

The following example shows how to set `DEFAULTPRINTINGHOST` to a mixed list of PostScript and Interpress printers.

```
(SETQ DEFAULTPRINTINGHOST
```

```
' (MAUI |Tremor:mv:envos|))
```

- or -

```
(SETQ DEFAULTPRINTINGHOST
  ' (MAUI "Tremor:mv:envos"))
```

MAUI is the name of a PostScript printer, |Tremor:mv:envos| the name of an interpress printer. Each interpress printer name must be surrounded by vertical bars (|) or double quotes (").

DEFAULTPRINTERTYPE

The default printer type for all the available printers.

```
(SETQ DEFAULTPRINTERTYPE NIL)
```

Possible values are 'POSTSCRIPT, 'INTERPRESS, and NIL meaning unspecified. Note that 'POSTSCRIPT and 'INTERPRESS are all preceded by single quote marks ('), but that NIL is not.

If all your printers are PostScript printers you would make the following setting.

```
(SETQ DEFAULTPRINTERTYPE 'POSTSCRIPT)
```

If all your printers are not of the same type set DEFAULTPRINTERTYPE to NIL, and add the following command for each printer.

```
(PUTPROP 'Printer-Name 'PRINTERTYPE 'Type)
```

Where 'Printer-Name is the name of the printer and 'Type is one of 'POSTSCRIPT, 'INTERPRESS, or 'PRESS, for example.

```
(PUTPROP 'MAUI 'PRINTERTYPE 'POSTSCRIPT)
```

```
(PUTPROP '|Tremor:mv:envos| 'PRINTERTYPE 'INTERPRESS)
```

IDLE.PROFILE

The lines below set the IDLE.PROFILE such that any user with a valid UNIX login is allowed to exit idle mode.

```
(LISTPUT IDLE.PROFILE 'AUTHENTICATE 'UNIX)
```

The value of AUTHENTICATE determines what mechanism is used to check passwords. If 'UNIX, it checks your password with SunOS. If T, it uses the NS authentication protocol (this requires the presence of an NS Authentication server accessible via the network). If NIL, the password is not checked at all--any password is accepted. The latter is only useful if ALLOWED.LOGINS contains *.

```
(LISTPUT IDLE.PROFILE 'ALLOWED.LOGINS '(*))
```

The value of ALLOWED.LOGINS determines who is allowed to exit idle mode. If the value is NIL no login is required at all to exit idle mode. If the value is '(*), the system requires a login but lets anyone exit idle mode.

```
(LISTPUT IDLE.PROFILE 'SAVEVM NIL)
```

This line sets the IDLE.PROFILE such that NoteCards does not save the virtual memory file to disk when it enters idle mode. To

have NoteCards automatically save the virtual memory file to disk when it enters idle mode, replace `NIL` in the line above with `T`.

\\BeginDST The day of the year on or before which Daylight Savings Time takes effect (i.e., the Sunday on or immediately preceding this day). Must be set to 98 in the USA if NoteCards is to perform time computations correctly. (Note: This number is subject to future Congressional legislation.) If you are in a region where Daylight Savings Time is not observed, use the value 367.

```
(SETQ |\\BeginDST| 98)
```

\\EndDST The day of the year on or before which Daylight Savings Time ends. Must be set to 305 in the USA.

```
(SETQ |\\EndDST| 305)
```

XCL:*LONG-SITE-NAME* A long version of your company's name, for example, "Envos Corporation."

```
(SETQ XCL:*LONG-SITE-NAME* "Envos Corporation")
```

XCL:*SHORT-SITE-NAME* A short version of your Company's name, for example, "Envos."

```
(SETQ XCL:*SHORT-SITE-NAME* "Envos")
```

[This page intentionally left blank]

If you encounter inexplicable problems shortly after you install NoteCards, they may be due to files being corrupted — the release tape may have been damaged, errors may have occurred while the tape was being read, etc. If you have unexplained problems, we recommend that you verify the checksums of your installed files.

Description

The script generates checksum files named *filename.check* and compares them to the released *filename.sum* residing in the */checksumdir* subdirectory.

The checksum script reports inconsistent files, the correct checksum values for the files, and an error message. The checksum of individual files can be generated with the UNIX command: **sum filename**.

Commands

ldechecksum [-cg] [ncdir [dir dirgroup]]	[Command]
-c	Generates checksums for your installed files and compares them with correct values. This is the default action.
-g	Generates checksums for the files specified.
<i>ncdir</i>	Name of the NoteCards installation directory. Usually it is /usr/local/lde .
<i>dir</i>	Any specific directory residing under <i>ncdir</i> . Only relative pathnames with respect to <i>ncdir</i> are accepted.
<i>dirgroup</i>	The directory group. Valid directory groups are system , fonts , and all .
system	includes lisp, sysouts, install.sunos3.mc68020, install.sunos4.mc68020, install.sunos4.sparc.
fonts	includes the display, interpress, press and postscript directories.
all	includes all of the above.

Output

As it begins checking each directory, the script prints a message in the form:

```
Checking directory: /usr/local/lde/subdir
```

Error and warning messages may be in one of two forms:

```
< E > 36610 6973 NoteCards.sysout
```

Indicates that file NoteCards.sysout is erroneous or does not reside in the directory. The correct checksum of 36610, together with the size (6973 kbytes) of the file, are shown.

```
< W > /usr/local/lde/fonts/display/chinese:  
Directory not installed
```

Indicates that Chinese fonts were not installed or were removed after NoteCards was installed.

Examples

```
prompt% ldechecksum /usr/local/lde
```

All files in the installed NoteCards directories in `/usr/local/lde` are checked.

```
prompt% ldechecksum /usr/local/somedir/lde system
```

This example checks all files in:

```
/usr/local/somedir/lde/install.sunos3.mc68020  
/usr/local/somedir/lde/install.sunos4.mc68020  
/usr/local/somedir/lde/install.sunos4.sparc  
/usr/local/somedir/lde/sysouts  
/usr/local/somedir/lde/lisp
```

```
prompt% cd/usr/local/lde
```

```
prompt% ldechecksum -c . fonts/display
```

This example checks only the display font directories. The period (.) is used because you are positioned under the current NoteCards installation directory.

[This page intentionally left blank]

abort	To terminate any action before it is finished. When selected from the "Notefile Ops" menu, Abort means to close a notefile without saving your changes to the notefile.
back links	System generated to-links. These links point from a Document or LinkIndex card back to the source cards from which the Document or LinkIndex was built. Hence the name "back link."
background menu	The menu brought up by holding the right mouse button down in the gray region not associated with any windows.
backward links	The same as from-links. This term is used when setting Browser and LinkIndex card parameters.
Banner	The location from which you access old cards and create new ones. Also called "notefile Banner." The "Solar System" Banner is shown below.
	
bit map	A two-dimensional grid of zeros and ones where a zero represents white space and a one represents black space. The screen is a bit-mapped display.
break	The state entered by NoteCards during error processing that allows you to recover from the error by typing Lisp commands in the break window. If you don't know what to do with a break, type ^ after the prompt to abort the operation, then start over. When a break has occurred, we recommend that you perform an Inspect & Repair on the notefile after you have closed it.
break window	A window that opens when a break occurs. The title is usually the name of the broken function.
button	A button on the two- or three-button mouse.
card	Refers to any card type in the NoteCards system. Contrast with the entry for note card .
card contents	The text or graphics in the body of a card.
card menu	The menu brought up when you hold the left mouse button down in a card's title bar.
card type	Specifies a card's functional capabilities. NoteCards comes with eight card types. Each card type is specialized to perform a specific of operation, e.g., Search cards perform searches on card titles. Document cards create documents.
card-type bit map	The image on the left of the link icon which indicates the card type. In the image below, the card-type bit map indicates a FileBox card. See the section "Change Display Mode" in Chapter 8 for more a complete list of card-type bit maps.
	
card UID	The number given to each card which uniquely identifies it. See Appendix A for more information.

caret	A blinking arrowhead in a window, indicating where the keyboard characters will appear when typed. You change the position of the caret by moving the mouse cursor and pressing the left mouse button.
cascading menu	Same as submenu.
cross-file link	A link which points to a destination card stored in a notefile other than the source card's notefile.
click	To press and release a mouse button, the left button unless otherwise indicated.
connected directory	The directory the system uses by default when you do not specify a complete path when saving, retrieving, or loading a file. Also referred to as the default directory.
connection	A line drawn between two nodes in a Graph or Browser card. A connection may or may not represent a link.
control point	A position that helps to determine the location and shape of a Sketch element. Each element has one or more control points. In the following sketch, the ellipse has three control points indicated by the boxes.

current selection	The text in a Text card that is marked as selected in some way (underlining, highlighting, etc.) and has the caret at one end of the selection, e.g.

This is ~~the selected text~~,
This is selected text,
This is ~~the selected text~~.

dashing	The property of a line that causes it to be dashed., e.g. - . - . - . - . - . - . - . - . Links in browser cards may be dashed.

default	An action taken (or value specified) unless another is specified by the user.

deleted icon	An icon which appears in a source card when the destination card a link points to is deleted. Shown below.

destination card	The card which is opened (or flashed if already open) when you click on a link icon.
directory	The name of a group of related files. In UNIX a directory is a file containing a list of other directories and files.
extension	A string appended to a file name, indicating the type of file. The extension is separated from the file name with a period; the version number is separated from the extension by a semicolon. Sketch files have the extension ".sketch" followed by a version number. See file name .

file name	A character string used to refer to a file stored on disk. A full file name is composed of the file name followed by the file extension, followed by the version number, e.g. "Solar System. NOTEFILE;2." Here the file name is "Solar System," the extension is "NOTEFILE," and the version number is "2." The file name and extension are separated by a period and the extension and version number are separated by a colon. See extension and version number .
file server	A computer that provides file storage and retrieval service for users on the network.
font	A collection of characters in one size and style of type, e.g., 10-point Modern Italic.
font family	A complete assortment of letters, numbers, punctuation marks, etc., of a given design, such as Modern or Classic.
font size	The distance from the top of the highest character in a font to the bottom of the lowest.
forward links	To-links and global to-links. This term is used when setting Browser and LinkIndex card parameters.
from-link	A link corresponding to every to-link and global to-link. From-links point from the destination card to the source card. All from-links are global.
global links	Links whose start point is the card itself and not some point in the card's contents.
global to-links	Links whose start point is a card itself and whose end point is another card. These links are not represented by link icons in a card's body. To see and access these link icons, you must choose the Show Links option from a card's left button title bar menu.
graph-based cards	Cards based on the graph editor. Graph and Browser cards are graph-based cards.
hard copy	The physical copy (on paper) of an on-screen document.
host	Any machine on a network. Often used to refer specifically to a machine that provides a network service, such as filing.
icon	An on-screen pictorial image which can represent some other object, such as card, window, or link.
image object	A graphic image, such as a Sketch drawing, graph, bit map, link icon, horizontal rule, etc.
initialization file	A file that is loaded when NoteCards is first started, to customize your environment according to your tastes and the idiosyncracies of your site.
justification	The uniform spacing of words in a line, so that the line ends flush with both margins.
label	A character string which does not represent a card in a Graph or Browser card. In the display below, "Planet" is a label.

Error in IMAGEOBJ
GETFN: GRAPHOBJ.GETFN

line bar	The left part of a text card where the cursor shifts from being left-pointing to right-pointing allowing you to select larger units (paragraphs and lines) of text.
link	A connection between a source card and a destination card.
link icon	The graphical representation of the link. Clicking on a link icon traverses the link it represents and opens the destination card, or flashes it if it is already open.
link type	A word or phrase assigned by the user which classifies the relationship between two cards. Examples of link types include explanation, question, and answer.
local links	Links whose start point is somewhere in the contents of a card. Local links contrast with global links.
menu	A collection of text strings, buttons, or icons generally used to present a set of possible actions on the screen for user selection with the mouse.
MenuBox Icon	The icon from which you access the NoteCards system menus. Also referred to as the MenuBox.
mouse	A pointing device equipped with buttons.
mouse cursor	A small image (usually an arrow ) on the display screen that tracks the position of the mouse and lets you do things like reposition the caret. The cursor changes shape under certain conditions. An hourglass shape () indicates that a process is going on which may take some time to complete. A small image representing the mouse () which indicates that the system is waiting for a confirmation response before a selected process is performed.
node	Refers to a card or label in a Browser graph. The graph below shows four nodes, one of which (Moons) is a label.
note cards	Refers to non-FileBox cards, i.e., Text, Sketch, Graph, Browser, Search, LinkIndex, and Document cards. The generic term for cards of all types is just "card."
notefile	The file produced by the NoteCards system that contains the card index and cards.
notefile index	A fixed-size index of all the cards in the notefile. Its size must be explicitly changed.

network	An interconnection of several computers and other devices, such as printers, that lets them communicate and share resources. Sometimes also used to refer to the medium itself, such as a coaxial cable in the case of the Ethernet. Also, "net."
number pad menu	A calculator-style menu in which numbers can be entered to specify such values as line thickness.
path name	The complete name of a file you want to access. Includes the name of the host file server, device, directory, subdirectories, file name, extension, and version number. For example, in UNIX a notefile path name might be {dsk}/usr/users/kmount/nc/notefiles/demo.notefile, where dsk is the name of a device, usr is the directory, users, kmount, nc, and notefiles are the subdirectories, and demo.notefile is the file name of the notefile you want to access.
persistent menu	A menu that stays open until you close the menu or a window it is attached to. Also referred to as a "permanent menu" and "fixed menu."
pixel	A pixel is the smallest element of a display surface (a dot on a screen) which can be independently assigned a color or intensity. A blend of the words picture and element.
pop-up menu	A menu that appears when you press a mouse button and disappears when you release the button. Usually appears at the location of the cursor. The background menu is an example of a pop-up menu. See also menu and background menu .
prompt window	A small window attached to the top of a card, icon, or editor window where process information is printed and where you are asked questions. See also system prompt window .
scroll bar	The narrow window that opens when you move the cursor just outside the left or bottom edge of a window. You use the scroll bar to move through a body of information. The scroll bar frequently does not appear unless there is more information than can be displayed in the window.
sketch-based cards	Cards based on the Sketch graphical editor. There is only one sketch-based card and it is the Sketch card.
screen point	The size of a single pixel on the display. A screen point is 1/72 of an inch, normally.
select	This term has several meanings depending on the context of its use. When referring to menus, select means: Move the mouse cursor over the menu command, press the mouse button until the command is highlighted, then release the mouse button. You also select text (see current selection).
source card	A card containing a link icon.

submenu

A menu obtained by sliding to the right off an option on another menu. The existence of a submenu is indicated by a gray arrow head in the extreme right margin of a menu option. In the example below **Close**, **Delete**, **Copy**, and **Move** have submenus. In the case of **Move**, the user has slid the mouse off the right of the **Move** option and the **Move Cards/Move Structure** submenu has appeared.

**sysout**

A frozen version of the Notecards environment. It contains all the information needed to initialize virtual memory when Notecards is started.

system prompt window

The black window, usually at the top of the screen, used to display system information.

**text-based cards**

Cards based on the TEdit text editor which can also contain the output from sketch-based and graph-based cards. The text-based cards are Text, FileBox, Search, LinkIndex, and Document cards.

title bar

The black bar containing the window's title that appears at the top of a card or window.

to-links

Links whose start point is in a card's contents and whose end point is another card. These links are represented as link icons in a card's body.

type size

The distance from the top to the bottom of the characters that represent the highest and lowest points in a character set. Measured in points.

type-in process

The editor process associated with a card or window which is the destination for keyboard input.

version number

The number at the end of the file name that indicates when the file was created with respect to other files of the same name. The system assigns each successive file created with the same name a higher version number. The higher the version number, the newer the file.

virtual memory

Working space on the local disk that can be used, with the aid of swapping programs, to emulate random access memory.

window

A defined area within a display screen that can be used as a working space. Multiple windows can appear simultaneously on one display screen, and can overlay one another.

window menu The menu that appears whenever you press the right button with the cursor in the black title bar of a card or window, or at the top of a window with no title bar.

[This page intentionally left blank]

NOTECARDS PROGRAMMER'S INTERFACE

Introduction

This document describes a facility whereby users with some programming know-how can obtain a software interface to NoteCards in Interlisp. In this way, they can create and modify Notefiles, cards and links under program control.

The functions described below are divided into 8 groups:

1. NoteFile Creation and Access
2. Creating and Accessing NoteCard Types
3. Creating NoteCards and FileBoxes
4. Accessing NoteCards and FileBoxes
5. Creating and Accessing Links
6. Creating and Accessing Link Labels
7. Customizing the NoteCards Interface
8. Handy Miscellaneous Functions

Information for Prerelease Users

The two main changes to NoteCards from 1.2 are multiple open notefiles and cards stored as datatypes rather than atoms. The former change probably has a greater effect on users of the programmer's interface. Many functions now take a NoteFile argument that didn't before. In addition, many functions have been renamed or dropped altogether. Though we attempted to preserve some backward compatibility by keeping around old function names, we strongly recommend that you go over all your code and bring it up to date with this documentation. (For example, the whole notion of "Substance types" has been removed along with the Substance fns, etc.)

Other changes to watch out for include: traversal of NoteCards structures ala browsers; copying of groups of cards and their "internal" links across notefiles; new <quietFlg> args to many of the notefile access functions; undisplaying cards without uncaching; case insensitivity in NCP.TitleSearch; and registering of cards by key in the new notefile hash table. There are lots of handy new functions like NCP.ChangeCardTypeFields, NCP.CreateCardTypeStub, NCP.CollectCards, NCP.CopyCards, NCP.ListOfOpenNoteFiles, NCP.NumCardSlotsRemaining, NCP.ExpandNoteFileIndex, NCP.NoteFileMenu, NCP.NoteFileProp, NCP.WhichNoteFile, NCP.CreateLink, NCP.CardUserDataProp, NCP.DisplayedCards, NCP.RegisterCardByName, NCP.LookupCardByName, NCP.ListRegisteredCards, NCP.OpenCard, NCP.CloseCards, NCP.CacheCards, NCP.UncacheCards, NCP.DisplayCard,

NCP.UndisplayCards, NCP.AskYesOrNo, NCP.CardNeighbors,
NCP.MapCardsOfType, NCP.MapLinksOfType.

1. NoteFile Creation and Access

Note that some of the following accept filename arguments, some take notefile object arguments and some can take either. In any case, if the function accepts a filename, the .notefile suffix will be attached if not already present.

(NCP.CreateNoteFile <Filename><quietFlg>)

If <Filename> is not already a notefile, then creates a notefile with name "<Filename>.NoteFile", and returns this filename which can later be passed to NCP.OpenNoteFile. If <quietFlg> is non-nil, then communicative messages are held to a minimum.

(NCP.OpenNoteFile <NoteFileOrFilename> <don'tCreateFlg> <convertw/oConfirmFlg> <quietFlg> <menuPosition> <readOnlyFlg> <Don'tCreateInterfaceFlg>)

<NoteFileOrFileName> can be either a notefile object or a file name. Opens notefile, returning resultant notefile object if successful, else nil. If <don'tCreateFlg> is non-nil, then a new file is not created if the given one doesn't exist. If <convertw/oConfirmFlg> is non-nil, then if needed, the file is converted to the most recent format without user confirmation. If <quietFlg> is non-nil, then communicative messages are held to a minimum. If <menuPosition> is non-nil, then it should be a position at which to bring up the notefile main menu icon. If <readOnlyFlg> is non-nil, then the notefile is opened for read only. If <Don'tCreateInterfaceFlg> is non-nil, then don't bring up a control panel menu for the notefile.

(NCP.CloseNoteFiles <NoteFilesOrT> <quietFlg>)

If <NoteFilesOrT> is a list (or a single notefile), then close all open notefiles on that list (or the single one). If T, then close all open notefiles. If <quietFlg> is non-nil, then communicative messages are held to a minimum.

(NCP.CheckpointNoteFiles <NoteFilesOrT> <quietFlg>)

If <NoteFilesOrT> is a list (or a single notefile), then checkpoint all open notefiles on that list (or the single one). If T, then checkpoint all open notefiles. In case of a system crash or abort, the notefile can be recovered to the last checkpoint. Note that closing a notefile does a checkpoint. <quietFlg> non-nil will keep messages to a minimum.

(NCP.AbortNoteFiles <NoteFilesOrT> <Don'tConfirmFlg> <quietFlg>)

If <NoteFilesOrT> is a list (or a single notefile), then abort all open notefiles on that list (or the single one). If T, then abort all open notefiles. Aborting a notefile closes it and scraps all work since last checkpoint or successful close. <quietFlg> non-nil will keep messages to a minimum. <Don'tConfirmFlg> non-nil will prevent the asking of user for confirmation before throwing away work since last checkpoint.

(NCP.CompactNoteFile <fromNoteFileOrFilename> <toFilename> <inPlaceFlg>)

<fromNoteFileOrFilename> can be either a notefile or a file name. It is compacted, usually recovering space. If <inPlaceFlg> is non-nil, then <toFilename> is ignored and the compaction is in place. Will close <fromNoteFileOrFilename> if it's currently open.

(NCP.CompactNoteFileInPlace <NoteFileOrFilename>)

Compacts <NoteFile> in place, replacing the old version. Equivalent to (NCP.CompactNoteFile <NoteFile> NIL T).

(NCP.NumCardSlotsRemaining <NoteFile>)

Returns the total number of cards that can be created in <NoteFile> before its index must be expanded. <NoteFile> should be an open notefile.

(NCP.ExpandNoteFileIndex <NoteFile> <numNewCardSlots> <QuietFlg>)

Causes <NoteFile> (which should be a valid notefile) to be checkpointed and then have its index expanded in place to make room for <num NewCardSlots> new cards. If <NoteFile> is currently closed, then it is opened, expanded and then closed immediately.

(NCP.RepairNoteFile <NoteFileOrFilename> <readSubstancesFlg>)

Runs the Inspect&Repair facility on <NoteFileOrFilename>. It must *not* be currently open. If <readSubstancesFlg> is non-nil, then the inspector will check the contents of card substances rather than the simpler check of substance length. This means the first phase of the inspector takes MUCH longer so use with care. See the documentation on the Inspect&Repair facility for more information.

(NCP.DeleteNoteFile <NoteFileOrFilename> <Don'tConfirmFlg> <quietFlg>)

Deletes the <NoteFileOrFilename> notefile. Must not be open. <quietFlg> non-nil will keep messages to a minimum. <Don'tConfirmFlg> non-nil will prevent the asking of user for confirmation before deleting.

(NCP.NoteFileFromFileName <Filename>)

Returns the notefile corresponding to Filename if any, else nil.

(NCP.FileNameFromNoteFile <NoteFile>)

Returns the full name of the given notefile.

(NCP.NoteFileMenu <NoteFile>)

Returns the main menu for <NoteFile>.

(NCP.OpenNoteFileP <NoteFile>)

Returns non-NIL if <NoteFile> is a currently open notefile.

(NCP.ValidNoteFileP <NoteFile>)

Returns non-NIL if the notefile is a valid notefile.

(NCP.NoteFileClosingP <DontCheckForAbortFlg >)

Returns non-NIL if it has been called from under a close notefile operation. If DontCheckForAbortFlg is NIL, aborting the notefile counts as closing it. If DontCheckForAbortFlg is non-NIL, aborting the notefile is considered a different operation, and the function will return NIL.

(NCP.ListOfOpenNoteFiles)

Returns a list of all currently open notefiles.

(NCP.CheckOutNoteFile <fromFilename> <toFilename>)

Copies <fromFilename> to <toFilename> unless <fromFilename> is locked. If successful, creates a lock file in <fromFilename>'s directory. The name of the lock file is formed by concatenating the atom LOCKFILE onto <fromFilename>.

(NCP.CheckInNoteFile <fromFilename> <toFilename>)

Check lock file for <toFilename>. If none, then just copy <fromFilename> to <toFilename>. If there is one and it's owned by us, then do the copy and remove the lock file. If there is a lock file owned by someone else or if date of <toFilename> is more recent than date of lock file, then print a message and do nothing.

2. Creating and Accessing NoteCard Types

These functions give the user access to the NoteCard user-defined types facility. (In the functions below, card type arguments should be atoms.) For example, one of the simplest card types commonly created is what we call a "form" card. At card create time, it adds certain predefined text to the card's contents. Otherwise, form cards behave just like Text cards. Figure 1 shows the code needed to implement a sample form card type. For a full explanation of this facility, see the NoteCards Types Mechanism documentation.

FooForm.AddFooFormType

```
(LAMBDA NIL                                     (* rht; "10-Jul-88 11:41")

  (* * This creates the FooForm card type,)

  (NCP.CreateCardType (QUOTE FooForm)
    (QUOTE Text)
    (QUOTE ((MakeFn FooForm.MakeFn)))
    (QUOTE ((DisplayedInMenuFlg T)))))
```

FooForm.MakeFn

```
(LAMBDA (Card Title NoDisplayFlg)
  (* * The MakeFn for the FooForm card type,
    Note the call to the Text card's makefn,*)

  (PROG1 (NCP.ApplySuperTypeFn MakeFn Card Title NoDisplayFlg)
    (NCP.CardAddText Card (CONCAT
      "Some initial text for the FooForm card."
      (CHARACTER 13)
      ">>field1<<"
      (CHARACTER 13)
      "etc."))))
```

Figure 1: Sample card type definition

(NCP.CardTypes)

Returns list of all currently defined NoteCard types.

(NCP.CardTypeP <type>)

Returns non-nil if <type> is an existing NoteCard type.

(NCP.CardTypeFns)

Returns a list of the valid Fns fields for NoteCard types. Currently, these include: MakeFn, EditFn, QuitFn, GetFn, PutFn, CopyFn, MarkDirtyFn, DirtyPFn, CollectLinksFn, DeleteLinksFn, UpdateLinkIconsFn, InsertLinkFn and TranslateWindowPositionFn.

[The following hooks should some day become legitimate Fns or Vars fields for NoteCard types. Currently, they are properties placed on the card type's atom.

WhenSavedFn

If you need to have certain functionality happen just before a card's contents is saved to the notefile, then make a function be the value of the WhenSavedFn prop of the card type atom. It will be called whenever a card's contents is saved.

WhenDeletedFn

If you need to have certain functionality happen just before a card is deleted, then make a function be the value of the WhenDeletedFn prop of the card type atom. It will be called whenever a card is deleted. If the function returns 'ABORT, then the deletion of the card will be aborted.

LinkIconLeftButtonFn

One may now specify an operation other than TraverseLink to be used when left buttoning in link icons. Just put the property "LinkIconLeftButtonFn" with the value of a function on the (destination card's) card type atom. The function will get called with two args, the destination card and the window containing the link icon. (This is similar to the ExtraLinkIconMenuItems card type property consulted by the link icon middle button code.)

AttachedBitMapFn

You may now supply a function to calculate the attached bitmap for a card type. This function should be the value of the AttachedBitMapFn prop of the card type atom, and it will be passed Card, ScaledHeightToMatch, and Scale. If it exists, it will be applied first in calculating the bitmap to be displayed. If it returns a bitmap, a list of heights and bitmaps will be computed and placed

on the LinkIconAttachedBitMap field of the card type. This hook may also be used to calculate the bitmap to be displayed on the right side of a link icon if it is a cross-file link and its attached bitmap is being displayed. In this case, the function should be the value of the AttachedBitMapFn prop of the card type atom 'CrossFileLink. (For computing the list of heights and bitmaps in an AttachedBitMapFn, see NCP.MakeTypeIconBitMapSet at the end of this section.)

Don'tForceFilingFlg

It is possible to turn off forced filing on either the card type level or the card level. To define all cards of a type as not needing filing, you should put the property "Don'tForceFilingFlg" with the value of T on the card type atom. To define an individual card as not needing filing, use the function (NCP.MarkAsNotNeedingFiling <card>) (see Section 8: Handy Miscellaneous Functions).

NewCardPos

If present, the value of this property determines where new cards of the type are brought up on the screen, assuming the RegionOrPosition argument now accepted by all card type makefns (passed to NC.DetermineDisplayRegion) is NIL.]

(NCP.CardTypeVars)

Returns a list of the valid Vars fields for NoteCard types. Currently, these include: SuperType, StubFlg, FullDefinitionFile, LinkDisplayMode, DefaultWidth, DefaultHeight, LinkAnchorModesSupported, DisplayedInMenuFlg, LinkIconAttachedBitMap, LeftButtonMenuItems and MiddleButtonMenuItems.

(NCP.CardTypeFnP <fn>)

(NCP.CardTypeVarP <var>)

Returns non-nil if <fn> (<var>) is a valid function (variable) field for NoteCard types, for example, the litatom MakeFn (DefaultWidth). In other words, <fn> (<var>) can serve as the <fn> (<var>) arg to NCP.CardTypeFn (NCP.CardTypeVar).

(NCP.CardTypeFn <type> <fn>)

Returns the <fn> field for <type>. Note that this may be a value inherited at card type creation from <type>'s super type.

(NCP.CardTypeVar <type> <var>)

Returns the <var> field for <type>. Note that this may be a value inherited at card type creation from <type>'s super type.

(NCP.CardTypeSuper <type>)

Returns the super type of <type>. Equivalent to (NCP.CardTypeVar <type> 'SuperType).

(NCP.CreateCardType <TypeName> <SuperType> <FnsAssocList> <VarsAssocList>)

Makes a new NoteCard type with name <TypeName> and super type <SuperType>. Any functions not appearing in <FnsAssocList> or vars not appearing in <VarsAssocList> will be inherited from <SuperType>.

Note that, for now, specializing the FileBox card type is very dangerous and has unknown repercussions.

(NCP.DeleteCardType <TypeName> <DeleteSubTypesFlg >)

Deletes the NoteCard type with name <TypeName>. If DeleteSubTypesFlg is non-NIL, then it recursively deletes all sub-types of <TypeName>. If DeleteSubTypesFlg is NIL, then attempting to delete a type with sub-types is an error.

(NCP.CreateCardTypeStub <TypeName> <SuperType> <FullDefinitionFileName> <FnsAssocList> <VarsAssocList>)

Makes a stub for a new NoteCard type with name <TypeName> and super type <SuperType>. Some subset of the fns and vars can appear in <FnsAssocList> and <VarsAssocList>, however, the full definition will be loaded from <FullDefinitionFileName> the first time an attempt is made to access an undefined field name.

(NCP.ChangeCardTypeFields <TypeName> <FnsAssocList> <VarsAssocList>)

<TypeName> should be an existing NoteCard type. Some subset of the fns and vars should appear in <FnsAssocList> and/or <VarsAssocList>. These will be changed in the card type and then the inheritance mechanism will propagate these changes to any inheriting card types. For example, to make some existing card type FOO appears in the card type menu, do (NCP.ChangeCardTypeFields 'FOO NIL '((DisplayedInMenuFlg T))).

(NCP.ApplyCardTypeFn <CardTypeFn> <Card> <arg1> ...)

This macro applies the card type fn <CardTypeFn> (unevaluated) of the card type of <Card> to <Card> and the other args.

(NCP.ApplySuperTypeFn <CardTypeFn> <Card> <arg1> ...)

This macro applies the card type fn <CardTypeFn> (unevaluated) of the super type of <Card>'s type to <Card> and the other args.

(NCP.IsSubTypeOfP <type1> <type2>)

Returns non-nil if type1 inherits directly or indirectly from type2, that is, type2 can be found somewhere up the SuperType chain from type1.

(NCP.TextBasedP <cardOrType>)

(NCP.SketchBasedP <cardOrType>)

(NCP.GraphBasedP <cardOrType>)

If <cardOrType> is a card then we use its type. Returns non-nil if that type inherits directly or indirectly from Text, Sketch or Graph respectively.

(NCP.AutoLoadCardType <TypeName>)

<TypeName> is currently undefined. This asks NoteCards to look around for the file containing it and load it. It searches NOTECARDSDIRECTORIES for a file named NC<TypeName>TYPE.

(NCP.LinkIconAttachedBitMap <TypeName> <Size>)

Returns the link icon attached bitmap of size Size for card type TypeName. Default size is determined by the global variable NCP.DefaultLinkIconAttachedBitMapSize, whose initial value is 17.

(NCP.MakeTypeIconBitMapSet <Bitmap> <Heights>)

Returns a list of heights and bitmaps to be used in determining the appropriately sized bitmap for a given link icon. (Typically used when supplying an AttachedBitmapFn - see above.) <Bitmap> will be scaled to all of the heights in <Heights>, which defaults to NC.DefaultLinkIconAttachedBitMapHeights if NIL.

3. Creating NoteCards and FileBoxes

The following functions create various sorts of cards and boxes within the currently open notefile.

(NCP.CreateCard <type> <NoteFile> <title> <nodisplayflg> <props> <parentfileboxes> <otherargs><InterestedWindow> <RegionOrPosition>)

Creates and returns a card of the given (possibly user-defined) type, with given title, props, and parents. <otherargs> is a possibly nil list of args that will be passed to the MakeCardFn of <type>. Card is initially displayed or not according to value of <nodisplayflg>. Note that actually a top level copy of <props> is used (i.e. (APPEND <props>)). <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

(NCP.CreateTextCard <NoteFile> <title> <nodisplayflg> <props> <parentfileboxes> <InterestedWindow> <RegionOrPosition>)

Creates and returns a new notecard having type Text. If <title> is non-nil, it is installed as the Notecard's title, otherwise the title is "Untitled." <props>, if non-nil, should be a prop-list of properties and values to be placed on the user property list of the Notecard. If <parentfileboxes> is non-nil, then it should be a list of FileBoxes in which to initially file this card. <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

(NCP.CreateFileBox <NoteFile> <title> <nodisplayflg> <props> <childcardsboxes> <parentfileboxes> <InterestedWindow> <RegionOrPosition>)

Creates and returns a new Filebox with title <title> (or a gensym'ed name if <title> is nil). It will initially contain child cards and boxes from the list <childcardsboxes> (if that arg is non-nil). If <parentfileboxes> is nil, then the new filebox will be filed in the value of (NCP.GetToBeFiledFileBox). The <props> arg is handled as it was for NCP.CreateNoteCard. <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

(NCP.CreateBrowserCard <NoteFile> <title> <paramList> <nodisplayflg> <props> <parentfileboxes> <InterestedWindow><RegionOrPosition>)

Creates and returns a new browser card with given title, props and parents. <paramList> should be a prop list of browser parameters. The properties currently recognized are:

ROOTCARDS	A list of Notecards to serve as roots of the forest or lattice generated by the browser. If omitted or NIL then user is asked to choose root cards.
LINKTYPES	A list of link types to follow when creating the browser. Any label present in the list having the backarrow prefix ("_") represents that link type but in the reverse direction. This list can also contain the atoms ALL or _ALL (<backarrow>ALL) in which case browsing will be done on all links in either the forward or reverse direction. If both ALL and _ALL (<backarrow>ALL) are specified, then links in both directions will be used (generally making a mess).
DEPTH	The depth at which to cut off the browser. This should be a non-negative integer. If NIL or omitted, then will assume no limit. (Currently integers greater than 9 are assumed equivalent to infinity.)
FORMAT	This should be a list of one, two or three elements. The first should be an atom indicating grapher format. The choices are FAST (layed out as a forest, sacrificing screen space for speed), COMPACT (layed out as a forest, using minimal screen space), LATTICE (layed out as a directed acyclic graph, the default), *GRAPH* (layed out as a graph, i.e. virtual nodes are eliminated). The second element of the FORMAT list, if present, should be either HORIZONTAL (the default) or VERTICAL specifying whether the graph is layed on its side or up and down. The third element, if present, should be the atom REVERSE. This indicates that horizontal graphs should be layed out from right to left instead of left to right and that vertical graphs should be layed out from bottom to top rather than vice versa.

If all of LINKTYPES, DEPTH, or FORMAT are omitted, the user is asked to choose them from a stylesheet. If one or more is specified, even as being NIL, the user is not prompted for them. <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

(NCP.CreateSketchCard <NoteFile> <title> <nodisplayflg> <props> <parentfileboxes> <InterestedWindow><RegionOrPosition>)

Creates and returns an initially empty sketch/map card having given title, props, and parents. <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

(NCP.CreateGraphCard <NoteFile> <title> <nodisplayflg> <props> <parentfileboxes> <InterestedWindow><RegionOrPosition>)

Creates and returns an initially empty graph card having given title, props, and parents. <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

(NCP.MakeDocument <NoteFile> <rootcard> <parametersProplist> <nodisplayflg> <props> <parentfileboxes><InterestedWindow> <RegionOrPosition>)

Creates and returns a Document card starting from <rootcard>. The user may specify new values for the set of parameters for making a document with <parametersProplist>. For example, a value of '(TitlesFromNoteCards Bold ExpandEmbeddedLinks ALL)

for <parametersProplist> would cause these values for the parameters TitlesFromNoteCards and ExpandEmbeddedLinks to be used, and the current defaults for the other parameters will be used. If no <parametersProplist> is provided, the user will be prompted for the parameters with a stylesheet. As usual, the resulting card will have the given props and parents. <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

(NCP.MakeLinkIndex <NoteFile> <linktypes> <backpointersP> <nodisplayflg> <props> <parentfileboxes> <InterestedWindow> <RegionOrPosition>)

Creates and returns a LinkIndex text card consisting of a sorted record of all instances of links in the current notefile having one of the given link types. <linktypes> can contain the litatoms ALL and/or _ALL (<backarrow>ALL) as well as any particular backwards links. (See the above description of NCP.MakeDocument.) Backpointer links are inserted in the text if <backpointersP> is non-nil. Resulting card will have given props and parents. <InterestedWindow> is a window used to attach a prompt window for messages. <RegionOrPosition> is used to position and/or shape the new card.

4. Accessing NoteCards and FileBoxes

The following functions provide access to the cards and boxes present in the current notefile. Note that whether a card's window has been brought up on the screen has little or no impact on most of the following functions. If the user changes some field of a card while that card is visible on the screen, then the field will update itself automatically. Thus, users can switch between program-driven and screen-interface-driven modes at will.

Most of the following functions take as first argument a card or filebox. If this does not in fact correspond to an existing card or box, then an error message is printed and nil is returned.

Cards can be displayed, cached or closed. A cached card has its information cached in memory thus saving time (to access) at the expense of space. All cards displayed on the screen are also cached. In almost all cases, users will need only use NCP.OpenCard and NCP.CloseCards. NCP.OpenCard does both caching and displaying while NCP.CloseCards does both undisplaying and uncaching, if necessary.

(NCP.OpenCard <card> <region/position> <typeSpecificArgs>)

Brings up on the screen the given card in the given region or at the given position. If <region/position> is nil, then user is asked to specify position with mouse. <typeSpecificArgs>, if any, will be passed to the card type's EditFn.

(NCP.CloseCards <cardOrListOfCards> <quietFlg>)

Undisplay and uncache all the cards in <cardOrListOfCards>. <quietFlg> non-nil cuts down on messages.

(NCP.DisplayCard <card> <region/position> <typeSpecificArgs>)

If <card> was cached but not displayed, then bring it up on the screen. The <region/position> argument is as in NCP.OpenCard. <typeSpecificArgs>, if any, will be passed to the card type's EditFn.

(NCP.UndisplayCards <cardOrListOfCards> <quietFlg> <writeChangesFlg>)

If any of <cardOrListOfCards> were displayed, then undisplay them. <quietFlg> non-nil cuts down on messages. Normally, changes are not written to the notefile when a card is undisplayed, but only when it is uncached. <writeChangesFlg> non-nil makes changes be written through to the notefile.

(NCP.CacheCards <cardOrListOfCards>)

If any of <cardOrListOfCards> are not currently cached, then cache them.

(NCP.UncacheCards <cardOrListOfCards> <quietFlg>)

If any of <cardOrListOfCards> are cached but not displayed, then uncache them. <quietFlg> non-nil cuts down on messages.

(NCP.CardDisplayedP <card>)

Returns non-nil if given card or box is currently displayed in a window.

(NCP.CardCachedP <card>)

Returns non-nil if given card's information is currently cached.

Most of the following functions leave the card in the same state as it was when they started (except NCP.BringUpCard, which makes it active). Thus, users needing to do several consecutive operations to the same card should consider temporarily caching the card's information via NCP.CacheCards (and then uncaching with NCP.CloseCards).

(NCP.CardType <card>)

Returns the type of <card> or NIL if the card does not exist.

(NCP.ValidCardP <card>)

Returns <card> if <card> exists (hasn't been deleted), otherwise returns NIL. (This is currently a synonym for NCP.CardType.)

(NCP.SameCardP <card1> <card2>)

Returns non-nil if <card1> is the same card as <card2>. Error if either arg is not a valid card.

(NCP.NewCardP <card>)

Returns non-nil if <card> is new; ie. not yet saved in the notefile. Error if the arg is not a valid card.

(NCP.CardBeingDeletedP <card>)

Returns non-nil if <card> is in the process of being deleted; for use with user-defined card types. Error if the arg is not a valid card.

(NCP.CardTitle <card> [<newtitle>])

Returns old title of <card>. If <newtitle> is present, then set <card>'s title to <newtitle>. <newtitle> can be an atom or string. Note, however, that all titles are converted internally to strings by NoteCards.

(NCP.FileCards <cards> <fileboxes>)

Every card or box in <cards> is filed in every box in <fileboxes>. Either arg may be a card object or a list.

(NCP.UnfileCards <cards> <fileboxes>)

Every card or box in <cards> is unfiled from every box in <fileboxes>. Furthermore if <cards> is the litatom ALL, then the boxes in <fileboxes> will be cleared of all children. Similarly, if <fileboxes> is the litatom ALL, then the cards and boxes in <cards> will be unfiled from all their parent boxes. Either arg may be a card object or a list.

(NCP.CardParents <card> <FollowCrossFileLinksFlg>)

Returns list of fileboxes in which <card> is filed. <FollowCrossFileLinksFlg>, if non-nil, causes cross-file links to be followed to recover fileboxes in remote notefiles in which <card> is filed.

(NCP.FileBoxChildren <filebox> <FollowCrossFileLinksFlg>)

Returns list of children of <filebox> in the order in which they appear in the box's textstream. <FollowCrossFileLinksFlg> is as in NCP.CardParents.

(NCP.GetLinks <cards> <destinationCards> <labels> <NoteFile>)

Returns list of all links from any of <cards> to any of <destinationCards> having any label in <labels>. Any of these arguments can be nil. For example, if <destinationCards> is nil, then all links pointing from <cards> to anywhere with a label in <labels> are returned. If both <cards> and <destinationCards> are nil, then <NoteFile> should not be nil and this returns all links in <NoteFile> having a label in <labels>. If all three args are nil, then this is a slow synonym for (NCP.AllLinks <NoteFile>).

(NCP.GetCrossFileLinkDestCard <CrossFileLinkCard> <InterestedWindow> <Don'tOpenDestNoteFileFlg>)

For a given <CrossFileLinkCard>, tries to follow the link to a remote card in the destination notefile and returns that card if found. If <Don'tOpenDestNoteFileFlg> is non-nil, then destination notefile must be open. <InterestedWindow> is an optional window argument whose prompt window is used for messages.

Cross-file link cards are "hidden" cards that serve as placeholders for true cross-file links. That is, a (two-way) cross-file link from card A to card B (in different notefiles) actually consists of 2 links and 2 cross-file link cards. In the source notefile, card A is linked to a cross-file link card AA. AA "knows" about the notefile that contains B and B's UID. Similarly, the destination notefile contains a cross-file link card BB which is linked to card B. Again, the substance of BB contains a filename "hint" for the source notefile as well as the

UID for A. One-way cross-file links only contain cross-file link cards in the source notefile. The destination card contains no record that it's been linked to.

(NCP.CardNeighbors <cards> <linkTypes> <FollowCrossFileLinksFlg>)

Return a list of cards each of which is one link away from some card in <cards>. Only links having types in <linkTypes> are considered. Both <cards> or <linkTypes> can be either nil, card objects (or link type atoms) or a list. Null <cards> means that all cards linked to by anyone are returned. <linkTypes> can include link types prefixed with the character '_' (<backarrow>). This means to follow links of that type in the reverse direction. <linkTypes> can also include either or both of the atoms ANY and _ANY (<backarrow>ANY). The former means to include any cards one link away in the forward direction, while the latter causes inclusion of any cards one link away in the backwards direction. <linkTypes>=NIL is equivalent to <linkTypes>=ANY. If <FollowCrossFileLinksFlg> is non-nil, then any links that cross notefile boundaries are followed to their remote destination cards. Otherwise, cross-file links are ignored.

(NCP.CardPropList <card>)

Returns the prop list of the given card.

(NCP.CardProp <card> <propname> [<newvalue>])

Returns old value of property <propname> on <card>'s prop list. If <newvalue> is present, then set <card>'s <propname> property to <newvalue>. (Semantics are analogous to the Interlisp function WINDOWPROP.)

(NCP.CardAddProp <card> <propname> <newitem>)

Adds <newitem> to the list present on the <propname> property of <card>. Returns old value of property. (Semantics are analogous to WINDOWADDPROP.)

(NCP.CardDelProp <card> <propname> <itemToDelete>)

Deletes <itemToDelete> from the <propname> property of <card> if it is there, returning the previous value of that property. If not there, return nil. (Semantics are analogous to WINDOWDELPROP.)

(NCP.CardRegion <card> [<newRegion>])

Returns the region of <card>. This works even if <card> is not currently up on the screen, since the region information is stored on the notefile. If <newRegion> is provided, then the saved region of the card is changed. If the card is currently displayed, then it is reshaped to the new region.

(NCP.CardSubstance <card> [<newSubstance>])

Returns the substance of <card>. For example, returns a textstream in the case that the type of <card> is built on the TEdit text editor. In general, this is what the PutFn of a card type writes down to the notefile and what the GetFn reads in. If a <newSubstance> argument is present, then the substance of the card is replaced and NCP.MarkCardDirty is called.

(NCP.CardAddText <card> <textstr> <loc>)

Adds the text within the string <textstr> to the text card <card>. If <loc> is the litatom START or END, then the text will be placed at the start or end of the card respectively. If <loc> is a number, then it is assumed to be a character count within the card at which to place the new text. If <loc> is NIL, then the text is placed at the current cursor location.

(NCP.ChangeLoc <card> <loc>)

Changes the cursor's location in <card>'s textstream to <loc>. Possible values for <loc> are as described for NCP.CardAddText.

(NCP.DeleteCards <cardOrListOfCards>)

Deletes the given cards and fileboxes from their notefile, or deletes just the one if <cards> is a single card object.

(NCP.CardNoteFile <card>)

Returns <card>'s NoteFile.

(NCP.CardWindow <card>)

Returns <card>'s window if <card> is currently displayed somewhere on the screen. (The function NCP.WindowFromCard is an alias for NCP.CardWindow.)

(NCP.CardFromWindow <window>)

Returns the card associated with <window>, or NIL if not a notecards window.

(NCP.CardFromTextStream <TextStream>)

Returns the card associated with <TextStream>, or NIL if <TextStream> doesn't belong to some text card.

(NCP.FileBoxP <card>)

Returns non-nil if <card> is a filebox.

(NCP.AllCards <NoteFile>)

Returns a list of all extant cards for the given notefile.

(NCP.CardsOfTypes <CardsOrNoteFile> <Types>)

Returns a list of all cards of the given type (or types) for the given notefile (or list of cards).

(NCP.AllBoxes <NoteFile>)

Returns a list of all fileboxes in the given notefile.

(NCP.MapCards <NoteFile><fn> <collectResultsPredicate>)

Maps down the set of all cards in the current notefile, applying <fn> to each. If <collectResultsPredicate> is non-nil, then for those cards satisfying the predicate, the values of <fn> applied to them are collected.

(NCP.MapCardsOfType <types> <NoteFile> <fn> <collectResultsPredicate>)

This is similar to NCP.MapCards, but only looks at cards whose type appears on <types>. <types> can be a single type or a list of types.

(NCP.ContentsFileBox <NoteFile>)

(NCP.OrphansFileBox <NoteFile>)

(NCP.ToBeFiledFileBox <NoteFile>)

These functions retrieve the three predefined FileBoxes for the currently open NoteFile. These boxes can be modified (but not deleted) by the user in the same way as any other filebox.

5. Creating and Accessing Links

Links consist of source card, destination card, link type, display mode and anchoring mode. The new function NCP.CreateLink can be used to create any sort of link. We still provide the four functions NCP.GlobalGlobalLink, NCP.LocalGlobalLink, etc. for those who have grown used to that style.

(NCP.GetLinks <cards> <destinationCards> <labels> <NoteFile>)

See documentation in the previous section.

(NCP.CreateLink <source> <destination> <linkType> <displayMode>)

<source> can be either a card or a list of two elements (<sourceCard> <sourceLoc>). <sourceCard> should be a card to use as the source of the link while <sourceLoc> should be either the atom GLOBAL (in which case a global-to-global link is created) or a Loc directive as described in NCP.CardAddText above, that is, an integer or one of the atoms START, END or NIL. This creates and returns a new link with type <linkType>, connecting <sourceCard> to <destinationCard>. For text cards, Loc, if present, designates where to insert the link. If the link is local-to-global, then <displayMode> should be a valid displaymode or NIL. (See description of NCP.LinkDisplayMode for the valid values for <displayMode>.) (In the future, Locs for non-text cards will be specifiable. In the far future, we hope to allow local anchoring at the destination end of the link as well as the source.)

(NCP.GlobalGlobalLink <label> <sourceCard> <destinationCard>)

Creates and returns a new link with label <label>, connecting <sourceCard> to <destinationCard>.

(NCP.LocalGlobalLink <label> <sourceCard> <destinationCard> <fromloc> <displaymode>)

Creates and returns a new link with label <label>, connecting from <fromloc> of <sourceCard> card to <destinationCard>. If <displaymode> is non-nil, then the new link is displayed in the given mode. Otherwise the default displaymode for the source card's type is used. See the description of NCP.LinkDisplayMode for the valid entries for the <displaymode> arg.

(NCP.GlobalLocalLink <label> <sourceCard> <destinationCard> <toloc>)

Not implemented at this time.

(NCP.LocalLocalLink <label> <sourceCard> <destinationCard> <fromloc> <toloc>)

Not implemented at this time.

(NCP.LinkDesc <link> <followCrossFileLinkFlg>)

Returns list of three items (<label> <sourceDesc> <destinationDesc>) where <label> is the link type and <sourceDesc> and <destinationDesc> have the form (<anchor mode> <card> <loc>). <anchor mode> is either LOCAL or GLOBAL, <card> is the card at this end of the link, and <loc> gives a position in the text of <card> if <anchor type> is LOCAL and <card>'s substance's type is TEXT. If the link is a cross-file link and if <followCrossFileLinkFlg> is non-nil, then the link will be traversed, opening the remote notefile if necessary to determine information about the source or destination card of the link.

(NCP.LinkDisplayMode <link> [<newdisplaymode>])

Returns old display mode of <link>. If <newdisplaymode> is present, then set <link>'s displaymode accordingly. If non-nil, it can be an instance of the LINKDISPLAYMODE record. Or it can be one of the litatoms Icon, Title, Label, or Both. Finally, it can be a list of three elements (<ShowTitleFlg> <ShowLinkTypeFlg> <AttachBitmapFlg>). Each element can have one of the three values T, NIL, or FLOAT. If a field, say <ShowTitleFlg>, has value FLOAT then the corresponding global parameter (DefaultLinkIconShowTitle, in this case) will be consulted to decide whether or not to display the destination card's title in this icon. (See Section 7 for a description of the global parameters.)

(NCP.CoerceToLinkDisplayMode <thing>)

Returns a LINKDISPLAYMODE record. Thing can be a LINKDISPLAYMODE record, cardtype, card, link, atom, or list. If thing is a LINKDISPLAYMODE record, that record is returned. If thing is a cardtype, the default LinkDisplayMode for that cardtype is returned. If thing is a card, the LinkDisplayMode of that card is returned. If thing is a link, the LinkDisplayMode of that link is returned. If thing is an atom or a list, then the corresponding LinkDisplayMode, as specified under **NCP.LinkDisplayMode** (see above), is returned.

(NCP.LinkType<link> [<newLinkType>])

Returns old linktype of <link>. If <newLinkType> is present, set <link>'s type to <newLinkType>.

(NCP.LinkSource <link>)

Returns the card at the source end of <link>.

(NCP.LinkDestination <link>)

Returns the card at the destination end of <link>.

(NCP.DeleteLinks <links>)

Removes all links in <links> (or just one if <links> is a single link object).

(NCP.ValidLinkP <link>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Returns non-nil if <link> is a link in the current notefile.

(NCP.SameLinkP <link1> <link2>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Returns non-nil if <link1> is the same link as <link2>. Error if either arg is not a valid link.

(NCP.AllLinks <NoteFile>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Returns a list of all existing links in <NoteFile>. (This is equivalent to but faster than (NCP.GetLinks NIL NIL NIL <NoteFile>).)

(NCP.MapLinks <NoteFile> <fn> <collectResultsPredicate>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Maps down the set of all links in the given notefile, applying <fn> to each. If <collectResultsPredicate> is non-nil, then for those links satisfying the predicate, the values of <fn> applied to them are collected.

(NCP.MapLinksOfType <types> <NoteFile> <fn>)
<collectResultsPredicate>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN This is similar to NCP.MapLinks, but only looks at links whose type appears on <types>. <types> can be a single type or a list of types.

6. Creating and Accessing Link Labels

Error in IMAGEOBJ
1GETEN: HRULE.GETEN The following functions allow the user to manipulate link labels.

(NCP.CreateLinkType <linkType> <NoteFile> <QuietFlg>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Creates a new link type with name <LinkType> in <NoteFile> unless there is already one defined by that name. A non-NIL <QuietFlg > suppresses the error message that is normally printed if the link type has already been defined for this notefile.

(NCP.DeleteLinkType <linkType> <NoteFile>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Deletes the link type <linkType> from <NoteFile>. The link type must exist and must not be the type of any existing link, and it must not be a system-defined link type (e.g. SubBox or BrowserContents).

(NCP.RenameLinkType <linkType> <newLinkType>)
<NoteFile>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Changes any links in <NoteFile> having link type <linkType> to have type <newLinkType>. <linkType> must exist and neither <linkType> nor <newLinkType> should be a system-defined type.

(NCP.LinkTypes <NoteFile>)

Error in IMAGEOBJ
1GETEN: HRULE.GETEN Returns a list of all existing link types in <NoteFile> including system-defined ones.

(NCP.ReverseLinkTypes <NoteFile>)

Returns a list of the reverse link types for every link type in <NoteFile>. Thus, whereas SubBox would appear in the list returned by NCP.LinkTypes, _SubBox (<backarrow>SubBox) would appear in the list returned by NCP.ReverseLinkTypes.

(NCP.UserLinkTypes <NoteFile>)

Returns a list of all existing user-defined link labels in <NoteFile>.

(NCP.SystemLinkTypeP <LinkType>)

Returns non-nil if <LinkType> is a system link type..

(NCP.ValidLinkTypeP <LinkType> <NoteFile>)

Returns non-nil if <LinkType> is a defined link type for <NoteFile>.

7. Customizing the NoteCards Interface

There are currently several areas where the user may tailor the NoteCards user interface: the NoteCards Session Icon menus, the left button menu on the title bar of a notefile's menu icon, the middle button menu of a notefile's menu icon, the ShowCards middle button menu on a notefile's menu icon, and the title bar menus of displayed cards and card types.

The Session Icon: The menus associated with this icon may be modified using the following functions:

(NCP.AddSessionIconMenuItem <MenuName> <Item>)

Adds the menu item <Item> to the session icon menu specified by <MenuName> (one of 'Card', 'NoteFile', or 'Other'). <Item> should be a complete menu item and may contain subitems in the standard format. For the Card and Other menus, the item can be a normal menu item. For the NoteFile menu, it must be slightly different. Instead of providing an expression to be evaluated as the second part of the menu item (and of any subitems), you should provide the name of a function of two arguments: NoteFile and Window. This function will be applied to these arguments when the menu item is selected.

Returns the item added if successful, NIL otherwise.

Example:

```
(NCP.AddSessionIconMenuItem ' NoteFile '(Foo% Function
NC.DoFoo "Performs the function Foo on this notefile") )
```

(NCP.RemoveSessionIconMenuItem <MenuName> <ItemName>)

Removes the menu item named <ItemName> from the session icon menu specified by <MenuName> (one of 'Card', 'NoteFile', or 'Other'). <ItemName> should be only the name of the menu item.

Returns the full item removed if successful, NIL otherwise

Example:

```
(NCP.RemoveSessionIconMenuItem ' NoteFile 'Foo% Function )
```

(NCP.RestoreSessionIconMenu <MenuName>)

Restores the menu specified by <MenuName> (one of 'Card', 'NoteFile', or 'Other') to its initial state. If <MenuName> is NIL, all three menus will be restored.

(NCP.SessionIconWindow)

Returns the session icon window.

(NCP.BringUpSessionIcon <IconPosition>)

Brings up the NoteCards icon at IconPosition. If no IconPosition is given and the icon is already on the screen, it will be flashed. If it is not on the screen, the user will be prompted to place it.

The left button menu on the title bar of a notefile's menu icons: The user may modify this menu using the following functions.

(NCP.AddNoteFileIconMenuItem <Item> <OpenOrClosedOrBoth>)

Adds the menu item <Item> to the NoteFile icon menu. <Item> should be a complete menu item and may contain subitems.. The second part of the menu item (and of any subitems) should be a function of two arguments: NoteFile and Window. Window will be the icon window for the notefile. This function will be applied to these arguments when this menu item is selected. <OpenOrClosedOrBoth> specifies for which type of notefile the new operation will be valid. If <OpenOrClosedOrBoth> is 'Open', the item will appear as an operation for open notefiles. If <OpenOrClosedOrBoth> is 'Closed', the item will appear as an operation for closed notefiles. If <OpenOrClosedOrBoth> is 'Both', the item will be available for both open and closed notefiles.

Returns the full item added if successful, NIL otherwise.

Example:

```
(NCP.AddNoteFileIconMenuItem '(Foo% Function NC.DoFoo
"Performs the function Foo on this notefile") 'Open)
```

(NCP.RemoveNoteFileIconMenuItem <ItemName>)

Removes the menu item named <ItemName> from the NoteFile icon menu.

Returns the full item removed if successful, NIL otherwise.

Example:

```
(NCP.RemoveNoteFileIconMenuItem 'Foo% Function )
```

(NCP.RestoreNoteFileIconMenu)

Restores the NoteFile Icon menu to its initial state.

The middle button menu of a notefile's menu icon: It is now possible for users to add menu items to this menu using the following functions.

(NCP.AddNoteFileIconMiddleButtonItem <Notefile><MenuItems>)

Adds list of menu items <MenuItems> to the middle button menu of the main menu icon corresponding to <Notefile>. These menu items will remain on the menu until the next time the notefile is closed. The second item of each menu item should be an atom that is the name of a function to be called when selected.

(NCP.AddDefaultNoteFileIconMiddleButtonItem <MenuItems>)

Adds list of menu items <MenuItems> to the middle button menu of the main menu icons for all notefiles. These menu items will remain on the menus for the life of the session. The second item of each menu item should be an atom that is the name of a function to be called when selected.

The ShowCards middle button menu on the notefile icon: Users can indicate that certain cards should be added to or deleted from this menu using the following functions.

(NCP.AddSpecialCard <Card>)

Adds <Card> to the list of special cards appearing in the middle button menu on the ShowCards option of the notefile icon (for the notefile containing <Card>).

(NCP.RemoveSpecialCard <Card>)

Removes <Card> from the list of special cards appearing in the middle button menu on the ShowCards option of the notefile icon (for the notefile containing <Card>).

The title bar menus of cards and card types: Users can add menu items to either a specific window containing a card, or to the default menu of a card type.

(NCP.AddTitleBarMenuItemsToWindow <Win> <Button> <NewMenuItems><TopOrBottom>)

Adds the menu items <NewMenuItems> to the title bar menu of <Win>. <Button> should be one of 'Left or 'Middle, corresponding to either the LeftButtonTitleBarMenu or the MiddleButtonTitleBarMenu. <Win> should be the window of a visible notecard. <TopOrBottom> should be one of 'Top or 'Bottom, indicating where in the menu the new items should appear.

(NCP.AddTitleBarMenuItemsToType <Type> <Button> <NewMenuItems> <TopOrBottom>)

Adds the menu items <NewMenuItems> to the title bar menu of all cards of type <Type>. <Button> should be one of 'Left or 'Middle, corresponding to either the LeftButtonTitleBarMenu or the MiddleButtonTitleBarMenu. <TopOrBottom> should be one of 'Top or 'Bottom, indicating where in the menu the new items should appear.

Menu of notefiles: the user may use the list and menu of noticed notefiles maintained by NoteCards.

NCP.NoticedNoteFileNames

Global var containing a list of the currently available notefile names noticed by NoteCards.

(NCP.NoticedNoteFileNamesMenu <IncludeNewNoteFileFlg> <AllowedOperations> <InterestedWindow> <Operation>))

Provides user with a menu of noticed notefile names. <IncludeNewNoteFileFlg> should be non-NIL if new notefiles are allowed. <AllowedOperations> should be one of the atoms: OPEN, CLOSED or NIL for both. <Operation> should be a string or atom containing the name of the operation to be performed on the result and the word NoteFile; e.g. (QUOTE Open% NoteFile). This is used in the prompt for a new notefile name. <InterestedWindow> is the window to receive a prompt window for any messages printed.

(NCP.ForgetNoteFileName <NoteFileOrFileName>)

The notefile is removed from the menu of noticed notefiles. It will not be added to the menu again until explicitly remembered using NCP.RememberNoteFileName regardless of other operations performed on the notefile.

(NCP.RememberNoteFileName <NoteFileOrFileName>)

The notefile is added to the menu of noticed notefiles. This is only necessary if the NoteFile name has been forgotten.

NCP.GrayShade

Global var containing the shade used for shading various menu items in the interface. The default value of NCP.GrayShade is GRAYSHADE. This variable should be changed with the function NCP.SetGrayShade (see below).

(NCP.SetGrayShade <Shade>)

This function should be used to change the value of NCP.GrayShade to <Shade>. In addition to changing NCP.GrayShade, it also resets all cached menus that use NCP.GrayShade. If <Shade> is NIL, NCP.GrayShade will not be changed, but the menus will still be reset. Returns the new value of NCP.GrayShade.

8. Handy Miscellaneous Functions

(NCP.BringUpNoteCardsIcon <IconPosition>)

Brings up the NoteCards session icon at the position <IconPosition>. If no position is given, will prompt the user to place the icon. If the icon is already on the screen and no position is given, it will be flashed. (equivalent to (NoteCards <IconPosition>).

(NCP.TitleSearch <NoteFile> <keys> <caseSensitiveFlg>)

Returns a list of all cards in <NoteFile> having all of the <keys> (can be atom, string or list) within their titles. Normally case insensitive unless <caseSensitiveFlg> is non-nil.

(NCP.PropSearch <NoteFile> <propOrPair> <propOrPair> ...)

Returns a list of all cards in <NoteFile> such that for every <propOrPair> arg, if it is atomic, then the card contains that property. If it is a list of two elements, then the card must have a property EQ to the first element with value EQ to the second element.

(NCP.WhichCard <x> <y>)

Returns the card currently displayed on the screen whose window contains the position in screen coordinates of <x> if <x> is a POSITION, the position (<x>,<y>) if <x> and <y> are numbers, or the position of the cursor if <x> is NIL. Returns NIL if the coordinates are not in the window of any card. If they are in the window of more than one card, then returns the uppermost. If <x> is a window, then NCP.WhichCard will return the card associated with that window. (The function NCP.WC is an alias for NCP.WhichCard.)

(NCP.WhichNoteFile <x> <y>)

Works just like NCP.WhichCard, returning the notefile corresponding to the indicated window. If the window is for a card, then the card's notefile is returned, if it's for a notefile menu, then

that notefile is returned. (The function NCP.WNF is an alias for NCP.WhichNoteFile.)

(NCP.NoteFileIconWindow <NoteFile>)

Returns the main menu icon window, if any, for given <NoteFile>.

(NCP.DisplayedCards <NoteFiles > <CardTypes >)

Returns a list of all cards currently displayed on the screen that are in one of <NoteFiles > and are of one of the types in <CardTypes >. (Shrunk ones are included.) If <CardTypes > is NIL, then looks at all card types. If <NoteFiles > is NIL, then looks at all notefiles.

(NCP.SelectCards <instigatingCardOrWindow> <singleCardFlg> <selectionPredicate> <message> <checkForCancelFlg> <NewCardFlg>)

Returns a list of those cards selected from the screen. A menu appears in or near <instigatingCardOrWindow> displaying <message> and having buttons for DONE, UNDO, CANCEL (unless <singleCardFlg> is non-nil, in which case there is only a CANCEL button) and NEW CARD (if <NewCardFlg> is non-NIL). Card selections must satisfy <selectionPredicate> and are made by left buttoning in the title bars of the desired cards. If user hits CANCEL button, then NIL is returned unless <checkForCancelFlg> is non-nil, in which case the atom DON'T is returned.

(NCP.DocumentParameters <parametersProplist>)

Returns the old value of the document parameters in the form of a proplist. If <parametersProplist> is non-nil then it should be a proplist whose properties are (some of the) valid document parameter names and whose values are permissible values for those parameters. The valid parameters and possible values are as follows:

HeadingsFromFileboxes	NumberedBold, UnnumberedBold, NONE.
TitlesFromNoteCards	Bold, NotBold, NONE.
BuildBackLinks	ToCardsBoxes, ToCards, ToBoxes, NONE.
CopyEmbeddedLinks	ALL, NONE, <listOfLinkLabels>.
ExpandEmbeddedLinks	ALL, NONE, <listOfLinkLabels>.

[See the Notecards user's manual for an explanation of these parameters and how their values affect the document created.]

(NCP.NoteCardsParameters <parametersProplist>)

Returns the old value of the global Notecards parameters in the form of a proplist. If <parametersProplist> is non-nil then it should be a proplist whose properties are (some of the) valid document parameter names and whose values are permissible values for those parameters. The valid parameters and possible values are as follows:

DefaultCardType	<legalCardType>
MenuLingersAfterNoteFileClose	T or NIL
ShowNoteFileOnCards	T or NIL

NewNoteFileInitialSize	<positive number (default is 1000)>
ForceFiling	T or NIL
ForceTitles	T or NIL
CloseCardsOffScreen	T or NIL
BringUpCardsAtPreviousPos	T or NIL
MarkersInFileBoxes	T or NIL
AlphabetizedFileBoxChildren	T or NIL
DefaultLinkIconAttachBitmap	T or NIL
DefaultLinkIconShowTitle	T or NIL
DefaultLinkIconShowLinkType	T or NIL
UseDeletedLinkIconIndicators	T or NIL
DelTEditProcessWhenShrinking	T or NIL
ExtraTEditProps	a prop list
EnableBravoToTEditConversion	T or NIL
IncludeCardObjectInShowInfo	T or NIL
LinkDashingInBrowsers	T or NIL
ArrowHeadsInBrowsers	one of the litatoms {AtEndpoint, AtMidpoint, None}
SpecialBrowserSpecs	T or NIL
DefaultFont	a font
LinkIconFont	a font
MenuFont	a font
NoteFileIndicatorFont	a font

Here, <legalCardType> should be an existing Notecard type, i.e. one that appears in the list returned by NCP.CardTypes.

(NCP.CoerceToInterestedWindow <WinOrCardOrNoteFile>)

Coerces a window, card or notefile into a window which can have a prompt window.

(NCP.PrintMsg <window> <clearFirstFlg> <arg1> <arg2> ...)

Prints a message in the prompt window of <window>. If <window> is NIL, then prints message in the Lisp prompt window. If <clearFirstFlg> is non-nil, then clears the prompt window first. The args are PRIN1'ed one at a time.

(NCP.ClearMsg <window> <closePromptWinFlg> <WaitMsecs>)

Clears the prompt window associated with <window> (or with the main Lisp prompt window if <window> is NIL) and closes it if <closePromptWinFlg> is non-nil. The prompt window will not be cleared before the specified wait has expired.

(NCP.AskUser <Msg> <prompt> <FirstTry> <ClearFirstFlg> <MainWindow> <DontCloseAtEndFlg> <DontClearAtEndFlg> <PROMPTFORWORDFlg>)

This function can be used to ask questions of the user in a window's prompt window. The <Msg> and <prompt> are printed along with <FirstTry> (if non-nil). The value returned is whatever the user types. If <ClearFirstFlg> is non-nil, then the prompt window is cleared first. If <MainWindow> is nil, then the top level prompt window is used. If <DontCloseAtEndFlg> is non-nil, then the prompt window won't be closed after the question is answered and if <DontClearAtEndFlg> is non-nil, then the prompt window won't be cleared at the end. If <PROMPTFORWORDFlg> is non-nil, then the PROMPTFORWORD typein protocol will be used rather than TTYIN. The former doesn't allow mouse editing of the string typed in. On the other hand, typing automatically overwrites the prompt when PROMPTFORWORD is used.

(NCP.AskYesOrNo <Msg> <prompt> <FirstTry> <ClearFirstFlg> <MainWindow> <DontCloseAtEndFlg> <DontClearAtEndFlg>)

This function can be used to ask yes/no questions of the user in a window's prompt window. The fields are as in NCP.AskUser except that PROMPTFORWORD is always used so there is no Flg for that.

(NCP.CardDates <Card>)

Returns a NOTECARDDATES record structure containing the dates of last modification of each of the four card parts of <Card>. The fields of the record are SUBSTANCEDATE, TITLEDATE, LINKSDATE and PROPLISTDATE.

(NCP.DetermineDisplayRegion <card> <region/position>)

Returns the region that <card> would occupy if displayed. If <region/position> is NIL, then asks the user to position a ghost region to get the position. Also checks previous size of card or default heights and widths for the card type to find the size. If BringUpCardAtPreviousPos is on, then won't require positioning of ghost region even if <region/position> is NIL.

(NCP.SetUpTitleBar <CardWindow> <CardType>)

This function is usually called from the MakeFn for those card types that inherit from a card type that doesn't display in a window, like the List or NoteCard type. It creates and installs left and middle menus using the menu items found in <CardType>'s definition. It also installs a default button event fn on the window.

(NCP.LinkFromLinkIcon <linkIcon>)

If <linkIcon> is an image object for a link icon, then returns the associated link. Note that link icons can be obtained by calling the card type's CollectLinksFn (see the card types mechanism documentation).

(NCP.MakeLinkIcon <link>)

If <link> is a valid link, then creates and returns a new link icon image object containing it.

(NCP.MarkCardDirty <card> <resetFlg>)

Mark <card>'s substance as dirty thus forcing it to be written down at the next save. If <resetFlg> is non-nil, then *unmark* <card> as dirty.

(NCP.MarkAsNotNeedingFiling <card>)

Mark <card> as not needing filing. This is done by setting the card's Don'tRequireFilingFlg prop to T.

(NCP.CoerceToCard <cardIdentifier>)

Return the card object (if any) associated with <cardIdentifier> which can currently be any of: a card object, window or text stream.

(NCP.CollectCards <RootCards> <LinkTypes> <MaxDepth> <FollowCrossFileLinksFlg>)

Starting from <RootCards> and following links having types in <LinkTypes> to a maximum depth of <MaxDepth>, collect and return a list of all cards encountered. A value of NIL for <MaxDepth> causes search to be "infinitely" deep. <LinkTypes> and <FollowCrossFileLinksFlg> are as described in NCP.CardNeighbors.

**(NCP.CopyCards <Cards> <DestNoteFileOrFileBox> <RootCards> <QuietFlg>
<CopyExternalToLinksMode> <InterestedWindow>)**

This copies all cards in <Cards> along with all links among them. If <CopyExternalToLinksMode> is 'COPY, external to-links will also be copied; if it is 'DON'TCOPY, external to-links will not be copied; and if it is NIL, the user will be asked if he/she wishes to copy these links. <DestNoteFileOrFileBox> designates a filebox in which to file the card copies. (If <DestNoteFileOrFileBox> is a notefile, then its Contents box is used.) <RootCards> should be a subset of Cards or NIL. If <RootCards> is NIL, then all the card copies are filed in the destination box, otherwise just those appearing in <RootCards>. If <RootCards> is the atom NONE, then none of the new cards will be filed in the destination filebox. <QuietFlg> cuts out the messages. Note that currently, <Cards> must all live in the same notefile, but this *can* be a different notefile from the destination notefile. <InterestedWindow> is a window used to attach a prompt window for messages.

**(NCP.MoveCards <Cards> <DestNoteFileOrFileBox> <RootCards> <QuietFlg>
<CopyExternalToLinksMode><InterestedWindow>)**

This moves all cards in <Cards> along with all links among them. If <CopyExternalToLinksMode> is 'COPY, external to-links will also be copied; if it is 'DON'TCOPY, external to-links will not be copied; and if it is NIL, the user will be asked if he/she wishes to copy these links. <DestNoteFileOrFileBox> designates a filebox in which to file the card copies. (If <DestNoteFileOrFileBox> is a notefile, then its Contents box is used.) <RootCards> should be a subset of Cards or NIL. If <RootCards> is NIL, then all the card copies are filed in the destination box, otherwise just those appearing in <RootCards>. If <RootCards> is the atom NONE, then none of the new cards will be filed in the destination filebox. <QuietFlg> cuts out the messages. Note that currently, <Cards> must all live in the same notefile, but this *can* be a different notefile from the

destination notefile. <InterestedWindow> is a window used to attach a prompt window for messages.

The following functions allow users to register cards by name for fast access. This is normally done using the card's notefile's system registry. Thus this registering is preserved over notefile closing.

(NCP.RegisterCardByName <Name> <Card> <RegistryCard>)

Stores <Card> in <RegistryCard> hashed under the name <Name>. If <RegistryCard> is nil, then use <Card>'s notefile's system registry.

(NCP.LookupCardByName <Name><NoteFileOrRegistryCard>)

If <NoteFileOrRegistryCard> is a registry card, then recovers the card that was hashed under <Name>. If <NoteFileOrRegistryCard> is a notefile, then use its system registry.

(NCP.UnregisterName <Name><NoteFileOrRegistryCard>)

If <NoteFileOrRegistryCard> is a registry card, then smashes whatever was stored under <Name>. If <NoteFileOrRegistryCard> is a notefile, then use its system registry.

(NCP.ListRegisteredCards <NoteFileOrRegistryCard> <IncludeKeysFlg>)

If <NoteFileOrRegistryCard> is a registry card, then returns the list of cards hashed in it. If <NoteFileOrRegistryCard> is a notefile, then use its system registry. If <IncludeKeysFlg> is non-nil, then return list of cons pairs with car=Name and cdr=Card.

One can associate functionality with the opening and closing of notefiles using two special List cards registered under the names OpenEventsCard and CloseEventsCard. Their substances each consist of a list of lisp s-expressions to be evaluated at notefile open and close time respectively. Thus, to cause a new expression to be evaluated at notefile open time, one cons's (or appends) the expression to the substance of OpenEventsCard (either via DEdit or NCP.CardSubstance). Note that during the evaluation of the expressions, the atom NoteFile is bound to the notefile being opened or closed. When a notefile is closed, the expressions in the CloseEventsCard are evaluated both just before the notefile is closed, and after it is finished being closed. In this case, the atom When is bound to either 'Before or 'After, indicating when the expressions are evaluated with respect to the close operation.

(NCP.GetOpenEventsCard <NoteFile>)

Returns the open events card for <NoteFile> creating a new one if necessary. Thus, this is basically just (NCP.LookupCardByName 'OpenEventsCard <NoteFile>), except that a new List card is created and registered under the name OpenEventsCard if none exists.

(NCP.GetCloseEventsCard <NoteFile>)

Returns the close events card for <NoteFile> creating a new one if necessary. Thus, this is basically just (NCP.LookupCardByName 'CloseEventsCard <NoteFile>), except that a new List card is

created and registered under the name CloseEventsCard if none exists.

Sometimes, it's nice to have a place to temporarily hang your hat, so to speak. For this purpose, we provide what are called *UserProps* for both card and notefile objects. These are temporary in that they vanish when the notefile closes.

(NCP.CardUserDataProp <Card><Prop> [<NewValue>])

Returns the value under the <Prop> user data prop for <Card>. If <NewValue> is present, then value under <Card>'s <Prop> is reset. (That is, it works like WINDOWPROP or NCP.CardProp.)

(NCP.NoteFileProp <NoteFile><Prop> [<NewValue>])

Returns the value under the <Prop> user data prop for <NoteFile>. If <NewValue> is present, then value under <NoteFile>'s <Prop> is reset. (That is, it works like WINDOWPROP or NCP.CardProp.)

(NCP.NoteFileAddProp <NoteFile><Prop> [<NewValue>])

Returns the value under the <Prop> user data prop for <NoteFile>. If <NewValue> is present, then it is added to the list under <NoteFile>'s <Prop>. If <NoteFile> has no value under <Prop>, then <NewValue> is placed on that property as a list. (That is, it works like WINDOWADDPROP.)

Error breaks/messages under the programmer's interface: When the programmer's interface detects an error, it calls NCP.ReportError or NCP.ReportWarning depending on the severity of the error. Normally the former causes a break while the latter merely prints a message. However, this behavior can be changed using the global var NCP.ErrorBrkWhenFlg, a litatom whose value should be one of NIL, ALWAYS or NEVER (default is NIL).

(NCP.ReportError <Function><Message>)

Forces a break using BREAK1 unless the value of NCP.ErrorBrkWhenFlg is the litatom NEVER. If so, then simply prints a message and continues.

(NCP.ReportWarning <Function><Message>)

Prints the given warning message <Message> unless the value of NCP.ErrorBrkWhenFlg is the litatom ALWAYS. If so, then forces a break with BREAK1.

There are a few old functions preserved for backward compatibility, but we encourage users to rewrite all their code to use only functions described above. The old functions still available are:
NCP.BringUpCard, NCP.ActivateCards, NCP.ActiveCardP,
NCP.DeactivateCards, NCP.ValidCard, NCP.GetContentsFileBox,
NCP.GetOrphansFileBox, NCP.GetToBeFiledFileBox,
NCP.GetLinkSource, NCP.GetLinkDestination,
NCP.CreateLinkLabel, NCP.DeleteLinkLabel,
NCP.RenameLinkLabel, NCP.GetLinkLabels,
NCP.GetUserLinkLabels, NCP.GetReverseLinkLabels,

Bitmap Editor

**Vista Laboratory
Xerox Special Information Systems**

November, 1988

The bitmap editor is invoked as follows.

(EditBitmap BitmapOrFile Window ...)

If BitmapOrFile is an existing bitmap, the user will be prompted to place a window displaying the existing bitmap. If BitmapOrFile represents a file containing a bitmap in binary form, it will be read from the file and subsequently edited via the window. If BitmapOrFile is non-NIL and Window is given, the bitmap will be edited within the existing window although it may be clipped if the bitmap is larger than the window. Finally, if both BitmapOrFile and Window are NIL, the user will be prompted to sweep out a region on the screen that will define the bitmap. The editing window is then placed as desired.

The four menu items at the top of the editor window set the primary drawing operation. Paint logically ORs the drawing bits with the bitmap bits to give the result. In Replace mode, all drawing bits replace the bitmap bits whether they are on or off. Invert does a logical exclusive OR between the drawing bits and the bitmap bits. Erase preforms a

logical AND between the inverse of the drawing bits and the destination bits. The drawing operation may also be changed via Parameter menu subitems.

A brief description of all the menu items follows.

Abort - Error out of the bitmap editor. Equivalent to a control-E.

Add Border - The bitmap is expanded by adding a border with a user specified width and texture.

Add Texture - Adds a user selectable texture to the entire bitmap.

Add Pattern - Allows the user to define a pattern (an independent bitmap) that may be placed in the primary bitmap, used for painting, etc.

Air Brush Size - Sets the size of the air brush.

Air Brush Speed - Sets the speed of the air brush. The affects the density of "spray."

Apply Operation to Copy and Original - Applies the primary bitmap operation (Paint, Replace, Invert, or Erase) to the original bitmap and an independent copy that is created and maintained by the primary editor. The copy may be separately edited.

Arrowhead - Sets the width and height of the arrowhead created by the Draw Arrow command.

Auto-Save File Name - Sets the name of the file to be used for auto-saving of the bitmap.

Auto-Save Interval - Sets the interval between automatic saving of the bitmap.

Auto-Save Status - Displays the current auto-save status, file name, and interval.

Averaging - Applies an averaging matrix to the entire bitmap. The weighted sum of each pixel and its eight neighbors is compared with a threshold. If the sum is greater than the threshold, the pixel is turned on (or left on), else it is turned off. The user may use a default averaging scheme or define her own in a Lisp executive.

Bitmap Editor Paint with Airbrush - Allows painting of the bitmap with an "air brush." The size, shape, and speed of the air brush may be changed via subitems of the Parameters menu item. The operation (Paint, Replace, Invert, or Erase) and the speed may be changed while in this mode by clicking the right mouse button and selecting the appropriate menu item.

Bitmap Editor Paint with Brush - Similar to the standard Interlisp-D paint facility. The size and shape of the brush are modified via subitems of the Parameters menu item. The operation (Paint, Replace, Invert, or Erase) may be changed while in this mode by clicking the right mouse button and selecting the appropriate menu item.

Bitmap Editor Paint with Pattern - Similar to Bitmap Editor Paint with Brush, but paints with a pattern (arbitrary bitmap) instead of a standard brush.

Brush Shape - Sets the brush and air brush shape. The available choices are round, square, horizontal, vertical, and diagonal.

Checkpoint Restore - Resets the bitmap to the state it was in just prior to the last Checkpoint Save.

Checkpoint Save - Saves the current bitmap locally. The saved bitmap is not written to a file, but merely saved as a window property. Each Checkpoint Save destroys the previous saved bitmap.

Clear - Clears the entire bitmap.

Clear All But Region - Clears the entire bitmap except for a region swept out by the user.

Clear Region - Clears a region swept out by the user.

Coloring - Menu subitems change coloring of the bitmap and regions.

Copy Operations - Menu subitems create and edit a copy of the bitmap.

Copy/Edit Pattern - Creates a copy of an existing pattern and opens an edit window on the pattern.

Create New Copy of Bitmap - Creates a copy of the existing bitmap and maintains it separately. The copy may be edited separately.

Dashing - Turns dashing on or off and sets the style. When dashing is on, all line drawing operations will be done with the existing dashing pattern.

Delete Pattern - Allows the deletion of one of the patterns currently defined for the bitmap editor.

Distort Region - Distorts a rectangular region of the bitmap. This operation is time consuming on an 1186 which does not have hardware floating point. The operation operates as follows. A rectangular region is first swept out by the user as in the figure to the left. The vertices are then moved with the left button resulting in a display as in the middle figure. The result is shown in the rightmost figure. Note that if the user wishes to replace the region with the distorted result, the editor must be in the REPLACE mode. Otherwise, the distorted region will be PAINTed over the original region.

Draw Arrow - Draws one or more line segments with an open arrow at the end point. The size of the arrow may be changed by setting the appropriate parameters.

Draw Circle - Draws a circle in the same manner as SKETCH. The circle will be drawn with the current drawing brush size and dashing.

Draw Closed Curve - Draws a closed curve in the same manner as SKETCH. The curve will be drawn with the current drawing brush size and dashing.

Draw Ellipse - Draws an ellipse in the same manner as SKETCH. The ellipse will be drawn with the current drawing brush and dashing.

Draw Filled Arrow - Draws one or more line segments with a filled arrow at the end point. The size of the arrow may be changed by setting the appropriate parameters.

Draw Grid - Draws a grid over the entire bitmap. The width and height of the grid is specified via a number menu. The grid will be drawn with the current drawing brush size and dashing.

Draw Grid in Region - Draws a grid in a specified region. The width and height of the grid is specified via a number menu. The grid will be drawn with the current drawing brush size and dashing.

Draw Lines - Draws one or more line segments in the same manner as SKETCH. The lines will be drawn with the current drawing brush size and dashing.

Draw Open Curve - Draws a closed curve in the same manner as SKETCH. The curve will be drawn with the current drawing brush size and dashing.

Draw Over Connected Pixels from Region - Draws over all "connected" pixels starting from one or more pixels in a small region. Drawing may be done with the current drawing brush or a pattern. A pixel is connected to another pixel if it is one of the eight neighbors of the pixel. The operation is as follows. Suppose we have a display as shown to the left. We then select starting pixels by placing the box cursor as shown in the right figure.

Suppose we then select a pattern as shown to the left below. The resulting display will appear as in the figure to the right. Note that the user is requested to select the offset of the drawing brush or pattern.

Draw Over Connected Pixels from Selected Pixel - Similar to Draw Over Connected Pixels from Region, but a single pixel is selected as the starting point. The user places a separate "magnifier" window. When the cursor enters the bitmap editor, it changes to rectangular crosshairs and the surrounding 64 pixels are magnified 8 times and displayed in the magnifier window. When the crosshairs are over the selected pixel, the left button is clicked to specify the starting pixel.

Draw Polygon - Draws a polygon in the same manner as SKETCH. The polygon will be drawn with the current drawing brush size and dashing.

Draw Rectangle - Draws a rectangle in the same manner as SKETCH. The rectangle will be drawn with the current drawing brush size and dashing.

Draw Text - Places text. The font family, size, and style may be changed via Parameters menu subitems. The text is typed into a prompt window and then moved to the desired position with the mouse.

Drawing Brush Size - Sets the size of the drawing brush.

Edges - Menu subitems trim the bitmap and add borders.

Edit - Menu subitems edit regions of the bitmap.

Edit Copy of Bitmap - Opens an edit window on the currently stored copy of the bitmap. See Create New Copy of Bitmap.

Edit Pattern - Opens an edit window on a selected pattern.

Edit Region - Opens an edit window on a selected rectangular region of the bitmap.

Erase Connected Pixels from Region - Erases all "connected" pixels starting from one or more pixels in a small region. A pixel is connected to another pixel if it is one of the eight neighbors of the other pixel.

Erase Connected Pixels from Selected Pixel - Similar to Erase Connected Pixels from Region, but a single pixel is selected as the starting point. The user places a separate "magnifier" window. When the cursor enters the bitmap editor, it changes to rectangular crosshairs and the surrounding 64 pixels are magnified 8 times and displayed in the magnifier window. When the crosshairs are over the selected pixel, the left button is clicked to specify the starting pixel.

Exact Size - Allows changing the size of the current bitmap by explicitly resetting the origin, width, and height in terms of the bitmap coordinates.

Expand - Expands the width and/or height of the bitmap by an integer factor of one to four.

Fill Box - Fills a specified rectangular region with the default texture.

Fill Box with Specified Color - Fills a specified rectangular region with a chosen texture.

Fill Region(s) - Fill one or more closed regions with the default texture.

Fill Region(s) with Specified Color - Fill one or more closed regions with a chosen texture.

Follow Pixels - Menu subitems follow connected pixels and erase or draw over them.

Font - Sets the font family, size, and style for text placement.

Get Fro

BOONE-V-COE

Plaintiffs, W. H. Boone and J.T. Coe, brought this action against defendant, J.F. Coe, to recover certain damages alleged to have resulted from defendant's breach of a parol contract of lease for one year to commence at a future date. It appears from the petition that the defendant was the owner of a large farm in Ford Co., Texas. Plaintiffs were farmers living in Monroe Co., Kentucky. In the fall of 1909, defendant made a verbal contract with plaintiffs, whereby he rented to them his farm in Texas for a period of 12 months, to commence from the date of plaintiff's arrival at defendant's farm. Defendant agreed that if plaintiffs would leave Kentucky and move to defendant's farm in Texas and take over the farm for 12 months after their arrival, the defendant would prepare a home on the farm for plaintiffs which they could occupy as residence. Defendant also agreed

The plaintiffs did move from Kentucky during the fall of 1909. Upon their arrival at the farm in December, defendant denied them entry to the farm. Plaintiffs then left, returning to Kentucky. In reliance on the contract for the farm, plaintiffs incurred costs of \$1400.

Defendant's demurred to the petition for damages which was sustained. Plaintiffs appeal. We concur with the previous decision.

CrossFile Links Destination NoteFile Browser

By: Daniel Jordan (Jordan.pa@Xerox.COM)

Stored: {qv}<notecards>1.3L>Library>DestNoteFileBrowser, .lcom, .ted
and {nb:parc:xerox}<notecards>1.3L>Library>DestNoteFileBrowser, .lcom, .ted
Written: October 10, 1988 by Dan Jordan
Last updated: January 6, 1989 by Dan Jordan
Supporting files: (all NC patches) dsjpatch075, dsjpatch076, rarpatch026

Introduction to the Destination NoteFile Browser

The Crossfile Links Destination Notefile Browser allows the user to modify and manage the destination notefiles associated with crossfile links in (source) notefiles. Using this facility, the user can easily move groups (or subgroups) of cross-linked notefiles to different directories and keep the cross-linked information between them up to date.

This facility features a "destination notefile browser" that displays in a window all destination notefiles for all crossfile links in a particular (source) notefile or group of notefiles. This browser is similar in appearance to a "file browser". Through a destination notefile browser, the directories or entire names of the destination notefiles associated with any crossfile links may be changed, to reflect changes in the location or name, respectively, of the actual destination notefile themselves.

Loading the Destination NoteFile Browser Package

Loading the Crossfile Links Destination Notefile Browser package is done in the same way as loading any other NoteCards library package. For example, you can type the following in an Interlisp exec:

```
(FILESLOAD (FROM NOTECARDS) DESTNOTEFILEBROWSER)
```

Alternatively, you can add the atom DESTNOTEFILEBROWSER to the global var NOTECARDSLIBRARYFILES in your init file. This will ensure that DESTNOTEFILEBROWSER is loaded when bringing up a fresh sysout. (Note that the supporting patch files are to be found on the directory specified by the global var NOTECARDSNEXTDIRECTORIES.)

Using the Destination NoteFile Browser

Once the package is loaded, the user can access the Crossfile Links Destination Notefile Browser facility by selecting the "Destination NoteFile Browser" item on the "Other" menu item on the Notecards main menu. The user will be prompted to specify a region for a window and a "destination notefile browser" window will be opened in that region. The user will then be prompted to select the source notefiles that are to be used as the basis for the computed set of crossfile link destination notefiles. That is, for the set of source notefiles selected, ALL crossfile link destination notefiles for ALL crossfile links in the source notefiles will be computed. The source notefiles will be displayed in the top window of the browser, and any resultant destination notefiles for this set of source notefiles will be displayed in the main browser window.

The directories or entire names of any of the destination notefiles may be changed by selecting the destination notefiles of interest as you would items in a "file browser". There are two commands available on a destination notefile browser:

Rename

The user will be prompted for a new name. The selected destination notefiles of all crossfile links for this group of source notefiles will have their names changed to this new name. If the new name is just a directory name, e.g., {qv}<ide>notefiles>, all selected destination notefiles will only have their directories changed and will retain their (root) filenames. If the new name is a complete filename (with directory), e.g., {qv}<ide>notefiles>new.notefile, all selected destination notefiles will have their names changed to exactly that new name. The browser will automatically be updated to reflect the destination notefile names.

Recompute

This command is used to update, or recompute, the information in the browser (e.g., after new crossfile links have been added to the source notefiles.) There are two subitems on this menu: **Same source notefiles** (the default) and **New source notefiles**. The browser will be recomputed with the same source notefiles, unless

New source notefiles has been selected, in which case the user will be prompted for a new set of source notefiles.

Notecards Bitmap Card

**Vista Laboratory
Xerox Special Information Systems**

November, 1988

This software implements bitmaps as a new substance type within Notecards. Although one can create and edit bitmaps within TEdit or SKETCH, the Bitmap Card gives more capabilities. The Bitmap Editor is described in a separate document (Reference 3). Editing is terminated via the Notecards left button title bar menu items (Close and Save, Delete Card, etc.).

Links are added, deleted, and moved via the Links menu item and its sub-items. Links are not actually part of the bitmap and so are not treated as items to be manipulated by the editor.

To install the Bitmap Card, load NCBITMAPCARD.LCOM which loads BITMAPEDITOR.LCOM and READNUM.LCOM. The Bitmap Editor also requires the Lispuser's package FILLREGION.

NCCollaboration

By: Randy Trigg (Trigg.pa@Xerox.COM)

Stored: {qv}<notecards>1.3L>Library>NCCollaboration, .lcom, .ted

Written: June 14, 1988 by Peggy Irish

Last updated: June 15, 1988 by Peggy Irish.

See also NCCollaboratorCard and NCHistoryCard packages.

INTRODUCTION

This package was written to assist people using the draft-passing style of collaboration. This style refers to settings in which a small number of collaborators work closely together, but not at the same time. Rather, they take turns using a single shared hypertext workspace. These collaborators need the ability to discuss the use of the medium as well as the work constituting the content of the project. In particular, they need tools to support the processes by which they monitor their own and each other's work.

To this end, several mechanisms have been created to support collaboration. First, the notion of having a notefile understand the identities and certain properties of its individual collaborators has been developed. (See NCCollaboratorCard documentation.) This has also been extended so that multiple simultaneous users may be recognized, in the case where several people are using a notefile while sitting together at a workstation. Second, a method for recording the changes made to a notefile by a collaborator has been implemented. (See NCHistoryCard documentation.) Finally, a "collaboratization" process for configuring a notefile so that it contains these mechanisms has been provided, and is contained in this package. (The NCCollaboratorCard and NCHistoryCard packages will automatically be loaded when NCCollaboration is loaded.)

LOADING NCCOLLABORATION

Loading the NCCollaboration package adds the menu item "Collaboratize" to the session icon notefile menu and to all notefile icons' left button

  "menusGETFN: BMOBJ.GETFN3UP GETFN: BMOBJ.GETFN3"

COLLABORATIZING A NOTEFILE

Selecting "Collaboratize" will cause a number of things to happen to the chosen notefile. A collaborator card will be created for the current collaborator. A new menu item, "Collaborator Info," will be added to the notefile icon's middle button menu. The NoteFile Use History filebox will be created to hold all history cards in this notefile. Also, as part of the opening of a collaboratized notefile, a history card will be created

and opened for the current notefile session. This card will automatically be filed in the NoteFile Use History filebox.

Creating a Collaborator Card

When a collaboratized notefile is opened, a menu of collaborators' names will appear, from which the current collaborator should select his name. During the collaboratization process, the notefile has no prior knowledge about collaborators;

therefore the menu will contain only the "New Name(s)" option: . The user should select "New Name(s)," which will cause a new collaborator card to

be opened. 

This collaborator card stores information about the current collaborator. The title of the card is initialized with the username of the collaborator, which he may change. The collaborator should fill in his or her initials by selecting the "?" with the left mouse button. A prompt window will appear, in which the collaborator can type his or her initials. These initials will appear in the titles of history cards created later. The collaborator may also change the Font property by selecting the existing Font value

and choosing the desired font properties from the resulting menu:  and then selecting DONE. The ExtraTEditProps property may also be changed by selecting the existing value of ExtraTEditProps and typing in the appropriate attribute-

value pairs. 

The Font and ExtraTEditProps properties define the defaults to be used in cards created by this collaborator. Once the collaborator is satisfied with the collaborator

card, he or she should select DONE. 

COLLABORATOR INFO

If the notefile icon middle button menu item "Collaborator Info" is selected, a menu containing the collaborators in this notefile will appear, with the current collaborator's name highlighted. Three commands also appear at the bottom of the

menu: 

The information in any of the collaborator cards may be changed at any time by selecting the name from this menu and editing the collaborator card that is brought up. The "New Name(s)" command is used as described in the **Creating a Collaborator Card** section, with the exception that a new collaborator card does not have a default title unless it is the first one created in the notefile. The "Remove Name" command allows the current user to remove a collaborator name from this notefile. The "Change current collaborator" command allows a different collaborator name to be chosen for the current session in this notefile.

CREATING A HISTORY CARD

Once collaboratized, (and upon collaboratization), a new history card is automatically created for a notefile each time the notefile is opened. Each history card is automatically filed in the NoteFile Use History filebox. Upon creation, each history

card is titled with the current date and the initials of the current collaborator. A time stamp is entered in the card to indicate when the current session

begin

For more detailed information on history cards, please see the history card documentati

NCCollaboratorCard

By: Randy Trigg (Trigg.pa@Xerox.COM)

Stored: {qv}<notecards>1.3L>Library>NCCollaboratorCard, .lcom, .ted

Written: June 14, 1988 by Peggy Irish

Last updated: June 15, 1988 by Peggy Irish.

See also NCCollaboration and NCHistoryCard packages.

INTRODUCTION

To allow a notefile to distinguish between collaborators, the Collaborator card type was created. A card of this type should be created for each person or set of persons working in a notefile. The collaborator card contains information relevant to collaboration, such as the user's name, initials, and preferred font. The initials are used by History cards, which are described in the History Card documentation. The font is automatically used to display text in cards created by the collaborator. When each collaborator or set of collaborators chooses a different font, it is easy to tell at a glance what work each person has contributed to a notefile's text. A collaborator card may also be created for multiple users, in the case where several people are working on a notefile together and want to claim group ownership of their contributions. When a collaborator (or set of collaborators) opens a "collaboratized" notefile, they are asked to identify themselves. The notefile then looks up their collaborator properties by searching for their collaborator card, and applies these properties to the working session.

LOADING NCCOLLABORATORCARD

This package should be used in conjunction with the NCCollaboration package. NCCollaboration should be loaded, and it will automatically load the NCCollaboratorCard and NCHistoryCard packages. (See the NCCollaboration documentation for details of its use.)

OPENING A COLLABORATIZED NOTEFILE

When a collaboratized notefile is opened, a menu of collaborators' names will appear, from which the current collaborator should select either his name or "New Name(s)." (During the collaboratization process, the notefile has no prior knowledge about collaborators; therefore the menu will contain only the "New Name(s)" option):

If one of the names is chosen, that collaborator will be instantiated as the current collaborator, and the corresponding collaborator information will be applied to the session. If "New Name(s)" is selected, the user will be prompted for a name. Then a new collaborator card will be created which has that name as its title:

The collaborator should provide a value for the Initials property by selecting the "?" with the left mouse button. A prompt window will appear, in which the collaborator can type the desired initials. These initials will appear in the titles of history cards created later. The collaborator may also change the Font property by selecting the existing Font value and choosing the desired font properties from the resulting menu:

Selecting DONE from the right side of this menu completes the Font property edit operation. The ExtraTEditProps property may also be changed by selecting the

existing value of ExtraTEditProps and typing the appropriate attribute-value pairs into the prompt window:

The Font and ExtraTEditProps properties define the defaults to be used in cards created by this collaborator. Once the collaborator is satisfied with the collaborator card, DONE should be selected.

COLLABORATOR INFO

If the notefile icon middle button menu item "Collaborator Info" is selected, a menu containing the collaborators in this notefile will appear, with the current collaborator's name highlighted. Three commands also appear at the bottom of the menu:

The information in any of the collaborator cards may be changed at any time by selecting the name from this menu and editing the collaborator card that is brought up. The "New Name(s)" command is used as described in the **OPENING A COLLABORATIZED NOTEFILE** section. The "Remove Name" command allows the current user to remove a collaborator name from this notefile. The "Change current collaborator" command allows a different collaborator name to be chosen for the

current session in this notefile.

NCDraftCard

By: Ramana Rao (Rao.pa@Xerox.COM)

Stored: {qv}<notecards>1.3k>library>NCDraftCard, .dcom, .ted

Last updated: Mar 30, 1987.

INTRODUCTION

This NoteCards library package defines a new card type called draft cards which supercede document cards. A draft card, primarily, collects the substance from a tree of cards starting from a set of root card, but also does auxiliary processing like sectioning and titling. (The process can be viewed and is implemented as a non-cyclic traversing and interpreting of a notecard network by invoking methods to process card and link types. The draft card defines a set of interpretation methods which implement functionality for document generation).

When a draft card is created, the user is asked to select a set of root card (using the standard NoteCards card selection interface). After this selection, the user is presented with a menu for defining the link and card categorys which are processed by the draft generator. After the draft is generated, a user can use the left button title bar menu to edit the draft style and recompute the draft. A programmer's interface function will be implemented on demand (or rather courteous request) or when I see a break in the clouds. Also true for a long list of desirable features.

CREATING A DRAFT

Draft cards are created by selecting Draft from the NewCards menu (assuming the NCDraftCard library package has been loaded). The user selects a set of root card for generating the document. Then the following draft style editor pops up allowing the user to edit the fields by selecting them. (This is not all there is to a document style as I will say below).

Draft Style Sheet	
ExpandLinks	(SubSection Expander)
BackToCards	NONE
CopyLinks	NONE
TitleLinks	NONE
SectionLinks	(SubSection)
ToSectionsLinks	(SectionPtr)
--DONE--	--CANCEL--

Selecting the items on the bottom line will generate the draft or cancel the creation. Each of the other lines represent a category of links or cards which provides specific functionality during draft generation. The *ExpandLinks* category define the link types which are expanded during draft generation i.e. the substance of the target card (the card pointed to by the link) is pulled into the draft and processed recursively. To prevent runaway loops, a card is only expanded once. The *BackToCards* category define the card types for which back links are put into the draft. Back links allow the user to return to the "underlying" card from the draft. *CopyLinks* are copied directly into the draft. *TitleLinks* produce titles in the draft by inserting the title of the card pointed to by the link. Similarly, *SectionLinks* produce section headings, but in addition they generate section numbers. The section numbers are generated according to "depth in tree using *SectionLinks*" i.e. the section number of a card has as many numbers as *SectionLinks* have been traversed to get to it. *ToSectionLinks* produce references to sections within the draft. Whenever a link of the *ToSectionLinks* category is encountered, the target card is checked for a section number and a reference of the form, "Section xx", is produced. This works for all sections which are part of the draft independent of whether they are before or after the section reference. All categories can be set to ALL, NONE, or a list of link or card types (using the interactive type selector which pops up when the user selects on the field).

The initial settings of the draft style sheet are inherited from a global default style. Any changes made to the style sheet only apply to the associated draft and do not affect the global default settings. To change the global default settings in the current sysout, the daring user can inspect and edit **ncdraft-default-style**. To maintain these defaults across sysouts the user can set **ncdraft-user-props** (a property list using the properties you see when you inspect **ncdraft-default-style**) in her init file. The user can also inspect and edit a draft's style by pulling across on "Edit Draft Style" item in the card menu. Inspecting styles will reveal a host of other parameters which will influence the draft generation process and will also more annoyingly reveal that the

field names which correspond to the link and card types have different names than in the style sheet editor. Use the field name you see in the inspector for adding an entry to **ncdraft-user-assoc** in your init file. (This is all hoaky, but at least functional. You are welcomed to bug me about how you can do something).

Alternatively draft cards can be created programatically as follows:

```
(NCP.MakeDraft <NoteFile> <rootcard> <style-assoc-list> <nodisplayflg> <props>
<parent-fileboxes>)
```

Currently Unimplemented. Bug me when you really need this. Creates and returns a draft card starting from <rootcard>. All parameters not set by <style-assoc-list> will be inherited from the default style. The resulting draft card will have the given props and parents.

DRAFT CARD OPERATIONS

The Draft Card operations are available via the left button (card) menu in the Draft Card card's title bar. **Recompute Draft** recomputes the draft using the associated root card and style. **Edit Draft Style** pops up the style sheet described above and allows you to change the link or card type categories. **Edit with Inspector** is a pull-across item of **Edit Draft Style** which allows you to inspect and edit all of the style parameters. Please READ the last section if you are going to do this.

KNOWN BUGS

Ha! All features, non-features, or future features.

FUTURE FEATURES

User Interface Improvements: Allow the user to edit all the style parameters with a style sheet editor that is like a form (like what FREEMENU would be if it were what it is trying to be). Right now my focus is more on what stylistic things a user might want to dictate, and not on how he will set these parameters.

Automatic generation of Table of Contents. You can do this in a separate draft card with the current functionality by being a little clever at defining which link types to expand, copy, section, or title depending on how you want it to come out.

Sectioning and Title Style parameters. Font choice and other looks options. The hidden style parameters are a small step in this direction, allowing bolding/notbolding of these as well as dictating number of carriage returns before and after a section.

Figure Numbering and Figure references.

Bibliographic References. You can use titling to achieve this with great pain currently, but better ways are coming along. A quick and dirty hack first, and then a full service hack that Miller is working on.

Draft/Network Coupling. Editing the draft would automatically edit the underlying substance. Not an easy feature to provide, but probably a very useful one.

Generate Draft to Tedit Stream.

NCGuidedTourCard

By: Randy Trigg (Trigg.pa@Xerox.COM)

Stored: {qv}<notecards>1.3L>Library>NCGuidedTourCard, .lcom, .ted

Written: August 1, 1988 by Randy Trigg

Last updated: May 5, 1989 by Peggy Irish.

Loads NCTableTopCard package.

INTRODUCTION

The author of a complex NoteCards network is sometimes faced with the problem of conveying its meaning to future online readers using the same hypermedia environment. The NoteCards guided tours library package provides a way to reify and manipulate branching paths through a NoteCards network, thus allowing readers to explore the notefile under the guidance of the notefile's author.

A guided tour is a graph whose nodes are tabletop cards (see the documentation for the NCTableTopCard NoteCards library package) and whose edges are GuidedTour links connecting the cards. Because the tabletop cards may have other links connecting them to other parts of the network, the guided tour is a subgraph of the subnetwork containing those cards. The guided tour card is implemented as a specialization of the NoteCards browser card. Thus, creating and editing a guided tour is almost identical to creating and editing a browser. The biggest change is the ability to "run" the guided tour by means of a row of buttons across the top of the browser window. In this way, readers and authors access the tour through the same graph-based interface.

Readers interested in learning more about the history of and motivation for the guided tour package (as well as the tabletop facility) are directed to the paper "Guided Tours and Tabletops: Tools for Communicating in a Hypertext Environment," by Randall H. Trigg, Conference on Computer-Supported Cooperative Work, September 1988. (Copies can be obtained by writing to SSLPapers.pa@Xerox.com.)

LOADING THE NCGUIDEDTOURCARD PACKAGE

Loading the NCGuidedTourCard package is done in the same way as loading any other NoteCards card type library package. For example, you can type the following at an Interlisp exec:

```
(FILESLOAD (FROM NOTECARDS) NCGUIDEDTOURCARD)
```

Alternatively, you can add the atom NCGUIDEDTOURCARD to the global var NOTECARDSLBRARYFILES in your init file. This will ensure that NCGUIDEDTOURCARD is loaded when bringing up a fresh sysout. Finally, if a link to a guided tour card is followed and the NCGUIDEDTOURCARD package is not currently loaded, then it will be auto-loaded by the system.

"RUNNING" A GUIDED TOUR

Operating or "running" a guided tour is done via the five buttons arrayed along the top of the guided tour card as shown below.

In each of the following operations, the current displayed tabletop is automatically closed down before bringing up the next. (This is made more efficient by not closing those cards shared by the current and next tabletops.)

START - Clicking on **START** causes the first tabletop in the tour to be brought up. For simple linear or singly-rooted tree structures there is an obvious "first" tabletop. Some tours, however, might have multiple roots, i.e. multiple nodes without incoming edges. In such cases, the user is asked to choose from a menu of possible starting tabletops.

NEXT - This is the standard way to move along a path. Clicking **NEXT** simply closes down the current tabletop and brings up the next one on the path. If the current node

is a branch point having multiple outgoing edges, then the user is asked to choose from a menu of possible next tablesps. In any case, the new current node is highlighted as is the edge that was followed.

PREVIOUS - Clicking here provides the reader with a menu of tablesps already visited. These appear in the order in which they were visited. Clicking on an item in the menu effectively JUMP's to that point in the tour.

JUMP - This operation is used to leave the current path by jumping to an arbitrary tabletop selected by the user from the guided tour graph (again after closing down the current tabletop).

RESET - This operation closes the current tabletop and resets the "state" of the guided tour. In particular, any highlighting of nodes and links in the guided tour graph is turned off and the PREVIOUS list is cleared.

At any point in time, the graph structure displayed in the guided tour card provides various indicators of the reader's place in the tour.

The node in the graph whose tabletop is currently open is highlighted in reverse-video. The nodes for tabletops previously visited are drawn with heavier borders. Finally, the edges corresponding to links followed using the NEXT command are displayed in bold. The guided tour card appearing above shows a point in time when the reader has visited five cards. Starting at "Introduction," the top branch was taken, two tabletops were visited, and then a JUMP was made to "GuidedTour intro" whereupon NEXT was again used to move to the presently displayed tabletop "GuidedTour creation."

This standard mode of operating a guided tour (using the buttons along the top of the card) is extended in several ways. First, because screen space is at a premium and

because the window containing the guided tour graph is often large, the user can run the tour from the guided tour window's shrunk icon, which is a miniture version of the guided tour window. This icon may be shaped to suit the user's needs and to fit the available screen space. The current tour stop is highlighted in reverse-video in the shrunk icon.

Second, it may be desirable to "circumvent" the tour by peeking at the cards in the next tabletop or by bringing up a tabletop without closing down the current one. This can be done directly by middle-buttoning the link icons appearing in the guided tour graph. (See the NCTableTopCard documentation for a description of tabletop operations.) Finally, it is important to emphasize that you can stray from the tour at any time by following links emanating from cards in the tabletop. Such explorations deeper into the notefile don't affect the current state of the tour.

CREATING AND MODIFYING GUIDED TOURS

There are two common styles of constructing tours. In the first, authors create an empty guided tour card and build and link together tabletops using the guided tour's editing menu. In the second, authors build a guided tour over already constructed tabletop cards. In any case, the elements of guided tour construction include creating guided tour cards, creating or including tabletops (and other tour nodes), linking together nodes in the tour, and modifying the tour.

Creating a new guided tour card

Creating a guided tour card is very much like creating a Browser card. Just choose GuidedTour from the NewCards menu on the notefile icon. If you want the guided tour to be empty, then choose DONE when asked to specify the tour's roots. Otherwise, select a set of starting cards (usually tabletops). Unlike browser cards, guided tour cards don't require you to specify a set of link types to follow. There is a default set of link types (initially the single GuidedTour link type) used by guided tour cards during creation and Recompute. Because of this, the BrowserSpecs stylesheet for guided tour cards doesn't contain the usual columns for link types.

Depth	Format	Orientation
0	*GRAPH*	Horizontal
1	LATTICE	Vertical
2	COMPACT	Reverse/Horizontal
3	FAST	Reverse/Vertical

Nodes in the guided tour are usually tabletops, but can be **arbitrary card** types. To add an existing card as a node in the guided tour, use the Add Node menu item just as for standard browsers. To create a new tabletop card from scratch, click on the Create TT Card item. You will be asked for cards to be included in the tabletop just as though you created the tabletop from the NewCards menu on the notefile icon. By *pulling across on the Create TT Card menu item*, you can create guided tour nodes which are cards of other types. If you use such non-tabletop cards in your tour, you'll find that they generally act similar to tabletop cards that contain only one card. (But see the Handy Hooks section below to change this default behavior.)

Nodes in the guided tour can be linked together **using the Create Link** menu item. Normally, you will not be asked to specify a link type when creating a link using the editing menu. (If, however, the default set of link types has been changed to have greater than one element, then **a menu of link types is popped up for you** to select from.) Note also that new links created from the editing menu are always "Global" links.

As with standard browser cards, guided tours can be modified by adding new nodes and edges, removing old ones, rearranging nodes spatially within the tour, and annotating the tour using labels. In addition, it's usually a good idea to specify explicitly what the roots of the tour should be. (Roots can be (re-)specified by selecting the Change Browser Roots item from the middle button title bar menu of the guided tour card.) Otherwise, tour readers clicking on START have to choose from a system-constructed menu of all nodes in the tour that don't have incoming edges.

To create a new guided tour **card programmatically**, call `NCP.CreateCard` just as **you would** to create a browser card:

See the [documentation on NCP.CreateCard](#) for details on the args.

Equivalent to hitting **START** on guided tour card **GTCard**.

Equivalent to **hitting NEXT** on guided **tour card GTCard** except that if `Don'tCloseCurrentFlg` is non-nil, then current **tabletop won't be closed down first**.

Equivalent to hitting PREVIOUS on guided tour card GTCard except that if Don'tCloseCurrentFlg is non-nil, then current tabletop won't be closed down first.

Equivalent to hitting JUMP on guided tour card GTCard *except that if*

Don'tCloseCurrentFlg is non-nil, then current tabletop won't be closed down first. Also if *NextNode* is a valid node in the graph, then user won't get bugged; we'll jump directly to that card.

(NCGT.ResetTour GTCard Don'tCloseCurrentFlg)

Equivalent to *hitting RESET* on guided tour card GTCard except that if

Don'tCloseCurrentFlg is non-nil, then current tabletop won't be closed down first.

Handy Hooks

GuidedTourBringUpFn. If this prop is on a card type's atom, then when cards of that type are encountered in guided tours, they are brought up by calling this function.

(This is useful when you don't want the default behavior for stops in the tour that aren't tabletop cards.) This function is expected to return the list of cards it brings up.

GuidedTourCloseDownFn. If this prop is on a card type's atom, then when cards of that type are encountered in *guided tours*, they are closed down by calling this function. (Note: This prop doesn't seem to be called anywhere, as of the version of October 19, 1988.)

GTNextTourStopFn. This function is called by *NCGT.NextTourStop*, and its job is to "filter" the list of possible next tour stops from the *current tour stop*. The list of next cards (the destination cards of the *NCGT.GuidedTourLinkTypes* links from the current tour stop) is passed to the *GTNextTourStopFn*, which returns some sublist of the next cards. Both the card type atom of the card in the current tour stop and the *card type atom of the guided tour card* are checked for the *GTNextTourStopFn*. If both card type atoms have a *GTNextTourStopFn*, only the one from the current tour stop cardtype is called.

GTCreateGuidedTourLinkFn. If this prop is on the card type atom of the guided tour card, then this function is called whenever a new link is created using the graph edit menu of the guided tour card. This is a way of getting control over *the type of link used*, whether it's global or local, etc.

GTResetGuidedTourFn. If this prop is on the card type atom of the guided tour card, then this function is called whenever the guided tour is reset.

GTBringUpCachingFn. This is an *NCP.CardUserDataProp* of a guided tour card which is called each time a card or tabletop is brought up.

GTCloseDownCachingFn. This is an *NCP.CardUserDataProp* of a guided tour card which is called each time a card or tabletop is closed down. If this prop is non-nil, all cards in the guided tour stop which are being closed are merely undisplayed -- they are still cached. It is the job of the **GTBringUpCachingFn** and the *GTCloseDownCachingFn* to decide which of these cached but undisplayed tour stop cards should be uncached.

GTCleanUpCachingFn. This is an *NCP.CardUserDataProp* of a guided tour card which is **called** when a guided tour card is closed. Its job is to clean up whatever cached but undisplayed guided tour stop cards are still laying around from the *GTBringUpCachingFn* and the *GTCleanUpCachingFn*.

ImmediatelyGoToNextGTStopFn. Whenever a new **guided** tour stop card is brought

up, its card type atom is checked for this function. If the function exists and returns non-NIL, NCGT.NextTourStop is immediately called. Thus, for example, it is possible for a user **to travel** through a whole guided tour, by merely pressing a guided tour's Start button.

Global Variables

NCGT.GuidedTourLinkTypes

This variable is initially bound to the single atom GuidedTour. The link types on this list will be the only legal link types users will be able to create in a guid

The NCHACKS Library Package

Xerox Corporation

Randy Trigg

[First written: 8/23/85 Randy Trigg]
[Last updated: 8/18/87 Peggy Irish]
[Code: {qv}<notecards>1.3k>library>nchacks.dcom]
[Doc: {qv}<notecards>1.3k>library>nchacks.ted]

This document describes a library package containing miscellaneous handy functions written using the programmer's interface for use in NoteCards Release 1.3k. It is hoped that you will find these useful not only for their functionality, but also as examples of the sort of code that can be written using the programmer's interface.

I encourage any readers who have created such functions themselves to send me the code and a short description and I'll incorporate into this package.

These functions all apply to groups of cards (and often to a notefile as well) and allow searching for text, global replacement of text, removal of deleted link icons, sorting of link icons, making link icons invisible, card collection by date, and creating chains of cards using a given link type.

The following functions are applicable to sets of cards and allow global searching, replacing, and chain creation. For those that take a CardsOrNoteFile argument, it can either be single card, a list of cards or a notefile. In the latter case, the entire notefile is used. To allow user selection of cards, pass (NCP.SelectCards) as the CardsOrNoteFile argument. (NCHACKS.MakeChain takes a Cards argument which can either be a single card or a list of cards, but not a notefile.)

(NCHACKS.TextSearch String WildCards? CardsOrNoteFile ReturnLocsFlg)

This goes through the list of cards looking for occurrences of text string String. WildCards? being non-nil means wild card characters may appear in String. The pound sign character '#' matches any single character, asterisk '*' matches any sequence of characters, and single quote, "'" can be used to quote one of the wildcard characters.

If ReturnLocsFlg is nil, then this just returns a list of cards containing at least one occurrence of String. If ReturnLocsFlg is non-nil, then this returns a list of lists. Each sublist has as first element a card ID followed by the locations of occurrences of String. These are single integers if WildCards? is nil and correspond to the location of the first character of String in the text. If WildCards? is non-nil, then these are two element lists of start and end locations of the matching string.

Any cards in Cards that are not TEdit-based cards are ignored (i.e. their card type must inherit from the Text card type).

(NCHACKS.GlobalTextReplace String1 String2 WildCards? CardsOrNoteFile)

This goes through the list of cards replacing every occurrence of text string String1 by String2. WildCards? being non-nil means wild card characters may appear in String1. The pound sign character '#' matches any single character, asterisk '*' matches any sequence of characters, and single quote, "'" can be used to quote one of the wildcard characters.

Any cards in Cards that are not TEdit-based cards are ignored (i.e. their card type must inherit from the Text card type).

(NCHACKS.RemoveDeletedIconsFromTextCards CardsOrNoteFile)

This removes all deleted link icons from the TEdit-based cards in the list of cards.

(NCHACKS.ReorderLinkIconsInTextCards CardsOrNoteFile OrderingFn QuietFlg)

This moves link icons around in each of the TEdit-based cards in the list of cards so that they appear in sorted order. OrderingFn should be a function which accepts two link arguments (the destination cards of the links) and returns non-nil if the first should appear ahead of the second. OrderingFn can also be the atom ALPHABETIZE in which case NC.IDAlphOrder (orders by title of link's destination card) will be the ordering fn used. If OrderingFn is NIL, then the card's OrderingFn card prop is checked. If that card prop is NIL, then NC.IDAlphOrder is again used.

(NCHACKS.MakeLinkIconsInvisible CardsOrLinksOrNoteFile Invisibility)

CardsOrLinksOrNoteFile should be one of: a card, a link, a list of cards and links, or a notefile. Make any link icons for given links or contained in given cards or notefile (but only those in TEdit-based cards) invisible or not depending on whether Invisibility is ON or OFF.

(NCHACKS.DateSearch DateString1 DateString2 CardsOrNoteFile)

This goes through the list of cards looking for occurrences of card parts modified between the dates DateString1 and DateString2. If DateString1 is NIL, then it defaults to a very early date. If DateString2 is NIL, then it defaults to current date. If you provide values for either DateString1 or DateString2, they should be strings in the same format as that returned by the (DATE) format, i.e. "1-Jan-85 00:00:00".

This returns a list of lists, one sublist for each card modified between the given dates. This sublist consists of the card ID followed by two-element lists containing the card part name that was modified and the date of last modification. For example, if there was one hit, you might get something like (({CardObject}#56,164470 (SUBSTANCEDATE "23-Aug-85 19:15:27") (TITLEDATE "23-Aug-85 19:15:44")))

(NCHACKS.CardsModifiedBetweenDates CardsOrNoteFile CardTypes ModifiedRange LastModifiedRange CreatedRange)

This function goes through the list of cards or the notefile looking for cards of types in CardTypes which satisfy all of these criteria: they were modified in the range ModifiedRange, and last modified in the range LastModifiedRange, and created in the range CreatedRange. Each range should be a list of two dates, each in the form DD-Mon-YY (i.e. "1-Jan-85"). Any of the ranges may be NIL, which means not to include that type of modification/creation. If the first (earlier) date in a range is NIL, then it defaults to the earliest known date. If the second (later) date in a range is NIL, then it defaults to the current date. CardTypes should be a list of card types. CardsOrNoteFile should be a list of cards or an open notefile. The cards which meet all of the given criteria are returned in a list.

Examples:

(NCHACKS.CardsModifiedBetweenDates (NCP.WNF) '(Text FileBox) ("3-Jul-87" "10-Jul-87") NIL NIL)

would return all cards of type Text and FileBox in the notefile pointed to by the mouse which were modified between the dates of July 3, 1987 and July 10, 1987.

(NCHACKS.CardsModifiedBetweenDates (NCP.WNF) 'Text NIL ("1-Jun-87" NIL) (NIL "31-May-87"))

would return all cards of type Text in the notefile pointed to by the mouse which were created on or before May 31, 1987, and last modified after June 1, 1987.

(NCHACKS.MakeChain LinkType Cards Position AddCRFlg)

This creates links between successive cards in Cards each of type LinkType positioned at Position. Thus the first card in Cards will be linked to the second, the second to the third, etc. (No link will be built from the last card in Cards.) Position should be in the same form as that accepted by NCP.CardAddText, i.e. either an integer location or one of the litatoms START or END. If the AddCRFlg is non-nil and Position is one of START or END, then a carriage return is inserted after the link icon in the case of START or before the link icon in the case of END.

Any cards in Cards that are not TEdit-based cards are ignored (i.e. their card type must inherit from the Text card type).

NCKey

By: Ramana Rao (Rao.pa@Xerox.COM)

Stored: {qv}<notecards>1.3k>library>NCKey, .dcom, .ted

Last updated: July 13, 1987.

Requires: TEditKey Lispusers Package

INTRODUCTION

This NoteCards library package provides an extensible keyboard interface to useful Notecard Operations (useful means that I needed them at the time). In particular, NCKey provides keystroke commands for creating a link to a new text card using the current selection as either the title or the text of the new card (I was taking a large document and bashing it into a notecards hierarchy, so you can see why these were useful), entitling a card using the current selection, deleting all the "DeletedLinkIcon", and coercing the type and displaymode of all the links in the current card. However, the particular functions provided are not so important as the ability to easily bind your own functions to keys. Possibilities for functions as demonstrated by my bindings (the default bindings) include using available functions in NCHACKS or writing your own (or begging, asking, or demanding some one else to write) functions using the NC Programmer's Interface.

USING THE KEYBOARD INTERFACE

NCKey requires TEditKey but doesn't expect that it be previously loaded. NCKey actions are invoked by typing Meta-W followed by a single character. Currently, the single character can not be Meta-ed (but I realize that this is a pain since you want to be able to keep holding down the Meta key while striking the second character). The mapping from dispatch character to an action routine is made using *NCKEY-BINDINGS*. The default mapping is the following:

Inserts a Link Using Selection as Title	(J j)
Inserts a Link Using Selection as Text	(K k)
Removes Deleted Link Icons	(R r)
Sets Title Using Selection	(T t)
Coerces Links using Global Parameters	(L l)
Brings Up Help Menu	(?)

These items and their operation are described in greater detail below.

CUSTOMIZING OR EXTENDING THE KEYBOARD INTERFACE

The provided mechanism isn't particularly elaborate or elegant, but it's basically good enough for most purposes. You can edit the variable `*NCKEY-BINDINGS*` to remap the bindings to the provided action routines or to bind new action routines. This variable is INITVAR-red by this package, so users can put their own binding in their INIT files. Below is a specification of the syntax of `*NCKEY-BINDINGS*`:

`*NCKEY-BINDINGS*` = (<Binding Triple>*)

<Binding Triple> = (<Key Group> <Action-Fn> <Description String>) | NIL

A NIL <Binding Triple> is used to indicate a space in the Help menu.

<Key Group> = <Key> or (<Key>*)

<Action-Fn> = <function> or (<function> <Action-arg>*).

In the first case, the function is applied to a default set of parameters (<function> CARD NOTEFILE TEXTSTREAM SEL). In the second case, the form is eval-led.

<Action-arg> = The keywords CARD, NOTEFILE, TEXTSTREAM, TEXTOBJ, or SEL or an evalable form using these keywords as arguments. For example, either of the following may be used as an Action-Fn Item:

(RandomFunction CARD NOTEFILE)

(AnotherRandomFunction (HelloFn SEL) TEXTOBJ).

<Description String> is used in the Help menu (Meta-W ?) to indicate what the key is bound to.

(NCKEY-BUILD-HLP)

After editing *NCKEY-BINDINGS*, you must call this function to update the Help menu (Meta-W ?).

PROVIDED ACTION-FNS AND PARAMETERS

NCKEY-DEFAULT-CARDTYPE = Text

NCKEY-DEFAULT-TITLE = "Untitled"

NCKEY-DEFAULT-LINKTYPE = Unspecified

NCKEY-DEFAULT-DISPLAYMODE = NIL

These four user parameters are used by the Provided Action-fns as default values. There is a tradeoff between just using default value and prompting the user for values. I opted for default values because 1) they're a little easier and 2) a major point of this was to get something keyboardishly quick. All of these user parameters are INITVAR-red by this package, so users can put their own bindings in their INIT files.

NCKEY-CREATE-LINK-WITH-TITLE

NCKEY-CREATE-LINK-WITH-TEXT

These create a new card and insert a link to this card into the current card. The current selection is used as either the title or the text of the new card, and is also deleted from the current card.

NCKEY-MAP-LINKS

This function coerces the type and displaymode of all the links in the current card using *NCKEY-DEFAULT-LINKTYPE* and *NCKEY-DEFAULT-DISPLAYMODE* .

(NCHACKS.RemoveDeletedIconsFromTextCards CARD)

This function is obviously a part of NCHACKS and demonstrates an Action-FN which takes arguments other than the default arguments. It removes all the delete icons from the current card.

NCKEY-ENTITLE

This function sets the title of the current card using the current selection. It leaves the current selection alone.

NCKEY-HELP

This function brings up the help menu of the current key bindings. Remember that (NCKEY-BUILD-HELP) should be called to update the help menu after editing the key bindings.

KNOWN PROBLEMS

As mentioned above, the dispatch character can't be a META-character.

NCPPath

By: David Newman (Newman.pasa@Xerox.COM)

NCPPathParse, NCPPathUse

INTRODUCTION

This file is a module designed to allow a programmer to specify a path through a notecards network and a root card, and obtain from these a data structure describing all the paths through the network from the root card that match the path specification. The function `NCPPath.FSM.PathCollect` is the top level function. In conjunction with `NCPPathParse` (which translates a simple path language into the path descriptor that `NCPPath.FSM.PathCollect` requires), it returns a collection of paths for the programmer to manipulate. A typical call to the `NCPPath` functions should look like the following.

```
(NCPPath.FSM.PathCollect (NCPPathParse <Path-description> ) <RootCard>)
```

This package and its functions are implemented on a bastardized finite state machine model. The key difference is that in order to allow the imposition of limits on loops in the finite state network (limits on the number of times a loop can be traversed), the number of times each loop is traversed must be recorded in the finite state machine. In addition, this system will not collect any paths which attempt to traverse the same link of a notefile in the same direction a second time.

The data structures of this system include the InterLisp datatypes `NCPPathFSM`, `NCPPathFSMNode`, and `NCPPathPathStep`, and two list structures. A collection is a list of paths. A path is a list of pathsteps with the root card at the end. Paths contain the steps taken in reverse order, and the various paths in a collection share cons cells in order to conserve memory. Please note also the descriptions of the three records listed below.

RECORDS

`NCPPathFSM`

[Datatype]

The fields of an `NCPPathFSM` are `InitialState`, `CurrentState`, `Path`, and `LoopLimitAList`. Each is a Lisp POINTER. `InitialState` and `CurrentState` contain objects of type `NCPPathFSMNode`, and are the current and initial states of the finite state machine respectively. The `Path` field contains the intermediate

results of a traversal through the NoteCards network. Finally, LoopLimitAList is an a-list that keeps track of the number of times any loop in the finite state transition network has been traversed.

NCPPathFSMNode [Datatype]

The fields of an NCPPathFSMNode are Predicate, Card/Link, Direction, NextNodes, and LoopLimit. The first and fourth are POINTERS, the second and third are FLAGS, and the last is an INTEGER. The Predicate field points to a function or LAMBDA expression, which when applied to a notecard or link returns T or NIL; this indicates whether the item in question will satisfy the next step in the path description. The Card/Link flag indicates whether the Predicate is to be applied to links or cards, (T indicates links and is the default, while NIL indicates cards), and the Direction flag indicates whether a link is to be followed in a forward direction or a backward direction (T indicates forward, and is the default setting). NextNodes is a list of the next nodes in the finite state transition network, and hence is essentially a list of arcs away from the current node. Lastly, LoopLimit indicates the number of times that a loop beginning with the current node may be traversed; its default value is one.

NCPPathPathStep [Datatype]

An NCPPathPathStep has only two fields, both of which are POINTERS. the Link field contains a link in the notecards network, and the Direction field indicates the direction that this link was followed.

FUNCTIONS

NCPPath.FSM.PathCollect *PathSpec RootCard*) [Function]

This function collects a list of complete paths starting at RootCard as specified by PathSpec. The paths are really a network as they share CONS cells, and are actually reversed. The end of each is a pointer to the ID for RootCard. The first item in each path is actually the NCPPathFSM representing the remaining parts of the path to be collected. When the paths are complete, this is a NIL.

(NCPPath.FSM.RealPathCollect *FSMInstance RootCard*) [Function]

This function does the real work of NCPPath.FSM.PathCollect after that function has done the error checking. (FinishedPaths has an extra NIL at the front, so the CDR at the end removes it)

(NCPPath.FSM.FirstStep *RootCard FSMInstance*) [Function]

This function takes care of the case where the first NCPPathFSMNode has a list as its NextState.

(NCPPath.FSM.RealFirstStep *RootCard FSMInstance*) [Function]

This function is specially intended to get the first set of links from a path specification (the NCPPathFSM) and its root card. It constructs the first level or two of the tree of working paths. The function handles the special case where the first two FSMNodes in NCPPathFSM include card predicates.

(NCPPath.FSM.ListFirstSteps *RootCard FSMInstance*) [Function]

This function gets the first set of links from a path specification and a root card. End is bound specially so that all the paths created will share their last cons cells.

(NCPPath.FSM.AddPotentialSteps *FSMInstance*) [Function]
 Add all potential steps to the Path in *FSMInstance* without checking them against any specification.
 Returns a list of NCPathFSMs

(NCPPath.FSM.ListMultiplePaths *FSMInstance*) [Function]
 This function is intended to help out with the problem of true FSMs. It takes a NCPathFSM that has a list of FSMNodes as its CurrentState, and returns a list of NCPathFSMs each of which has one of the FSMNodes as its CurrentState.

(NCPPath.FSM.ComputeMultipleCollections *FSMInstance*) [Function]
 This function handles the case where the NextNodes field of the NCPathFSMNode in the CurrentState field of *FSMInstance* is a list rather than an individual FSMNode.

(NCPPath.FSM.AddNextSteps *FSMInstance*) [Function]
 This function adds the next set of steps to a particular path. That is, it takes a path, gets the NCPathFSM representing the PathSpec and the last link of the path, and adds each of the appropriate next steps to that path - returning a list of several paths with common CONS cells. It also puts the next state of the NCPathFSM on the front of the Path for the next time around.

(NCPPath.FSM.IncrementUseCount *FSMInstance*) [Function]
 Increment the count kept in the AList on the FSM indicating how many times the CurrentState has been used in this path.

(NCPPath.FSM.AddStep Step *FSMInstance*) [Function]
 Given an old FSMInstance and a new step, this function adds the step to the path in the FSMInstance. This function also increments the CurrentState to the NextState

(NCPPath.FSM.NextState *FSMInstance*) [Function]
 This function returns the next state in *FSMInstance* which defines a path specification. If the CurrentState of *FSMInstance* is NIL, we report the error and return NIL.

(NCPPath.FSM.LoopLimitExceededP *FSMInstance*) [Function]
 This predicate determines whether or not the FSMNodeInstance stored in the CurrentState of *FSMInstance* has been used too many times to get to the current place in the path. This function determines if a limited loop has been followed too many times.

(NCPPath.FSMState.ComputeCollection *FSMInstance*) [Function]
 This function takes an NCPathFSM as its single argument. The CurrentState of the NCPathFSM specifies a card rather than a link. If the last step of the path meets specification, and the next node in the NCPathFSM specifies a link, the path is returned. If the last step of the path meets the specification, and the next node in the NCPathFSM specifies a card, the intervening links are added, and the list of new paths is returned.

(NCPPath.FSMState.ListNextSteps *PathStepORCard FSMNodeInstance*) [Function]

This function finds the next steps that can be taken from a particular point in a path. It accepts either a card or a link as the indicator of the current path position and it returns a list of links.

(NCPATH.FSMState.SpecifiesCardP *FSMState*) [Function]

This function returns T iff the FSM-State is not NIL and it's CARD/LINK flag indicates that the

predicate is to be applied to a CARD.

(NCPATH.FSMState.SpecifiesLinkP *FSMNodeInstance*) [Function]

This function returns T iff the FSM-State is not NIL and the LINK/CARD flag indicates that the predicate is to be applied to a LINK.

(NCPATH.FSMState.TerminalP *FSMNode*) [Function]

This function determines whether or not a NCPATHFSM node is a terminal node. That is, whether or not there is a transition to another node from this one.

(NCPATH.Collection.ComputeNextCollection *PathCollection*) [Function]

This function computes a new list of FSMs from an old one. The new FSMs are created by taking an old FSM and adding one step to its path. This function also distinguishes the case where the next step is specified as a card predicate rather than a link predicate.

(NCPATH.Collection.CollectMultiplePaths *Collection*) [Function]

This function takes a collection of NCPATHFSMs and expands those that have multiple FSMNodes as their CurrentState into a list of NCPATHFSMs each having one FSMNode as its current state.

(NCPATH.Collection.ListRemovablePaths *Collection*) [Function]

List those paths of Collection which are complete, or loopy, or which have traversed the same loop of the FSM too many times.

(NCPATH.Collection.ListFinishedPaths *Collection*) [Function]

List those paths in Collection that are complete as specified. These are the paths that the user wants to see.

(NCPATH.Path.Create Root FirstStepLink *FSMInstance*) [Function]

This function creates a new path. Since a path is a list of NCPATHPathStep in reverse order with a root card ID at the end, we create the first step and the root and cons them together.

(NCPATH.Path.End *Path*) [Function]

This function returns the end card in a path by taking the last step of the path and using the Direction field to determine whether to return the source or destination of the link in the Link field.

(NCPATH.Path.AddStep Step *Path*) [Function]

Given Path and a new step, this function adds the step to the Path

(NCPATH.Path.LastStep <i>Path</i>)	[Function]
Since a Path is a reversed list, we just take the CAR to get the last step.	
(NCPATH.Path.StepInPathP <i>TestStep Path</i>)	[Function]
This predicate determines <i>if TestStep is in Path</i> or not.	
(NCPATH.Path.EQUAL <i>Path1 Path2</i>)	[Function]
This function checks for equality of two paths that are still reversed, and have the root card at the end. It is significantly faster than EQUALALL, but uses a number of CONS cells.	
(NCPATH.Path.LoopsP <i>Path</i>)	[Function]
This predicate returns T iff the last step in Path makes Path circular.	
(NCPATH.PathStep.End <i>PathStep</i>)	[Function]
This function returns the card at the appropriate end of PathStep, as indicated by the Direction field of the PathStep.	
(NCPATH.PathStep.PotentialSteps <i>PathStep Direction</i>)	[Function]
This function computes the possible next links from the link in PathStep.	
(NCPATH.PathStep.MeetsFSMCardSpecificationP <i>PathStep FSMNode</i>)	[Function]
This function determines whether or not the card specified <i>by PathStep</i> meets the specification of <i>FSMNode</i> .	
(NCPATH.Apply <i>FSMNodeInstance Item</i>)	[Function]
This function is anticipated to make the general path language easier to implement. It will look at the NCPATHFSMNode and it will use APPLY appropriately, else it will perform the right parsing and whatnot and then use apply.	
(Copy.NCPATHFSM <i>FSMInstance</i>)	[Function]
This function copies an NCPATHFSM much faster than COPYALL does. It should save time in NCPATH.FSM.IncrementCurrentState.	
(Copy.NCPATHFSMNode <i>FSMNodeInstance</i>)	[Function]
This function duplicates an NCPATHFSMNode.	
(NCPATH.Link.ListPotentialSteps <i>PreviousLink PreviousDirection Direction</i>)	[Function]
This function takes a link, the direction it was followed, and another direction flag, and returns a list of all potential links that may be the next step in the path from the appropriate end of the Link in the. The second Direction flag determines which way the found links are followed.	
(NCPATH.NoteCard.ListPotentialSteps <i>Card Direction</i>)	[Function]
This function returns the potential links that might be of use from Card.	
(NCPATH.Link.GetCard <i>PreviousLink Direction</i>)	[Function]
Given a link and a flag, this function decides which end of the link (source card or destination card) to return	

NC Path Language Description

<path>	::= <path step> (<path step> ...) (<path>) (<path> <repeater exp>)
<path step>	::= <path step descriptor> (<path step op> <path step> ...)
<path step descriptor>	::= <literal descriptor> <functional descriptor> ANY <lisp-variable>
<literal descriptor>	::= <link-type> @<card-type> _<link-type> _@<card-type>
<functional descriptor>	::= #<lisp-link-predicate> @#<lisp-card-predicate> _#<lisp-link-predicate> _@#<lisp-card-predicate>
<path step op>	::= OR AND NOT
<repeater exp>	::= <repeater token> <repeater token> <depth cutoff>
<repeater token>	::= + *
<depth cutoff>	::= <positive integer>
<positive integer>	::= <digit> <digit> <positive integer>
<digit>	::= 1 2 3 4 5 6 7 8 9 0

Notes:

- 1) The characters #, @, and _ are called the prefix of a path step descriptor, and their order is unimportant.
- 2) Note that <lisp-variable> *must have* a value parseable as a <path step descriptor>.

NCPPathParse

By: David Newman (Newman.pasa@Xerox.COM)

NCPPath, NCPPathUse

INTRODUCTION

This package parses expressions of a simple path description language into NCPPathFSM data structures for use by NCPPath.FSM.PathCollect. The language is described by a BNF grammar in the file NCPPathLanguage.TEdit. A simpler description of the language follows.

PATH DESCRIPTION LANGUAGE

The basic units of the language are path step descriptors. Each descriptor is either a literal descriptor or a functional descriptor. The literal descriptors consist of link types and card types currently existing in the active notefile. Functional descriptors are the names of lisp predicates that can be applied to a link or card, and which return T or NIL. A proposed new step in a path through a notefile is accepted when it is of the type specified by a literal descriptor or when application of the function specified by a functional descriptor returns T. Each path step descriptor has an optional prefix of several characters. The character @ indicates that the descriptor specifies the card at the end of the path step. The character # prefaces all functional descriptors. The character _ indicates that links followed in obtaining this step should be followed backwards. Path descriptors can be combined into other descriptors by the use of AND, OR, and NOT subject to the restriction that all descriptors in a combination must either apply to cards or links. Lastly, repetitive path structures may be specified using a number or Kleene star notation. See the examples below.

EXAMPLES

FOO is a function name, GOODP is a function name, and BAR is a variable with value @#GOODP.

(NCPPathParse (QUOTE #FOO))	(NCPPathParse (QUOTE @#FOO))
(NCPPathParse (QUOTE _@#FOO))	(NCPPathParse (QUOTE BAR))

```

(NCPPathParse (QUOTE @Text))          (NCPPathParse (QUOTE SubBox))
(NCPPathParse (QUOTE (SubBox)))        (NCPPathParse (QUOTE (@#FOO)))
(NCPPathParse (QUOTE (SubBox FiledCard)))
(NCPPathParse (QUOTE (@#FOO @#FOO)))  (NCPPathParse (QUOTE (AND @#FOO BAR)))
(NCPPathParse (QUOTE (OR @#FOO (AND @Text BAR))))
(NCPPathParse (QUOTE (#FOO *3)))      (NCPPathParse (QUOTE ((#FOO #FOO) *3)))

```

FUNCTIONS

(NCPPathParse *Expression*) [Function]
 This function is intended to be the top-level function that parses an expression into an FSM that NCPPath.FSM.PathCollect can deal with.

(NCPPathParse.FSMFromPathSpec *Expression*) [Function]
 This function is intended to be the top-level function that parses an expression into an FSM that NCPPath.FSM.PathCollect can deal with.

(NCPPathParse.Path *Expression*) [Function]
 This function parses an individual path as a list of steps or repeater expressions.

(NCPPathParse.PathStep *Expression*) [Function]
 This function parses an individual step of a path. A step is either a path step descriptor or some combination of descriptors.

(NCPPathParse.PathStepDescriptor *Expression*) [Function]
 Parses a path step descriptor. A descriptor is a literal descriptor, a functional descriptor, a "don't care" expression, or a variable pointing to a descriptor of one of the other types. The variable is checked for immediate circularity, but not for indirect circularity; either of these conditions could cause an infinite loop.

(NCPPathParse.LiteralPathDescription *Expression*) [Function]
 This function parses path descriptors that literally describe what kind of object qualifies as a step in the path sought through the notecards network.

(NCPPathParse.FunctionalPathDescription *Expression*) [Function]
 This function parses path descriptors that give function names which act as predicates to determine whether a link or card matches this step in the path descriptor.

(NCPPathParse.CreateFSMNode *Item Link/CardFlag DirectionFlag FunctionFlag*) [Function]
 This function creates the NCPPathFSMNodes that will become part of the NCPPathFSM being created by NCPPathParse. It contains a call to the code which creates the LAMBDA expressions to be used as predicates if necessary.

(NCPPathParse.CreatePredicateForm *Type Link/CardFLAG*) [Function]

This function creates a LAMBDA expression that will serve as a predicate. See NCPPathParse.CombinePredicates.

(NCPPathParse.RepeaterExpression *RepeaterExpression LoopSteps*) [Function]

This function parses repeater expressions.

(NCPPathParse.RepeaterToken *RepeaterExpression LoopSteps*) [Function]

Creates a repeater loop with no limit, or with infinite limit

(NCPPathParse.LimitedRepeaterToken *RepeaterExpression LoopSteps*) [Function]

This function parses repeater tokens that have an integral limit.

(NCPPathParse.LoopDecision *Expression LoopSteps MinimumRepeat Symbol*) [Function]

This function decides what kind of loop is to be created (requiring one or zero passes through the loop) and then creates a description of that loop.

(NCPPathParse.CreateLoop *LoopSteps MinTimes MaxTimes*) [Function]

Here we create an expression describing a loop that NCPPathParse.CoalesceStates can transform into an actual loop.

(NCPPathParse.PathStepOperation *Expression*) [Function]

Here we parse combinations of pathsteps. Combinations are created using AND, OR, and NOT, to combine other pathsteps.

(NCPPathParse.FunctionP *Function*) [Function]

This function returns T if its argument names an appropriate function for use as a predicate in an NCPPathFSMNode.

(NCPPathParse.CheckAndComputeFlag *StepList FlagName*) [Function]

This function computes the Direction and Card/Link flags when parsing a combination FSMNode. It also determines if the flags involved match, and notifies the user if they do not. It returns NIL if the flags do not match.

(NCPPathParse.CombinePredicates *StepList Operation*) [Function]

This function builds the LAMBDA expression that will be the predicate in a combination FSMNode.

(NCPPathParse.CombinationExpressions *StepList Operation*) [Function]

This function combines pathstep specifications using AND, OR, or NOT into a single NCPPathFSMNode.

(NCPPathParse.CoalesceStates *NodeList*) [Function]

This function takes a lisp-style list of NCPPathFSMNodes and turns them into a linked list. The linked list will include circularities where repeater expressions exist.

(NCPathParse.CoalesceRepeaterStates *LoopList* Next Limit) [Function]

This function creates the circular linked list structure that repeater expressions need.

(LOGEQUAL . *U*) [Function]

This function is a logical operator. It determines if the arbitrary number of arguments are logically equal or not.

(NAND . *Args*) [Function]

This function is a logical operator similar to AND or OR, except that it performs the logical operation of (NOT (AND *Args*)).

NCPATHUse

By: David Newman (Newman.pasa@Xerox.COM)

NCPATH, NCPATHParse

INTRODUCTION

This package is intended to provide some functions useful to the programmer using the NCPATH package. These functions allow the programmer to transform the data returned by NCPATH.FSM.PathCollect into something more useful to a particular application. Also, three functions intended for use as Print definitions for the three major datatypes in NCPATH are included in this file.

FUNCTIONS

(NCPATH.GetCardPathListsFromPathCollection *PathCollection*) [Function]

This function collects a list of cards traversed by each path in PathCollection. Thus, it returns a list of lists. Each sublist is a list of all the cards traversed in a particular path.

(NCPATH.GetTerminalsFromPathCollection *PathCollection*) [Function]

This function returns a list of the terminal cards in a collection of paths. It is intended to assist the user in getting the results desired from what NCPATH.FSM.PathCollect returns.

(NCPATH.GetUniqueTerminalsFromPathCollection *PathCollection*) [Function]

This function is very similar to NCPATH.GetTerminalsFromPathCollection, but it collects only unique terminal cards, where the other function can collect multiple copies of the same terminal card.

(NCPATH.ReverseAndSeparatePaths *PathCollection*) [Function]

The results of NCPATH.FSM.PathCollect is a list of lists, each sublist being a path in the collection. These paths share cons cells for efficiency, and are stored with the steps in the paths in reverse order. This function accepts the result of NCPATH.FSM.PathCollect, and returns a list of paths with their steps in the correct order, and broken apart such that no cons cells are shared between paths.

(PathStepPrint *Instance Stream*) [Function]

This function is intended to be a print definition for the NCPATHPathStep datatype.

(PrintFSM *Instance Stream*) [Function]

This function is intended for use as a print definition for the NCPATHFSM datatype.

(PrintFSMNode *Instance Stream*)

[Function]

This function is to be a print definition function for FSMNodes.

NCScreen

By: Randy Trigg (Trigg.pa@Xerox.COM)

Stored: {qv}<notecards>1.3k>library>NCScreen, .dcom, .ted

Last updated: May 4, 1987.

INTRODUCTION

This NoteCards library package provides a set of user-callable functions that can be used to manipulate cards on the screen. Other NoteCards library packages including NCCluster use NCScreen functions.

FUNCTIONS FOR LAYING OUT CARDS

(SCREEN.LayoutCardsInSquare <StartPos> <Cards>)

Lay out the cards appearing in the list <Cards> in a square arrangement with the upper left corner of the first card at the position <StartPos>. The number of columns is equal to the floor of the square root of the number of cards. Card windows are arranged in row order attempting to fit all windows on the screen without overlapping. However, some windows may overlap in order to fit each window on the screen.

(SCREEN.LayoutCardsInCascade <StartPos> <Cards>)

Lay out the cards in <Cards> in a cascaded overlapping deck with the upper left corner of the first, deepest card at the position <StartPos>. Calls SCREEN.GetCascadePosition.

(SCREEN.GetCascadePosition <Window>)

This function is used to determine the position for the next card in a cascade. It takes one argument which is a window and returns the position of the upper left corner for the next cascaded window. The spacing between cards in the cascade is determined by the global variables SCREEN.CascadeXSpace and SCREEN.CascadeYSpace (initially set to 3 and 8, respectively).

(SCREEN.LayoutCardsInSurround <CenterCard> <Cards>)

Arranges the cards in the list <Cards> around three sides of the card <CenterCard>. Cards are placed in order down the right side, the left side, and along the bottom. Note: this may not display all cards in <Cards>. The number of cards displayed is returned.

(SCREEN.SurroundCardWithFileBoxContents <Card> <Box>)

Arrange the child cards of the filebox <Box> around the card <Card>. If either arg is NIL, then the user is asked to select. This calls SCREEN.LayoutCardsInSurround. If some cards in <Box> could not be displayed, then a statement to that effect is printed in the prompt window.

MISCELLANEOUS HANDY FUNCTIONS

(SCREEN.MoveCardToPos <Card> <Pos> <Corner>)

Move the <Card> card's window such that its <Corner> corner is at the position <Pos>. <Corner> should be one of the litatoms UL, LL, UR, or LR. The default is UL. If the card is not currently on the screen, then it will be brought up. This calls SCREEN.MoveWinToPos.

(SCREEN.MoveWinToPos <Win> <Pos> <Corner>)

Move the <Win> window so that its <Corner> is at the position <Pos>. <Corner> should be one of UL, LL, UR, or LR as above. If the window doesn't completely fit on the screen at that position, then it is moved so it does.

(SCREEN.WinLLCorner <Win>)

(SCREEN.WinLRCorner <Win>)

(SCREEN.WinULCorner <Win>)

(SCREEN.WinURCorner <Win>)

These functions return the positions of the various corners of the window <Win>.

(SCREEN.WinShrinkAndPlace <Win>)

Shrink the window <Win> (if not already shrunk) and place so its upper left corner is at the upper left corner of <Win>.

NCTableTopCard

By: Randy Trigg (Trigg.pa@Xerox.COM)¹

Stored: {qv}<notecards>1.3L>Library>NCTableTopCard, .lcom, .ted

Written: July 30, 1988 by Randy Trigg

Last updated: May 5, 1989 by Peggy Irish.

See also NCGuidedTourCard package.

¹ The first version of TableTops was written by Jeff Shrager and subsequently modified by George Cole.

INTRODUCTION

Tabletop cards are a means in NoteCards of capturing the layout of some set of cards on the screen. A tabletop is a snapshot which includes the list of cards, the shapes of their windows, their positions on the screen, the scrolled locations (vertically and possibly horizontally) of the windows' contents, and the order in which to open the windows so that the original (possibly) overlapping arrangement can be preserved. Tabletops have three main uses: (1) as a means of storing card layout across notefile closings/openings. In this case, the system constructs and maintains the tabletop automatically. (2) as aids for online demonstrations of notefiles and to help in creating hard copy screen snapshots for offline presentations. Here, the user creates the tabletop card manually. (3) as "stops" along a NoteCards guided tour. In what follows, I describe the system support for the first two cases. For a description of the use of tabletop cards in guided tours, see the documentation on the NCGuidedTourCard package.

LOADING THE NCTABLETOPCARD PACKAGE

Loading the NCTableTopCard package is done in the same way as loading any other NoteCards card type library package. For example, you can type the following at an Interlisp exec:

```
(FILESLOAD (FROM NOTECARDS) NCTABLETOPCARD)
```

Alternatively, you can add the atom NCTABLETOPCARD to the global var NOTECARDSLIBRARYFILES in your init file. This will ensure that NCTABLETOPCARD is loaded when bringing up a fresh sysout. Finally, if a link to a

tabletop card is followed and the NCTABLETOPCARD package is not currently loaded, then it will be auto-loaded by the system.

SAVING A TABLETOP AT NOTEFILE CLOSING

Using a tabletop, one can save the screen layout of cards from a notefile in such a way that the layout can be reinstated the next time the notefile is opened. This allows for greater continuity of work across notefile closings and reopenings. When this package is loaded, the "NoteFile ops" left-button menu available from the notefile icon is augmented slightly. The new pull-across menu for "Close" appears as follows

Choosing the option **Close Saving TableTop** causes the current layout of cards with open (or shrunk) windows to be saved in a special tabletop and then the notefile to be closed. The next time the notefile is opened, those same cards will be brought up and arranged (or shrunk) according to the saved layout. (The NCTABLETOPCARD package will be auto-loaded if necessary.)

BUILDING AND MANIPULATING TABLETOPS BY HAND

You can create a tabletop card in the usual way, namely by middle-buttoning the NewCards menu on the notefile icon and choosing **TableTop**. You will be asked if you want to use a template tabletop for the creation of this new tabletop. Frequently a user will want several tabletops to share one or more windows, so this option allows one tabletop to be modeled easlily after another. Selecting Yes allows you to pick a tabletop to be used as a template for the new tabletop. Then you will be asked to select the cards to persist from the template, ie. which cards should actually exist in both tabletops.

You will also be asked to select the cards to copy from the template. These cards will be copied for the new tabletop, preserving the title, size, shape, location, and default looks of the original cards.

If you don't use a template tabletop, you'll be asked to select a set of cards to form the contents of the tabletop. Select these in the usual way, by holding the shift-key down and left-buttoning in the card windows' titlebars. You'll notice that the tabletop card's window is rather small and has no directly editable substance. Nonetheless, the contents of a tabletop card can be easily modified through a set of tabletop operations available from the card's middle-button titlebar menu.

In addition, each of these operations is available from (the middle-button menu of) any link icon pointing at the tabletop card.

The operations available for tabletop cards are:

Recompute TableTop - Before choosing this operation, you presumably will have rearranged the cards in the tabletop changing some aspect of their layout. Choosing Recompute causes the new layout to be installed in the tabletop card.

Recompute TableTop pull across menu -

New Cards - This operation requires you to specify a new set of cards. That is, the tabletop is recomputed from scratch.

New Cards In Order - This operation requires you to specify a new set of cards, like the **New Cards** menu item. The order in which you choose the new cards is the order in which the cards will appear when you bring up the tabletop.

With Template - This operation asks you to select an existing tabletop to be used as a template for this tabletop.

Add cards to TableTop - This lets you add one or more cards to the tabletop by shift-selecting their windows' titlebars (or links icons pointing at them) in the usual manner. Once the selection is made, the tabletop is recomputed so that the new cards will be ordered correctly relative to the cards already in the tabletop.

Remove cards from TableTop - This brings up a menu containing the titles of all cards in the tabletop. Choose a card to remove by selecting from this menu. A second menu will then pop up containing the remaining cards. In this way, as many cards as desired can be removed from the tabletop. You'll be asked to confirm the removal of all selected cards as soon as you click outside of one of the card title menus.

Show cards in TableTop - This brings up a menu containing the titles of all cards in the tabletop. You can then select from this menu to bring up a single card in the tabletop at its assigned position/shape and scrolled properly.

Bring up TableTop - This opens all cards in the tabletop and positions, shapes, scrolls, shrinks and orders their windows according to the layout information stored in the tabletop. Any cards already open are moved into place and scrolled and shaped (or shrunk) appropriately.

Close down TableTop - This closes any open cards in the tabletop.

The above description covers the standard operation of tabletops. There are, however, two exceptional cases having to do with unopened cards in the tabletop. First, you might try to add a card to the tabletop whose window is not currently open

(or shrunken). In this case, the card's most recent position is used and it will appear in the bottom-most position in the window overlap ordering.

Second, you might try to recompute your tabletop even though one or more cards are not currently open. That causes something like the following

interactIOGETFN: BMOBJ.GETFN3ÓÑ

Of the three choices, **Cancel** aborts the Recompute operation. **Keep** causes the card to remain in the tabletop. (Note however, that it will be moved to bottom-most in the overlap ordering.) **Remove** causes the card to be removed from the tabletop.

INFORMATION STORED IN A TABLETOP CARD

As mentioned above, the tabletop card stores layout-related information for each of its cards. This includes: the card window region (i.e. shape and position); the scrolling positions (both vertically and horizontally if any); and whether the card's window is shrunken and if so, the position of its icon. Furthermore, the tabletop keeps the list of cards sorted according to the window overlapping ordering (a.k.a. the TOTOPW ordering). If the **Recompute** sub-command **New Cards In Order** was used to select the cards in the tabletop, then the list of cards is kept in the order specified.

In addition, extra information is kept for certain card types. For browser-based cards, tabletops record information about the shrunken browser overview window (if and where it is attached and its region) and whether the links legend and Editor menu windows are currently open. For Sketch-based cards, tabletops record whether the Sketch editing menu is attached.

PROGRAMMER'S INTERFACE TO TABLETOP CARDS

To create a new tabletop card programmatically, call `NCP.CreateCard` as follows:

**(NCP.CreateCard 'TableTop NoteFile Title NoDisplayFlg Props
ParentFileBoxes ListOfCards InterestedWindow)**

Here, all the parameters are as per the documentation of `NCP.CreateCard` except that `ListOfCards` should be a list of (open or shrunken) cards whose layout is to be the tabletop card's initial substance.

The following functions can be used to programmatically manipulate tabletop cards and their contents.

(NCTableTop.BringUpTableTop TableTopCardOrWindow DoNotUncacheFlg)

The tabletop is brought up, that is, its cards opened and layed out appropriately on the screen. `TableTopCardOrWindow` can be either a tabletop card object or the window for same. Normally, if the tabletop card itself isn't part of the tabletop being displayed, it is cached, the cards in the tabletop are displayed, and the tabletop card is uncached. A non-NIL `DoNotUncacheFlg` will prevent the uncaching of the tabletop card (this is useful, for example, when control of caching is desired at the Guided Tour level -- see the `NCGuidedTour` package documentation).

`NCTableTop.BringUpTableTop` returns the list of cards it brought up.

**(NCTableTop.OpenCardInTableTop TableTopCardOrWindow
InterestedWindow)**

This causes a single card within a tabletop to be opened and positioned, shaped, etc.

at its proper location. A pop-up menu is used to elicit the card to be opened from the user.

(NCTableTop.CloseDownTableTop TableTopCardOrWindow)

Close any open cards in the tabletop.

(NCTableTop.RemakeTableTop TableTopCardOrWindow ListOfCards RetainClosedCardsFlg NoToTopOrder)

Rebuild the tabletop to contain the cards appearing in **ListOfCards**. If **RetainClosedCardsFlg** is non-nil, then even closed cards in **ListOfCards** will be included in the tabletop. If **NoToTopOrder** is non-NIL, the cards are ordered in the tabletop according to the order in which they appear in **ListOfCards**, instead of by their overlapping order on the screen, which is the default.

(NCTableTop.RecomputeTableTop TableTopCardOrWindow NoToTopOrder)

Recompute the tabletop contents. Normally, the cards in the tabletop are open and arranged in a new arrangement when this call is made. If **NoToTopOrder** is non-NIL, the order of the cards in the tabletop is not altered according to their overlapping order on the screen, which is the default.

(NCTableTop.RemoveCardsFromTableTop TableTopCardOrWindow CardsToRemove)

Remove cards in the list **CardsToRemove** from the tabletop's substance. Returns the cards actually removed.

(NCTableTop.AddCardsToTableTop TableTopCardOrWindow CardsToAdd InterestedWindow)

Add cards appearing in **CardsToAdd** to the substance of the tabletop.

(NCTableTop.CardsInTableTop TableTopCard)

Return the list of cards currently appearing in the tabletop.

(NCTableTop.TableTopBasedP CardOrCardType)

Return non-nil if **CardOrCardType** is either a tabletop card or a card of a type that inherits from tabletop card. (It does the obvious thing if **CardOrCardType** is a card type.)

(NCTableTop.CollectCards RootTableTopCards LinkTypes MaxDepth FollowCrossFileLinksFlg)

This function is analogous to NCP.CollectCards. It starts from a list of tabletop cards given by **RootTableTopCards** and computes the transitive closure by following links of types appearing on **LinkTypes** to a maximum depth specified by **MaxDepth** where the depth 1 cards are the cards directly in the tabletop su

TextCardKeys

by Kirk Kelley (Kelley.pa@Xerox.COM)

{QV}<NoteCards>1.3k>library>TextCardKeys.dcom
Last updated: Jan 29, 1988

Introduction

Ever wish you could capture the structure of your ideas before they escaped short-term memory?

TextCardKeys sets special keys on your keyboard to create with one chord a new text card linked from your caret location.

Initial Settings

For a See link type: META asterisk (META SHIFT 9)

For an Include link type: META open paren (META SHIFT 9)

To close a card: META close paren (META SHIFT 0)

The new cards come up with default titles ready to be edited.

For See links, the title is an asterisk.

For Include links, the title is empty.

The new cards also come up already positioned on the screen.

The best way to see how it works is to load it and try it out. I use this with `ForcedFiling` turned off and find my hands rarely need to leave the keyboard.

Philosophy

TextCardKeys facilitate one of the proposed new ways of keeping track of cards. In this new way cards would always be linked somewhere. It is hoped this will eliminate the need for forced filing, Orphans, the To Be Filed box, un-filed cards, and all of the concepts and mechanisms surrounding them.

Changing Settings

The following is the nitty gritty for those that want to program different behavior or settings.

NC.CreateLinkedTextNoteChar [variable]

This is the key for creating a "See" link. It comes set to 298 (Meta asterisk).

NC.CreateLinkedTextNoteLinkType [variable]

This is a string containing the type of link for the above character. It comes set to "See".

NC.CreateLinkedTextNoteTitle [variable]

This is a string containing the initial title for the above link. It comes set to "".

NC.CreateLinkedTextInclusionChar [variable]

This is the key for creating an "include" link. It comes set to 296 (Meta open-paren).

NC.NC.CreateLinkedTextInclusionLinkType [variable]

This is a string containing the type of link for the above character. It comes set to "Include".

NC.CreateLinkedTextNoteTitle [variable]

This is a string containing the initial title for the above link. It comes set to "".

NCP.NewTextCardRegion [function]

Alter this to change where, and what shape, cards will automatically have when positioned on the screen. To turn off auto-positioning, have this return NIL.

If you change any of the above settings, I would be interested to know how you change them

One of the key components of CLOS in inheritance. The CLOS Browser provides functionality for displaying this structure and for extending it. It also provides functions for displaying and changing the class definitions and method definitions which make up a system written in CLOS.

Creating a Browser

A browser can be created in two ways:

- Via a menu option from the Background Menu
- By calling the function CLOS-BROWSER:BROWSE-CLASS on a class

Creating a browser via the Background Menu

When the CLOS-BROWSER module is loaded, an entry is added to the Background Menu, as shown below:

Selecting the menu item BrowseClass brings up a window, with a prompt for the name of the class to use as the root of the browser as shown below.

Type in the name of the class you wish to browse at the flashing cursor, and the class graph will be drawn in the window.

Creating a browser programmatically

Browsers can also be created by calling the function BROWSE-CLASS:

(BROWSE-CLASS &OPTIONAL CLASS-NAME-OR-LIST &KEY :WINDOW-OR-TITLE :GOOD-CLASSES :POSITION) **[Function]**

This function brings up a browser on the class named or the list of classes named. If a window is supplied for the :WINDOW-OR-TITLE argument, then the browser is created in that window, else an appropriately sized window is created. The window is positioned at the :POSITION argument or, if not supplied, then the position is set via the mouse. If a text string is supplied for the :WINDOW-OR-TITLE argument, then that string is used for the window title, else the string "CLOS-browse" is used. If :GOOD-CLASSES is supplied, then only those classes in the list are displayed.

Using the Class browser

Instances of CLOS-BROWSER are operated on through a mouse-based interface.

Buttoning on the browser will cause one of the following menus to be popped up:

- One menu appears when the left or middle button is pressed while the mouse is in the title bar. This menu has operations that apply to the browser itself.
- The other menu appears when the middle button is pressed when the mouse is on one of the nodes in the browser.

If the left button is pressed when the mouse is on a node, that node is boxed. This marks the node for some operations.

Options in the title bar menu

The following menu appears when you left- or middle-button in the title bar.

Recompute and it's suboptions

Selecting the Recompute option and dragging the mouse to the right causes the following submenu to appear:

Most of these items change the appearance of the browser, not the contents.

Recompute	Recomputes the browser from the starting objects. It does not recompute the labels for each node if those labels are cached in the Label-Cache slot of the browser.
Recompute Labels	Recompute the browser from the starting objects, including the labels.
Recompute inPlace	Recompute the browser without affecting the scrolled location of the lattice within the window.
Clear caches	Clear the caches of the nodes.

Browser looks and it's suboptions

Selecting the Browser looks menu item and sliding to the right causes the following submenu to appear:

Selecting one of these options changes the looks of the browser.

Shape to hold	Make the window for the browser just large enough to contain the browser.
Change font size	Causes a menu of alternative font sizes to pop up. Selecting one of these causes the browser to be redrawn with the nodes at that font size.
Change format	Causes the following menu to appear:

Horizontal/Lattice Lays out the grapher as an horizontal lattice.

Vertical/Lattice Lays out the grapher as a vertical lattice.

Horizontal/Tree Lays out the grapher as a horizontal tree.

Vertical/Tree lays out the grapher as a vertical tree.

Options in the Middle-button menu

The following menu appears when you middle-button over a node in the graph:

Edit and it's suboptions

Selecting **Edit** causes an editor on the class definition to be brought up. Sliding the mouse to the right causes the following menu to appear:

Edit Edits the class named by the node

Inspect Inspects the class object named by the node.

Add Method

Selecting the **Add Method** option brings up an editor window with a template for a method to be added to that class. When the editor is done the method is installed for that class and the menu updated.

Browse

Selecting the **Browse** option causes a browser to be created starting with that class as the root.

Print and it's suboptions

Selecting Print prints out the class definition. Sliding the mouse to the right causes the following menu to appear:

Print	Print's the class definition
Describe	Describes the class, listing it's metaclass, it's supers classes, it's subclasses, it's CPL, and the number of methods specialized to it.
Documentation	Print's the documentation string for the class

Specialize

Selecting the Specialize option brings up an editor window with a template for a subclass to be added to that class. When the editor is done the class is installed and the browser updated.

Slots

Selecting the Slots option is the same as selecting the Edit option, it brings up an editor on the class definition.

Methods

The Methods option allows you to edit one of the methods defined for that class. Selecting it and sliding to the right brings up the following sub-menu:

Local	Bring up a menu of the local methods, ie methods directly defined for this class

Inherited	Bring up a menu of the methods this class inherits from it's superclasses.
All	Bring up a menu of all the methods defined for this class, both local and inherited.

Selecting an item with the left button from the resulting menu brings up an editor on that method. If there are multiple methods that apply, a gray triangle appears in the right edge of the menu next to that item. Sliding to the right brings up a menu of method specializers to select the appropriate method.

== IMINDEX ==

The file IMINDEX contains the functions used for creating and editing index image objects, and inserting them into a Tedit document. When a Tedit document containing index objects is formatted for printing, the index objects do not appear, but information about the index objects is put into an auxilliary "IMPTR" file. The functions in IMTOOLS can be used to take a set of IMPTR files, and generate an index.

Adding an Index Object to a Tedit Document

The simplest way of adding an index object to a Tedit document is to type ctrl-O while typing at Tedit, which will cause a window to pop up asking you to type a form to eval:

Typing (IM.INDEX.CREATEOBJ) will create an empty index object, indexing the term NIL, inserted in the Tedit document at the caret. Index objects appear in the Tedit window as words with boxes around them:

Using the IM Index Menu

An easier way to put many index objects into a Tedit document is to type (IM.INDEX.MENU) at the lisp exec, which will prompt you to position a menu that looks like this:

If the caret is blinking in a Tedit window, selecting [Index Selection as Term] with the left button will create and insert an index object that indexes the selected string. For example:

Before: and after:

Selecting [Index Selection as Term] with the MIDDLE button will insert an index object that indexes the selected string, and then create an index object editing window, that can be used to edit the values of the fields in an index image object.

Editing an Index Object in a Tedit Document

If you select an index object, a menu will appear asking whether you want to edit the contents of the index object:

If you select [Edit Index], you will be prompted to position an index object editing window, which looks like the following:

This is a freemenu that allows you to edit the values of the fields in an index image object. Selecting [Store Props] stores the values in the editor into the object itself -- if the "Name:" field is changed, the Tedit window will change to show the new index name. Selecting [Close Window] will close the editor window. Note that any changes are lost if you close an index object editing window without storing the new property values.

Index Object Properties

There are more properties in an index object than show in the window initially; the window can be scrolled or reshaped to see and edit the other properties. The fields are interpreted as follows:

Note: The properties listed with "()", such as "Type():", interpret their value as a list of take a list of items, delimited by spaces. The other properties interpret their value as an atom, including spaces.

Name: Value is the name used to sort and merge index entries. This should normally be all-uppercase. The [Index Selection as Term] item in the IM Index menu will automatically uppercase the selection if it is not all-uppercase, and put the real value in the "Text:" field. Examples:
 Name: FOO
 Name: BAR

Type(): Value is the type of object being indexed. If NIL, this stands for an English term. Other types are used for indexing lisp functions, variables, etc. Note that upper/lower case is important. Examples:
 Type(): Function
 Type(): Editor Command

Note: The special types CHAPTER and SUBSEC (all-uppercase) are used to create entries in the table of contents, as described below. These cannot be used as index entry types.

Text: Value is the name actually printed in the index. If NIL, the value of the "Name:" property is used. This is usually used when indexing non-uppercase items. Another place where this is useful is when you want an item containing strange characters to appear in a different place in the index. For example, if Name: = FOO and Text: = *FOO*, the item "*FOO*" will appear in the index among the "F" items instead of the "*" items.

Info(): Value is a list of "information" words, that mean something to the indexing programs. There are a few info words likely to be used by IMINDEX users. One is the word *PRIMARY*, which indicates that this is a primary reference. In the index, primary index page numbers are printed first, in a bold font. Another is the word *NOPAGE*, which indicates an index entry that should not be printed with a page number. This can be used to generate entries such as "FOO, see BAR". Example:
 Info(): *PRIMARY*

SubSec(): Probably not much use for IMINDEX users. Value is a reverse list of nested subsection and chapter numbers. For example,
 SubSec(): 4 2 99
 indicates subsection 4 inside subsection 2 inside chapter 99. This is not used with normal index entries, except that chapter numbers, if given, are used when generating the page number in the index. For example, if the index entry specified chapter 99, and it was on page 5, it would appear in the index as 99.5.

Another use for this field is if you use IM index objects to generate a table of contents, by creating index objects with type of CHAPTER or SUBSEC, as described below. In this case, the SubSec field is used to specify the subsection numbers.

Page#: The value of this field is replaced with the page number when the Tedit textstream containing the index image object is hardcopied. Not much use to change, but it is possible.

SubName:
SubType():
SubText: Name, Type, and Text values for a sub-entry, if any, which appears under the main entry in the index.

SubSubName:
SubSubType():
SubSubText: Name, Type, and Text values for a sub-sub-entry, if any.

Adding New Types to the IM Index Menu

If all of the index entries in a document are terms, it is very easy to use the IM Index menu to index them. However, if there are a lot of Functions, variables, etc., you may need to edit each index entry to change the type. To make this easier, you can use the [>>Add Type<<] button in the IM Index menu to add new selections to the IM Index menu. If [>>Add Type<<] is selected, the system will prompt you to type a type name, and add a new item to the menu. For example, if you started with the initial menu, and added a new entry for the type "Function", the menu would be changed to look like the following:

```

IM Index menu
Index Selection as Function
Index Selection as Term
>>Add Type<<
>>Close Menu<<

```

If [Index Selection as Term] is selected, an index object will be created indexing the the current Tedit selection, with the type of Function.

Saving and Retrieving Tedit Documents with IM Index Objects

Tedit documents containing IM Index objects can be saved using the ordinary Tedit "Put" command, which will store all of the indexing information in the index objects. Note, however, that it is necessary to load the IMINDEX package before editing any Tedit documents containing IM Index objects -- otherwise Tedit will print the message "WARNING: Document contains unknown image objects", and all index objects will appear as the following:

```

Unknown IMAGEOBJ type
GETFN: IM.INDEX.GETFN

```

If this happens, it will not be possible to use these index image objects, or re-save the Tedit document. Close the Tedit window, load IMINDEX.DCOM, and call Tedit to edit the document again.

Hardcopying a Tedit Document Containing Index Objects

A Tedit document containing index objects can be hardcopied using the normal [Hardcopy] menu button, or from the Filebrowser. Index image objects will not appear in the final hardcopy. However, while the document is being formatted, the index objects will put indexing information in an auxilliary file with the extension "IMPTR". The first time an index object is formatted, it will try to open an imptr file on the connected directory, printing a message in the prompt window: "Opening index pointer file: {DSK}<LISPFILES>FOO.IMPTR...done". When the formatting is completed, another message will appear: "Closing index pointer file: {DSK}<LISPFILES>FOO.IMPTR;1...done".

The directory used for the imptr file is the currently-connected directory (which can be changed using the CONN command). The file name used is the file name of the Tedit file, if there is one. For example, if the Tedit file is XYZ.TEDIT, the imptr file would be XYZ.IMPTR. If the Tedit text stream doesn't have a name (for instance, if the Tedit window has been brought up but never saved) the file name NONAME.IMPTR is used. The extension is always IMPTR.

For Hackers Only: If there is a need to use a different filename for the imptr file, it is possible to specify this programmatically by changing textstream properties of the Tedit textstream before the hardcopy operation. If the value of the textstream property IM.INDEX.PTRFILENAME is non-NIL, it is used as the file name for the IMPTR file. If the value of the textstream property IM.INDEX.PTRFILE is non-NIL, it is the stream used for the IMPTR information.

Creating Indices and Tables of Contents From IMPTR Files

The file IMTOOLS.DCOM contain the routines used to create indecies and tables of contents for documents in IM format. These will also produce indicies and tables of contents from IMPTR files created by IM index objects. Loading this file will automatically load IMINDEX.DCOM, if it is not already loaded. Note, however, that you can load IMINDEX (for the purpose of editing Tedit documents with IM index objects) without loading IMTOOLS.

IMTOOLS contains the following useful functions:

(MAKE.IM.INDEX OUTFILE.FLG VOLUME.INFO IMPTR.FILES IMPTR.TYPES) [Function]

MAKE.IM.INDEX takes a number of IMPTR files, and produces an index, formatted like the one in the IRM. If OUTFILE.FLG is NIL, the output file is just sent to the default printer. If OUTFILE.FLG is T, the outfile textstream is simply returned. If OUTFILE.FLG = anything else, it is taken as a file name of an interpress file which is created <but not printed>.

VOLUME.INFO is a list of lists specifying which chapters are associated with which volumes in a large multi-volume document (like the IRM). For an example of the format, see the variable IM.MANUAL.VOLUMES in IMTOOLS. If NIL, no volume numbers are printed in the index.

IMPTR.FILES is a list of IMPTR files to be used to create this index. If NIL, any index info loaded in by explicitly calling GRAB.IMPTR is used (see IMTEDIT.TEDIT). When doing the IRM, all of the IMPTR files are loaded into global variables using GRAB.IMPTR, but users of IMINDEX probably want to specify the values specifically.

IMPTR.TYPES should be a list of IM index types to be included in the index, specified as lists. For example, if IMPTR.TYPES = ((Function)(Variable)), only function and variable entries would be listed in the index. If IMPTR.TYPES = NIL, all index entries in the IMPTR files are used.

(MAKE.IM.TOC OUTFILE.FLG CHAPTER.NUMBERS IMPTR.FILES) [Function]

MAKE.IM.TOC takes a number of IMPTR files, and produces a table of contents, formatted like the one in the IRM. All im index entries whose type is CHAPTER or SUBSEC are used as chapter and subsection pointers.

OUTFILE.FLG and IMPTR.FILES are interpreted similar to MAKE.IM.INDEX.

CHAPTER.NUMBERS is either: NIL, meaning to generate TOC of ALL data in the specified imptr files; a single number, meaning to generate a chapter TOC for that chapter; or a list of numbers, meaning to generate a TOC for those chapters.

***** The IMNAME Database Package *****

IM format is the text formatting language that the Interlisp Reference Manual is represented in. It is somewhat like TEX source code, in that there are keywords, and brackets are used to delimit text. However, IM format was specifically designed for representing the Interlisp Manual, so the "text objects" used are semantically meaningful objects within the manual, such as "function definition", "lisp code", "subsection".

IMNAME is a package designed to help people who may frequently need to modify IM format files. Usually, a large document (such as the Interlisp Manual) is stored in a number of separate files, and it is difficult to know which file contains a particular piece of information. IMNAME contains functions for analyzing a set of IM format files and building a database of "IM Names" (functions, variables, property names, etc) with pointers to the files where they are defined. Using this database, other functions allow the user to specify an IM name, and bring up a Tedit window on the appropriate file, with the cursor positioned at the right place. This tool has been very helpful to the people updating the Interlisp Reference Manual.

***** Using IMNAME to access IM format files. *****

The normal way of using an IMNAME database is by creating an "IM name inspector". This can be done using either of the following two functions:

```
(MAKE.IM.INSPECTOR hashFileName)
or
(IMNAME hashFileName)
```

hashFileName should be the name of the IMNAME database hashfile to use for this inspector. One can create multiple IM name inspectors point to the same hashfile, or to different hashfiles. Currently, I know of only two IMNAME hashfiles; the one for the Interlisp Manual and one for the Loops Manual. If hashFileName is the atom INTERLISP or LOOPS, this Inspector will point to the appropriate hashfile. If hashFileName is omitted, it will assume that the Interlisp Manual hashfile is desired for people whose default host is Phylum, and the Loops Manual for people on Ivy. (Other people can set up their own default IMNAME hashfile by setting the global variable IM.NAME.DEFAULT.HASHFILE).

MAKE.IM.INSPECTOR sets up an "IM Inspector Window", which contains a menu. Initially, this contains the single selection "Type an IM name", which (when buttoned) prompts the user to type a name which will be looked up in the database. If an IM name is found in the hashfile, another window will appear below the first one, containing all of the "types" that the given name is known by. For example, a name may be known as both a variable and a function. If one of these types is selected, a third menu will appear below the second, listing references to the name in different files. Selecting one of the references will move the cursor in a TEDIT window (if there exists an active TEDIT window to the appropriate file), or create a new TEDIT window to the file. [Note: If a name is only known to be of one type, the "type menu" step is omitted.]

Other functions:

```
(INSPECT.IM imname hashFileName)
```

This allows the searching for a single IM name, using several pop-up menus. In general, it is easier to use the IM name inspector.

```
(GET.IM.NAME.LIST hashFileName)
```

Returns a list of all of the IM names known within the specified hashFileName.

***** Updating an IMNAME database. *****

IMNAME works by referencing a hashfile database containing IM names and pointers to files where these names are referenced. As a set of files is modified, this information will become obsolete. In particular, simply adding a few characters to a file will invalidate all pointers to positions later in the file. This can be tolerated for awhile (it is rare that IM format files will be changed enough such that the pointers are totally off), but eventually, it is necessary to update the IMNAME database, using the following function:

```
(IMNAME.UPDATE.HASHFILE oldHashFileName addFileList deleteFileList flushDisappearedFlg )
```

This function updates an IMNAME database hashfile. First, it looks at the list of files referenced in the hashfile, and determines which of these files have been updated, by comparing version numbers. Next, every updated file is reanalyzed with IMTRAN, and updated index information is stored into an in-core hasharray. Finally, the entries in the old hashfile are read in, merged with the new info, and written out to a new hashfile.

oldHashFileName is the name of the hashfile to be updated (Note that this file must be named explicitly --- no file searches are done so that the user will not inadvertently start updating the main manual database). The new hashfile will be created as the new version of the same file name. addFileList is a list of files that will be analyzed, and added to the database. deleteFileList is a list of files that will be deleted from the database. addFileList and deleteFileList can be used to "manage" a database, as new files are added to a document, and old ones are removed, split up, or renamed. flushDisappearedFlg determines what IMNAME.UPDATE.HASHFILE will do if it finds that some of the files in the database have disappeared (and they are not named on deleteFileList). If flushDisappearedFlg = T, the info for those files will simply be deleted. If flushDisappearedFlg = ERROR, IMNAME.UPDATE.HASHFILE will return without doing anything if files have disappeared. If flushDisappearedFlg = <anything else>, the info on the disappeared files will simply be retained.

To create a new IMNAME hashfile, pass a non-existent file name as oldHashFileName, and give a list of files as addFileList. In this case, a new hashfile will be created just from the internal hasharray info.

***** The IMTEDIT IM-to-TEDIT translation program. *****

author: Michael Sannella
file: IMTEDIT.DCOM
loads file: IMTRAN.DCOM
related files: IMTOOLS.DCOM

IM format is the text formatting language that the Interlisp Reference Manual is represented in. It is somewhat like TEX source code, in that there are keywords, and brackets are used to delimit text. However, IM format was specifically designed for representing the Interlisp Manual, so the "text objects" used are semantically meaningful objects within the manual, such as "function definition", "lisp code", "subsection". IM format is described in detail below.

IM format files are easy to edit using Tedit, but they don't look very pretty. To produce the manual, use the function IM.TEDIT, which translates IM format files to formatted Tedit text streams. These text streams can be proofread and edited by the user, or automatically printed.

A useful feature of IM.TEDIT is that is very forgiving about errors in IM format, even misplaced bracket errors! This is not to say that the output will be pretty, but at least the translation program will not bomb out on you.

***** Formatting a File with IM.TEDIT *****

To translate an IM format file into a formatted Tedit text stream, use the following function:

(IM.TEDIT INFILE.NAME OUTFILE.FLG) [Function]

This function takes an IM format file, and produces a formatted Tedit text stream. *INFILE.NAME* is the name of an IM format file. *OUTFILE.FLG* determines what happens to the translated textstream. If *OUTFILE.FLG* = T, the Tedit textstream is returned by IM.TEDIT. A Tedit window showing the translated document can be created by typing **(TEDIT (IM.TEDIT xxx T))**. If *OUTFILE.FLG* = NIL, the document is immediately sent to the printer. If *OUTFILE.FLG* = anything else, it is taken as a file name for the Interpress file which is created <but not printed>.

As IM.TEDIT runs, it prints out warning messages. These messages are also saved in the file <infile>.IMERR.

Important note: It is necessary to understand that IM.TEDIT produces a totally separate document from the IM format original. Any edits to this document will NOT be reflected in the original. In general, all of the editing should be done to the IM format files, to insure that there are no inconsistencies.

Note: If IM.TEDIT is called with *OUTFILE.FLG* = T to produce a textstream, and **IM.INDEX.FILE.FLG** (below) is set to T to add index information to the textstream, the textstream cannot be stored or printed. **IM.INDEX.FILE.FLG** should only be set to T if IM.TEDIT is called with *OUTFILE.FLG* not T, so it automatically prints the document to a printer or interpress file.

***** Variables Affecting IM.TEDIT *****

The operation of IM.TEDIT affected by a number of variables:

IM.NOTE.FLG [Variable]

If T, notes will be printed out, otherwise they will be suppressed. Initially NIL. (Note: If this is T, the translation programs will print out a message to remind you that notes will be printed.)

IM.DRAFT.FLG [Variable]

If T, the output will have "--DRAFT--" and the date printed on the top and bottom of every page. Initially NIL.

IM.CHECK.DEFS [Variable]

If T, checks whether variables and functions are bound/defined in the current Interlisp environment, and prints a warning if not. For functions, will also check arg list consistency. Initially NIL.

IM.EVEN.FLG [Variable]

If T, IM.TEDIT will add an extra page at the end of the file saying "[This page intentionally left blank]". This can be used if you need a document with an even number of pages (for double-sided copying). Initially NIL.

The following FLGs are only of interest when generating an index:

IM.INDEX.FILE.FLG [Variable]

If T, index information will be added to the formatted Tedit text stream, and the file <infile>.IMPTR will be generated containing index information when the formatted Tedit textstream is printed. Initially NIL.

IM.REF.FLG [Variable]

If T, the translation program will try to resolve cross-references by looking at various hash tables. Initially NIL.

IM.SEND.IMPLICIT [Variable]

If T, send "implicit references" for functions and variables (if not in index hash array). Initially NIL. {fn...} or {var...} objects generate "implicit references" if they are not contained in the index hash tables. This can be used to find variables and functions that are not formally defined, but only mentioned.

***** Producing an Index and Table of Contents *****

The file IMTOOLS.DCOM contains functions for gathering index information, generating an index and a table of contents, and using index information to resolve cross-references.

Currently, these tools are rather primitive. Eventually, it is hoped that they will be improved to make this process easier.

To produce an index and TOC:

(1) Evaluate (SETQ IM.INDEX.FILE.FLG T), which tells IM.TEDIT to create index pointer files <XX>.IMPTR.

- (2) Run (IM.TEDIT <file> <ipfile>) on all files in the document
- (3) Evaluate (INIT.INDEX.VARS) to clear the index.
- (4) For each of the files in the document, load the index information by evaluating (GRAB.IMPTR xxx.IMPTR).
- (5) Generate an index by evaluating (MAKE.IM.INDEX OUTFILE.FLG), where the argument OUTFILE.FLG is interpreted the same as in IM.TEDIT.
- (6) Generate a table of contents by evaluating (MAKE.IM.TOC OUTFILE.FLG), where the argument OUTFILE.FLG is interpreted the same as in IM.TEDIT.

To generate formatted files with cross-references resolved, do the following:

- (1) Evaluate (SETQ IM.INDEX.FILE.FLG T), which tells IM.TEDIT to create index pointer files <XX>.IMPTR.
- (2) Run (IM.TEDIT <file> '{NULL}FOO.IP) on all files in the document
- (3) Evaluate (INIT.INDEX.VARS) to clear the index.
- (4) For each of the files in the document, load the index information by evaluating (GRAB.IMPTR xxx.IMPTR).
- (5) Evaluate (SETQ IM.REF.FLG T), which tells IM.TEDIT to resolve cross references using the loaded index information.
- (6) Format all of the files using (IM.TEDIT <file> <ipfile>).

Note that creating a formatted file with cross-references requires formatting the file twice.

The process of formatting a large set of documents such as the IRM can be automated using the following function:

(DO.MANUAL CHAPNAMES MAKE.INDEX.FLG GET.REFS NO.IP.FLG) [Function]
 Formats the IRM manual chapters specified by CHAPNAMES, producing Interpress files, "imptr" files (explained below), and error files. Uses the global variable **IM.MANUAL.DIRECTORY** (initially {erinyes}<lispmanual>) to indicate where the IRM files are taken from, and where the processed files should go.

Note: **DO.MANUAL** initially puts all files on {DSK}, and then copies them to the value of **IM.MANUAL.DIRECTORY**. Therefore, you should have at least 3000-4000 free pages on DSK.

"IMPTR" files are files with the extension "**IMPTR**" (such as ChapLitatoms.IMPTR), which contain index info, including the page number where each index appears. These are generated whenever a chapter is formatted. These must be read in to generate an index, or format a chapter resolving cross-references.

CHAPNAMES indicates which chapters should be processed. If *CHAPNAMES* = a list of chapter file names such as (ChapLitatoms ChapStack), only these chapters are formatted. If *CHAPNAMES*=**T**, all chapters in the IRM are formatted. If *CHAPNAMES*=**NIL**, all chapters that have been modified since the corresponding Interpress files were made are formatted. The global variable **IM.MANUAL.CHAPTERS** specifies all of the chapters, and all of the sub-files in each chapter, and the chapter numbers.

If *MAKE.INDEX.FLG* is non-**NIL**, after processing the chapters, the index, title pages, and many tables of contents are generated. Note that if this is done, all of the IMPTR files for all of the chapters are loaded again.

If *GET.REFS* is non-**NIL**, all of the IMPTR files are loaded before any of the chapters are processed, and all cross-references in the chapters are resolved.

If *NO.IP.FLG* is non-**NIL**, the chapters are formatted to the interpress file **{NULL}FOO.IP**, and thus not kept. This can be used when you simply want to generate all of the IMPTR files, but do not want the interpress files.

Ideally, all you should need to do to re-format the IRM is:

(DO.MANUAL T NIL NIL T) --- to generate the IMPTR files

(DO.MANUAL T T T) -- to generate the Interpress files, and the index.

If **DO.MANUAL** doesn't do exactly what you want, the code is fairly self-explanatory.

***** Modifying the dimensions of the formatted pages *****

Note on modifying the formatting tools for different paper sizes: All of the lengths that IMTEDIT uses (left margin size, page height, etc.) are stored in global variables, set in the filecoms of IMTEDIT. IMTEDITCOMS also includes comments documenting the meaning of each of these global variables. Modify these variables until you get what you want.

***** Known problems with IMTEDIT *****

Currently, IM.TEDIT produces a good-looking document. However, there are some features that I was not able to provide, because Tedit did not provide the formatting capability. These are as follows:

(1) Footnotes. Tedit does not supply footnotes. Currently, I "fake" footnotes by positioning them in-line after the paragraph wherein they were created. They also will not appear within definitions, tables, or lisp code.

(2) Tables. Tedit doesn't do table formatting. Currently, IM.TEDIT simply prints out the items in the table without formatting.

***** IM Format Description *****

This is a complete description of the syntax and vocabulary of "IM format". The general syntax is not likely to change, but the vocabulary will probably be extended as the Interlisp Manual is edited, and we discover new text objects that we need.

IM Format Syntax

An IM-format file consists of a linear string of visible, editable characters (and Tedit image objects, which are treated like characters). No funny control characters are allowed. "Text" is defined to be a linear string of characters, organized into paragraphs (delimited by blank lines), interspersed with any number of "Text Objects". Text Objects are used to specify the meaning of various pieces of text, which may be processed and formatted in different ways.

Text Objects can be divided into two types: those that take a single unnamed argument, and those that take a number of labeled arguments. All of the 'arguments' to Text Objects can be arbitrary text, organized in paragraphs, and including sub-text-objects nested to any level.

Text Objects within a file and arguments within a text object are specified using the characters "{" and "}". These characters are ALWAYS interpreted as Text Object delimiters or Text Object argument delimiters---there are special text objects for indicating that you really want a left or right bracket character as part of your text.

The format of Text Objects is:

```
{<TOname> <TOarg>}          -      single argument TO
{<TOname> {<TOargname1> <TOarg1>} {<TOargname2> <TOarg2>} .... }  -      multi-
argument TO
```

Between a TOname or TOargname and its TOarg, and between named TOargs, there can be any combination of spaces, tabs, and CRs. These can be used to make your file look better.

In order to help with the problem of matching brackets in large TOs (such as SubSecs, which can extend over many pages), I have introduced a new piece of syntax: Begin and End:

```
"{Begin <TOname> <tag>}"      is treated exactly like "{<TOname> "
"{End <TOname> <tag>}"        is treated exactly like "}"
except that additional checks are made when the file is processed that the "Begin"s and "End"s
match up. The (optional) "<tag>"s can be used as an additional check, to distinguish between
different TOs of the same type. If you use a Begin TO, you should use a matching End TO.
```

Note that Begin and End TOs can be used with TOs that have labeled args, for example:

```
{Begin SubSec <tag>}
{Title ----}
{Text
.
.
}
{End SubSec <tag>}
```

In order to allow the IM format translation program to recover from errors (like missing brackets), information has been included in the program about what TOs "should" appear in other TOs. In general, "complex" TOs such as LabeledLists can only appear in other complex TOs. "Simple" TOs such as Lisp can appear within anything. These rules are defined on a per-argument basis for TOs with multiple labeled arguments --- for example, a LabeledList can appear within the "Text" argument of a FnDef, but not within the "Name" argument. This feature should not cause any problems, as long as TOs are used "reasonably."

Other rules followed by the translation program: FnDef's, VarDef's, Def's, etc can only appear at the "top-level", or inside a SubSec or Chapter. (this rule is very useful, because it helps trap many bracket errors before they propagate too far) Footnotes may not be nested.

New feature <which may get changed>: If a TO name is unrecognized, it will be printed out surrounded by brackets. For example, {FOO} will actually print as "{FOO}". This allows simple expressions to be bracketed without actually using the "{bracket ...}" TO.

Text Objects currently defined:

(note: the order of arguments in multi-argument TOs IS significant.)

(note: No distinction is made between upper and lower case in the TO names and the argument names, or in Begin/End tags)

(note: Many TO names and argument names have synonyms. These are indicated below.)

***** Plain Text Text objects *****

<paragraph>

All plain text is organized into paragraphs, delimited by blank lines.

{Chapter {number <number>} {title <title>} {text <text>} }

Specifies the number, title, and text of a chapter. If the number is not specified, the IM format translator will ask you to supply a number.

{subsec {title <title>} {text <text>} }

This can be used to generate sections, subsections, etc. to any depth. Heirarchical numbering is done automatically.

{Comment <text>}

Used to insert comments (which won't appear in the final formatted output).

{Note <text>}

Inserts comments that may be printed in the final formatted output, depending on the value of the variable IM.NOTE.FLG. Should be used for comments such as {Note I should write something about X here}

{foot <text>}

Generates a footnote. Footnotes may not occur within other footnotes. Currently, Tedit does not support footnotes, so these are just printed after the paragraph in which they appear.

Synonyms: footnote -> foot

{sub <text>}

Subscripts <text>.

{super <text>}

Superscripts <text>.

{it <text>}

Used to italicize pieces of text.

Synonyms: italics, emphasize -> it

{rm <text>}

Used to print text in the default, "roman" font.

{lisp <text>}

The text object for normal single-line references to lisp code. This is used for writing things like: "Obviously, {lisp (CONS 'A 'B)} evaluates to {lisp (A . B)}."

{lispcode <text>}

The text object for multiline lisp code, which do not appear in the middle of text, and have to be formatted differently. Spaces, tabs, and carriage returns are significant within <text>.

***** TOs for Interlisp manual objects *****

{FnDef {Name <name>} {Args <args>} {Type <keywords>} {Text <text>} }

This is used to define all lisp system functions. It needs to know the name of the function, and the args, and the text of the function description. (If the function has 0 args, the {Args --} argument may be omitted.) {Type ...} is an optional argument used to specify the argument type of the function. If the keywords NLambda or NoSpread (case doesn't matter) are included in <keywords>, the function is specified to have the corresponding argument type.

Synonyms: FnName -> Name

 FnArgs -> Args

 FnType -> Type

{vardef {name <name>} {text <text>} }

Used to define system variables.

{propdef {name <name>} {text <text>} }

Used to define property names.

```
{MacDef {Name <name>} {Args <args>} {Type <keywords>} {Text <text>}}
```

Like FnDef, but for macros.

```
{arg <name>}
```

Used to talk about an abstract argument to a function, such as "x" or "y" or "number". It is used primarily within function definitions.

```
{fn <name>}
```

Used to talk about the name of a function. i.e.: "...it calls {fn CONS} to do something."

```
{var <name>}
```

Used to talk about a system variable.

```
{prop <name>}
```

Used to talk about a property name.

```
{Mac <name>}
```

Like Fn, but for macros.

```
{EditCom <name>}
```

Used to talk about an edit command.

```
{BreakCom <name>}
```

Used to talk about a break command.

```
{PACom <name>}
```

Used to talk about a programmer's assistant command.

```
{FileCom <name>}
```

Used to talk about a file package command.

***** Indexing Text objects *****

The following TOs (for indexing, defining, and referencing) all deal with objects with specific "object-types." The Interlisp Manual contains a very large number of names (CONS, NIL, FOO, etc). It is not enough just to list the name in the index --- it is also important to indicate WHAT the name is (a function, a variable, an error message, etc.) An "object-type" is essentially the description that would be printed in the index to describe a particular name. In IM format, such a description is given by a list of words, within parenthesis. [note upper/lower case are NOT distinguished in "object-types"] For example:

(Function)
 (Error Message)
 (Transor Command)
 (Compiler Question)

Some commonly-used object-types may be abbreviated with single words:

FN	->	(Function)
Var	->	(Variable)
Prop	->	(Property Name)
BreakCom	->	(Break Command)
EditCom	->	(Editor Command)
PACom	->	(Prog. Asst. Command)
FileCom	->	(File Package Command)
Error	->	(Error Message)
Litatom	--,	
Atom	--->	(Litatom)

[note: In {PageRef ...} and {SectionRef ...}, the word TAG can be used to refer to tags, as specified below. The word FIGURE is a synonym for TAG; this can be used to refer to a figure tag. The word TERM can be used in {index ...} to index an English term.]

{index <text>}

Creates an index reference. Some of the text objects (such as function definitions) will automatically create an index reference, but it is useful to be able to create one explicitly. This should have the format:

{index <keywords> <object> <object type>}

<keywords> (optional) can be any combination of the words

BEGIN

END

PRIMARY

<object> can be any number of words.

<object type> should be an object-type as specified above.

If this is omitted (<text> does not end with ") and

the last word in <text> is not one of the special object-type words), then this is the index of a term.

This can also be specified by using the word TERM.

Examples: {index *PRIMARY* BLOBBY (Transor Command)}
 {index SELF-DESTRUCT SEQUENCE INITIATED Error}
 {index *BEGIN* *PRIMARY* file names}

{indexX {name <name>} {type <type>} {info <info words>} {text <text>}}

{subname <name>} {subtype <type>} {subtext <text>}

{subsubname <name>} {subsubtype <type>} {subsubtext <text>}}

Used for creating special index references whose printname is different from the "index name", or who have sub-index entries, or should not have page numbers in the index. <name> is the index name, used for referencing the object, and alphabetizing the index entry. <type> is the object type. <info words> (optional) can contain one or more of the keywords *BEGIN*, *END*, *PRIMARY*. <text> is the text printed in the index for this index entry.

Example: {indexX {name +} {type (Infix Operator)} {text {lisp {arg X}+{arg Y}}}} could be used to index "+" as an infix operator so that it would appear in the index alphabetized near other "+"s, but printing as "A+B".

The arguments {subname <name>} {subtype <type>} {subtext <text>} {subsubname <name>} {subsubtype <type>} {subsubtext <text>} are all optional. These are used to specify 1st and 2nd level subentries in the index. The subentry can have their own type and text definition, although these are mostly terms.

If <info terms> includes *NOPAGE*, this indicates that the index entry should not have a page number associated with it. This can be used with subentries to create "See also..." notes. Within a list of subentries, the *NOPAGE* entries will always be listed last.

Example: The following set of indexx commands:

```
{indexX {name FOO} {type (Big Command)} {text {lisp /FOO/}}}  
{indexX {name FOO} {type (Big Command)} {subname ZZZ}}  
{indexX {name FOO} {type (Big Command)} {subname BAZ}}  
{indexX {index *NOPAGE*} {name FOO} {type (Big Command)} {subname See also BAR}}  
{indexX {name FOO} {type (Big Command)} {subname BAZ} {subsubname QWERTY}  
{subsubtype VAR}}}
```

Would produce the index entries:

```
/FOO/ (Big Command) x.xx  
  BAZ x.xx  
    QWERTY (Variable) x.xx  
  ZZZ x.xx  
  See also BAR
```

```
{Def {type <type>} {name <name>} {printname <pname>} {args <args>} {parens} {noparens}  
{text <text>} }
```

May be used to specify the definition of anything. <type> should be an object-type, as specified above. <name> should be the name of the object, ideally a single word. If {printname <pname>} (optional) is given, it will be used for printing the object in the top line of the definition and in the index. If {printname <pname>} is not given, the printed name is specified by {name <name>}, {args <args>}, {parens}, and {noparens}. <args> should be the "arguments" of this object. [{args <args>} is optional.] Normally, {Def will put parenthesis around the object if and only if {Args <args>} is given. {parens} and {noparens} (if given) can be used to change this default behavior. Examples:

```
{Def {Type (Blobby Command)} {Name DOBLOB} {Args A B}  
  {Text ....}}  
{Def {Type (CLISP Character)} {Name +} {PrintName {lisp {arg X}+{arg Y}}}  
  {Text ....}}}
```

```
{Tag <tag>}
```

This may be used to associate <tag>, a single word (upper/lower case doesn't matter), with a particular place in the text. This can be referenced by {SectionRef and {PageRef as described below.

```
{SectionRef <object-type> <object>}  
{PageRef <object-type> <object>}
```

These TOs are used to provide a cross-reference facility. {SectionRef will print "section " and the section that the "main" occurrence of the object with the given type occurs. <"main"

shall remain undefined for now> {PageRef prints "page " and the appropriate page number. If <object-type> is "Tag", these TOs can refer to tags generated with {Tag <tag>}. Examples:
 {SectionRef Fn CONS} could print "section 3.1.1"
 {PageRef (File Package Type) Expressions} could print "page 14.34"
 {PageRef Tag CompilingCLISP} could print "page 20.42"

Note: {PageRef...} and {SectionRef...} can only be used to reference 1st level index references. They cannot be used to reference subentries generated with {indexx...}

{Term <text>}

Prints <text> exactly as given, and also puts it into the index. Equivalent to "<text>{index <text> Term}".

{Figure {tag <tag>} {text <text>} {caption <text>} }

Prints a simple "figure", with figure text and caption as specified by the "text" and "caption" arguments. "{tag <tag>}" is an optional argument which, if specified, generates a tag at the beginning of the figure. This tag can be used to refer to the page or section that this figure appears on (using {PageRef Figure <tag>} or {SectionRef Figure <tag>}), or to refer to the figure number (using {FigureRef <tag>}).

{FigureRef <tag>}

Prints "figure" and the figure number of the figure with the specified tag.

***** Complex Text objects *****

{numberedlist {item <text>} {item <text>} {item <text>} ...}

Used for making numbered lists of items.

Synonyms: Text -> Item

{unnumberedlist {item <text>} {item <text>} {item <text>} ...}

Like {numberedlist ...}, except that it uses bullets to mark each item in the list.

Synonyms: UnlabeledList -> Unnumberedlist

Text -> Item

{labeledlist {name <text>} {item <text>} {name <text>} {item <text>} ...}

Used for making a table associating a set of labels with descriptions of their meanings.

The argument {LName <text>} can be used to add a label left-justified on the page.

Either an LName or a Name, or both, can appear as labels for an item. If an LName is supposed to be on the same line as a Name, it should appear first: {Labeledlist {LName xx} {Name yy} {item zz} ...}

Synonyms: Label -> Name

Text -> Item

{Table {Column} ... {Column} {First <text>} {Next <text>} {Next <text>} ... {First <text>} ... }

Used for formatting multi-column tables. The number of {Column}'s before the first {First or {Next indicates how many columns the table should have. If no {Column}'s are given,

the default is three columns. There are other formatting arguments, but they will probably change. <<<Note: This is not currently supported in Tedit. Currently, this TO only prints out the values of each {First} or {Next} argument, without formatting. Do not use tables>>>

***** Other Text objects *****

{Include <filename>}

Used to include the text of one file within another. Files may be nested arbitrarily deep.

{Lbracket}

{Rbracket}

{bracket <text>}

These are used to insert the curly-bracket symbol into the text. {Lbracket} and {Rbracket} insert left and right brackets, and {bracket <text>} puts brackets around the given piece of text.

The following TOs are used to specify certain non-typeable characters.

{CRsymbol} or {cr} - carriage return symbol

(currently a superscripted 'CR')

{pi}	-	Greek letter pi
{plusminus}	-	Plus or Minus ("+" + "-")
{GE}	-	greater than or equal (">" + "=")
{LE}	-	less than or equal ("<" + "=")
{NE}	-	not equal ("=" + " ")
{endash}	-	short dash
{emdash}	-	long dash
{ellipsis}	-	ellipsis (...)
{bullet}	-	bullet
{anonarg}	-	long dash (should be used in the argument list of a function definition to specify the "unspecified arguments" specified in the current manual with a dash)

FORMATTING AN INDEX

Creating a properly formatted index takes a certain amount of work (about 2 hours).

- Type in your Executive (TEDIT (MAKE.IM.INDEX T NIL '(filenames) NIL))
- Save the resulting file in {ERIS}<Doc>LoopsBeta>Ref>RefIndex-Raw.tedit.
- Now start dithering. The task is to change all the separators in the file. For example, the index program returns pages in the form 1.2; 10.5,38; 18.3-4. The Index format we use is in the form 1-2; 10-5; 10-38; 18-3. Unfortunately, you can't make all the necessary changes in a global substitute, since many of the separators are also in the text and the comma requires that you repeat the chapter number. Here goes:
 - Fix the commas. Do a Find on a comma (.). Everywhere a comma occurs in a page number, change it to a semicolon (;) and repeat the chapter number and a dot before the page number. For example, 10.5,38 becomes 10-5; 10-38.
 - Fix the dashes. Do a Find on a dash (-). Everywhere a dash occurs in a page number, delete it and the following page number.
 - Fix the period. Except for the form #., you can use a global substitute from a period to a dash (. to -). This takes about 20-30 minutes, as there are about 700 substitutions.

I really recommend saving the file at this point.

- Hardcopy the index. Make whatever page breaks and other changes you feel are necessary. Make a final hardcopy and save the file.

ARCLEANUP Package --- Michael Sannella
(and augmented by Susana Wessling, 26-mar-87)

The file {eris}<lispcore>internal>library>ARCLEANUP.LCOM contains a few functions used to update the AR database and to print summaries.

```
(AR.CLEANUP UPDATE.FLG INDEX.LOCAL.DIR SUMMARY.FLG SUMMARY.LOCAL.DIR ]
```

This is the main function, which should be run every few days, preferably just as you go out the door (so your machine can crunch on it overnight). If UPDATE.FLG is non-NIL, all of the ARs that have been touched since the last update are scanned, and the AR database is updated. If SUMMARY.FLG is non-NIL, a set of summaries is generated on {eris}<lispars>summaries> and press-fied.

INDEX.LOCAL.DIR and SUMMARY.LOCAL.DIR are used if you want the AR index and/or the summary reports to be cached on a local disk. This speeds up the process considerably, along with reducing ethernet load. If non-NIL, each of these should be a host/directory pair, which will be PACKed on the front of a filename to generate the caching filename. These are not just flags, with caching defaulting to {DSK}, so that I can use multiple partitions for caching. The issue is space: Sometimes the local disk does not have enough room for two copies of the AR index, or for both the txt and press version of the grang summary.

Example:

```
AR.CLEANUP (T NIL T NIL)
-- does cleanup with no caching

AR.CLEANUP (T {DSK} T {DSK2})
--- caches index on {DSK}, and the summaries on {DSK2}

AR.CLEANUP (T {DSK})
--- just does index update, caching on {DSK}.
```

Another useful function:

```
AR.CLEANUP.REDO.SUMMARIES: just generates summaries, does not do a new cleanup.
```

The AREDIT Interlisp bug database system

author: Michael Sannella

files: {eris}<lispcore>library>AREDIT.DCOM

doc: {eris}<lispcore>library>AREDIT.TEDIT

uses: All Tedit files

The file AREDIT.DCOM contains a number of tools useful for examining, editing, and submitting ARs ("Action Requests") related to the Interlisp-D system. These tools are loosely based on the "Adobe" tools in the Tajo environment. The Interlisp-D support group uses this system to keep track of the state of outstanding bug reports. There are currently over 2000 ARs in the database.

These tools can be used from any machine running Interlisp-D which can establish a leaf connection to the Phylex: file server, where the database files are currently stored, and the ERIS file server.

After loading AREDIT.DCOM, the user can create two types of windows: AR edit forms and AR Query forms.

The AR Edit Form

An AR edit form is used to examine, edit, and submit ARs. To create an AR Edit Form, evaluate (AR.FORM). Interlisp will prompt you to specify a region for the form window -- the best size to give it is one about half the width of the screen and at least half the height of the screen. The form window which will appear contains three subwindows: (1) On the top is the message subwindow, where prompts and status messages are printed; (2) in the middle is the command subwindow, a menu of commands for editing / submitting ARs; (3) on the bottom is the form subwindow, where the information in an AR is displayed.

The command subwindow contains the following commands:

New -- Buttoning this word clears the fields of the AR in the form subwindow. Some fields (**Source**, **Submitter**, **Status**) are initialized to appropriate values for a new AR.

Get -- Buttoning this retrieves the AR whose number follows "**Number:**" in the command subwindow.

Put -- Buttoning this will either store an edited AR, or submit a new AR. Which one (submit new or store old) depends on whether the last operation was "**New**" or "**Get**". If the current AR displayed was retrieved with "**Get**", then "**Put**" will store it as the old AR. If this AR was built up from scratch after buttoning "**New**", then "**Get**" will submit it as a new AR. The title of the form subwindow gives an indication of what state the form is in: if it says "New Bug Report", then "**Put**" will submit it. If it says "Editing AR xxx", then "**Put**" will store it. [There are plans to improve this interface]

Number: -- This is a text field just like text fields in the form window (see below) used to specify the number used by "**Get**". Buttoning the word "**Number:**" will pending-delete-select the value of the field, so you can delete it and insert a new number. If the character carriage-return is typed, then a "**Get**" is automatically done on the value of this field. This is faster than typing a number, and buttoning "**Get**".

The form subwindow contains a large number of fields. The meaning of these fields is described in XXX. The value of these fields can be edited as follows:

"Enumerated fields" can only contain certain values. These are indicated in the form subwindow by field names followed by curly-braces "{}". To change the value of one of these fields, button the field name; a menu of permissible values will appear; select a value; it will be inserted between the braces.

[note: Some of the enumerated field values are dependent on other fields. For example, the values of "Subsystem:" depend on the value of "System:" -- if the "System:" value is changed, the "Subsystem:" value is automatically set to NIL. The fields with this relationship are System:/Subsystem: and Machine:/Disk:.]

"Text fields" can contain arbitrary text. These fields do not have braces after the field name. The text can be edited using normal Tedit editing. Buttoning the field name will pending-delete-select the entire field value, which allows the whole field to be easily deleted.

[note: Currently, stored ARs only contain straight text. Any tedit formatting information put into an AR will be lost when the AR is stored. Image objects (like bitmaps) are also not stored.]

[note: A few of the text fields, like "Number:", are read only --- they cannot be edited by the user.]

[note: in older versions of AREDIT, some text fields (such as "Attn:") could only contain a certain number of characters. The user could type as many characters as he wanted, but an error would occur when the "Put" command was executed. This has now been changed --- any text field can contain an arbitrary number of characters.]

The AR Query Form

An AR Query Form is used to search the AR database for all ARs with particular characteristics. One can search for all ARs with a given name in the "**Attn:**" field, all ARs which have **Status:** = Open, etc. These ARs can be sorted, and a summary of the selected ARs can be printed into a file.

To create an AR query form, evaluate (AR.QFORM.CREATE). Interlisp will prompt for a region (the default size is ok), and create a window with three subwindows: (1) on top, a message subwindow, for printing prompts and messages; (2) in the middle, a browser subwindow, used for displaying the ARs selected by a query; (3) on the bottom, the AR query command subwindow, containing a number of commands and fields.

The Ar Query command subwindow contains the following fields/ commands:

Query List: -- This field is used to specify which ARs the "**Query**" command will search for. This field should be filled with an AR query spec, which has one of the following forms:

(<field> HAS <val>) searches for all ARs whose text field <field> contains <val>. <string> may either be an Interlisp string or an atom. The search is case-independent: foo matches Foo matches FOO.

(<field> IS <val>) searches for all ARs whose enumerated field <field> has the value <val>.

(AND <spec1> <spec2> ... <specN>) returns all ARs satisfying ALL of the given specs.

(OR <spec1> <spec2> ... <specN>) returns all ARs satisfying ANY of the given specs.

[note: an implicit (AND) is wrapped around the value of the "Query List:" field, so just giving a number of specs will AND them together.]

Not every AR field can be searched for in the same way: some can only be searched with HAS, some can only be searched with IS, and some (like the Description: field) cannot be searched at all. To find out the possible query specs, button the words "**Query List:**" --- this will put up a menu of all of the permitted searching options. Some of these menu items have submenus. When one of the options is selected, it is added at the end of the value of this field.

Examples:

Query List: (Subject: HAS foo)

Searches for all ARs whose subject contains the string "foo".

Query List: (Status: IS Open) (Attn: HAS sannella)

Searches for all open ARs which have "sannella" in the Attn: field.

Query List: (OR (Status: IS Declined) (Status: IS Superceded))

Searches for all ARs with Status: either Declined or Superceded.

Sort List: -- This field determines how the Query-ed ARs will be sorted. Currently, ARs can only be sorted by the values of enumerated fields. Buttoning the words "**Sort List:**" will put up a menu of the permitted field names -- selecting one will add it to the value of this field.

Example:

Sort List: Status: Priority:

This will sort first by the Status: field, and then by the Priority: field.

[note: After sorting by all given fields, if two ARs are the same, they are sorted by AR number. Therefore, if this field is left blank, the queried ARs will be in numerical order]

Query -- Buttoning this command will initiate the query specified by the "**Query List:**" field, and sort it according to the value of the "**Sort List:**" field. While the query is in progress, the AR query command subwindow is greyed-out. When the query is completed, the numbers, subjects, etc of the ARs which have been found are displayed in the AR query browser subwindow. This window can be scrolled both vertically and horizontally.

Print File: -- This field can be filled in with a file name, which is used to specify the file that the **Print** command should store a report. If left blank, a window will pop up on the screen, and the information will be displayed there.

Print -- This prints a detailed summary of all of the ARs from the last **Query** into the file given in the **Print File:** field.

To generate and print a summary of a selected group of ARs, fill in the **Query List:** and **Sort List:** fields, select **Query** and wait for the query to complete, fill in the **Print File:** field, and select **Print**. The summary is rather wide -- it may be a good idea to use the LANDPRESS package to print it out sideways on a printer.

The AR query browser window:

This window shows a short summary (one line each) of the ARs that have been queried. Left-buttoning one of the AR lines will call AR.SHOW on that AR, to display it. Middle-buttoning an AR line will "**Get**" that AR into a specified AR edit form window.

Background menu commands:

When AREDIT is loaded, the item "AREdit" is added to the background menu, with a number of subitems. These are interpreted as follows:

AREdit -- Creates a new AR edit form, initially cleared.

New AR Form -- Same as AREDIT

Load AR Form -- prompts the user for a number, and creates a new AR edit form, with the specified AR number loaded initially.

AR.SHOW -- prompts the user for a number, and calls AR.SHOW, an old version of AREDIT which quickly displays the contents of a given AR. It prompts for a window region the first time it is used -- thereafter it uses the same window.

AR Query Form -- Creates a new AR query form.

Auxiliary AR edit form commands.

Pressing the left mouse button in the title bar of the AR Edit form command subwindow will bring up a menu of less-used commands:

Clear -- Clears ALL the fields of the current AR. Similar to **New**, except that none of the fields like **Source**:, etc., are filled in. This is useful when you are submitting an AR for someone else.

New

Get

Put -- the same as the **Commands** in the edit command subwindow.

Put&Get -- prompts the user for a number, **Puts** the current AR, and **Gets** the given numbered AR. Useful when scanning through a number of ARs.

GetFromFile -- Prompts the user for a file name, and loads the information from that file into the AR edit form subwindow. If this file is not in the right format, an error will be generated.

PutToFile -- Prompts the user for a file name, and stores the information from the AR into that file.

Locally caching the AR index.

All AR query operations use the information in the "AR Index" file. This file, which is updated every few days, is stored as {eris}<lispars>AR.INDEX. To speed up Query operations, this file can be copied to a local file server, or the local hard disk. Warning: this file is currently ~700 IFS pages long, and it will undoubtedly get larger. Also, it is the responsibility of the user to make sure that they update their local version of AR.INDEX when the master copy is updated.

To use a local version of AR.INDEX, give the file name as an argument to AR.QFORM.CREATE:

(AR.QFORM.CREATE '{DSK}AR.INDEX).

Global Variables that control AREDIT

The following are global variables that can be set to alter the operation of AREDIT. These are the only global variables that it is safe to change.

AR.ENTRY.LIST.WINDOW.FIELDS -- Controls which fields are displayed in the AR query browser window, along with the widths of the fields.

AR.ENTRY.LIST.PRINT.FIELDS -- Controls the fields displayed by the **Print** command of the AR query form.

AR.ENTRY.LIST.PRINT.MULTILINE.FLAG -- if non-NIL, the **Print** command of the AR query form will print all of the characters in each field, using multiple lines for those field values bigger than the field width allowed. If NIL, each AR will use only one line, truncating any field values that are too big.

DATEPATCH

By: Bill van Melle
(vanMelle.pa@Xerox.com)

DATEPATCH fixes some bugs and extends the functionality of the date functions DATE, GDATE and IDATE.

Date Parsing

The date parser (IDATE) now handles all dates legal in RFC822 syntax (except the silly single-digit military time zones). In addition, it handles months spelled out, months abbreviated with a period, and ignores initial strings of the form "{letter}*", assuming these to be specifying a day, as in "Monday, May 1, 1989". In addition to the official time zone specifications, it also recognizes any in the list TIME.ZONES, whose format has changed slightly:

TIME.ZONES [Variable]

An association list whose elements are of the form (*offset regzone dstzone*), where *offset* is the number of hours west of GMT (note that this, unfortunately, is opposite in sign to the RFC822 standard, but is strictly an internal matter), *regzone* is a string specifying the time zone normally, and *dstzone* is a string specifying the zone when daylight savings time is in effect. If *dstzone* is omitted, then there is no representation for that zone in daylight savings time, and DATE is forced to use absolute syntax (e.g., +0400).

The initial value of TIME.ZONES is

```
( ( 8 "PST" "PDT" )
  ( 7 "MST" "MDT" )
  ( 6 "CST" "CDT" )
  ( 5 "EST" "EDT" )
  ( 0 "GMT" "BST" )
  ( 0 "UT" )
  (-1 "MET" "MET DST" )
  (-2 "EET" "EET DST" ) )
```

IDATE also accepts an optional argument DEFAULTTIME, which is interpreted as a number of seconds past midnight. If the date string does not contain a time, DEFAULTTIME is used; if DEFAULTTIME is NIL, IDATE returns NIL in this case (as it always has).

Date Output

The date printers (DATE and GDATE) now produce appropriate time zones outside of the U.S. Given a choice of time zones, they take the first entry found in TIME.ZONES. In addition, they support a few more DATEFORMAT options:

MONTH.LONG [DateFormat Option]

Provides for full names of months rather than the first three characters. For instance, (DATE (DATEFORMAT MONTH.LONG SPACES NO.TIME)) might produce "20 February 87".

MONTH.LEADING

[DateFormat Option]

Causes the month to be produced as a word before the day and the day to be followed by a comma. For instance, (DATE (DATEFORMAT MONTH.LEADING MONTH.LONG YEAR.LONG NO.TIME)) might produce "February 20, 1987". MONTH.LEADING implies SPACES and inhibits NUMBER.OF.MONTH.

CIVILIAN.TIME

[DateFormat Option]

Specifies 12-hour time instead of 24-hour (military) time. For instance, (DATE (DATEFORMAT CIVILIAN.TIME NO.DATE NO.SECONDS)) might produce "11:34pm".

For completeness, listed below are all the DATEFORMAT options currently supported.

Those affecting the date portion:

NO.DATE	Omit the date portion (month, day, year, day of week).
NUMBER.OF.MONTH	Use a number for the month instead of spelling it.
MONTH.LONG	Spell the month out instead of abbreviating it.
MONTH.LEADING	Month before day, spelled out, comma after day.
YEAR.LONG	Use 4 digits for year instead of 2.
DAY.OF.WEEK	Include day of week (it appears at the end of the string, in parentheses).
DAY.SHORT	Use 3-letter abbreviation for day.
SLASHES	Separate parts of date with slashes instead of hyphens.
SPACES	Separate parts of date with spaces instead of hyphens.
NO.LEADING.SPACES	Omit leading spaces (default is a fixed format that always "lines up"). This also affects the hour when CIVILIAN.TIME is specified.

Those affecting the time portion:

NO.TIME	Omit the time portion (hour, minutes, seconds, zone).
NO.SECONDS	Omit seconds.
CIVILIAN.TIME	12-hour instead of 24-hour time.
TIME.ZONE	Include time zone specification.

FILEBANGER

Filed as {eris}<lispcore>internal>library>FileBanger.*
Not for customer release

Basic Functions

(DOFILEBANGER *Destination Length NoBreak*)

Starts a new file banger in its own process. The device and directory specified by *Destination* will be where the test files are created during the testing. Each file will be *Length* bytes long. The file banger performs consistency checks on all the files it creates after each operation. If those consistency checks fail, it will print a message indicating what it found wrong, and if *NoBreak* is NIL will open a break window.

To stop the file banger process, one may (KILL.PROCESS 'FILEBANGER), provided that only a single file banger is in operation.

(FILEBANGER *TestFile Destination MakeWindow NoBreak InParms OutParms*)

Enters a loop of creating, manipulating, and deleting files, making consistency checks after each pass. *TestFile* may be the name of a file (whose contents are used as the contents of the test files), or an integer, in which case a test file of that many random bytes is created. *Destination* is the device and directory to be tested (normally this should be {DSK}<LispFiles>). *MakeWindow*, if T, causes a fresh window to be created; that window is used for progress messages as the test runs. If *MakeWindow* is NIL, the regular TTY window for the process is used (and created, if need be!). If the test's consistency checks fail, FILEBANGER will print a message in the status window; if *NoBreak* is NIL, it'll also stop and open a break window. If you are interested in really stressing the file system, you may specify PARAMETERS arguments to be given to OPENSTREAM when files are opened. *InParms* is used when opening for input, and *OutParms* when opening for output. We don't recommend the use of these arguments.

Generally speaking, the test file should be of a good length (5000 bytes or more), to assure that the files spread out to cover the disk volume you're testing.

FILEBANGER continues to run until interrupted from the outside somehow. The easiest way to arrange that is to run it in its own process (using DOFILEBANGER) and use KILL.PROCESS.

Recommended Operation

(DOFILEBANGER '{DSK}<LispFiles> 5000 NIL)

This will open a TTY window for the FILEBANGER process, and print small ongoing status messages there; you will need to do something to prevent the scrolling from hanging things up when the TTY window is full (either type ahead some spaces in that window, or arrange for the window not to pause when it fills up). To stop the file banger when it has run long enough, do (KILL.PROCESS 'FILEBANGER) in the top-level TTY window.

Likely Error Messages

HARD DISK ERROR

The low-level disk code hit a hard error on the disk, and was able to complete its operation to the extent of recognizing the error. Indicates a bad spot on the disk.

VERIFY ERROR

The disk-page label checking code found an inconsistency. While this might be software, it is most likely to be controller trouble or a bad spot on the disk.

(infinite uninterruptible loop)

The low-level disk code hit a snag so severe that it could never complete the disk operation at all. This should never happen. If it does, suspect IOP trouble.

File1 and File2 differ at byte xxx

Two files should have been identical but weren't. Suspect software problems, unless the error follows a particular drive, processor, or IOP.

File1 has length xxx, but File2 has length yyy.

Two files should have been identical but weren't. Suspect software problems, unless the error follows a particular drive, processor, or IOP

LISP DIAGNOSTICS

Date : 05 - 21 - 1985

This document describes Lisp Diagnostics program for Xerox 1108 and Xerox 1109 workstations.

To start it, load LISPDIAGNOSTICS.DCOM from the Lisp Library.

As soon as it finishes loading the file, a menu will appear.
You will have 2 choices, i.e. : Start Exercise and Stop Exercise.

If the file has previously been loaded, you'll only have to type :
(MAKEDIAGNOSTICSMENU) to make the menu appear.
When you select Start Exercise, the following message will appear on the
Top level typescript window :

Legend

! -> Completed !DIAGNOSE of MACROTEST
@ -> Completed TANSPEED benchmark
-> Completed BROWSE benchmark
□ -> Found a Clearing House on the Ethernet
- -> Looked, but failed to find a Clearing House
[xxx] -> Tried 32 retrievals from CH and got xxx failures
{xxx} -> Copied and deleted xxx copies of the Disk file
(xxx) -> Finished with xxx'th run of the EMUPROC loop
GDATE on new line marks release of working set pages

In addition to that, a window appears on top of the menu, it describes the
current activity indicated by a black rectangular cursor.

They are :

1. Swap out working set.
2. Ethernet activity.
3. Disk Activity.
4. Benchmark.

To stop the diagnostics, simply click the Stop Exercise selection.

(This package was superficially tested on Intermezzo>Full.sysout on
05 - 21 - 1985 by G. Santosa)

NSMAIL

INTRODUCTION

The module NSMAIL implements the protocols to allow Lafite to be used to send and retrieve Xerox NS Mail. Load the file NSMAIL.LCOM. To run this in Lyric, you must have loaded the LispUsers module NSRANDOM as well (q.v. for important loading information). If you don't have NSRANDOM loaded, you can't use the "Put to file" command described below.

If you have both Grapevine and NSMAIL implementations loaded, you must set Lafite's mode to NS. Use the "NS Mode" subitem underneath Lafite's Quit command, or call (LAFITEMODE 'NS). You must also be a registered NS user, and have a mailbox.

ATTACHMENTS

The main difference between this and earlier versions of NSMAIL is that "attachments" are no longer left in your mailbox to be read later with, for example, Viewpoint. Instead, Lafite retrieves the entire attachment and encapsulates it into an image object that is enclosed as part of the text message, immediately following the header. A typical attachment appears in a mail message as:

Attachment: 

If you click inside the object with any mouse button, you are offered a menu of things you can do with the attachment. The choices vary according to the type of attachment:

View as text	This brings up a window in which is displayed the raw content of the attachment as ascii bytes. Runs of non-ascii bytes are replaced by nulls to reduce the amount of garbage. Some attachments are utter gibberish, but some, such as Viewpoint documents and Interpress masters, contain sections that are plain text. With this command, you may be able to decide whether you care to do anything further with the attachment. (Sorry, there is no Viewpoint to TEdit converter, nor are there plans for one.)
Put to file	This prompts you for a file name, and creates a file to contain the attachment. The file must be on an NS file server for this command to be very useful; otherwise, information will be lost. Once the file is so stored, you can retrieve it from Viewpoint and manipulate it just as if you had originally retrieved it as mail in Viewpoint.

Send to Printer	This command is only available for attachments that are in the form of an Interpress master. The command prompts you for a printer (must be one that accepts Interpress, of course), and sends the attachment to it for printing.
Expand folder	This command is only available for attachments that are in the form of a "folder". A folder is a mechanism for collecting several objects into a single one. The Expand folder command splits the attachment up into its component objects, each of which can be manipulated in the same way as a top-level attachment. For example, if the folder contains an Interpress master, you can print it.

If you use the Put to file command on a folder, the name component of the file name you type will be treated as the name of a new subdirectory, and the components of the folder will appear as files in that subdirectory. For other types of attachments, Put to file (usually) produces an ordinary (non-directory) file.

Messages containing attachments are otherwise just like formatted messages—you can move them to other folders, and you can forward them (assuming the mail is received by another Lafite recipient and did not have to pass through a mail gateway).

There is currently no mechanism for creating your own attachments to send to other users.

MISCELLANY

If you prefer the old behavior of leaving the attachments behind in the mailbox, set the variable NSMAIL.LEAVE.ATTACHMENTS to T, but this use is discouraged. You must take care to regularly retrieve your mail from somewhere (such as Viewpoint) that will flush out all the mail; otherwise, the mail with attachments, whether you want them or not, accumulate on the server.

When in NS mode, Lafite will want your NS login identity. Normally, if your NS password differs from your default password, you will be prompted to login. You can also call (LOGIN 'INS::) yourself to set your NS login.

You can freely intermix Grapevine and NS mail in the same mail folder if you like, but the Answer command always treats the selected message as if it were one in the current mode. So if you try to answer a Grapevine message while in NS mode, some confusion may result. Also, the status window always shows you mail status only of the current mode.

SOURCELOOKUP

INTRODUCTION

This module provides a mechanism to locate the source file and floppy in which a particular system function is defined. It is designed for use with the set of Xerox LISP source files distributed on floppy with the Lyric release. This module uses the WHEREIS module distributed with Lisp Library documented in Section 23 of the *Interlisp Reference Manual*.

LOADING THE MODULE

SOURCELOOKUP requires WHEREIS.DCOM and HASH.DCOM to be loaded. The variable WHEREIS.HASH must be set to the hash file LYRICSOURCES.WHEREIS. All these files are distributed on the floppy labeled Lyric Sources #10. The hash file must reside on a random access device. To use the hash file on FLOPPY do the following:

```
(SETQ WHEREIS.HASH '({FLOPPY}LYRICSOURCES.WHEREIS))
```

The variable LyricSourceIndex will be set to a list where each element is a list whose CAR is the name of a Lyric Source floppy and CDR is the list of files contained on the floppy.

USER FUNCTION

```
(LOCATE.FUNCTION function)
```

If *function* is defined in a distributed source file prints out the appropriate file name and floppy and returns the file name; else prints "*function* not found" and returns NIL.

EXAMPLES

```
(LOCATE.FUNCTION 'SETQ)
```

The function **SETQ** is defined in the file **LLINTERP** located on floppy **Lyric Source #5**.

```
(LLINTERP)
```

```
(LOCATE.FUNCTION 'UNDEFINED)
```

UNDEFINED not found.

NIL

SETUP instructions for
PC Emulation virtual hard disk and real PC floppy disk access

1. Make sure all of the normal PCE .DCOM files are loaded to run PCE:
(PCEWINDOW, PCE, PCEERD, PCEDISPLAY, PCEKEYBOARD).
2. Select PC Emulation on the background MENU. This may take a while to load the PC fonts.
3. Put MSDOS disk in floppy drive. Select BOOT in the command window.
4. If the PCE boots ok, then select QUIT in the the command window.
5. Now we will make a virtual hard disk for the PCE.

From LISP do the following:

- ```
1_(PCE.CREATE.ERDFILE 'PCE.DISK 50)
 (* this will make a lisp file PCE.DISK which is nearly 2
 megabytes big - make sure you have enough disk space)
```
6. Reboot the PCE (BOOT command) and make sure configuration has the right file name PCE.DISK for the ERDFILE using the CONFIG command.
  7. From the PC window:  
  
-FDISK  
 (\* create DOS partition using all of the disk )  
  
-FORMAT C:/V/S  
 (\* format the rigid disk, put a syste on it, and label)  
  
-COPY A:\*. \* C:  
 (\* copies all of the system files from floppy to ERD)
  8. Select QUIT from the COMMAND window.
  9. You may now boot from the ERD (emulated rigid disk) by selecting FIXED DISK as boot device and Set-Config from the configuration window.
  10. From LISP exec:  
  
2\_ LOAD(VPCDISK.DCOM) (\* loads in LISP virtual PC disk/floppy and real PC floppy access)  
3\_ (VPCDISK.CREATE.DEVICE 'PCDISK 'PCE.DISK T) (\* associates ERDFILE PCE.DISK with a device name PCDISK)  
4\_ DIR {PCDISK}PCDISK:\* (\* directory listing of the PC DISK)  
5\_(SETQ PC.TEXTFILE.EXTENSIONS '(TXT PAS BAS 1 2 3] (\* list of PC file extensions which are treated as TEXT type files)  
6\_(VPCDISK.CREATE.DEVICE 'PCFLOPPY '{PCFLOPPY}) (\* associates real PC floppy driver with {PCDISK} device PCFLOPPY)  
 (\* make sure real floppy is in the disk drive when you execute this)  
7\_DIR {PCDISK}PCFLOPPY:\* (\* directory listing of the real floppy)
  11. At this point you are set up to do any LISP commands you want such as Filebrowser, Hardcopy, TEdit, etc. using the {PCDISK}PCDISK: for the virtual hard disk, and {PCDISK}PCFLOPPY: for real PC floppies.
  12. Try using Filebrowser and then selecting a textfile that has one of the extension names you setup in PC.TEXTFILE.EXTENSIONS above, and selecting HARDCOPY.
  13. Try using TEDIT on a floppy file such as {PCDISK}PCFLOPPY:README.1 and then editing the file and writing (PUT) it back. and then reselect it from filebrowser and selecting hardcopy. (Make sure floppy is not write-protected.)
  14. You may also access files on sub-directories. IE, {PCDISK}PCDISK:<DIR>FILE - However, you cannot delete or create directories from LISP. You have to do this from the PC window.

## MASTERSCOPE EXTENSIONS

1. More than one type of executable thing.

All possible executable thing types are stored on MSFNTPES, which is a list of MSANALYZABLE records:

(filepkgname setname getdef-fn)

Vanilla Masterscope starts with it set to

((FNS FNS GETDEF))

and new things get added to it through MSADDANALYZE (see below).

The filepkgname must be the File Manager name of the new executable thing. MSADDANALYZE will barf if filepkgname is not on IL:FILEPKGTYPEES.

The setname must be the name Masterscope uses for a set of the new executable things.

The getdef-fn has to take the same arguments as GETDEF and return NIL or a definition suitable for Masterscope munching.

MSGETDEF, MSEDITF, MSSEEKTYPE, MSMARKCHANGED, and MSADDANALYZE look at MSFNTPES

Subject: New Lispcore>Library package: MesaTypes  
To: Lispcore^, Lispsupport, Sheil, Cooper, Purcell

Announcing a new Lispcore>Library package: MesaTypes

By Tayloe Stansbury with help from Richard Burton.

This package introduces three new clisprecordtypes which allow you to describe any block of bits with an arbitrarily nested datatype. You can define multidimensional, nonstandardly indexed arrays with multi-word elements; records with multi-word fields; and multi-word types. Special accessfns cover up the necessary \BLTs and LOCFs. Appropriate create methods are automatically provided. The package also provides a number of macros for manipulating instances of such types.

Anyone who wants to use graceful datatypes to describe some arbitrary chunk of memory (e.g. ethernet, rs232, nsfiling, any file system) will probably find this package useful; most of the 1108 file system now depends on it. People translating Mesa system code into Lisp will find it particularly useful.

This message is stored as Lispcore>Library>MesaTypes.tedit. Proper external documentation of this package will follow release of the 1108 file system. Extensive examples of its use can be found in the first few pages of stansbury>newdlionfs>dlionfs.

-- Tayloe.

## Common Lisp package code and symbol conversions

Ron Fischer

[This document is for developers only. It is not intended to be part of any external software release.]

The package code can behave mighty strangely if not operated "just so." Please read this document carefully.

### Loading

The package code is now loaded in the full.sysout. It lives in {Eris}<LispCore>Library> on

CMLSYMBOL.DCOM

CMLPACKAGE.DCOM

### Initializing

Packages, as you might expect, must be bootstrapped carefully. At its simplest, initialization is accomplished by calling just one function:

```
(package-init t)
```

#### simple startup

```
(package-init &optional (convert? nil))
```

[Function]

Clear, make structures of, initialize & convert symbols (if convert? is t) to, and enable use of the symbol package system. On a DandTiger this takes about 25 minutes.

The bootstrap actually takes place in three steps. The first one creates all the package structure needed. The second passes over all the atoms in the sysout to "tag" them with packages. The third enables the package world.

#### step 1: make system packages

```
(package-make)
```

[Function]

Create, but do not fill with symbols, the base packages that need to exist. Also enables the package qualifier characters in the readtables and saves the old definitions of \READ.SYMBOL and \MKATOM.

#### step 2: convert existing symbols

```
(package-hierarchy-init &optional (convert? nil))
```

[Function]

Fill all the initial system packages with their proper symbols, moving litatoms into appropriate places and such. If convert? is non-nil then symbols whose pnames have fake package qualifiers, like cl:length, will be converted IN PLACE to remove the qualifier. If conversion takes place you cannot fully disable the package system.

#### step 3: enable package system, remove old hacks

The third part of the bootstrap enables the use of packages by the reader, printer and friends. This involves redefining \MKATOM and \READ.SYMBOL. Also, if \*package\* is set to nil things will not go well. Please use package-enable and package-disable to start and stop, as these fellows know what they're doing. These faithful functions are available on a menu by calling package-menu.

```
(package-enable &optional (package *interlisp-package*))
```

[Function]

Turn on the package system, making package the current one and redefining \READ.SYMBOL and \MKATOM appropriately.

```
(package-disable)
```

[Function]

Turn off the package system and restore the old definitions of \READ.SYMBOL and \MKATOM. After disabling, symbols interned under the package system will not be eq to symbols of the same name reread.

```
(package-menu)
```

[Function]

Make a menu that allows turning the package system on or off without using the reader.

```
(package-hacks-disable)
```

[Function]

Eliminates package simulation hacks when loading over an old sysout. These hacks cannot be re-enabled.

(pkgconvert-enable) [Function]

Enables a change in the behavior of the function `\\READ.SYMBOL` (using the function `check-symbol-namestring`), which converts symbols being read based on their "looking like" a package prefixed symbol name. "Looking like" is defined by a table in the global `litatom-package-conversion-table`.

litatom-package-conversion-table [Variable]

a global variable containing a list of clauses used by the functions `package-hierarchy-init` and `check-symbol-namestring` to determine if a symbol "looks like" is trying to be package qualified. The list contains clauses with the following structure:

*(prefix-string list-of-exception-strings package-name-string where)*

*prefix-string* - string containing the prefix of symbols which this clause converts, eg "CL:"

*list-of-exception-strings* - list of strings naming symbols which this clause should leave alone, eg ("CL:FLG")

*package-name-string* - string containing the name of the package that symbols converted by this clause should wind up in, eg "LISP"

*where* - either :INTERNAL or :EXTERNAL, indicates whether symbols converted by this clause should be external or internal in their package.

The initial value of this variable is:

```
(
 ("CL:"
 ("CL:FLG" "CL:MAKE-SYMBOL" "CL:COPY-SYMBOL" "CL:INTERN"
 "CL:MAKE-KEYWORD" "CL:GENTEMP" "CL:KEYWORDP")
 "LISP" :external)
 (":" nil "KEYWORD" :external)
)
```

## Notes & cautions

The read functions may return strings if you use package qualifier syntax and `*package*` does not contain a package. This is part of debugging code that Bill put into them. Beware especially of making `*package*` NIL without calling `package-disable`.

The list of conversion clauses is searched linearly, hence longer prefixes should come before shorter ones with the same chars in them, ie put a clause for "CL: " before one for "CL:".

## Missing features

Cannot be placed early into loadup due to dependancies on CL files.

Apropos (and other Interlisp litatom functions) are not redefined to operate with packages.

## Performance

There have been some small improvements since these timings were taken.

```
FILEDATES : (("21-Jul-86 14:12:17" .
{ERIS}<LISPCORE>CML>LAB>CMLPACKAGES.;129))
```

Testing symbol / litatom creation. Old array package. There are 6 random symbols made (new ones). intern is a factor of 16 slower, conses heavily, makes 3 strings for each call.

```
85#(TIMEALL (TIME.MKATOM))
Elapsed Time = .336 seconds
SWAP time = .32 seconds
CPU Time = .016 seconds
PAGEFAULTS = 8
LISTP
9
```

```
86#(TIMEALL (TIME.INTERN))
Elapsed Time = .449 seconds
SWAP time = .188 seconds
```

```

CPU Time = .261 seconds
PAGEFAULTS = 5
LISTP STRINGP
423 18

```

**Peano**

---

---

Maintained By: Frank Shih (Shih.envos@Xerox.com)

This document last edited on 8-Nov-88

**INTRODUCTION**

Peano is an ancient graphics demo.

**OPERATION**

(PEANODEMO *LEVEL SCALE*)

[Function]

Runs a demo in PEANOWINDOW (set first time), drawing Peano curves to level *LEVEL* with lines *SCALE* units wide.

## Read and Print state profile

There are a large number of special variables that control reading and printing. Taken together these comprise a "mode of operation" for the reader and printer. Because there are a fair number of such variables a method for capturing and restoring their state has been provided.

```
(xcl:make-read-print-profile &key (readtable *readtable*) (read-base *read-base*) (read-suppress *read-suppress*)
(package *package*) (read-default-float-format *read-default-float-format*) (print-escape *print-escape*) (print-
pretty *print-pretty*) (print-circle *print-circle*) (print-base *print-base*) (print-radix *print-radix*) (print-case
print-case) (print-gensym *print-gensym*) (print-level *print-level*) (print-length *print-length*)) [Function
]
```

Creates a read-print-profile object. The default values of its components are taken from the current special bindings of the variables shown in the argument list above.

```
(xcl:copy-read-print-profile profile) [Function]
```

Creates a new read-print-profile object and copies the values in the slots of profile into the new one.

```
(xcl:read-print-profile-p object) [Function]
```

Returns true if the object is a read-print-profile, otherwise false.

```
(xcl:read-print-profile-readtable profile) [Function]
(xcl:read-print-profile-read-base profile) [Function]
(xcl:read-print-profile-read-suppress profile) [Function]
(xcl:read-print-profile-package profile) [Function]
(xcl:read-print-profile-read-default-float-format profile) [Function]
(xcl:read-print-profile-print-escape profile) [Function]
(xcl:read-print-profile-print-pretty profile) [Function]
(xcl:read-print-profile-print-circle profile) [Function]
(xcl:read-print-profile-print-base profile) [Function]
(xcl:read-print-profile-print-radix profile) [Function]
(xcl:read-print-profile-print-case profile) [Function]
(xcl:read-print-profile-print-gensym profile) [Function]
(xcl:read-print-profile-print-level profile) [Function]
(xcl:read-print-profile-print-length profile) [Function]
(xcl:read-print-profile-print-array profile) [Function]
(xcl:read-print-profile-print-structure profile) [Function]
```

profile must be a read-print-profile object. Returns the named slot of the read-print-profile. A corresponding setf method is provided for each slot.

```
(xcl:save-read-print-profile profile) [Function]
```

Capture bindings of special read & print variables into the profile. Returns profile.

```
(xcl:with-read-print-profile profile-form &body forms) [Macro]
```

Binds all the special read & print variables to the values in the profile and executes the body forms as in a let. Returns the value of the last of the forms.

```
(xcl:restore-read-print-profile profile) [Function]
```

Restore values of special read & print bindings from profile. Sets current bindings. Returns T.

```
xcl:*default-read-print-profile* [Variable]
```

Holds a simple default read-print-profile. When possible programs should default to the current settings of the read-print variables by capturing them with save-read-print-profile instead.

```
(xcl:find-read-print-profile name) [Function]
```

Since read-print-profiles enclose readtables and packages, which are available by name, named read-print-profiles

are also available.

This function will retrieve one of the following "standard" read-print-profiles:

LISP: LISP readtable and USER package, others nominal.

XCL: XCL readtable and XCL-USER package, ditto above.

INTERLISP: INTERLISP readtable and INTERLISP package, ditto.

This function is case insensitive. It returns NIL if a profile by that name is not found.

(xcl:list-all-read-print-profile-names) [Function]

Returns a list of strings containing the names of all available read-print-profiles.

## WHEREIS

The WHEREIS package extends the function WHEREIS such that, when asked about a given name as a function, WHEREIS will consult not only the commands of files that have been noticed by the file packages, but also one or more hash file data bases that associate function names with file names.

(WHEREIS NAME TYPE FILES FN) [Function]

Behaves exactly like the standard WHEREIS function (see the *Interlisp-D Reference Manual*) unless *TYPE*=FNS (or NIL) and *FILES*=T. In this case, WHEREIS will consult, in addition to the files on FILELST, the hash files that are on the value of WHEREIS.HASH. Note: normally the user will just enter the full name of a file onto WHEREIS.HASH, but as WHEREIS begins to use it, it will convert the entry into a cons of the name and the hash file handle.

Many system functions, such as the editors, call WHEREIS with *FILES*=T, so loading this package automatically makes any information contained in the WHEREIS data base files available throughout the system.

---

## Creating a Where Is Data Base

---

Information may be added to an existing WHEREIS hash file, or by creating new data bases. It is often useful to have a separate data base for large user systems, explicitly calling the following function:

(WHEREISNOTICE FILEGROUP NEWFLG  
DATABASEFILE) [Function]

Inserts the information about all of the functions on the files in *FILEGROUP* into the WHEREIS data base contained on *DATABASEFILE*. If *DATABASEFILE* is NIL, the first entry on WHEREIS.HASH is used.

*FILEGROUP* may be simply a list of files, in which case each file thereon is handled directly; but it may also be a pattern to be given as a file group argument to DIRECTORY, so \* may be used.

If *NEWFLG* is non-NIL, a new version of *DATABASEFILE* will be created containing the data base for the functions specified in *FILEGROUP*. If *NEWFLG* is a number, the hash file will be created with *NEWFLG* entries. Otherwise, it will be created to allow 20,000 entries.

Example:

The following sequence of actions will cause all of the files on the PROJECT directory to be noticed by the WHEREIS package.

```
(WHEREISNOTICE ' <PROJECT>* . T ' <PROJECT>PROJECTWHEREIS.HASH)
(push WHEREIS.HASH
 (FINDFILE ' <PROJECT>PROJECTWHEREIS.HASH))
```

One of the key components of CLOS in inheritance. The CLOS Browser provides functionality for displaying this structure and for extending it. It also provides functions for displaying and changing the class definitions and method definitions which make up a system written in CLOS.

## Creating a Browser

---

A browser can be created in two ways:

- Via a menu option from the Background Menu
- By calling the function CLOS-BROWSER:BROWSE-CLASS on a class

### Creating a browser via the Background Menu

When the CLOS-BROWSER module is loaded, an entry is added to the Background Menu, as shown below:

Selecting the menu item BrowseClass brings up a window, with a prompt for the name of the class to use as the root of the browser as shown below.

Type in the name of the class you wish to browse at the flashing cursor, and the class graph will be drawn in the window.

## Creating a browser programmatically

Browsers can also be created by calling the function BROWSE-CLASS:

**(BROWSE-CLASS &OPTIONAL CLASS-NAME-OR-LIST &KEY :WINDOW-OR-TITLE :GOOD-CLASSES :POSITION)** **[Function]**

This function brings up a browser on the class named or the list of classes named. If a window is supplied for the :WINDOW-OR-TITLE argument, then the browser is created in that window, else an appropriately sized window is created. The window is positioned at the :POSITION argument or, if not supplied, then the position is set via the mouse. If a text string is supplied for the :WINDOW-OR-TITLE argument, then that string is used for the window title, else the string "CLOS-browse" is used. If :GOOD-CLASSES is supplied, then only those classes in the list are displayed.

## Using the Class browser

---

Instances of CLOS-BROWSER are operated on through a mouse-based interface.

Buttoning on the browser will cause one of the following menus to be popped up:

- One menu appears when the left or middle button is pressed while the mouse is in the title bar. This menu has operations that apply to the browser itself.
- The other menu appears when the middle button is pressed when the mouse is on one of the nodes in the browser.

If the left button is pressed when the mouse is on a node, that node is boxed. This marks the node for some operations.

### Options in the title bar menu

The following menu appears when you left- or middle-button in the title bar.

### Recompute and it's suboptions

Selecting the Recompute option and dragging the mouse to the right causes the following submenu to appear:

Most of these items change the appearance of the browser, not the contents.

|                   |                                                                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Recompute         | Recomputes the browser from the starting objects. It does not recompute the labels for each node if those labels are cached in the Label-Cache slot of the browser. |
| Recompute Labels  | Recompute the browser from the starting objects, including the labels.                                                                                              |
| Recompute inPlace | Recompute the browser without affecting the scrolled location of the lattice within the window.                                                                     |
| Clear caches      | Clear the caches of the nodes.                                                                                                                                      |

### Browser looks and it's suboptions

Selecting the Browser looks menu item and sliding to the right causes the following submenu to appear:

Selecting one of these options changes the looks of the browser.

|                  |                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Shape to hold    | Make the window for the browser just large enough to contain the browser.                                                                    |
| Change font size | Causes a menu of alternative font sizes to pop up. Selecting one of these causes the browser to be redrawn with the nodes at that font size. |
| Change format    | Causes the following menu to appear:                                                                                                         |

Horizontal/Lattice Lays out the grapher as an horizontal lattice.

Vertical/Lattice    Lays out the grapher as a vertical lattice.

Horizontal/Tree    Lays out the grapher as a horizontal tree.

Vertical/Tree    lays out the grapher as a vertical tree.

## Options in the Middle-button menu

The following menu appears when you middle-button over a node in the graph:

## Edit and it's suboptions

Selecting Edit causes an editor on the class definition to be brought up. Sliding the mouse to the right causes the following menu to appear:

Edit      Edits the class named by the node

Inspect      Inspects the class object named by the node.

## Add Method

Selecting the Add Method option brings up an editor window with a template for a method to be added to that class. When the editor is done the method is installed for that class and the menu updated.

Browse

Selecting the Browse option causes a browser to be created starting with that class as the root.

## Print and it's suboptions

Selecting Print prints out the class definition. Sliding the mouse to the right causes the following menu to appear:

|               |                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Print         | Print's the class definition                                                                                                              |
| Describe      | Describes the class, listing it's metaclass, it's supers classes, it's subclasses, it's CPL, and the number of methods specialized to it. |
| Documentation | Print's the documentation string for the class                                                                                            |

## Specialize

Selecting the Specialize option brings up an editor window with a template for a subclass to be added to that class. When the editor is done the class is installed and the browser updated.

## Slots

Selecting the Slots option is the same as selecting the Edit option, it brings up an editor on the class definition.

## Methods

The Methods option allows you to edit one of the methods defined for that class. Selecting it and sliding to the right brings up the following sub-menu:

|       |                                                                                  |
|-------|----------------------------------------------------------------------------------|
| Local | Bring up a menu of the local methods, ie methods directly defined for this class |
|-------|----------------------------------------------------------------------------------|

|           |                                                                                      |
|-----------|--------------------------------------------------------------------------------------|
| Inherited | Bring up a menu of the methods this class inherits from it's superclasses.           |
| All       | Bring up a menu of all the methods defined for this class, both local and inherited. |

Selecting an item with the left button from the resulting menu brings up an editor on that method. If there are multiple methods that apply, a gray triangle appears in the right edge of the menu next to that item. Sliding to the right brings up a menu of method specializers to select the appropriate method.

---

---

**COLOROBJ**

---

---

By: Greg Nuyens (Nuyens.pa@Xerox.com)

uses: COLOR

COLOROBJ provides an Interlisp-D imageobject which allows the color to be set on an imagestream. The default image looks like this:

Unknown IMAGEOBJ  
GETFN: COLOROBJ.GETFN

The color of the object can be changed by middle-clicking on the object.

(COLOROBJ.CREATE Color)

[Function]

Creates a single colorobj. Color is optional and defaults to COLOROBJ.DEFAULT.COLOR.

COLOROBJ.DEFAULT.COLOR

[Variable]

Determines the initial color of a colorobj. Default is RED.

---

---

**HostUp**

---

---

By: Johannes A. G. M. Koomen  
(Koomen.wbst@Xerox or Koomen@CS.Rochester.edu)

This document last edited on December 27, 1988

**SUMMARY**

This module provides the function HOSTUP? which attempts to find out if a given host is currently available. Contrast this to the system function HOSTNAMEP, which returns T if it has *at any time* successfully opened a connection to given host, whether or not it is currently available.

**DETAILS**

(HOSTUP? hostname) [Function]

Returns T if and only if the given host is currently responding. No distinction is made between dead and non-existing hosts.

HOSTUP.TIMEOUT [Global variable]

The function HOSTUP? returns NIL if no response is received from the given host within HOSTUP.TIMEOUT milliseconds. Default value is 15,000.

HOSTUP.RETRYCNT [Global variable]

This variable indicates the number of times the function HOSTUP? sends requests to the given host. Each time through the loop the function waits longer by a geometrically increasing amount of time, such that the total time does not exceed HOSTUP.TIMEOUT. Default value is 5. Hence, in the default case, a call to HOSTUP? with a dead host ends up sending a request to the host 5 times, waiting for an answer about 500, 1000, 2000, 4000 and 8000 milliseconds, respectively.

## IRIS

---

---

By: Nuyens (Nuyens.pa@Xerox.Com)

Requires: COLOR and COLOROBJ

This document last edited on January 31, 1987.

### INTRODUCTION

The LispUsers module IRIS is a collection of functions for using an IRIS (Integrated Raster Imaging System) with Interlisp-D. The IRIS is a sophisticated 3-d color graphics workstation produced by Silicon Graphics Incorporated. Much of its imaging system is implemented in special purpose VLSI, making it a very powerful graphics engine.

IRIS provides three separate ways to exploit the IRIS in Interlisp-D. The first is to use the IRIS as an Interlisp-D imagestream. In this capacity the IRIS serves as the output device for a program which needn't even know that it is outputting to the IRIS. Thus standard system utilities (such as GRAPHER, SKETCH, and TEDIT) can make use of the IRIS without change. The images produced by these system utilities can then be manipulated with the special abilities of the IRIS (3-d rotation, color updates, double buffering, object definitions, etc.)

The second mode of use for the IRIS is to directly access the IRIS graphics library. In this mode, Interlisp-D provides stubs for the functions in the IRIS graphics library. Thus, Interlisp-D provides the illusion of having the IRIS as a direct device like the standard screen. However, it is actually a separate computer accessible across the 10-MB Ethernet.

The third mode is to use the view controller to interactively view scenes created with either of the two modes. The view controller allows the user to create an object once (interactively or via program) but then view the object many times on the IRIS without recreating the object. This object downloading allows real-time rotation of the object displayed on the IRIS.

This package also implements boot service for the IRIS workstation. The D-machine supplies the boot program to the IRIS over the Ethernet, eliminating the need for a floppy-disk on the IRIS.

This package benefited substantially from comments and improvements by Stu Card, Michel Desmerais and Lennart Lovstrand.

### FILE DESCRIPTION

The implementation includes the following files:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOADIRIS    | after loading this file, the user will be prompted to place the IRIS icon. Buttoning this icon will produce a menu including the choice "create loadup panel". Choosing this item will produce a panel which can load the IRIS files. Button the "Standard" entry in the loadup panel, then button on the small SGI logo next to "Load". Prior to being able to run any applications, the IRIS must be running the terminal program. This can be booted from the floppy on the IRIS or from the Lisp workstation. To use the workstation as a bootserver, the boot file for the IRIS terminal program (see msg below) must be copied to {DSK}irisbootfile (or a directory in the list IRISBOOTDIRECTORIES) on the Dandelion that is to be the bootserver. At that point, hit the reset button on the IRIS and type 'n' to the monitor prompt on the iris. That will initiate a net boot from the Dandelion. |
| IRISSTREAM  | The file which contains the Interlisp-D imagestream definition for the IRIS. Thus, the standard Interlisp-D graphics facilities can be applied to an open IRIS imagestream. After this is loaded, images which are processed through the standard hardcopy menu can be sent to the IRIS. "Iris" will appear as a printer when the "to a printer" choice is made from the roll-off menu entry "Hardcopy".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| IRISLIB     | this file contains the stubs for the functions in the IRIS library. For instance, corresponding to the function circf (found in the IRIS documentation), there is a function IRIS.CIRCF . The arguments are as listed in the IRIS documentation with the addition of the argument SPPstream. This is the SPP connection opened to the IRIS. (If omitted, it defaults to the value of IRISCONN, which is set by OPEN.IRISCONN). Where an argument is a matrix, it is passed to the lisp function as a list of the rows, each row itself a list. When a library fn returns a matrix, the appropriate (usually floatp) matrix is passed in and the elements are set.                                                                                                                                                                                                                                           |
| IOLIB       | this file contains the communication primitives which are used by the fns on IRISLIB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| IRISNET     | this file contains the network support for the iris. The IRIS must be on the same network as the D machine (the IRIS doesn't handle routing through the gateway properly). If the IRIS is being bootservered from the Lisp workstation, the boot server software will set IRISNSHOSTNUMBER automatically. (The diagnostic messages can be inhibited by setting \IRIS.VERBOSE to NIL. They are left in because they can be useful when initially getting the IRIS to boot).                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| IRISVIEW    | This file contains the functions supporting the interactive viewing menu, together with the object definition facility it uses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| IRISDEMOFNS | This file contains an example 3-d function for the IRIS. It is a function called TETRA which draws a colored, 3-d recursive tetrahedron.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| IRIS.TEDIT  | This file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## GETTING STARTED

**N.B.** All variables and functions in this document are written as in the old Interlisp readtable. To type in the examples in this document, bring up an "Old-Interlisp" Exec. (available from the background menu by rolling off "exec" and then "Interlisp".)

-1) type (FILESLOAD LOADIRIS)

It will ask you to position the following (SGI) icon:

(it can be recreated later by typing (IRIS.CREATE.ICON) at the Interlisp executive).

**0) Next type (FILESLOAD IRISSTREAM IRISVIEW)**

### **1) Boot the IRIS**

If you have a floppy drive for your IRIS, use it to boot the IRIS GL2 (XNS) Terminal program. ( If your IRIS is a workstation, not a terminal, you need to run the WSIRIS program available from SGI).

If you do not etherboot, you must set the variable IRISNSHOSTNUMBER. (see variables section below.)

If you have no floppy, you are going to "etherboot" the IRIS. To begin ensure that IRISBOOTDIRECTORIES is set properly. (see Magic Variables section below).

Press a mouse button in the SGI icon. Choose "Enable bootserver". Now boot the IRIS (by pressing the black button labelled "reset" on the IRIS display). To the prompt on the IRIS, type (on the iris keyboard) N (followed by carriage return). To the eventual prompt "connect to which host?" type < (carriage return). Etherbooting will automatically set the variable IRISNSHOSTNUMBER. Status messages will be printed to the promptwindow. The IRIS will beep when it is finished booting.

### **2) Open an IRIS stream**

Button in the IRIS stream and choose "Create IRISView panel". Confirm the command by clicking left button of the mouse. "Connected" should print on the IRIS screen, and then the screen should turn black and display axes. (**N.B.** If at any time the screen goes completely blank, touch any key on the IRIS keyboard. The IRIS has a dubious screen-saver "feature".)

## **Modes**

The modes of use of the IRIS are as follows:

### **Interlisp-D display stream**

In this mode, the IRIS is acting like a window on the Lisp machine. To see updates as they occur toggle the "Double Buffer" button on the IRISView Controller. It will respond "Single buffering". Then press the "2D-Home" button on the IRIS. To demonstrate this, try the use of commands like

```
(PROGN (DSPCOLOR 'BLUE \IRISSTREAM)
```

```
 (PRINTOUT \IRISSTREAM T "Let's here it for ")
```

```
(DSPCOLOR 'RED \IRISSTREAM)
```

```
(PRINTOUT \IRISSTREAM "COLOR." T)
```

```
(DSPCOLOR 'BLUE \IRISSTREAM))
```

NOTE that the first time a font family is defined it will download the font after loading the spline font definitions. This will take a few minutes.

```
(DRAWLINE 0 0 400 200 2 NIL \IRISSTREAM 'RED)
```

```
(FORCEOUTPUT IRISCONN)
```

Since the SPP stream buffers, sometimes it will be necessary to (FORCEOUTPUT IRISCONN). (There is a function simply called F that will do this for you.)

These simple instructions indicate the use of the IRIS as an Interlisp Device Independent Graphics (DIG) stream. See the IRM for further examples common to all DIG devices. For interactive graphics, the following sections contain other uses of the IRIS.

## Output stream for Sketch and TEdit

TEdit and Sketch can make use of the above display stream facilities. To see an example color document, do the following. (If you don't want to see the sketch in the document, you may omit loading sketch and sketchcolor, since they are slow to load.)

```
(FILESLOAD COLOROBJ SKETCH SKETCHCOLOR)
```

```
(TEDIT 'IRIS-EG.TEDIT)
```

### To print a TEdit (or sketch) to the IRIS

First time: Press "2D-Home". In the title bar of the window, use the right button to bring up the default window menu. Pick the roll-off item Hardcopy. Rolloff into "hardcopy to printer", then choose "Iris". Choose "yes" to the menu saying "Make this the default printer".

Later times: The IRIS will now be the default printer, so just press "2D-Home" and choose Hardcopy from the default window.

### To use Sketch

From the background menu, choose "SKetch". Build a closed polygon (with the  in the sketch menu). Choose "change" in the sketch menu. Pick a control point of the polygon you just built. Pick "filling color" from the menu that appears. From the menu that appears, pick a filling color.

### Clearing the IRIS

In the IRIS icon is an entry "clear IRIS". It will return the IRIS to the original state with the white screen, etc.

### Defining new colors

At any time the color menu is presented, "new color" may be selected. RGB will provide color sliders and CNS will provide an english description of colors. A window will pop up asking for a name for the color. Type in a name, and that name will appear in the color menu from then on.

## Using the IRISVIEW controller

**N.B.** When an IRISview controller is initially opened, the IRIS will be double buffering. This means that any drawing on the iris occurs on the back of two buffers. "Swap Buffers" must be chosen to bring the back buffer to the front. This includes "Clear IRIS" and other drawing commands. Double buffering can be turned off with the "Double Buffer" button, but moving images are much smoother with it turned on.

This window allows you to define objects on the IRIS and control your view of them.

### Changing the scene:

First, select "change scene". You will be prompted with the predefined scenes as examples. Choose "axes". After a moment (during which "defining object for axes" is printed), an XYZ axes picture will appear on the screen. Try choosing each of the 3 home buttons to see the effect.

Press the "2d Home" button. (This actually means to move the view such that the IRIS simulates an 1108 screen in size and view). Now change the scene to "SKULL". Again after a delay, a Grateful Dead logo will be displayed.

### Defining a scene:

We are going to define a scene that calls a function on the file IRISDEMOFNS so type

(FILESLOAD IRISDEMOFNS)

Button "Change Scene". Choose "New Scene" from the Menu. In response to "Scene Name", type "TETRA". In response to "Form to eval" click in the window the message is printed in and then type

(TETRA) [carriage return]

When the object is displayed, press each of the "Home" buttons to see different home positions. (2D-Home is perhaps best).

### Viewing the scene:

Before viewing the scene, choose the "Double Buffer" option. Now hold the left button down on the item marked "Background:" in the view controller. Choose the background color for the object. White is often a good choice. (Note that sliding off the menu at this point will display "none" as the background. This means that each time the scene is drawn will be on top of the previous result. This can give very pleasing, flashy results. Experiment a bit. It's great fun (and you are probably being paid for it!))

### Adjusting the view:

Bug the part of the free menu marked  This will move the image in the positive x axis. Similarly with the other hand icons. Holding down the shift key will reverse the direction in the same axis. Bugging the  entry in the view controller will let you change the "delta" for translation.

Now bug the part of the free menu marked . This will rotate the image in that axis. Holding down the shift key will reverse the direction of rotation.

Bugging the  entry will let you choose a new "theta" for rotation (in degrees).

### **Home:**

Bugging "home" will return the scene to the original view. It is often a good idea to choose "Home" before changing scenes.

### **Axes:**

Bugging the "axes" entry in the menu will superimpose a set of three dimensional axes on the view for reference purposes. It defines the axes of rotation controlled by the view controller and the directions of translation. (The axes look best against a black background, I think)

### **Forgetting a Scene:**

Reclaims the space inside the IRIS and removes scene names from the scene menu. All but one scene may be deleted.

### **Defining a scene containing a sketch (or Tedit):**

Button "Change Scene". Choose "New Scene" from the Menu. In response to "Scene Name", type "IRIS-EG". In response to "Form to eval", click in the window the message is printed in and then type a carriage return.

The view controller will prompt with "Make object then type RETURN". Now, hardcopy the sketch exactly as above. (periodically the view controller will flash the screen to remind you that you are still making the object). When you are finished, type carriage return as before. The current scene name will be printed in the view controller.

## **Troubleshooting:**

### **"Iris Terminall SPP not responding" printing in prompt window**

This may occasionally print when the Dlion is too busy to service the SPP connection to the IRIS. If it repeats, however, this means that a previous IRIS stream has been lost. Bring up a process status window by choosing PSW in the background, then choose the process (Iris Terminal SPP#2 for instance) and bug "kill" in the PSW. Be sure to kill the correctly numbered process. "Iris Terminal SPP" is not the same as "Iris Terminal SPP#3".

### **Magic Variables**

IRISNSHOSTNUMBER

[Variable]

contains the 48 bit etherhostnumber of the IRIS. If you are etherbooting, this will be set automatically. Otherwise, set it to a string like "0#4000.12000.41504#0" as described on page 31.9 of the IRM.

\IRIS.DEBUG

[Variable]

Defaults to NIL. If T, when fonts are created, only the first lowercase letters will be defined. This is much faster than loading the whole font.

IRISBOOTDIRECTORIES

[Variable]

For users still running with the R1B version of the IRIS terminal program, the file concerned is called xiris. This is the file that should be copied to {core}irisbootfile. However, for users running R1C (also referred to as GL2), it is necessary to obtain an updated version of the terminal program from SGI. (It was named simply "iris" on the tape we received.) This variable must contain the list of directories where the boot files are to be found. (For instance, very fast booting may be obtained by copying the boot files to the {core} device and putting {core} at the front of IRIS.BOOTDIRECTORIES.)

IRIS.VERBOSE

[Variable]

Defaults to T. Says whether or not status messages are printed during font creation etc.

\IRISSTREAM

[Variable]

contains the IRIS stream that is current.

IRISCONN

[Variable]

contains the SPP connection that is current.

**KOTOLOGO**

---

---

By: Masinter (Masinter.PA@Xerox.COM)

Uses: none

This document last edited on August 17, 1988.

**INTRODUCTION**

Makes a Koto-style logo window.

(KOTOLOGOW *string where title angledelta*)

[Function]

Works like LOGOW did in Koto. Put *string* as the main logo name, with *title* in the window title. *angledelta* is the angle at which the little windows go. *where* is either a position or an old window. For example (KOTOLOGOW "the string" NIL "the title" 30) produces:

**LispNerd**

---

---

By: Maxwell (Maxwell.pa)

DICTCLIENT, DINFO

INTERNAL

## INTRODUCTION

The LispNerd provides a menu-based interface to the Interlisp Reference Manual. The data for the LispNerd is stored on the Dictionary Server, and is accessed via DICTCLIENT. Because of certain licensing agreements we have with Houghton-Mifflin, the Dictionary Server should only be used by people within PARC. Hence LispNerd has not been released as a LispUsers package.

## HOW TO USE THE LISPNERD

When you load the LISPNERD, it adds a new menu item called "Search IRM" to the background menu. Bugging "Search IRM" causes the LispNerd to prompt the user for keywords in the prompt window. It then produces a menu of items that have at least two of the keywords in their definitions (perhaps with submenus, if there is more than one class of items). Bugging one of these items will cause the LispNerd to fetch the documentation for that item using DINfo.

For example, if you type the input "draw line function", you will get the following menu:

where each of the entries has a sub-menu of the items that have the keywords listed in the entry.

If you type the input "date", you will get a menu all of the items in the Interlisp Reference Manual that have the word "date" in them. Putting parenthesis around items means that the items should all be treated as one keyword for the purposes of sorting them into groups. For instance, the input "(draw draws)(line lines) function" will look for all of the items that have "draw" OR "draws" in their definition.

LispNerd only fetches 50 entries at a time, so sometimes you will see an entry in the menu that says something like ". . . + 103 more". Clicking this item will cause the LispNerd to fetch the next 50 entries. Also, when there is more than one class of entries, sometimes a sub-menu will only list the number of

entries it has, and not the entries themselves. To get the entries, click the menu item with the keywords in it, and LispNerd will recompute the menu with just those keywords.

Please send all bug reports to [Maxwell.pa](mailto:Maxwell.pa).

**MATHTONS**

---

---

By: Tad Hogg (Hogg.pa@Xerox.com)

**INTRODUCTION**

This file defines the translation array needed to convert from the Press MATH font to corresponding NS characters. This allows documents containing the MATH font to be printed on Interpress printers.

The array \MATHTONSARRAY contains the translations for most of the characters. Some may not be available on particular printers, causing them to appear as black boxes.

**MICROTEK**

---

---

By: Ron Clarke (RClarke.pa@Xerox.COM)

This document last edited October 31, 1988

**INTRODUCTION**

MICROTEK is an image processing software package that enables you to operate Microtek Models-300 and 300A Intelligent Image Scanners with the Xerox 1108 and 1186 workstations. The Microtek MS-300, 300A, and MSF-300C are high-resolution optical scanners that can convert text, artwork, photographs, etc, into digital form for processing by computer. The digitized images that are output to the computer contain up to 300 black and white dots for every linear inch of the original document. Page size can be as large as 8.5 by 14 inches. Sophisticated firmware in this scanner enables the user to set the scanning area and control brightness, contrast, scaling, shading and other characteristics of the scanned images through simple commands transmitted from the 1108 or 1186. Two basic scanning modes are supported: Line Art mode for accurate capture of completely black-and-white material, and Halftone mode for faithful reproduction of material with varied shading. Mixed-mode scanning is also available.

With the MICROTEK software package you will be able to: Set the scanner to capture images of all kinds, with desired visual effects, and transmit them to the 1108/1186, save scanned images to disk, floppy or file server for later reloading to recreate images and print scanned images to a Xerox 4045 or 8044 laser printer.

**SOFTWARE REQUIRED**

MICROTEK.DFASL

MICROTEKPRINT.DFASL (if you have a Xerox 4045 or 8044 laser printer)

DLRS232C.LCOM

EDITBITMAP.LCOM

READNUMBER.LCOM

4045XLPSTREAM.DFASL (if you have a Xerox 4045 laser printer)

**FONTS USED**

MODERN 10, 12 BOLD

Other useful software for manipulating the scanned image:

Lispuser's Packages:

ACTIVEREGIONS, ACTIVEREGIONS2, AIREGIONS, FILLREGION

**HARDWARE REQUIRED**

Xerox 1108 with RS232C port (E-30 upgrade kit). It is also recommended that the 1108 have 3.5 meg of memory and a floating point processor (CPE board) to enable faster scanning and creation of bitmaps.

Xerox 1186. It is also recommended that the 1186 have 3.7 meg of memory.

Microtek MS-300, MS-300A, or MSF-300C Intelligent Image Scanner with optional serial port.

### CABLE CONFIGURATION

Note that the cable configuration is DIFFERENT for the MSF-300C scanner. Plugging a standard RS232C cable into the MSF-300C DB25 connector may result in damage to the equipment.

#### RS232C Port (DTE)      MICROTEK MS-300, MS-300A - DB25 Connector

| Signal  | Pin | Pin | Signal  |
|---------|-----|-----|---------|
| FGround | 1   | 1   | FGround |
| TD      | 2   | 3   | RD      |
| RD      | 3   | 2   | TD      |
| Sground | 7   | 7   | Sground |

Pins 5, 6, 8 and 20 are jumpered together on the RS232C port end of the cable.

#### RS232C Port (DTE)      MICROTEK MSF-300C- DB25 Connector

| Signal | Pin | Pin | Signal |
|--------|-----|-----|--------|
| TD     | 21  | 3   | RD     |
| RD     | 9   | 2   | TD     |
| Ground | 5,7 | 7   | Ground |

### DOCUMENTATION REQUIRED

Microtek MS-300, MS-300A, or MSF-300C Intelligent Image Scanner Operation Manual

### LOADING MICROTEK

Make sure that DIRECTORIES contains the directory where the required software is located. When the file MICROTEK.DFASL is loaded, the item "MicrotekScanner" will be added to the Background menu. If you have a Xerox 4045 or 8044 laser printer load MICROTEKPRINT.DFASL. If you have a Xerox 4045 laser printer load 4045XLPSTREAM.DFASL. Your 4045 laser printer should be connected to the TTY/DCE port.

### RUNNING MICROTEK

The process of running the Microtek scanner software consists of three phases: Scanner initialization, scanning, and creating a bitmap of the scanned image that can eventually be printed. Each of these are controlled by different menus within the Microtek Scanner Control Window.

### SCANNER INITIALIZATION

Set the Microtek scanner so that it is operating at 19200 baud by setting its internal DIP switches (See Microtek Operating Manual for details). Turn on the Microtek scanner. Select "MicrotekScanner" from the background menu and the Microtek Scanner Control window (figure 1) and Microtek Scanner Pagemap window (figure 2) will be created. (Note you may have to do a control-E and retry if cursor flashes while trying to create the control window). The scanner pagemap window is used to select the area of the image to be scanned and to select the page length. The scanner control window is used to set all other scanner parameters, start and stop scanning as well as to initiate creation and printing of scanned image bitmaps. After these windows have been created, the RS232 port will be initialized to

19200 baud and an attention command will be sent to the scanner. If all cables are connected properly and the scanner is on, the message "MICROSCAN 300(A) V# is ready" will be displayed in the Microtek Status Window. If the cable is configured incorrectly or the scanner is not on or ready the message "Microtek Not Responding ... Check scanner and cable" will appear instead.

**Microtek Status Window**

FIGURE 1 - MICROTEK SCANNER CONTROL WINDOW

Before scanning can be initiated, a number of parameters have to be set by the user via the Microtek Command Menu and Microtek Configuration Menu as follows:

**Microtek Command Menu:**

**Output FileName** Left buttoning on this item allows you enter the name of the file on disk, floppy or filesaver where the scanned data is to be saved. Be sure to type a carriage return to terminate this entry.

**Microtek Configuration Menu:**

**Reduction** Left button on the number next to the item Reduction and a menu will appear. Reduction can be changed from 0%, which corresponds to scanning at 300 dots per inch (DPI) to 75%, which corresponds to 75 DPI.

**GrayLevel** Left button on the number next to the item GrayLevel and a menu will appear allowing you to choose from a selection of gray levels based on grain size and number of gray levels within that grain size.

**Contrast** Left button on either the the left or right arrow to either decrease or increase the contrast setting.

**Brightness** Left button on either the the left or right arrow to either decrease or increase the brightness setting.

**FIGURE 2 - MICROTEK SCANNER PAGEMAP WINDOW**

**BackGround** Select either HALFTONE or LINEART as the primary scanning mode for the image. Line Art mode is for accurate capture of completely black-and-white material, and Halftone mode for faithful reproduction of material with varied shading.

**Pagelength** Move the cursor to the vertical ruler of the page map ( figure 2 ). The cursor will change to a right pointing triangle. Position this triangle and left-button to select the pagelength. The page length will also show up in the configuration menu. The page length should be set so that it is longer

than the actual page length of the document to be scanned. Otherwise you will get a paper jam message at the completion of scanning. The minimum page length is 3 inches and the maximum page length is 14 inches.

**Frame** The scanning frame is an area within the document that will be scanned. The maximum scanning frame is 8.5" by 14". Left button on the item Frame and you will be prompted to sweep out an area on the scanner page map to select the primary area to be scanned. The horizontal and vertical rulers and the page map grid dots can be used as a guide in determining the dimensions of the scanning frame. When the the scanning frame has been swept out, a box of the scanned area will be drawn on the page map and the actual X and Y coordinates of the top lefthand corner and lower righthand corner will appear next to corresponding items on the configuration menu (See Figure 2).

**Windows 1- 4** Windows are areas within the scanning frame that are scanned in a different mode from the rest of the frame. If LINEART mode is selected as the background, all material in any windows you set will be scanned in Halftone mode, and vice versa.

The method used to set the windows is similar to that used to set the scanning frame except that you first need to specify whether the window is to be selected or not. This is done by left buttoning on the YES/NO indicator next to each window. A menu will pop-up and will allow you select "yes" or "no". After making your selection, left buttoning on the appropriate Window # will cause you to be prompted to sweep out an area within the scanning frame. Each selected window will be displayed and have a unique shade to it (See Figure 2). The only restriction is that the scanning mode must not change more than twice in one 8.5" horizontal scan line. Thus, if two windows lie across the same scan line they must extend to the edges of the page setting area. (Note that material to the left and right of the frame is scanned but not transmitted to the 1108.) You can select different windows for halftone vs lineart mode by switching between backgrounds. The item above WINDOW1 indicates which window mode is selected. An illegal window setting will result in an error message when you attempt to scan. Also note that the windows will be displayed on the scanner pagemap only if there is a "yes" next to the window number.

## SCANNING

After the Microtek scanning parameters have been initialized, the document to be scanned should be placed in the scanner top-first with the image to be scanned facing away from the user. Scanning is initiated by left-buttoning SCAN on the Microtek Command Menu. The software first creates a scratch file in {CORE} for storage of the incoming data. It then sends the scanning parameters to the scanner and if all are valid the scanning process starts as indicated by movement of the rollers. You have up to 5 minutes to insert a document before the scanner automatically stops. After scanning has been completed you will be notified in the status window that it is saving the core file to the file specified in Output Filename. It takes approximately 20 minutes to scan an 8.5" x 11" document at 300 DPI.

You may stop the scanning at any time by selecting STOP. The document will be ejected and the scanner reset. You can also explicitly reset the scanner by selecting RESET. This closes the scanner scratch file if it is open, sends a reset command to the scanner and then sends the attention command. If everything is reset properly, you will get the message "MICROSCAN 300(A) V# is ready" in the status window.

## CREATING BITMAPS OF SCANNED IMAGES

The Microtek Display Menu is used to create bitmaps from a file that contains scanned data. Select SOURCE FILENAME and enter the name of the file that contains the scanned data. Select BITMAP NAME and enter the name of a variable that you would like the bitmap bound to. **Be sure to type a carriage return to terminate the entry of each of these items.** Left button on the number next to

SHRINKFACTOR and choose a factor by which you want the bitmap shrunk. The default value is 1. Left button on the item next to ROTATION and choose how you want the scanned image to be rotated. The default is "none." After these items have been set, you can then select CREATE BITMAP to start the bitmap creation process. The status window will be updated as it proceeds to create the bitmap and finally, you will be prompted to sweep out a scrollable window to display the bitmap. NOTE: Depending on the size of the bitmap, rotation may take a "very" long time and will look like your machine has frozen...be patient, it will come back. If you desire to save the bitmap(s) on a file you can do the following:

```
(SETQ filenameCOMS '((VARS bitmapname1 bitmapname2 etc))).
(MAKEFILE '{device}<directory>filename)
```

### PRINTING BITMAPS OF SCANNED IMAGES TO A XEROX LASER PRINTER

If you have the package MICOTEKPRINT loaded you will have a MicrotekPrint Menu under your display menu (See Figure 1). Select BITMAPNAME on the display menu and enter the name of the bitmap that you would like to print. To select where on the page the bitmap is printed, left button XPOS and YPOS and enter a number. For the 4045 laser printer the values of XPOS can be between 0 - 2550 and YPOS, between 0 - 3300. 1" = 300 print units o 4045 . For an 8044 Interpress laser printer the values of XPOS can be between 0 - 21590 and YPOS, between 0 - 27940. 1" = 2540 Interpress units. The scale that an image is printed at is dependent upon its initial scanned reduction/DPI. You can increase or decrease the scale at which the bitmap is printed by buttoning on the number next to the item SCALE and selecting a scaling factor. On an 8044 Interpress printer a scale of 8:1 will magnify an image by 8 times on printing , 1:1 will print at true size and 1:8 reduce the image by 8 times. Values in between are also available. On a 4045 laser printer only a limited number of scale factor are availble and is dependent upon the original scan reduction as shown in the table below.

| REDUCTION (%) | RESOLUTION (DPI) | SCALES ALLOWED |
|---------------|------------------|----------------|
| 0             | 300              | 1:1, 2:1, 4:1  |
| 5             | 285              | 1:1, 2:1, 4:1  |
| 10            | 270              | 1:1, 2:1, 4:1  |
| 15            | 255              | 1:1, 2:1, 4:1  |
| 20            | 240              | 1:1, 2:1, 4:1  |
| 25            | 225              | 1:1, 2:1, 4:1  |
| 33            | 200              | 1:1, 2:1, 4:1  |
| 35            | 195              | 1:1, 2:1, 4:1  |

| REDUCTION (%) | RESOLUTION (DPI) | SCALES ALLOWED |
|---------------|------------------|----------------|
| 40            | 180              | 2:1, 1:1, 1:2  |
| 45            | 165              | 2:1, 1:1, 1:2  |
| 50            | 150              | 2:1, 1:1, 1:2  |
| 55            | 135              | 2:1, 1:1, 1:2  |
| 60            | 120              | 2:1, 1:1, 1:2  |
| 67            | 100              | 1:1, 1:2, 1:4  |
| 70            | 90               | 1:1, 1:2, 1:4  |
| 75            | 75               | 1:1, 1:2, 1:4  |

Select **PRINT** to initiate the printing process. **NOTE:** The amount of reduction that you will be able to do is dependent upon the number bits that were originally scanned in. If you make the scale too small nothing will be printed out.

#### OTHER ITEMS AND GENERAL COMMENTS

On the Microtek Command Menu, left buttoning the item **PAGEMAP** will alternately open and close the scanner pagemap window. Left buttoning on the item **QUIT** will close the input and output streams to the scanner, shutdown the RS232C port and close the scanner pagemap and control windows. The following icon will be displayed if you shrink the Microtek Scanner Control window.

The Microtek Pagemap window will close when you shrink the Microtek Scanner Control window and has to be explicitly opened when the Microtek Scanner Control window is expanded again. This is done by buttoning on **PAGEMAP** in the Microtek Command Menu window.

Within Interlisp you normally cannot create bitmaps larger than approximately 2.1 million pixels (about 1400 x 1400). The Microtek scanner software allows you to create bitmaps much larger than this but at the cost of using a correspondingly large amount of virtual memory. If you are near your maximum vmemsize, as determined by comparing (VMEMSIZE) to (VOLUMESIZE 'volumename), there is a good chance you could crash your system if you create a very large bitmap...caveat emptor. In addition you will not be able to call the function **EDITBM** to edit bitmaps larger than 2.1 million pixels.

The reduction % used to scan the original image is stored on the property list of the atom that the bitmap is bound to. It is saved as the property "Resolution" and is in %. This is used to determine the appropriate values that will make an image 1:1 when printed. If you attempt to print a bitmap to an Interpress printer that was not created by use of the Microtek scanner software you will be prompted to enter a scale explicitly. The following table indicates the 8044 laser printer scale used for scanned images and can be used as a guide when attempting to print bitmaps not created by the Microtek software.

| <u>REDUCTION (%)</u> | <u>RESOLUTION (DPI)</u> | <u>SCALE</u> |
|----------------------|-------------------------|--------------|
| 0                    | 300                     | .240         |
| 5                    | 285                     | .252         |
| 10                   | 270                     | .266         |
| 15                   | 255                     | .282         |
| 20                   | 240                     | .300         |
| 25                   | 225                     | .320         |
| 33                   | 200                     | .360         |
| 35                   | 195                     | .369         |
| 40                   | 180                     | .400         |
| 45                   | 165                     | .439         |
| 50                   | 150                     | .480         |
| 55                   | 135                     | .533         |
| 60                   | 120                     | .600         |
| 67                   | 100                     | .720         |
| 70                   | 90                      | .800         |
| 75                   | 75                      | .960         |

Further information about the Microtek scanner can be obtained from:

## NSCOPYFILE

---

---

By: Bill van Melle (vanMelle@Xerox.com)

The module NSCOPYFILE modifies COPYFILE so that if both the source and destination files are on NS file servers, the copying is done by an NSFiling-specific copy routine. This routine copies *all* attributes of the source, including non-standard ones, such as those used by Viewpoint. Thus, you can safely copy Viewpoint files from inside Lisp without losing information. In addition, if the copy is from an NS file server to itself, the copy is performed by the server itself, which is considerably faster than shipping the file over the Ethernet.

In addition, you can also copy entire directories, by specifying directory names as the source and destination, e.g.,

```
(COPYFILE "{FS:}<Carstairs>Lisp" "{FS:}<Calvin>Lisp>Current")
```

The destination directory must not already exist, since this operation creates an entirely new directory, whose contents are a copy of all the source directory's offspring, to all levels. If the destination directory happens to exist but has no children, it is considered vestigial and is quietly deleted first (Lisp usually suppresses such directories when performing a directory enumeration).

You can also use RENAMEFILE in the same manner to either rename a directory, or to move an entire directory and its descendents to a new node in the file server's hierarchy, or to a new server altogether. You must, of course, have access rights to delete the source directory *and* all its children, and the destination must be on an NS file server.

A word about protection: when a file is copied or moved, the new file is given "defaulted" access rights, i.e., its protection is set as specified by its new parent (sub)directory, just as if you had created the file afresh by any other means. Thus, if the original file happened to have its own explicit protection, that protection is ignored. When copying or moving an entire directory, only the top-level directory receives default protection, so if any individual descendent file had non-default protection, that protection is copied verbatim. This can lead to confusion—you may want to use the NSPROTECTION module to change the new directory's descendents to default protection. See the documentation of NSPROTECTION for more discussion about protection issues. Note that if a file/directory is renamed within the same parent directory, the operation is considered merely "changing the name", and its protection is left unchanged.

Note: If you are using the FILEWATCH module, be aware that files being copied between NS servers do not appear (because the files are not opened by the normal Lisp file system).

**POSTSCRIPT**

---

---

By: Matt Heffron (BEC.HEFFRON@ECLA.USC.EDU)

**INTRODUCTION**

The PostScript package defines a set of imageops for printers which understand the PostScript page description language by Adobe. At Beckman we have successfully used TEdit, Sketch, LISTFILES, and HARDCOPYW to an Apple LaserWriter and an AST TurboLaser PS. The PostScript imagestream driver installs itself when it is loaded. All symbols in the PostScript driver are located in the INTERLISP: package.

**VARIABLES**

POSTSCRIPT.FONT.ALIST [InitVariable]

POSTSCRIPT.FONT.ALIST is an ALIST mapping Xerox Lisp font names into the root names of PostScript font files. It is also used for font family coercions. The default value should be acceptable for any of the fonts which are built into the Apple Laserwriter.

POSTSCRIPTFONTDIRECTORIES [InitVariable]

POSTSCRIPTFONTDIRECTORIES is the list of directories where the PostScript .PSCFONT font files can be found. The default value is: ("{DSK}<LISPFILES>FONTS>PSC>").

\POSTSCRIPT.SHORTEDGE.SHIFT [InitVariable]

\POSTSCRIPT.SHORTEDGE.SHIFT is the distance (in points) to shift the image perpendicular to the short edge of the paper. A positive value gives a shift upward in portrait mode, and to the right in landscape mode. The default value is: 0.

\POSTSCRIPT.LONGEDGE.SHIFT [InitVariable]

\POSTSCRIPT.LONGEDGE.SHIFT is the corresponding variable for shifts perpendicular to the long edge of the paper. A positive value here gives a shift to the right in portrait mode and downward in landscape mode. The default value is: 0.

\POSTSCRIPT.SHORTEDGE.PTS [InitVariable]

\POSTSCRIPT.SHORTEDGE.PTS indicates the printable region of the page (in points) along the short edge of the paper. It should be adjusted to allow for any shifts of the image (see above). The default value is: 576 (= 8 inches).

\POSTSCRIPT.LONGEDGE.PTS [InitVariable]

\POSTSCRIPT.LONGEDGE.PTS indicates the printable region of the page (in points) along the long edge of the paper. It should be adjusted to allow for any shifts of the image (see above). The default value is: 786.24 (= 10.92 inches).

#### HINT

The AST TurboLaser PS has an imageable area on the page which is a different size than that of the Apple LaserWriter. The values of \POSTSCRIPT.SHORTEEDGE.PTS and \POSTSCRIPT.LONGEDGE.PTS for the AST are 575.76 and 767.76, respectively.

\POSTSCRIPT.MAX.WILD.FONTSIZE [InitVariable]

\POSTSCRIPT.MAX.WILD.FONTSIZE indicates the maximum point size that should be returned from FONTSAVAILABLE when the SIZE argument is wild (i.e. \*). All integer point sizes from 1 to \POSTSCRIPT.MAX.WILD.FONTSIZE will be indicated as available. The default value is: 72.

POSTSCRIPT.PREFER.LANDSCAPE [InitVariable]

POSTSCRIPT.PREFER.LANDSCAPE indicates if the OPENIMAGESTREAM method should default the orientation of output files to LANDSCAPE. It can have one of three values: NIL, T, or ASK. NIL means prefer portrait orientation output, T means prefer landscape, and ASK says to bring up a menu to ask the preferred orientation if it wasn't explicitly indicated in the OPENIMAGESTREAM call (with the ROTATION option). The default value is: NIL.

POSTSCRIPT.TEXTFILE.LANDSCAPE [InitVariable]

POSTSCRIPT.TEXTFILE.LANDSCAPE indicates if the printing of TEXT files (e.g. LISTFILES, ...) should force the orientation of output files to LANDSCAPE. The default value is: NIL.

POSTSCRIPT.BITMAP.SCALE [InitVariable]

POSTSCRIPT.BITMAP.SCALE specifies an independent scale factor for display of bitmap images (e.g. window hardcopies). Values less than 1 will reduce the image size. (I.e. a value of 0.5 will give a half size bitmap image.) The position of the scaled bitmap will still have the SAME lower-left corner (i.e. the scaled bitmap is not centered in the region of the full size bitmap image). The default value is: 1.

#### HINT

Setting POSTSCRIPT.BITMAP.SCALE to 0.96, instead of 1, will give cleaner BITMAP images on a 300 dpi printer. (This corrects for the 72 ppi imagestream vs. the 75 dpi printer, using 4x4 device dots per bitmap pixel.) Also, values of 0.24, 0.48 and 0.72, instead of 0.25, 0.5 and 0.75, will also give cleaner images for reduced size output. In general, use integer multiples of 0.24 for a 300 dpi printer.

POSTSCRIPT.TEXTURE.SCALE [InitVariable]

POSTSCRIPT.TEXTURE.SCALE specifies an independent scale for the display of bitmap textures. The value represents the number of device space units per texture unit (bitmap bit). The default value is 4, which represents each bit of the texture as a 4x4 block, so that textures are approximately the same resolution as on the screen (for 300 dpi output devices, such as the Apple Laserwriter).

The PostScript package extends the allowed representations of a texture, beyond 16-bit FIXP and 16x16 bitmap, to ANY square bitmap. (If the bitmap is not square, its longer edge is truncated from the top or right to make it square.) Use this feature with caution, as large bitmap textures, or sizes other than multiples of 16 bits square, require large amounts of storage in the PostScript interpreter (in the printer controller), and can cause limitcheck errors when actually printing.

Anywhere that a texture or color can be used on an imagestream or in the specification of a BRUSH, you can instead give a FLOATP between 0.0 and 1.0 (inclusive) to represent a PostScript halftone gray shade. (0.0 is black and 1.0 is white. Specifically, the value sets the brightness of the shade.) The value you specify will not be range checked, and will be passed directly through to the PostScript setgray operator. (E.g. you can pass 0.33 as the color to DRAWLINE to get a dark gray line with approximately 67% of the pixels in the line black.)

POSTSCRIPT.IMAGESIZEFACTOR

[InitVariable]

POSTSCRIPT.IMAGESIZEFACTOR specifies an independent factor to change the overall size of the printed image. This re-sizing affects the entire printed output (specifically, it superimposes its effects upon those of POSTSCRIPT.BITMAP.SCALE and POSTSCRIPT.TEXTURE.SCALE). Values greater than 1 enlarge the printed image, and values less than 1 reduce it. An invalid POSTSCRIPT.IMAGESIZEFACTOR (i.e. not a positive, non-zero number) will use a value of 1. The BITMAPSCALE function for the POSTSCRIPT printer type does NOT consider the POSTSCRIPT.IMAGESIZEFACTOR when determining the scale factor for a bitmap.

## MISCELLANEOUS

The SCALE of a PostScript imagestream is 100. This is to allow enough resolution in the width information for fonts to enable TEdit to correctly fill and justify text.

The first time any PostScript imagestream is created (even if only to hardcopy a bitmap or window) the DEFAULTFONT is instantiated (unless a FONTS option was given to the OPENIMAGESTREAM, in which case the initial font for the imagestream will be set to that font, or to the CAR if a list).

The PostScript imagestream method for FILLPOLYGON uses the global variable FILL.WRULE as the default value for the WINDINGNUMBER argument. (This is the same variable which is used by the DISPLAY imagestream method for FILLPOLYGON.)

The PostScript imagestream method for OPENIMAGESTREAM (and, therefore, SEND.FILE.TO.PRINTER), supports an IMAGESIZEFACTOR option to change the size of the printed image. The IMAGESIZEFACTOR re-sizing is combined with the POSTSCRIPT.IMAGESIZEFACTOR to produce an overall re-sizing of the printed image. A HEADING option is also supported to give a running header on each page of output. The value of the HEADING option is printed at the top left of the page, followed by "Page " and the appropriate page number. They are printed in the

DEFAULTFONT (unless a FONTS option was given to the OPENIMAGESTREAM, in which case it will be that font, or to the CAR if a list).

The PostScript package is contained in the files: POSTSCRIPT.LCOM & PS-SEND.LCOM, with the source in the files: POSTSCRIPT & PS-SEND. The module PS-SEND.LCOM is required and will be loaded automatically when POSTSCRIPT.LCOM is loaded. It contains the function which is called by SEND.FILE.TO.PRINTER to actually transmit the file to the printer. It is, by its nature, quite site specific, so it is in a separate file to make modifying it for any site relatively simple. System record declarations required to compile POSTSCRIPT can be found in EXPORTS.ALL.

I'm pretty sure that the output generated by the PostScript imageops fully conforms to the Adobe Systems Document Structuring Conventions, Version 2.0, January 31, 1987.

### Including Other PostScript Operations

If you wish to insert your own specific PostScript operations into a PostScript imagestream, you can do so with the following functions:

(POSTSCRIPT.OUTSTR *STREAM STRING*) [Function]

POSTSCRIPT.OUTSTR outputs a string or value to the imagestream. *STREAM* must be an open PostScript imagestream. *STRING* is the value to output (STRINGP and LITATOM are most efficient, but any value can be output (its PRIN1 pname is used)).

(POSTSCRIPT.PUTCOMMAND *STREAM STRING ... STRING*) [NoSpread Function]

POSTSCRIPT.PUTCOMMAND is more general for sequences of commands and values. It calls POSTSCRIPT.OUTSTR repeatedly to output each of the *STRING* arguments to *STREAM*.

(\POSTSCRIPT.OUTCHARFN *STREAM CHAR*) [Function]

\POSTSCRIPT.OUTCHARFN is used to output the characters forming the text of a PostScript string (e.g. the argument to a show or charpath operator). *STREAM* is the open PostScript imagestream to output to, and *CHAR* is the CHARCODE of the character to output. The / (slash), ( and ) (parenthesis) characters will be quoted with /, and characters with ASCII values less than 32 (space) or greater than 126 (tilde) will be output as *lnnn* (in octal). \POSTSCRIPT.OUTCHARFN will output the ( character to open the string, if necessary. Use POSTSCRIPT.CLOSESTRING (below) to close the string.

(POSTSCRIPT.CLOSESTRING *STREAM*) [Function]

POSTSCRIPT.CLOSESTRING closes a PostScript string (e.g. the argument to a show or charpath operator). *STREAM* is the open PostScript imagestream. It is important to use POSTSCRIPT.CLOSESTRING to output the ) character to close the string, because it also clears the stream state flag that indicates that a string is in progress (otherwise, the next POSTSCRIPT.PUTCOMMAND would output the commands to close the string and show it).

### Warning

Do not attempt to create a PostScript font larger than about 600 points, as much of Interlisp's font information is stored in SMALLP integers, and too large a font would overflow the font's height, or the width for any of the wider characters. (I know that 600 points is a ridiculously large limit (about 8.3 inches), but I thought I'd better mention it, or someone might try it!)

**Changes from the Lyric Release**

The Medley release of this PostScript imagestream driver changed the default value of POSTSCRIPT.TEXTFILE.LANDSCAPE from T to NIL. It also added the support for the HEADING option.

**Known Problems/Limitations**

The output generated for a PostScript imagestream is rather brute force. It isn't particularly careful to generate the smallest output file for a given sequence of operations. Specifically, it often generates extra end-of-lines between PostScript operator sequences (this has no effect on the printed output, only on the file size).

Using BITMAPs or Functions as BRUSH arguments to the curve drawing functions is not supported, nor is using a non-ROUND BRUSH with DRAWCIRCLE or DRAWELLIPSE.

There is no support for NS character sets other than 0, and there is no translation of the character code values from NS encoding to PostScript encoding.

There is no support for color.

\POSTSCRIPT.OUTCHARFN is pretty wimpy in its handling of TAB characters. It just outputs 8 SPACES for the TAB.

I haven't yet documented how to build the .PSCFONT files for any new fonts that become available, I'll do that eventually.

---

---

**PS-PATCH**

---

---

By: Will Snow (snow.envos@xerox.com)

Requires: POSTSCRIPT

This module fixes some bugs in software other than postscript. If you are going to load sketch, load it BEFORE you load this patch. If you load sketch after loading this patch, evaluate the following form in an Interlisp Executive:

```
(MOVD (QUOTE NEW-SK-PICK-FONT) (QUOTE SK.PICK.FONT) NIL T)
```

This will make the printing of sketches with text in them reasonable.

---

**PS-RS232**

---

By: Matt Heffron (mheffron@orion.cf.uci.edu)

Requires: POSTSCRIPTSTREAM, PS-SEND, DLRS232C

The module PS-RS232 defines a printing host named PS-RS232 which sends PostScript output to a printer over the {RS232} port of the 11xx. It also puts a function onto AROUNDXITFNS which reinitializes the {RS232} port after returning from LOGOUT. The BaudRate and other parameters of the {RS232} port are controlled by the following variables.

**VARIABLES**

PS-RS232-BAUD [InitVariable]

This is the BaudRate for the {RS232} port output stream. Defaults to: 9600.

PS-RS232-DATABITS [InitVariable]

This is the BitsPerSerialChar for the {RS232} port output stream. Defaults to: 8.

PS-RS232-PARITY [InitVariable]

This is the Parity for the {RS232} port output stream. Defaults to: NONE.

PS-RS232-STOPBITS [InitVariable]

This is the NoOfStopBits for the {RS232} port output stream. Defaults to: 1.

PS-RS232-FLOWCONTROL [InitVariable]

This is the FlowControl for the {RS232} port output stream. Defaults to: XOnXOff.

## XORcursorPatch

---

---

By: Christopher Lane (Lane@sumex-aim.stanford.edu)

This document last edited on July 22, 1987

### INTRODUCTION

This module allows the 1186/Daybreak (only) users to twiddle the hardware bits so that they can have an inverting cursor (white on black and black on white instead of black on everything) and provides a patch to keep the system from undoing the effect when calling VIDEOCOLOR to reset the screen.

### USE

(DOVE.XOR.CURSOR *FLG*)

[Function]

The argument *FLG*, if T, will switch to the inverting cursor mode. If *FLG* is NIL it will switch back to normal mode. If *FLG* is a number between 0 and 15 then it is used as the 'mix-in rule' and has an effect according to the table below.

### Mix-in rules

|    | Screen    | Source   | Cursor Mode |                                                                                                                                                                                                                                                                                                                                                  |
|----|-----------|----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | All Black | None     |             | This table is relative to the normal mode of the display (1), normal screen, normal cursor in paint mode. The inverted display, (VIDEOCOLOR T), would be 13, inverted screen and inverted cursor in paint mode. There is probably a more precise or logical way to notate these modes, but this should give you a rough idea of what's available |
| 1  | Normal    | Normal   | Paint       |                                                                                                                                                                                                                                                                                                                                                  |
| 2  | Normal    | Inverted | Paint       |                                                                                                                                                                                                                                                                                                                                                  |
| 3  | Normal    | None     | mode.       |                                                                                                                                                                                                                                                                                                                                                  |
| 4  | Inverted  | Normal   | Erase       |                                                                                                                                                                                                                                                                                                                                                  |
| 5  | All Black | Inverted | Paint       |                                                                                                                                                                                                                                                                                                                                                  |

| 12 | Inverted  | None     |             |                                                                                                                                                                                                                                                                                                                                                  |
| 13 | Inverted  | Inverted | Paint       |                                                                                                                                                                                                                                                                                                                                                  |
| 14 | Inverted  | Normal   | Paint       |                                                                                                                                                                                                                                                                                                                                                  |
| 15 | All White | None     |             |                                                                                                                                                                                                                                                                                                                                                  |

### Note

The function is set up such that when trying different modes, you must do a (DOVE.XOR.CURSOR) (no argument) between calls.

No warranty expressed or implied, but we have been using it locally without problem (at least as far as I know). Enjoy.

The following notes explain my (woz) idea of what the edit-interface should be responsible for, and what constitutes and "editor".

An editor is a symbol whose function takes the args (structure props options) and starts an interactive editor on the structure. PROPS is a property list, and OPTIONS is a list of keywords, both affecting the behavior of the editor. The property :completion-fn specifies the function to be called when the user completes the edit. The completion-fn will be called with the arguments (structure props options changed?), where structure is the edited structure (even on abort, so that the edit interface could implement "undo abort"), props and options are as specified on the call to the editor and will be used to figure out what to do with this completion, and changed? is NIL (no changes made), T (changes made), or :ABORT (user wants to abort changes). It is then up to the completion function to do the right thing with the result of the edit.

The goal is that the editor doesn't know anything about who started it, where the structure came from, or what to do with it when it's done. And the edit-interface doesn't know anything about the editor's data structures.

In the case of open edit sessions (open or shrunk):

If the editor is told to start an edit, the editor must look for one already existing that matches (this can't be the responsibility of the edit interface, because it doesn't know about existence of open edits). the editor should restart the existing edit, processing any new props or options appropriately.

The markaschanged issue:

Since the editor knows it may have open edits, it needs to provide a hook for when the world gets changed underneath the editor. in this world this means markaschanged. in this case the editor should try to restart itself with the new structure. in other words, sedit::markaschangedfn should call edit-definition to start a new edit. the editor will then notice it has a matching edit open and restart itself with the new info.

This model is complicated by the fact that markaschanged gets called as a result of completion.

Presently \*ignore-changes-on-completion\* controls the behavior in this case. Ideally, the editor would just say "i know it got changed, i just changed it!", and it would ignore the call.

The new version of SEdit (1/25/91) is very close to this definition, with the following exceptions, which can be fixed upon implementation of this edit interface design:

- the completion-fn is called with (context structure changed?) since all of SEDITE's completion-fns expect these args. this should be fixed in handle-completion.
- in the abort case, undo is run until there are no more changes to undo, since sedit is sometimes handed structures "in place", destructive edits need to be undone, and thus the completion-fn never gets to see the edits. this can be fixed in the function complete.

-

To make this editor active, call (il:editmode editor-name), where editor-name is the symbol defined above. The function xcl::edit will then start the active editor.

xcl::edit-expression provides an example of starting the editor on an unnamed structure, where eqness is expected upon completion.

xcl::edit-definition provides a replacement for il:editdef, if il:getdef and il:putdef work correctly on all types.

:dontwait

the editor (sedit) should not wait. don't wait is part of the editinterface features. if its going to wait, the editinterface should create the event and bind it in the completionfn to the notified by the completionfn.

need published edit-expression command. same as ed, but takes an expression, waits for once-only completion, and returns the expression. eg for FIX

sedit should provide a published interface to creating gaps, for use by make-prototype-defn.

edit interface may need a way to ask editor if it has an open edit for name/type

deal with editdates

an editor used to install itself by replacing EDITL and EDITE, then editmode was created to look for Definition-for-EDITE property on the symbol returned by editmode. now an editor is defined as a function which takes (expr props options) and implements at least the props :completion-fn

and :root-changed-fn. EDITMODE then returns the name of this function so the current editor can be applied.

# TCP-IP

---

The Transport Control Protocol - Internet Protocol (TCP-IP) family of networking protocols was developed under the auspices of the Department of Defense to standardize communication mechanisms within Department of Defense networks such as the ARPANET.

The protocols are documented in a collection of working papers known as Requests for Comments (RFCs). Appropriate RFC numbers appear throughout this document as new protocols are introduced.

## Requirements

---

TCP-IP has both hardware and software requirements.

### Hardware

- Ethernet
- Cooperating host (yours or theirs)
- 110X/118X with an Ethernet controller (usually co-resident on an otherwise inhabited module)
- XCVR interface cable
- XCVR installed on an Ethernet with a logical (direct or internet) connection to the cooperating host.

### Software

You need the files enumerated in the section titled "Interlisp Files." Files loaded by the high-level modules TCPFTP, TCPFTPSRV, TCPCHAT, and TCPTFTP automatically load their dependencies. If you load files from floppy, you must load their dependencies first:

| File       | Dependencies                |
|------------|-----------------------------|
| TCP        | TCPLLLIP                    |
| TCPCHAT    | TCP, CHAT                   |
| TCPCONFIG  | None                        |
| TCPDEBUG   | TCP                         |
| TCPDOMAIN  | TCPUDP                      |
| TCPFTP     | TCPNAMES, TCP               |
| TCPFTPSRV  | TCPFTP                      |
| TCPHTE     | None                        |
| TCPLLAR    | None                        |
| TCPLLLICMP | None                        |
| TCPLLLIP   | TCPHTE, TCPLLLICMP, TCPLLAR |
| TCPNAMES   | None                        |
| TCPTFTP    | TCPUDP                      |
| TCPUDP     | TCPLLLIP                    |

## User Interface

---

TCP does not have a user interface module of its own. Its functions and variables are accessible via an Interlisp Executive, and you can direct some of its debugging information to a window.

As a network protocol module, it extends capability to other programs which may have their own window interfaces, for example, Chat and FileBrowser.

## Installation

---

The first step in installing TCP-IP is to add your workstation to a network supporting TCP-IP and communications with others on the net. The rest of this section contains a step-by-step set of directions for this installation.

After you are on the network, load the required .LCOM modules for the type of service you want. For a full description of these modules, see the Interlisp Files section.

| Module    | Implementation                      |
|-----------|-------------------------------------|
| TCPFTP    | TCP-based file transfer protocol    |
| TCPFTPSRV | TCP-based FTP server                |
| TCPCHAT   | TELNET protocol for the Chat system |
| TCPTFTP   | TFTP protocol                       |

### Obtaining Network Addresses

The first thing you need to do is to get a TCP-IP address assigned to each of your workstations from your network administrator. If your site supports Domains, get the name of your local domain and the addresses of your domain server(s) from your network administrator. You will also need to know the network addresses and operating system of the hosts you want to communicate with and the addresses of any network gateways you have.

Note: The maximum length of the domain and organization fields is 20 characters each.

Be sure to find out whether your net is a true Class A, B or C network and is not broken up into subnets. If it is broken up into subnets, be sure to read the discussion on SUBNETMASKs in the Primer on IP Networks section.

### Differences between TCP and the Medley File Systems

When running TCP-IP to a Sun from an 11xx, directory enumeration on an unmatched directory path returns a listing for the top-level directory of the logged-in user. The TCPFTP protocol does not support directory creation.

Warning: When running TCP-IP to a Sun, a file which is still open on the Sun can be deleted.

### Creating HOST.TXT File

Create a HOSTS.TXT file containing entries for the TCP-IP hosts needed by the user community and place a copy of the file on either a directory contained in the DIRECTORIES search path of each workstation on the net or the local disk of each Interlisp workstation.

The following is a sample HOSTS.TXT file:

```
; Hosts.txt,
; Internet Hosts Table for Networks 192.20.10.0 and 174.23.0.0
; 12-Dec-86
;
; The format of this file is documented in RFC 810, "DoD Internet
; Host Table Specification", which is available online at SRI-NIC
; as the file
; [SRI-NIC] <RFC>RFC952.TXT
;
; It may be retrieved via FTP using username ANONYMOUS with
; any password.
;
; or as the file
;
; [INDIGO] <RFC>RFC952.TXT
; Read access to GV World. Valid GV credentials required.
;
; The format for entries is:
;
; GATEWAY: ADDR, ADDR : NAME : CPUTYPE : OPSYS : PROTOCOLS :
; HOST: ADDR, ALTERNATE-ADDR (if any): HOSTNAME,NICKNAME : CPUTYPE :
; OPSYS : PROTOCOLS :
;
; Where:
;; ADDR = internet address in decimal, e.g., 26.0.0.73
;; CPUTYPE = machine type (Xerox-11xx, VAX-11/780, SUN, etc.)
;; OPSYS = operating system (UNIX, TOPS20, TENEX, VMS, Interlisp, etc.)
;; PROTOCOLS = transport/service (TCP/TELNET, TCP/FTP, etc.)
;; : (colon) = field delimiter
;; :: (2 colons, NO space between) = null field
;
HOST : 192.20.10.1 : Bach : Xerox-1108 : Interlisp : TCP/TELNET, TCP/FTP
:
HOST : 192.20.10.3 : PARC-VAXC : VAX-11/780 : UNIX : TCP/TELNET, TCP/FTP
:
HOST : 192.20.10.15 : Oberon : VAX-11/780 : VMS : TCP/TELNET, TCP/FTP :
HOST : 192.20.10.71 : Explorer : TI-EXPLORER : TOPS-20 : TCP/TELNET,
TCP/FTP :
HOST : 174.23.77.22 : Sunrise : SUN : UNIX : TCP/TELNET, TCP/FTP :
HOST : 174.23.30.21 : Rutgers : VAX-11/780 : TOPS-20 : TCP/TELNET,
TCP/FTP :
HOST : 174.23.76.21 : Simba : SYMBOLICS : SYMBOLICS-3600 : TCP/TELNET,
TFP/FTP :
GATEWAY : 192.20.10.240, 174.23.77.250 : Hellsgate : VMS : IP/GW :
```

This example shows a host table that indicates that there are four hosts (Bach, PARC-VAXC, Oberon, and Explorer) on net 192.20.10.0, three hosts (Sunrise, Rutgers, and Simba) on net 174.23.0.0 and a gateway (Hellsgate) that connects the two.

In regard to the OPSYS field in the HOSTS.TXT file, it is preferable to use values recognized by the Lisp variable NETWORKOSTYPES. Interlisp is the default value if a host's OSType is not declared.

Note that if any host is accessible via another network protocol (for example, PUP or NS), you may desire to call the host by an unambiguous name when it is accessed via TCP. You can do this by giving it an unambiguous name in the HOSTS.TXT file.

If you ever modify the HOSTS.TXT table after TCP.LCOM has been loaded, use the function (`\HTE.READ.FILE 'HOSTTABLE`) to reread the file.

For example,

```
(\HTE.READ.FILE '{DSK}<LISPFILES>HOSTS.TXT)
```

TCP.ALWAYS.READ.HOSTS.FILE

[Variable]

Initially set to T. Setting it to NIL causes the system to parse the HOSTS.TXT file only when the filename (stored in the configuration file) is different from the previously read filename, or the write date of the file has changed. The HOSTS.TXT file will always be read at least once when loading the software into a clean sysout.

## Creating the Local IP.INIT File

TCP.CONFIGURE brings up a menu that you complete.

```
Exec 3 (XCL)
3/36> (tcp.configure)
#<window @ 47,55554>
3/37>
```

```
TCP Configuration
Apply! Reset! Quit!

Host Name: Panther
Host Address: 13.2.77.8
Network Address: 13.2.77.0
Subnet mask: 13.252.205.0
Default Gateway: 192.20.10.240
Local Domain:
Domain servers:
Hosts.txt file: {Dsk}<Lispfiles>HOSTS.TXT
```

```
Writing {dsk}ip.init... done.

TCP Configuration
Apply! Reset! Quit!

Host Name: Panther
Host Address: 13.2.77.8
Network Address: 13.2.77.0
Subnet mask: 13.252.205.0
Default Gateway: 192.20.10.240
Local Domain:
Domain servers:
Hosts.txt file: {Dsk}<Lispfiles>HOSTS.TXT
```

If any field does not apply to your site, leave it blank.

Selecting **Apply!** writes the file {DSK}<LISPFILES>IP.INIT to the local disk.

Note: The file {DSK}<LISPFILES>IP.INIT must exist on each Interlisp machine before TCP.LCOM is loaded. And this file *must* remain on the workstation and must not be copied to other workstations. Also, the font GACHA 12 MRR must be available.

Selecting **Reset!** resets the menu to the original state.

Selecting **Quit!** closes the window.

You must perform the TCP.CONFIGURE step individually on each workstation, but you need to perform it only once. As long as there is an IP.INIT file on the workstation, the TCP-IP module will be configured automatically whenever it is loaded or initialized.

If you change your IP.INIT file while TCP-IP is running, you will be prompted to confirm **Restarting TCP**. In most cases, you should confirm the restart.

## Adding Host and Operating System Names to NETWORKOSTYPES

The variable NETWORKOSTYPES is used during Chat to determine the sequence of characters to send when performing auto-login. There should be an entry in NETWORKOSTYPES for each TCP host that you want to communicate with in the form (TCPHOSTNAME . OSTYPE).

For example:

```
((SUNRISE . UNIX) (RUTGERS . TOPS-20) etc)
```

## End-of-Line Conventions

To ensure correct line spacing, set the TCPFTP.EOL.CONVENTION switch. The associated function takes one argument, TYPE, which sets it correctly. TYPE can be one of the following:

|       |                                     |
|-------|-------------------------------------|
| CR    | Set EOL to CR                       |
| LF    | Set EOL to LF                       |
| CRLF  | Set EOL to CRLF                     |
| OS    | Set it to something based on the OS |
| Other | Set it to the default (CRLF)        |

## Loading TCP

Make sure the variables `DIRECTORIES` and `LISPUSERSDIRECTORIES` point to the location of the `.LCOM` files of TCP-IP, or that they are in the connected directory.

You can then load `TCP.LCOM` which in turn loads its dependent files.

If you plan to do TCP file transfers, load `TCPFTP`.

If you plan to use the 11xx Lisp workstation as a `TCPFTP` Server host, load `TCPFTP.SRV`. To start the server, evaluate `(TCPFTP.SERVER)`. An Interlisp machine running the `TCPFTP` server should be identified as a TOPS-20 machine in the other Interlisp machines' `HOSTS.TXT` table. It will thus masquerade as a TOPS-20 server.

The rest is automatic. You can treat an Interlisp host running the server just like any other `TCPFTP` server. The default path for resolving filenames is `{DSK}<LISPFILES>`, but you can change or override it.

For example, assume `{ERIC}` is a machine running the FTP server. From another machine which has `TCPFTP` loaded, you can do `SEE {ERIC}{FLOPPY}FOO`, which will type out the file `FOO` located on the floppy drive of `{ERIC}`.

If you plan to Chat to a TCP host, load `CHAT`, `CHATTERMINAL`, `DMCHAT` and then `TCPCHAT.LCOM`. Be sure that hosts with which you wish to chat have their `NETWORKOSTYPES` set.

If you plan to use the TCP Trivial File Transfer Protocol, load `TCPTFTP`.

Interlisp's `TCPTFTP` also provides a `TCPTFTP` server. Load `TCPTFTP.LCOM` and evaluate `(TFTP.SERVER)`. You can then use the appropriate TFTP commands to copy files from the Interlisp machine; for example `TFTP.PUT` and `TFTP.GET`.

## Verifying TCP Connections

Load `TCPDEBUG`. Execute `(TCPTRACE T)` and you will be prompted to open a window to show TCP packets. Select `INCOMING`, `OUTGOING` and `CONTENTS` from the window's menu. If the host that you are communicating with has a TCP echoserver process you can then try `(TCP.ECHOTEST 'HOSTNAME 3)`. For example, using the above `HOSTS.TXT` file this would be `(TCP.ECHOTEST 'SIMBA 3)`.

You will be prompted to open a window for the echo test and should see text, for example:

```
This is byte number 21
This is byte number 45
This is byte number 69
```

You should also see packets being sent and received in the `TCPTRACE` window.

Note: If a remote host is not running a TCP echo server process you will not get this response.

---

## Connecting, Transferring Files, and Chatting to a Host

First log in to the host by typing `(LOGIN 'HOST)`; for example, `(LOGIN 'SUNRISE)`. You will then be prompted for a user name and password. This will be sent to the host when you attempt to `CONNECT` or `Chat`.

Use the command `CONN {HOST}<DIRECTORY>SUBDIR>` to connect to a particular host. The local directory delimiters `<` and `>` can be used when connecting or file transferring. When communicating with a remote host you can specify the directory path as `<DIRECTORY> SUBDIRECTORY> SUBDIRECTORY. . .`, and the appropriate delimiters are presented to the remote host. Determination of what delimiter is presented depends upon the value of the `OSTYPE` field in the `HOSTS.TXT` file. If the field is empty, `OSTYPE = 'Interlisp'` is the default.

Using the above `HOST.TXT` file as an example you can do the following:

```

 UNIX CONN {SUNRISE}<DIR>SUBDIR>SUBDIR>
 VMS CONN {OBERON}<DIR>SUBDIR>SUBDIR>
 TOPS-20 CONN {RUTGERS}<DIR>SUBDIR>
 SYMBOLICS-3600 CONN {SIMBA}<DIR>SUBDIR>

```

You can then do a `DIR` of the remote host, `COPYFILE` files to and from the host, assuming `TCPFTP` is loaded, `MAKEFILE`, etc.

Since the `TCPFTP` specification does not specify file type conventions, the variable `TCP.DEFAULT.FILETYPES` is used to associate a file's extension with the type of file it is. It is a list in the form (extension . type); for example,

```
((LCOM . BINARY) (TXT . TEXT) etc)
```

Since UNIX systems are case-sensitive, you should also have the lower case version of the file extensions on this list. If a file extension is not found on this list, the variable `TCP.DEFAULTFILETYPE` is used as the default file type during file transfers.

To Chat to a remote host, select Chat from the background menu and enter the host name when prompted. You will be prompted for a Chat window and should then be able to chat to the host. If you have problems opening the Chat connection, try `(CHAT 'HOST 'NONE)`. This will suppress the automatic login.

Warning: If no username or password has been provided for the TCP host, the default ID and password will be sent. This may create a security hazard.

---

## Making a Sysout that Contains TCP-IP

---

1. Load Medley sysout.
2. Create TCP host table.
3. Load `TCPCONFIG.LCOM` and run `TCP.CONFIGURE` if there is no `IP.INIT` file on local disk.
4. Load `TCP.LCOM`, `TCPFTP.LCOM`, `TCPCHAT.LCOM`.
5. Load `TCPDEBUG.LCOM` if you always want to have trace and echo facilities available.
6. Evaluate `(TCP.STOP)`
7. Evaluate `(STOPIP)`
8. Evaluate
 

```
(SETQ RESTARTETHERFNS (LIST ' (LAMBDA NIL (AND \IPFLG
(\IPINIT)))))
```
9. Load any other files that you want in this sysout.

10. Evaluate SYSOUT to the device of your choice. Evaluate (`\TCP.INIT`) to re-enable TCP.
11. Load TCP sysout on other machine.
12. Create TCP host table.
13. Evaluate (`TCP.CONFIGURE`) and identify the new machine.
14. Evaluate (`\TCP.INIT`) to re-enable TCP.
15. Evaluate (`\IPINIT`) to restart the IPLISTENER process.

## TCP-IP Protocol Layers

---

The TCP-IP family consists of four principal protocol layers: the link layer, the internet layer, the transport layer, and the application layer.

### Link Layer

The physical link layer, the medium for transferring packets between hosts, is assumed to be any medium capable of transporting packets of data between hosts. Common link layers in this family include the Ethernet and the ARPANET.

The Address Resolution (AR) Protocol enables hosts to map between internet addresses and link layer addresses.

For example, the internet layer protocol IP (see below) uses a 32-bit combined unique host and network address; the host address field is of variable size and depends on the pattern encoded in the high-order bits of the address. On the other hand, the 10 MB Ethernet uses a fixed-size 48-bit unique host address. The Address Resolution protocol, documented in RFC826, allows hosts to discover dynamically the link layer address equivalents of other internet hosts.

### Internet Layer

The internet layer is responsible for routing packets between hosts. Unlike the link layer, the internet layer is capable of moving packets between hosts that are not connected to the same network. The term IP in TCP-IP refers to the Internet Protocol, the protocol that performs this task in the TCP-IP family. IP is documented in RFC791. IP is not assumed to be error-free; packets may be lost or duplicated while moving through the internet. It is the responsibility of the transport layer (see below) to guarantee perfect delivery, should the client require it.

IP also depends on an associated protocol called the Internet Control Message Protocol (ICMP). ICMP is responsible for handling exception conditions that arise between hosts using IP. Such conditions include the inability to deliver packets, errors in packet formats, etc. ICMP is documented in RFC792.

### Transport Layer

The transport layer is responsible for assuring error-free, duplicate-free, sequenced delivery of packets between communicating processes. The most common transport layer is TCP, the Transport Control Protocol. TCP maintains the appearance of a perfect byte stream between processes. TCP is documented in RFC793.

An unreliable transport layer called the User Datagram Protocol (UDP) allows for packet exchange between communicating processes, but makes no attempt to guarantee delivery, suppress duplication, etc. Clients of UDP must provide their own error-recovery mechanisms if necessary. UDP is documented in RFC768.

## Application Layer

Many applications exist in the TCP-IP family. The most common applications are file transfer, virtual terminal interaction, and mail delivery.

### File Transfer

Two principal file transfer applications are in use: FTP, based on TCP and documented in RFC765; and TFTP (the Trivial File Transfer Protocol), based on UDP and documented in RFC783. Both are implemented in Interlisp, and are discussed at greater length below.

### Virtual Terminal Interaction

The TELNET protocol, documented in RFC854, specifies the protocol for virtual terminal interaction between a user and a remote system. The Chat module will use the TELNET protocol to connect to TCP-only hosts.

### Mail Delivery

The Simple Mail Transfer Protocol (SMTP) enables the delivery of mail between system elements using TCP. It is not currently implemented in Interlisp. SMTP is documented in RFC821. The format of messages is described in RFC822.

---

## Primer on IP Networks

The Internet Protocol internetwork is a collection of IP networks, a subset of which may communicate with each other. Each network is assigned an IP address, which is composed of a network number and a host number. No two hosts in the internetwork have the same network and host number combination; the composition of the network and host number for a particular host unambiguously identifies that host within the internetwork.

### Network Addresses

The address space of the internetwork is formed of the concatenated network and host numbers of its constituent hosts, and is 32 bits long. This 32-bit address space is currently partitioned into three classes of network addresses, known as class-A, class-B, and class-C:

Class-A addresses consist of 7 bits of network number and 24 bits of host number.

Class-B addresses consist of 14 bits of network number and 16 bits of host number.

Class-C addresses consist of 21 bits of network number and 8 bits of host number.

Thus, there may be 128 class-A networks, 16,384 class-B networks, and over two million class-C networks. In addition, a single class-A network has the capacity to address over 16 million hosts, while a class-C network can address only 255 hosts. The class to which a particular IP network belongs may be determined by examining the most significant bits of its address.

Network number assignments are strictly controlled by a central authority. Institutions requesting network assignments are given class-A, -B, or -C networks

depending on their estimated eventual size (numbers of hosts). Sites without assigned network numbers may request an assigned number by contacting:

Joyce Reynolds  
 USC Information Sciences Institute  
 4676 Admiralty Way  
 Marina del Rey, California 90292-6695  
 Phone: (213) 822-1511  
 ARPANET: JKREYNOLDS@USC-ISIF.ARPA

IP addresses are normally stored or exchanged as single 32-bit numbers. The printed representation of an IP address takes the form W.X.Y.Z, where W through Z are the decimal equivalents of each of the 8-bit bytes that constitute the address. Class-A addresses are of the form N.H.H.H; class-B addresses are of the form N.N.H.H; and class-C addresses are of the form N.N.N.H, where N indicates a byte of the network number, and H indicates a byte of the host number.

Class-A: N.H.H.H The first number is between 0-127 (for example, 122.0.2.1)

Class-B: N.N.H.H The first number is between 128-191 (for example, 153.4.23.5)

Class-C: N.N.N.H The first number is between 192-255 (for example, 194.5.67.3)

For example, 36.47.0.12 is an address on network 36, a class-A network; and 192.10.200.1 is an address on network 192.10.200, a class-C address.

## Broadcast Address

The Internet Protocol defines an address in which the host field contains all ones to be a broadcast address for its network. Thus, the address 36.255.255.255 is the broadcast address on network 36, and 192.10.200.255 is the broadcast address on network 192.10.200.

## Subnets

It is quite common for class-B networks to be partitioned into a set of smaller subnetworks, which are really class-C networks, but have the wrong network number to be recognized as class-C networks. This is just as common is partitioning a class-A network into many class-B subnetworks. An implementation of TCP-IP that is not prepared to handle this violation of the IP standard will not be able to communicate with hosts on the same network but different subnetworks. Fortunately, extending an IP implementation to support subnetworks is straightforward.

SUBNETMASK is a 32-bit parameter that resembles an IP address. The purpose of the mask is to enable a host to determine when a destination IP address is or is not on the same subnet as the sending host itself.

The SUBNETMASK has the following properties:

- The bitwise-AND of a source host's address (for example, this machine) and the SUBNETMASK must be equal to the bitwise-AND of a destination host's address and the SUBNETMASK if and only if the two hosts are on the same subnetwork.
- The bitwise-AND of a source host's address and the SUBNETMASK must not be equal to the bitwise-AND of a destination host's address and the SUBNETMASK if and only if the two hosts are on different subnetworks.

As an example, consider network 39.0.0.0. This is a class-A network. Suppose this network consists of a number of subnetworks; for example, subnetworks with numbers like 39.47.\*.\* and 39.9.\*.\*. According to the IP specification, these subnetworks should

really be one monolithic network, such that a host desiring to communicate with any other host whose address begins with 39... should have to take no special action with regard to routing packets to that host. Let us assume that this is not the case. The only way a machine has of telling which hosts are on different networks is to compare the masked version of the address with the masked version of its own address.

To continue the example further, assume the following:

Host A has address 39.9.0.6. Host A's SUBNETMASK is 39.255.0.0.

Host B has address 39.9.0.7. Host B's SUBNETMASK is also 39.255.0.0.

Host C has address 39.47.0.6. Host C's SUBNETMASK is also 39.255.0.0.

When host A sends to host B, it compares its masked address with host B's masked address, and finds them equal:

$39.9.0.6 \text{ AND } 39.255.0.0 = 39.9.0.0$ ;  $39.9.0.7 \text{ AND } 39.255.0.0 = 39.9.0.0$

However, when host A sends to host C, it finds the masked comparison does not match:

$39.9.0.6 \text{ AND } 39.255.0.0 = 39.9.0.0$ ;  $39.47.0.6 \text{ AND } 39.255.0.0 = 36.47.0.0$

Class-A networks that are subdivided into class-B subnetworks have SUBNETMASKs that look like X.255.0.0, where X is the class-A network number. Likewise, class-B networks subdivided into class-C subnetworks have SUBNETMASKs that look like X.Y.255.0, where X.Y is the class-B network number. Finally, networks in which subnet routing is not in use have SUBNETMASKs identical to their network addresses. For example, if network 36 did not use subnet routing, its SUBNETMASK would be 36.0.0.0.

The definitive document on this approach to subnetwork routing is RFC940.

---

## Interlisp Files

The files that implement the TCP-IP protocol suite are divided into two classes: those that implement low-level functionality, normally not of interest to general users, and those that implement higher-level functionality for user programs (either application or transport layer protocols).

The higher-level functions reside in the files TCP, TCPDEBUG, TCPFTP, TCPCHAT, TCPNAMES, TCPUDP, and TCPFTP.

|           |                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCP       | The TCP layer. Implements TCP streams, based on the buffered TCP device (for example , BIN runs in microcode).                                                                          |
| TCPDEBUG  | Contains routines to help debug TCP and TCP-based applications.                                                                                                                         |
| TCPFTP    | Contains the TCP-based file transfer protocol. Creates a new virtual I/O device, allowing transparent filing operations with TCP-only hosts.                                            |
| TCPFTPSRV | Contains the TCP-based FTP server program. When the server program is running on a Xerox 1100-series workstation, other TCP-based hosts may transfer files to and from the workstation. |
| TCPNAMES  | Implements translation of file name formats between operating system types.                                                                                                             |
| TCPCHAT   | Implements the TELNET protocol for the Chat system.                                                                                                                                     |
| TCPUDP    | Contains the UDP layer.                                                                                                                                                                 |

TCPTFTP      Implements the TFTP protocol. Creates a buffered TFTP device to allow efficient bulk transfer between hosts.

The low-level functions reside in the files TCPLLLIP, TCPLLLICMP, TCPLLLAR, TCPHTE, and TCPCONFIG.

TCPLLLIP      Implements the IP layer.

TCPLLLICMP    Implements ICMP for IP.

TCPLLLAR      Implements ARP for the 3- and 10-megabyte Ethernets.

TCPHTE        Implements the functionality necessary to parse RFC810-style HOSTS.TXT files. This allows name-to-address translation within the Interlisp host.

TCPCONFIG     Provides a function to carry on a configuration dialog when TCP-IP is first installed on a machine. This file needs to be loaded only once, to produce the file {DSK}IP.INIT. Thereafter, TCPCONFIG is needed only to reestablish or modify IP parameters.

TCPDOMAIN     Implements a domain host address lookup client.

## TCP

TCP implements the transport control protocol for Interlisp. After TCP is loaded, Interlisp supports a TCP stream capable of bidirectional I/O to a remote system element. The following functions are intended for use by applications programs.

(TCP.OPEN *DST.HOST DST.PORT SRC.PORT MODE ACCESS NOERRORFLG*  
*OPTIONS*) [Function]

Opens a TCP stream to *DST.PORT* on *DST.HOST* from *SRC.PORT*.

*DST.HOST* can be a host name, an IP host address in text format (such as 192.10.200.1), or the 32-bit integer representation of an IP host address as returned by the function DODIP.HOSTP (which is documented under TCPLLLIP).

*DST.PORT* is a 16-bit number representing a TCP port open in LISTENING mode on the remote system.

*SRC.PORT* is also a 16-bit number, but may be supplied as NIL to obtain a defaulted unique local port number.

*MODE* is either ACTIVE, meaning to act as initiator of the connection, or PASSIVE, meaning to wait for a remote system element to initiate the connection.

*ACCESS* is either INPUT, OUTPUT, or APPEND (OUTPUT and APPEND are treated in the same manner).

If *NOERRORFLG* is non-NIL, TCP.OPEN will return NIL if the connection fails; otherwise, TCP.OPEN will call ERROR to signal failure.

*OPTIONS* is an optional parameter which allows the application program to control some of the characteristics of the TCP connection. *OPTIONS* is supplied in property-list format. Currently, the only recognized option is MAXSEG, whose value should be the number of data bytes the remote TCP sender is allowed to place into a single TCP segment (Ethernet packet). The maximum value of MAXSEG is 536.

If `TCP.OPEN` succeeds, it returns a `STREAM` open as specified by `ACCESS`. The generic operations `BIN`, `BOUT`, `PEEKBIN`, `BINS`, `BOUTS`, `READP`, `EOFP`, `OPENP`, `GETFILEPTR`, `FORCEOUTPUT`, and `CLOSEF` may be performed on streams opened for suitable access.

(`TCP.OTHER.STREAM STREAM`) [Function]

Returns the `STREAM` open in the other direction with respect to `STREAM` (for example, if `STREAM` is open for `INPUT`, `TCP.OTHER.STREAM` returns a `STREAM` open for `OUTPUT`, and vice versa).

(`TCP.URGENT.EVENT STREAM`) [Function]

Returns an event upon which a user process may wait for `URGENT` data to arrive on `STREAM`.

(`TCP.URGENTP STREAM`) [Function]

Returns `T` if `STREAM` is currently reading `URGENT` data.

(`TCP.URGENT.MARK STREAM`) [Function]

Marks the current point in `STREAM` as the end of `URGENT` data. `STREAM` must be open for `OUTPUT`.

(`TCP.CLOSE.SENDER STREAM`) [Function]

Closes the output side of `STREAM`, which may be either the `INPUT` or `OUTPUT` stream for the connection. This function differs from `CLOSEF` in that the `INPUT` side of the connection is not closed (although the remote system element may close the connection once the local output side of the connection is closed).

(`TCP.STOP`) [Function]

Disables the TCP protocol, closing all open TCP streams.

(`\TCP.INIT`) [Function]

(Re)initializes the TCP module.

`\TCP.DEFAULT.RECEIVE.WINDOW` [Variable]

Is the default number of bytes allowed outstanding from the remote system. It is initially 4,096.

`\TCP.DEFAULT.USER.TIMEOUT` [Variable]

Is the default number of milliseconds a remote system element is allowed to remain silent before the TCP connection is declared broken. It is initially 60,000.

## TCPDEBUG

TCPDEBUG implements tracing and test functions used to debug TCP and TCP-based applications.

(TCPTRACE)

[Function]

Opens a trace window and attaches a menu to the window's top.

| TCP Trace Window                                                                                                                    |             |           |
|-------------------------------------------------------------------------------------------------------------------------------------|-------------|-----------|
| Incoming                                                                                                                            | Transitions | Contents  |
| Time                                                                                                                                | Outgoing    | Checksums |
| RECV: from 192.9.200.1:23 to 192.9.200.43:57511<br>69478473..69478482/57550 [ACK,PSH] window = 2048<br>checksum = 16401 length = 10 |             |           |

The menu entries represent state changes or data elements to be traced; each entry is a toggle. Clicking on the toggle once will activate the trace of the particular element and will gray-over the entry; clicking a second time will deactivate the tracing and ungray the menu item. The following data elements/transitions may be displayed:

|             |                                                                                         |
|-------------|-----------------------------------------------------------------------------------------|
| Contents    | Displays a line's worth of packet contents. The Incoming or Outgoing switch must be on. |
| Incoming    | Displays incoming data.                                                                 |
| Outgoing    | Displays outgoing data.                                                                 |
| Checksums   | Displays checksums for each TCP segment.                                                |
| Time        | Displays the time interval since the last action on the connection.                     |
| Transitions | Displays state transitions on the TCP state machine.                                    |

(PPTCB *TCP FILE*)

[Function]

Prints the state of a TCP connection. PPTCB is normally the INFO function for the process that monitors a connection; thus, selecting INFO in the process status window will cause a window to pop up containing a report on the status of the associated connection.

(TCP.ECHOTEST *HOST NLINES*)

[Function]

Opens a TCP connection to the TCP echo port on *HOST* and sends *NLINES* of random text. The echo responses are displayed in a window. If *NLINES* is NIL, the echo test will run forever.

(TCP.ECHO.SERVER *PORT*)

[Function]

Starts a TCP echo server on *PORT* (defaults to the TCP echo port). It is usually more useful to start the echo server as a process by doing (ADD.PROCESS ' (TCP.ECHO.SERVER *PORT*) ).

(TCP.SINK.SERVER *PORT*)

[Function]

Starts a TCP sink server on *PORT* (defaults to the TCP sink port). Any data sent to this port will be acknowledged and discarded. As with the TCP echo server, it is usually more useful to start this server as an independent process.

(TCP.FAUCET *HOST PORT NLINES*)

[Function]

If *HOST* is non-NIL, this function opens a connection to *PORT* on *HOST* and sends *NLINES* of text (the default is to send lines of text forever). *PORT* defaults to the TCP sink port. If *HOST* is NIL, this function waits for a remote system to connect to the TCP faucet port and then sends out *NLINES* of random text.

## TCPFTP

TCPFTP implements a virtual I/O device that performs Lisp filing operations transparently using the RFC765 FTP protocol. The standard filing operations of reading, writing, renaming, deleting, and directory enumeration are supported by the TCPFTP device. However, neither random access filing nor GETFILEINFO are supported, as there is no protocol specification for performing these operations on files. Interlisp operations such as RECOMPILE will not work when files are stored on TCPFTP file servers.

Once TCPFTP is loaded, filing operations should be transparent to users; no additional initialization need be performed. There are, however, three important global variables:

TCPFTP.EOL.CONVENTION

[Variable]

This variable controls the end-of-line convention used with files accessed via TCP. Generally, you should set it to match the convention on the system where the files reside. The value can be one of those shown below.

(TCPFTP.EOL.CONVENTION *TYPE*)

[Function]

Sets the variable TCP.EOL.CONVENTION to *TYPE*. *TYPE* can be one of the following:

|       |                                     |
|-------|-------------------------------------|
| CR    | Set EOL to CR                       |
| LF    | Set EOL to LF                       |
| CRLF  | Set EOL to CRLF                     |
| OS    | Set it to something based on the OS |
| Other | Set it to the default (CRLF)        |

TCPFTP.DEFAULT.FILETYPES

[Variable]

This variable is an association list, keyed by common extensions of file names, and contains appropriate file types (for example, TEXT or BINARY) for such files. The TCPFTP protocol provides no mechanism for determining the type of a file about to be retrieved. The file type is usually known in the case of output operations (for example, COPYFILE or MAKEFILE to a file server). However, in the case of COPYFILE from a file server, the TCPFTP module has to infer the file type from other knowledge. The module tries to match the extension of the file name with an entry on the list TCPFTP.DEFAULT.FILETYPES. If it finds a match, it uses the value of the entry in the list as the file type of the file; if it doesn't find a match, it uses the value of TCP.DEFAULTFILETYPE for the file type of the file.

TCP.DEFAULTFILETYPE

[Variable]

If no matching extension is found for the file being opened, the TCPFTP module uses the value of TCP.DEFAULTFILETYPE as the file type of the remote file. The initial value of TCP.DEFAULTFILETYPE is BINARY.

The following functions are available for debugging broken file server connections.

(FTPDEBUG *FLG*) [Function]

If *FLG* is T, this function opens a scrolling trace window that displays FTP commands as they are issued. PUPFTP commands will also be displayed in this window (the window is the value of FTPDEBUGLOG).

(\TCP.BYE *HOST*) [Function]

Breaks an FTP connection to *HOST*.

(\TCPFTP.INIT) [Function]

(Re)initializes the TCPFTP module.

## TCPFTPSRV

The TCPFTPSRV module contains a program which implements an FTP service for Interlisp. When this program is running on a workstation, other hosts are able to store and retrieve files from the workstation.

(TCPFTP.SERVER PORT DEFAULT.FILE.PATH) [Function]

To start the server program, evaluate the form (TCPFTP.SERVER). If *PORT* is supplied, the FTP server program will listen for connections on the TCP port specified by *PORT*; otherwise, the server will listen on the default FTP server port, port 21.

If *DEFAULT.FILE.PATH* is supplied, the initial path for resolving file names will be relative to *DEFAULT.FILE.PATH*; the default value of this variable is {DSK}<LISPFILES>.

TCPFTP.SERVER.USE.TOPS20.SYNTAX [Variable]

This variable controls whether file names sent back to FTP client programs are formatted in Tops-20 or Interlisp syntax. If the variable is true (the default), all file names will be formatted in Tops-20 syntax. This permits an Interlisp workstation to masquerade as a Tops-20 mainframe for the purposes of file transfer to and from other vendors' machines.

## TCPNAMES

The TCPNAMES module provides a set of functions for translating among the file-naming conventions of different operating systems. This is needed by the TCPFTP module in order for it to convert between Interlisp format file names and the file name formats of other operating systems.

(REPACKFILENAME.STRING NAME FOROSTYPE) [Function]

*NAME* is a file name in some operating system's format. *FOROSTYPE* is the name of an operating system. REPACKFILENAME.STRING attempts to translate *NAME* into a format acceptable to the operating system named by *FOROSTYPE*. *NAME* may be a string or atom; the function always returns a string.

Currently acceptable operating system types are:

IFS  
INTERLISP  
MS-DOS  
SYMBOLICS-3600  
TENEX  
TOPS-20 (also TOPS20)  
UNIX  
VMS

(TI-Explorers should use TOPS-20 as their operating system.)

The correspondence between the target operating system type and the file name translation function is maintained in an extensible hash table.

(\REPACKFILENAME.NEW.TRANSLATION *OSTYPE FUNCTION*) [Function]

This function adds a new file name translation function for a new operating system type. The function must be a LAMBDA-NOSPREAD function, and must be prepared to receive either a single property-list format argument, such as would be returned by UNPACKFILENAME, or an arbitrary number of arguments in property-list format.

File names in the above format will be passed to the translation function adhering to the conventions of many operating systems; the function must recognize the operating system type and produce the desired output format, which must be a string.

\REPACKFILENAME.OSTYPE.TABLE [Variable]

This variable is the hash table that stores the correspondence between operating system types and translation functions.

## TCPCHAT

TCPCHAT implements the TELNET protocol for virtual terminal I/O between Interlisp and a remote system. Once loaded into Interlisp, the standard Chat system will use TCP TELNET to communicate with hosts that are believed to support the protocol.

No user-callable functions reside in this module, although the following variables may be of interest.

TCPCHAT.TELNET.TTY.TYPES [Variable]

This variable is an association list that maps internal names of Chat terminal emulators to official terminal names as specified in RFC884, the TELNET Terminal Type Option. This allows TCPCHAT to set the user's terminal type automatically when a connection is established.

TCPCHAT.TRACEFLG [Variable]

If this variable is non-NIL, TELNET negotiations will be printed to TCPCHAT.TRACEFILE (see below). This is sometimes useful in debugging negotiation problems.

TCPCHAT.TRACEFILE [Variable]

TELNET negotiations are printed to this file if TCPCHAT.TRACEFLG is non-NIL.

## TCPUDP

UDP implements the user datagram protocol. The following functions are meant to be called by client applications.

(UDP.INIT) [Function]

Initializes the UDP module. This function is normally called when UDP is loaded and should not need to be called again under normal circumstances.

(UDP.STOP) [Function]

Disables the UDP module, closing any open UDP sockets.

(UDP.OPEN.SOCKET *SKT# IFCLASH*) [Function]

Opens a socket for UDP operations.

*SKT#*, if supplied, is a 16-bit number and will default to a number between 1,000 and 65,535.

*IFCLASH* specifies what to do if the requested socket is already open and is handled as in *OPENPUPSOCKET* and *OPENNSOCKET* (see the *IRM*).

It returns an instance of an *IPSOCKET*.

(UDP.CLOSE.SOCKET *IPSOCKET NOERRORFLG*) [Function]

Closes an open *IPSOCKET*. If *IPSOCKET* is not an open socket and *NOERRORFLG* is *NIL*, an error will occur; otherwise, *NIL* is returned if the socket is not active, and *T* is returned if the socket is active.

Any remaining packets on the socket's input queue are discarded when this function is called.

(UDP.SOCKET.EVENT *IPSOCKET*) [Function]

Returns an event that a process may use to wait for packet arrival on *IPSOCKET*.

(UDP.SOCKET.NUMBER *IPSOCKET*) [Function]

Returns the socket number of *IPSOCKET*.

(UDP.GET *IPSOCKET WAIT*) [Function]

Returns the next packet waiting on *IPSOCKET*. If no packets are waiting, does one of the following based on the value of *WAIT*.

|            |                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>NIL</i> | Returns immediately.                                                                                                             |
| <i>T</i>   | Waits forever for a packet to arrive.                                                                                            |
| a number   | <i>FIXP</i> waits up to <i>WAIT</i> milliseconds for a packet to arrive and returns <i>NIL</i> if none arrived during that time. |

Thus, this function is like *GETPUP* and *GETXIP*.

(UDP.SETUP UDP *DESTHOST DESTSOCKET ID IPSOCKET REQUEUE*) [Function]

Initializes a fresh packet (as returned from *\ALLOCATE.ETHERPACKET*). The packet will be sent to *DESTSOCKET* on *DESTHOST*.

*ID* is a number to be placed in the IP header ID field (zero is fine).

*REQUEUE* specifies what to do with the packet after it is sent; *NIL* (the default) means no special treatment; *FREE* means to release the packet and return it to the free packet queue. Any instance of a *SYSQUEUE* will cause the packet to be queued on the tail of the specified queue.

*UDP.SETUP* initializes all IP and UDP fields and sets the packet up as a minimum-length UDP packet.

(*UDP.SEND IPSOCKET UDP*) [Function]

Sends *UDP*, a UDP-formatted packet, out from *IPSOCKET*.

(*UDP.EXCHANGE IPSOCKET OUTUDP TIMEOUT*) [Function]

Sends *OUTUDP* out from *IPSOCKET* and waits *TIMEOUT* milliseconds for a response; returns *NIL* if no response came in during the specified interval, or the packet that did come in during that time.

Clears the socket's input packet queue before waiting for a packet to arrive.

(*UDP.APPEND.BYTE UDP BYTE*) [Function]

Appends *BYTE* to the UDP data portion of *UDP* and increments the UDP and IP length fields by one.

(*UDP.APPEND.WORD UDP WORD*) [Function]

Appends *WORD* to the UDP data portion of *UDP* and increments the UDP and IP length fields by two.

(*UDP.APPEND.CELL UDP CELL*) [Function]

Appends *CELL* to the UDP data portion of *UDP* and increments the UDP and IP length fields by four.

(*UDP.APPEND.STRING UDP STRING*) [Function]

Appends *STRING* to the UDP data portion of *UDP* and increments the UDP and IP length fields by the length *STRING*.

## TCPTFTP

TFTP implements the trivial file transfer protocol. This protocol is useful for transferring unimportant files rapidly (for example, between workstations and printers). The following user-callable functions exist.

(*TFTP.PUT FROM TO PARAMETERS*) [Function]

Sends a file to a TFTP host.

*FROM* may refer to any accessible file; *TO* must refer to a file accessible via TFTP.

No attempt is currently made to translate between Interlisp file name syntax and remote system file name syntax for *TO*.

For example, if *TO* resides on a UNIX host, it would take a syntax like *{HOST}/DIRECTORY/SUBDIRECTORY/FILENAME*.

*PARAMETERS* is currently a list of parameters in the same format used by *OPENFILE* in *.PARAMETERS*; for example `((EOLCONVENTION 1) (TYPE TEXT))`.

Note: TFTP transfers between Xerox Lisp and UNIX hosts initiated from Xerox Lisp should have the *PARAMETERS* argument be `'((EOLCONVENTION 10))`.

`(TFTP.GET FROM TO PARAMETERS)` [Function]

Gets a file from a TFTP host. *FROM* must be a file accessible by TFTP; *TO* may be any file.

The file name syntax caveats for *FROM* are the same as for *TO* in *TFTP.PUT*. *PARAMETERS* is also as in *TFTP.PUT*.

`(TFTP.SERVER LOGSTREAM)` [Function]

Starts a TFTP server process.

*LOGSTREAM* may be left *NIL*, causing a new window to appear when the TFTP server is first invoked. Remote systems that support TFTP clients may store or retrieve files through any Interlisp workstation running the TFTP server.

The full Interlisp syntax for file names is supported; thus, requests to store files whose names include hosts will result in the Interlisp workstation's transparently storing the files on the designated hosts.

`(\TFTP.OPENFILE FILENAME ACCESS RECOG PARAMETERS)` [Function]

Returns a *STREAM* to open for *ACCESS* on *FILENAME*.

*PARAMETERS* is the usual format; *TYPE* is the only recognized parameter (*BINARY* opens a stream in *octet* format; *TEXT*, the default, opens a stream in *NETASCII* format; see RFC783).

*BIN*, *BOUT*, *READP*, *EOFP*, etc., may be used on this stream.

The stream is not *RANDACCESSP*.

`(\TFTP.CLOSEFILE STREAM)` [Function]

Closes the open stream. This is normally useful for streams open for *OUTPUT*; for *INPUT* streams, end-of-file will occur eventually.

## TCPLLIB

For users planning implementations on top of IP, the following low-level TCP functions are available.

### IP Socket Access

`(\IPINIT)` [Function]

Reinitializes the IP world; for example, after some catastrophe.

`(\STOPIP)` [Function]

Disables IP.

(DODIP.HOSTP *NAME*)

[Function]

If *NAME* is an integer, *NAME* is returned unaltered. If *NAME* is a text format IP host address (such as 192.10.200.1), DODIP.HOSTP returns its integer representation.

If *NAME* is a string or atom name, DODIP.HOSTP attempts to convert *NAME* to its IP host address integer value, using information supplied in the HOSTS.TXT file (see TCPHTE, below), followed by doing a domain query if TCPDOMAIN is loaded.

If *NAME* is unknown, DODIP.HOSTP returns NIL.

If *NAME* is known, it is cached with its corresponding address so that the function IPHOSTNAME may be used later to convert the address back to a name.

(IPHOSTNAME *IPADDRESS*)

[Function]

Tries to convert *IPADDRESS* to a host name.

If *IPADDRESS* has no known name, it is converted to the text representation of an IP address (for example, 192.10.200.1).

(IPTRACE *MODE*)

[Function]

Turns on tracing of IP activity. This function is like PUPTRACE and XIPTRACE, which are documented in the IRM.

If *MODE* is NIL, IP tracing is disabled.

If *MODE* is T, verbose IP tracing is enabled.

If *MODE* is PEEK, concise IP tracing is enabled. If *MODE* is either T or PEEK, the user is prompted for a window into which trace output will be printed.

(\IP.ADD.PROTOCOL *PROTOCOL SOCKETCOMPAREFN NOSOCKETFN INPUTFN ICMPFN*)

[Function]

Defines a new IP-based protocol. The lowest-level IP functions maintain a list of active protocols and perform packet delivery based on the existence of open sockets for protocols of received packet types.

*PROTOCOL* is a protocol number, a number between 1 and 255. The following protocols are defined and should not be disturbed:

|      |    |
|------|----|
| TCP  | 6  |
| ICMP | 1  |
| UDP  | 17 |

*SOCKETCOMPAREFN* is a function with two arguments, an IP packet that has just been received and an open IPSOCKET. This function should return NIL if the packet does not belong to the supplied socket, or T if it does. The function will typically be interested in the IPSOCKET field of the IPSOCKET.

*NOSOCKETFN* is a function with one argument, an IP packet that has just been received. Its purpose is to handle received packets for which no socket can be found. If *NOSOCKETFN* is NIL, the default function, \IP.DEFAULT.NOSOCKETFN, will be used; this function simply returns an ICMP message indicating the socket is unreachable.

*INPUTFN* is a function with two arguments, a received IP packet and an open IPSOCKET. The *INPUTFN* is supposed to handle reception of packets when

their destination socket has been found. If *INPUTFN* is *NIL*, the default function, `\IP.DEFAULT.INPUTFN`, will be supplied.

*INPUTFN* enqueues the received packet on the *IPSQUEUE* field of the *IPSOCKET* if the current queue length (stored in the *IPSQUEUELENGTH* field) is less than the allocated length (stored in the *IPSQUEUEALLOC* field).

*INPUTFN* also increments the *IPSQUEUELENGTH* field, and notifies the event stored in the *IPSEVENT* field.

*ICMPFN* is a function with two arguments and is called when an ICMP packet referring to the protocol is received. The first argument is a pointer to the received ICMP packet. The second argument is a pointer that may be used as if pointed to the original outgoing packet included in the ICMP data. This allows the protocol functions to parse the data in the ICMP packet to determine which socket sent the offending packet. The *ICMPFN* must never attempt to deallocate the packet identified by the second argument; however, it is quite permissible (and expected) that the *ICMPFN* will release the packet identified by the first argument. The default *ICMPFN* simply releases the packet identified by the first argument.

`\IP.ADD.PROTOCOL` returns an *IPSOCKET* datum, which represents the active protocol; it is not in fact a useful *IPSOCKET* and may be safely ignored.

`(\IP.DELETE.PROTOCOL PROTOCOL)` [Function]

Deactivates a protocol with protocol number *PROTOCOL*. Any open sockets are closed.

`(\IP.OPEN.SOCKET PROTOCOL SOCKET NOERRORFLG SOCKETCOMPAREFN NOSOCKETFN INPUTFN)` [Function]

Attempts to open an *IPSOCKET* for protocol *PROTOCOL*.

*SOCKET* is the identifying information for this socket; this quantity will be *EQUAL*-compared with other sockets open on *PROTOCOL*. Should a match be found, an error will occur unless *NOERRORFLG* is *T*, in which case the existing socket will be returned.

*SOCKETCOMPAREFN*, *NOSOCKETFN*, and *INPUTFN* may be supplied to override the functions specified when the protocol was defined; they are not normally useful, however.

`(\IP.CLOSE.SOCKET SOCKET PROTOCOL NOERRORFLG)` [Function]

Closes a socket open on *PROTOCOL*. *SOCKET* is the same quantity passed to `\IP.OPEN.SOCKET`; it is currently not an instance of an *IPSOCKET*. If *NOERRORFLG* is *T*, an error will not occur if the socket is not found.

## IP Packet Building

The following functions are useful for placing bytes into IP packets (as allocated by `\ALLOCATE.ETHERPACKET`).

Most applications will probably want to define a block record to overlay the data portion of an IP packet. Here is an example of such a block record.

Note: Users who are developing new IP-based protocols will need to load `EXPORTS.ALL` from the library.

```
(ACCESSFNS UDP
 ((UDPBASE (\IPDATABASE DATUM)))
 (BLOCKRECORD UDPBASE
 ((UDPSOURCEPORT WORD)
 (UDPDESTPORT WORD)
 (UDPLENGTH WORD)
 (UDPCHECKSUM WORD)))
 (ACCESSFNS UDP
 ((UDPCONTENTS
 (\ADDBASE
 (\IPDATABASE DATUM)
 (FOLDHI \UDPOVLEN BYTESPERWORD)))))))
```

(\IP.APPEND.BYTE *IP BYTE INHEADER*) [Function]

Appends *BYTE* to the IP data portion of *IP* and increments the IP length field by one. If *INHEADER* is *T*, the *IPHEADERLENGTH* field is appropriately incremented so that the bytes appear to have been appended to the options portion of the IP header. There must not be any data bytes in the data portion of the packet if this function is to work correctly.

(\IP.APPEND.WORD *IP WORD INHEADER*) [Function]

Appends *WORD* to the IP data portion of *IP* and increments the IP length field by two. *INHEADER* is as in \IP.APPEND.BYTE.

(\IP.APPEND.CELL *IP CELL INHEADER*) [Function]

Appends *CELL* to the IP data portion of *IP* and increments the IP length field by four. *INHEADER* is as in \IP.APPEND.BYTE.

(\IP.APPEND.STRING *IP STRING*) [Function]

Appends *STRING* to the IP data portion of *IP* and increments the IP length field by the length *STRING*.

## IP Packet Sending

(\IP.SETUPIP *IP DESTHOST ID SOCKET REQUEUE*) [Function]

Initializes *IP*. This function should be called just after *IP* is obtained from \ALLOCATE.ETHERPACKET; if this is not done, the append functions above will fail.

*DESTHOST* is the 32-bit IP address to which this packet will be sent.

*ID* is an arbitrary 16-bit quantity that will become the IPID field of the packet.

*SOCKET* is the open IPSOCKET from which the packet will be sent.

*REQUEUE* defaults to *FREE* and controls the disposition of the packet after transmission (see the *IRM* for the documentation of *SETUPPUP* or *FILLINXIP*).

(\IP.TRANSMIT *IP*) [Function]

Tries to send *IP*. Performs IP checksum algorithm prior to sending. Returns *NIL* if successful, otherwise it returns a status indication, such as *NoRouting* or

`AlreadyQueued`. This function is like `SENDPUP` and `SENDXIP`, except that no socket argument is required.

## TCPHTE

HTE provides functions for parsing `HOSTS.TXT` files as documented by RFC810. This file is loaded automatically by LLIP and is used by `\IPINIT` to read in the initial file, `HOSTS.TXT`. The following variable and function may be of interest.

`HOSTS.TEXT.DIRECTORIES` [Variable]

Is the search path for the file `HOSTS.TXT`. This variable is initialized to `NIL`; thus the search path to be used is by default `DIRECTORIES`.

`(\HTE.READ.FILE FILE WANTEDTYPES)` [Function]

Reads a `HOSTS.TXT` file.

`WANTEDTYPES` is a list of types drawn from the set `{HOST, NET, GATEWAY}`, to be read from the file; types not specified in `WANTEDTYPES` are ignored. `WANTEDTYPES` defaults to `(HOST)`.

## TCPDOMAIN

TCPDOMAIN enhances the host address lookup to do queries to a domain name server as specified by RFC883. This allows the system to only keep in memory the addresses of hosts that are actually communicated with, resulting in considerable savings of space on large networks. There is a slight delay in establishing communications with a host the first time. Since it is faster to initiate communications with hosts defined in the `HOSTS.TEXT` file, we recommend that frequently-communicated-with hosts be defined therein.

`(DOMAIN.INIT)` [Function]

(Re)initializes the TCPDOMAIN package.

`(DOMAIN.TRACE)` [Function]

Opens up a window for tracing domain queries. (The window is the value of `DOMAIN.TRACE.FILE`).

`(DOMAIN.LOOKUP NAME TYPE SERVER)` [Function]

Looks up a host named `NAME` and type `TYPE` from server `SERVER`. If `SERVER` is unspecified, uses the default server.

`(DOMAIN.LOOKUP ADDRESS NAME SERVER DONT.GET.OSTYPE)` [Function]

Looks up the address of host `NAME` from server `SERVER`. If `SERVER` is unspecified, uses the default server. If `DONT.GET.OSTYPE` is `T`, will not get the `OSTYPE` of the host.

`(DOMAIN.LOOKUP.NAMESERVER NAME SERVER)` [Function]

Looks up the server serving the domain of `NAME`. If `SERVER` is unspecified, chooses the "best" server based on its knowledge of the namespace.

`(DOMAIN.GRAPH WINDOW)` [Function]

Draws a graph of the namespace in window `WINDOW`. Opens a new one if `WINDOW` is unspecified.

## TCP Debugging Aids

---

With TCPDEBUG loaded use (TCPTRACE T) to open up a trace window of TCP traffic. The appropriate items need to be selected from the windows menu in order for data to be seen.

(SETQ TCPCHAT.TRACEFLG T) will print TELNET negotiations to a file, which is what the variable TCPCHAT.TRACEFILE points to.

(FTPDEBUG T) opens a scrolling trace window that displays FTP commands as they are issued. You will see unencrypted passwords if they are issued.

## Limitations

---

You must use the 1186 microcode in order for TCP-IP to work on an 1186 (microcode for the 1185 will not do).

TCP-IP will not work with UNIX systems that have trailer encapsulation enabled. Connections will hang and then eventually break.

Directory enumeration on a VMS system results in NIL.

## Known Problems in TCPFTPSRV

It does not handle error conditions in the middle of file transfers.

Doing a DIR gives you only filename and version: no author, creation date, etc. This is because the TCPFTP protocol specification doesn't support author, creation date, etc.

If there are multiple files on the system, deleting a file without specifying a specific version deletes the most recent version. The workaround is to give the specific version to delete.

The subdirectory structure is not presented back to the client host. If you have a file on both the <lispfiles> directory and a subdirectory, when you do a DIR \*.\* you do not see the subdirectory listed, but you do see that there are two files on the host with the same version number.

## References

---

Users with access to the ARPANET may retrieve any RFC from host SRI-NIC.ARPA with the file transfer protocol (FTP) anonymous log-in option. RFCs are stored under <RFC>RFCnnn.TXT, where nnn is replaced by the number of the particular RFC.

From points on the Xerox internet, the RFC files can be retrieved from {Indigo}<RFC>. {Indigo} is an IFS host. From Lisp, you can simply (LOGIN) and supply your GV credentials if you haven't already, open a FileBrowser on that directory, and retrieve the file to the local workstation environment.

The following RFCs are mentioned in this manual:

RFC765 (superseded by RFC 959)  
RFC768  
RFC783  
RFC791  
RFC792  
RFC793  
RFC810 (superseded by RFC 952)  
RFC814  
RFC821  
RFC822  
RFC826  
RFC854  
RFC894  
RFC895  
RFC903  
RFC904  
RFC940

## FREE MENU

---

Free Menus are powerful and flexible menus that are useful for applications that need menus with different types of items, including command items, state items, and editable items. A Free Menu lives in a window, which can be opened and closed as desired, or attached as a control menu to the application window.

---

### Making a Free Menu

---

A Free Menu is built from a description of the contents and layout of the menu. As a Free Menu is simply a group of items, a Free Menu Description is simply a specification of a group of items. Each group has properties associated with it, as does each Free Menu Item. These properties specify the format of the items in the group, and the behavior of each item. The function FREEMENU takes a Free Menu Description, and returns a closed window with the Free Menu in it.

Probably the easiest way to make a Free Menu is to define your own function which calls FREEMENU with the Free Menu Description right there in your function. This function can then also set up the Free Menu window as required by the application. The Free Menu Description is then saved as part of your function when you save your application.

Alternatively, you can save the Free Menu Description as a variable in your file, and then just call FREEMENU with the name of the variable. This may be a more difficult alternative if you want to use the backquote facility to build your Free Menu Description. See the section **Free Menu Item Descriptions**.

---

### Free Menu Formatting

---

A Free Menu can be formatted in one of four ways. The items in any group can be automatically layed out in rows, in columns, or in a table, or else the application can specify the exact location of each item in the group. Additionally, Free Menu keeps track of the region that a group of items occupies, and items can be justified within that region. This way an item can be automatically positioned at one of the nine justification locations, top-left, top-center, top-right, middle-left, etc.

---

### Free Menu Description

---

A Free Menu Description, specifying a group of items, is a list structure. The first thing in the list is an optional list of the properties of this group of items, in the form:

(PROPS <PROP> <VALUE> <PROP> <VALUE> ...)

The key word PROPS determines whether or not the optional group props list is specified. The section **Free Menu Group Properties** describes each group property. For now, the important property is FORMAT. The type of formatting determines the syntax of the rest of the Free Menu Description, in a very simple way.

When using EXPLICIT formatting, the rest of the description is any number of Item Descriptions, which have LEFT and BOTTOM properties specifying the position of the item in the menu. The syntax is:

```
((PROPS FORMAT EXPLICIT ...)
 <ITEM DESCRIPTION>
 <ITEM DESCRIPTION> ...)
```

When using ROW or TABLE formatting, the rest of the description is any number of item groups, each group corresponding to a row in the menu. These groups are identical in *syntax* to an EXPLICIT group description, with an optional PROPS list and then any number of Item Descriptions, except that the items need not have LEFT and BOTTOM properties, as the location of each item is figured out by the formatter. But the order of the rows and items is important. The menu is layed out top to bottom by row, and left to right within each row. The syntax is (the comments are not part of the description):

```
((PROPS FORMAT ROW ...) ; props of this group
 (<ITEM DESCRIPTION> ; items in first row
 <ITEM DESCRIPTION> ...)
 ((PROPS ...) ; props of second row
 <ITEM DESCRIPTION> ; items in second row
 <ITEM DESCRIPTION> ...))
```

When using COLUMN formatting, the syntax is identical to that of ROW formatting. However each group of items corresponds to a column in the menu, rather than a row. The menu is layed out left to right by column, top to bottom within each column.

Finally, a Free Menu Description can have recursively nested groups. Anywhere the description can take an Item Description, it can take a group, marked by the key word GROUP. A nested group inherits all of the properties of its mother group, by default. However, any of these properties can be overridden in the nested groups PROPS list, including the FORMAT. The syntax is:

```
(; no PROPS list, default row format
 (<ITEM DESCRIPTION> ; first in row
 (GROUP ; nested group, second in row
 (PROPS FORMAT COLUMN...) ; optional props
 (<ITEM DESCRIPTION> ...) ; first column
 (<ITEM DESCRIPTION> ...))
 <ITEM DESCRIPTION>)) ; third in row
```

Here is an example of a simple Free Menu Description, for a menu which might provide access to a simple data base:

```
(((LABEL LOOKUP SELECTEDFN MYLOOKUPFN) (LABEL EXIT SELECTEDFN MYEXITFN))
 ((LABEL Name: TYPE DISPLAY) (LABEL "" TYPE EDIT ID NAME))
 ((LABEL Address: TYPE DISPLAY) (LABEL "" TYPE EDIT ID ADDRESS))
 ((LABEL Phone: TYPE DISPLAY)
 (LABEL "" TYPE EDIT LIMITCHARS MYPHONEP ID PHONE)))
```

This menu has two command buttons, LOOKUP and EXIT, and three edit fields, with ID's NAME, PHONE, and ADDRESS. The Edit items are initialized to the empty string, as in this example they need no other initial value. The user could click after the Name: prompt, type a person's name, and then press the LOOKUP button. This would cause the function MYLOOKUPFN to be called, which could look at the NAME Edit item, lookup that name in the data base, and then fill in the rest of the fields appropriately. Note that the PHONE item has MYPHONEP as a LIMITCHARS function. This function would be called when editing the phone number, in order to restrict input to a valid phone number. After looking up Perry, the Free Menu might look like:

```
LOOKUP EXIT
Name: Herbert Q Perry
Address: 13 Middleperry Dr
Phone: (411) 767-1234
```

Here is a more complicated example:

```
(((PROPS FONT (MODERN 10))
 ((LABEL Example FONT (MODERN 10 BOLD) HJUSTIFY CENTER))
 ((LABEL NORTH) (LABEL SOUTH) (LABEL EAST) (LABEL WEST))
 ((PROPS ID ROW3 BOX 1)
 (LABEL ONE) (LABEL TWO) (LABEL THREE))
 ((PROPS ID ROW4)
 (LABEL ONE ID ALPHA)
 (GROUP (PROPS FORMAT COLUMN BACKGROUND 23130 BOX 2 BOXSPACE 4)
 ((TYPE NWAY LABEL A BOX 1 COLLECTION COL1 NWAYPROPS (DESELECT T))
 (TYPE NWAY LABEL B BOX 1 COLLECTION COL1)
 (TYPE NWAY LABEL C BOX 1 COLLECTION COL1))
 ((TYPE STATE LABEL "Choose Me" BOX 1 MENUITEMS (BRAVO DELTA)
 INITSTATE DELTA LINKS (DISPLAY (GROUP ALPHA)))
 (TYPE DISPLAY ID ALPHA LABEL "" BOX 1 MAXWIDTH 35)))
 (LABEL THREE)))
```

which will produce the following Free Menu:

```
Example
NORTH SOUTH EAST WEST
ONE TWO THREE
A Choose Me
B DELTA
C
ONE THREE
```

And if the Free Menu were formatted as a Table, instead of in Rows, it would look like:

| Example |                                                                                           |       |      |
|---------|-------------------------------------------------------------------------------------------|-------|------|
| NORTH   | SOUTH                                                                                     | EAST  | WEST |
| ONE     | TWO                                                                                       | THREE |      |
|         | <div> <div>A</div> <div>Choose Me</div> <div>B</div> <div>DELTA</div> <div>C</div> </div> |       |      |
| ONE     |                                                                                           | THREE |      |

## Free Menu Group Properties

Each group has properties. Most group properties are relevant, and should be set, in the group's PROPS list in the Free Menu Description. User properties can freely be included in the PROPS list. A few other properties are setup by the formatter. After the Free Menu is created, group properties can be accessed by the macro FM.GROUPPROP or FM.MENUPROP.

|             |                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID          | The identifier of this group. Setting the group ID is desirable, for example, if the application needs to get handles on items in particular groups, or access group properties.                                                                                                                                                                      |
| FORMAT      | One of ROW, COLUMN, TABLE, or EXPLICIT. The default is ROW.                                                                                                                                                                                                                                                                                           |
| FONT        | A font description of the form (FAMILY SIZE FACE), or a FONTDESCRIPTOR data type. This will be the default font for each item in this group. The default font of the top group is the value of the variable DEFAULTFONT.                                                                                                                              |
| COORDINATES | One of GROUP, or MENU. This property applies only to Explicit formatting. If GROUP, then the items in the explicit group are positioned in coordinates relative to the lower left corner of the group, as determined by the mother group. If MENU, which is the default, then the items are positioned relative to the lower left corner of the menu. |
| LEFT        | Specifies a left offset for this group, pushing the group to the right.                                                                                                                                                                                                                                                                               |
| BOTTOM      | Specifies a bottom offset for this group, pushing the group up.                                                                                                                                                                                                                                                                                       |
| ROWSPACE    | The number of bits between rows in this group.                                                                                                                                                                                                                                                                                                        |
| COLUMNSPACE | The number of bits between columns in this group.                                                                                                                                                                                                                                                                                                     |
| BOX         | The number of bits in the box around this group of items.                                                                                                                                                                                                                                                                                             |
| BOXSHADE    | The shade of the box.                                                                                                                                                                                                                                                                                                                                 |
| BOXSPACE    | The number of bits between the box and the items.                                                                                                                                                                                                                                                                                                     |
| BACKGROUND  | The background shade of this group. Nested groups will inherit this background shade, but items in this group and nested groups will not. This is because in general it is difficult to read text on a                                                                                                                                                |

background, so items appear on white background by default. This can be overridden by the BACKGROUND Item Property.

---

## Other Group Properties

---

|           |                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------|
|           | The following group properties are setup and maintained by Free Menu. The application should probably not change any of these properties. |
| ITEMS     | A list of the items in the group.                                                                                                         |
| REGION    | The region that is the extent of the items in the group.                                                                                  |
| MOTHER    | The ID of the group that is the mother of this group.                                                                                     |
| DAUGHTERS | A list of ID of groups which are daughters to this group.                                                                                 |

---

## Free Menu Items

---

Each Free Menu Item is stored as an instance of the Data Type FREEMENUITEM. Free Menu Items can be thought of as objects, each item having its own particular properties, such as its type, label, and mouse event functions. A number of useful item types, described in the section **Free Menu Item Types**, are predefined by Free Menu. New types of items can be defined by the application, using Display items as a base.

Each Free Menu Item is created from a Free Menu Item Description when the Free Menu is created.

---

## Free Menu Item Descriptions

---

A Free Menu Item Description is a list in property list format, specifying the properties of the item. For example:

```
(LABEL Refetch SELECTEDFN MY.REFETCHFN)
```

describes a command (Momentary) item labelled 'Refetch', with the function MY.REFETCHFN to be called when the item is selected.

None of the property values in an item description are evaluated. When constructing Free Menu descriptions that incorporate evaluated expressions, for example labels that are bitmaps, it is helpful to use the backquote facility. For example, if the value of the variable MYBITMAP is a bitmap, then

```
(FREEMENU `(((LABEL A) (LABEL ,MYBITMAP))))
```

would create a Free Menu of one row, with two items in that row, the second of which has the value of MYBITMAP as its label.

---

## Free Menu Item Properties

---

|      |                                                                                                                                                                                                                           |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      | The following Free Menu Item Properties can be set in the Item Description. Any other properties given in an Item Description will be treated as user properties, and will be saved on the USERDATA property of the item. |
| TYPE | The type of the item. Choose from one of the Free Menu Item type keywords MOMENTARY, TOGGLE, 3STATE, STATE, NWAY, EDITSTART, EDIT, NUMBER, or DISPLAY. The default is MOMENTARY.                                          |

|                 |                                                                                                                                                                                                                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LABEL           | An atom, string, or bit map. Bit maps are always copied, so that the original won't be changed. This property must be specified for every item.                                                                                                                                                                                      |
| FONT            | The font that the item will appear in. The default is the font specified for the group that this item is in. Can be a font description of the form (FAMILY SIZE FACE), or a FONTDESCRIPTOR data type.                                                                                                                                |
| ID              | May be used to specify a unique identifier for this item, but is not necessary.                                                                                                                                                                                                                                                      |
| LEFT and BOTTOM | When Row, Column, or Table formatting, these specify offsets, pushing the item right and up, respectively, from where the formatter would have put the item. In Explicit formatting, these are the actual coordinates of the item, in the coordinate system given by the group's COORDINATES property.                               |
| HJUSTIFY        | One of LEFT, CENTER, or RIGHT. Specifies that this item is to be horizontally justified within the extent of its group. Note that the main group, as opposed to the smaller row or column group, is used.                                                                                                                            |
| VJUSTIFY        | One of TOP, MIDDLE, or BOTTOM. Specifies that this item is to be vertically justified.                                                                                                                                                                                                                                               |
| HIGHLIGHT       | Specifies the highlighted looks of the item, that is, how the item changes when a mouse event occurs on it. See the section <b>Free Menu Item Highlighting</b> , below.                                                                                                                                                              |
| MESSAGE         | A string that will be printed in the prompt window after a mouse button is held down over this item for MENUHELDWAIT milliseconds. Or, if an atom, treat as a function to get the message. The function is applied to ITEM WINDOW BUTTONS, and should return a string. The default is a message appropriate to the type of the item. |
| INITSTATE       | The initial state of the item. This is only appropriate to TOGGLE, 3STATE, and STATE items.                                                                                                                                                                                                                                          |
| MAXWIDTH        | The width allowed for this item. The formatter will leave enough space after the item for the item to grow to this width without collisions.                                                                                                                                                                                         |
| MAXHEIGHT       | Similar to MAXWIDTH, but in the vertical dimension.                                                                                                                                                                                                                                                                                  |
| BOX             | The number of bits in the box around this item. Boxes are made around MAXWIDTH and MAXHEIGHT dimensions. If unspecified, no box is drawn.                                                                                                                                                                                            |
| BOXSHADE        | The shade that the box is drawn in. The default is BLACKSHADE.                                                                                                                                                                                                                                                                       |
| BOXSPACE        | The number of bits between the box and the label. The default is one bit.                                                                                                                                                                                                                                                            |
| BACKGROUND      | The background shade on which the item appears. The default is WHITESHADE, regardless of the group's background.                                                                                                                                                                                                                     |
| LINKS           | Can be used to link this item to other items in the Free Menu. See the section <b>Free Menu Item Links</b> .                                                                                                                                                                                                                         |

### Mouse Properties

The following properties provide a way for application functions to be called under certain mouse events. These functions are called with the ITEM, the WINDOW, and the BUTTONS depressed as

arguments. These application functions do not interfere with any Free Menu system functions that take care of handling the different item types. In each case, though, the application function is called *after* the system function. The default for all of these functions is NIL. The value of each of the following properties can be the name of a function, or a lambda expression.

|            |                                                                                                                                           |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| SELECTEDFN | The function to be called when this item is selected. Note that Edit and EditStart items cannot have a selectedfn. See Edit items, below. |
| DOWNFN     | The function to be called when a mouse button goes down over this item, or when the mouse moves over the item with buttons depressed.     |
| HELDFN     | The function to be called repeatedly while the mouse is held down over this item.                                                         |
| MOVEDFN    | The function to be called when the mouse moves off this item with buttons still depressed.                                                |

## System Properties

---

The following Free Menu Item properties are set and maintained by Free Menu. The application should probably not change these properties directly.

|                                          |                                                                                                                                                                                                                                           |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GROUPID                                  | The ID of the smallest group that the item is in. For example, in a row formatted group, the item's GROUPID will be set to the ID of the row that the item is in, not the ID of the whole group.                                          |
| STATE                                    | The current state of TOGGLE, 3STATE, or STATE items. The state of an NWAY item behaves like that of a toggle item.                                                                                                                        |
| BITMAP                                   | The bitmap from which the item is displayed.                                                                                                                                                                                              |
| REGION                                   | The region of the item, in window coordinates. This is used for locating the display position, as well as determining the mouse sensitive region of the item.                                                                             |
| MAXREGION                                | The maximum region the item may occupy, determined by the MAXWIDTH and MAXHEIGHT properties. This is used by the formatter and the display routines.                                                                                      |
| SYSDOWNFN<br>SYSMOVEDFN<br>SYSSELECTEDFN | These are the system mouse event functions, setup by Free Menu according to the type of the item. These functions are called before the users mouse event functions, and are used to implement highlighting, state changes, editing, etc. |
| USERDATA                                 | Any other properties are stored on this list in property list format. This list should probably not need to be manipulated directly.                                                                                                      |

## Predefined Item Types

---

### Momentary

---

Momentary items are like command buttons. When the button is selected, its associated function is called.

### Toggle

---

Toggle items are simple two-state buttons. When depressed the button is highlighted, and it stays that way until pressed again. The states of a toggle button are T and NIL, initially NIL.

---

### 3State

---

3State items rotate through NIL, T, and OFF, states each time they are pressed. The default looks of the OFF state are with a diagonal line through the button, while T is highlighted, and NIL is normal. The default initial state is NIL.

The following Item Property applies to 3State items:

|     |                                                                                                                                              |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------|
| OFF | Specifies the looks of a 3STATE item in its OFF state. Similar to HIGHLIGHT. The default is that the label gets a diagonal slash through it. |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------|

### State

---

State items are general multiple state items. The following Item Property determines how the item changes state:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHANGESTATE | This Item Property can be changed at any time to change the effect of the item. If a MENU datatype, then this menu is popped up when the item is selected, and the user can select the new state. Otherwise, if this property is given, it is treated as a function name, which is applied to ITEM WINDOW BUTTONS. This function can do whatever it wants, and is expected to return the new state (an atom, string, or bitmap), or NIL, meaning don't change state. |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The state of the item can automatically be indicated in the Free Menu, by setting up a DISPLAY link to a Display item in the menu (see **Free Menu Item Links** below). If such a link exists, the label of the DISPLAY item will be changed to the new state. Note that the possible states are not restricted at all, except that if a popup menu is used, of course the possible selections are restricted. The state can be changed to any atom, string, or bitmap, manually via FM.CHANGESTATE.

The following Item Properties are relevant to State items when building a Free Menu:

|           |                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MENUITEMS | If specified, should be a list of item to go in a popup menu for this item. Free Menu will build the menu and save it as the CHANGESTATE property of the item. |
| MENUFONT  | The font of the items in the popup menu.                                                                                                                       |
| MENUTITLE | The title of the popup menu. The default title is the label of the State item.                                                                                 |

### Nway

---

NWay items provide a way to collect any number of items together, in any format within the Free Menu. Only one item from each Collection can be selected at a time, and that item is highlighted to indicate so.

The following Item Properties are particular to NWay items:

|            |                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COLLECTION | An identifier that specifies which NWay Collection this item belongs to.                                                                                            |
| NWAYPROPS  | A property list of information to be associated with this collection. This property is only noticed in the Free Menu Description on the first item in a Collection. |

NWay Collections are formed by creating a number of NWay items with the same COLLECTION property. Each NWay item acts individually as a Toggle item, and can have its own mouse event functions.

Each NWay Collection itself has properties, its state for instance. After the Free Menu is created, these Collection properties can be

accessed by the macro FM.NWAYPROPS. Note that NWay Collections are different from Free Menu Groups.

There are three NWay Collection properties that Free Menu looks at:

|           |                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESELECT  | If given, specifies that the Collection can be deselected, yielding a state in which no item in the Collection is selected. When this property is set, the Collection can be deselected by pressing the Right mouse button on any item in the Collection. |
| STATE     | The current state of the Collection, which is the actual item selected.                                                                                                                                                                                   |
| INITSTATE | Specifies the initial state of the Collection. The value of this property is an item Link Description (see the section <b>Free Menu Item Links</b> .)                                                                                                     |

---

## Edit

Edit items are textual items that can be edited. The label for an Edit item cannot be a bitmap. When the item is selected an edit caret appears at that cursor position within the item, allowing inserting and deleting characters at that point. If selected with the Right mouse button, the item is cleared before editing starts. While editing, the Left mouse button moves the caret to a new position within the item. The Right mouse button deletes from the caret to the cursor. Control-W deletes the previous word.

Editing is stopped when another item is selected, when the user clicks in another tty window, or by the Free Menu function FM.ENDEDIT, which is called when the Free Menu is reset, or the window is closed. Additionally, the Free Menu editor will time out after about a minute, returning automatically. Because of the many ways in which editing can terminate, Edit items are not allowed to have a Selectedfn, as it is not clear when this function should be called.

Each Edit item should have an ID specified, which is used when getting the state of the Free Menu, since the string being edited is defined as the state of the item, and thus cannot distinguish edit items. The following Item Properties are particular to Edit items:

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAXWIDTH      | Specifies the maximum string width of the item, in bits, after which input will be ignored. If MAXWIDTH is not specified, the items becomes "infinitely wide" and input is never restricted.                                                                                                                                                                                                                                                                                                                                                                                 |
| INFINITEWIDTH | This property is set automatically when MAXWIDTH is not specified. This tells Free Menu that the item has no right end, so that the item becomes mouse sensitive from its left edge to the right edge of the window, within the vertical space of the item.                                                                                                                                                                                                                                                                                                                  |
| LIMITCHARS    | The input characters allowed can be restricted in two ways: If this item property is a list, it is treated as a list of legal characters; any character not in the list will be ignored. If it is an atom, it is treated as the name of a test predicate, which is applied to ITEM WINDOW CHARACTER when each character is typed. This predicate should return T if the character is legal, NIL otherwise. The LIMITCHARS function can also call FM.ENDEDIT to force the editor to terminate, or FM.SKIPNEXT, to cause the editor to jump to the next edit item in the menu. |
| ECHOCHAR      | This item property can be set to any character. This character will be echoed in the window, regardless of what character is typed. However the item's label contains the actual string typed. This is useful for operations like password prompting. If ECHOCHAR is used, the font of the item must be fixed pitch.                                                                                                                                                                                                                                                         |

Unrestricted Edit items should not have other items to their right in the menu, as they will be edited over. If the item is boxed, input is restricted to what will fit in the box. Typing off the edge of the window will cause the window to scroll appropriately. Control characters can be edited, including CR and LF, and they are echoed as a black box. While editing, the Skip/Next key ends editing the current item, and starts editing the next Edit item in the Free Menu.

---

## Number

Number items are Edit items that are restricted to numerals. The state of the item is coerced to the the number itself, not a string of numerals.

There is one Number specific Item Property:

|            |                                                                                               |
|------------|-----------------------------------------------------------------------------------------------|
| NUMBERTYPE | If FLOATP (or FLOAT), then decimals are accepted. Otherwise only whole numbers can be edited. |
|------------|-----------------------------------------------------------------------------------------------|

---

## EditStart

EditStart items serve the purpose of starting editing on another item when they are selected. The associated Edit item is linked to the EditStart item by an EDIT link (see **Free Menu Item Links** below). If the EditStart item is selected with the Right mouse button, the Edit item is cleared before editing is started. Similar to Edit items, EditStart items cannot have a Selectedfn, as it is not clear when the associated editing will terminate.

---

## Display

Display items serve two purposes. First, they simply provide a way of putting dummy text in a Free Menu, which does nothing when selected. The item's label can be changed, though. Secondly, Display items can be used as the base for new item types. The application can create new item types by specifying DOWNFN, HELDFN, MOVEDFN, and SELECTEDFN for a Display item, making it behave as desired.

---

## Free Menu Item Highlighting

Each Free Menu Item can specify how it wants to be highlighted. First of all, if the item doesn't specify a HIGHLIGHT property, there are two default highlights. If the item is not boxed, the label is simply inverted, as in normal menus. If the item is boxed, it is highlighted in the shade of the box.

Alternatively, the value of the HIGHLIGHT property can be a SHADE, which will be painted on top of the item when a mouse event occurs on it. Or the HIGHLIGHT property can be an alternate label, which can be an atom, string, or bitmap. If the highlight label is a different size than the item label, the formatter will leave enough space for the larger of the two.

In all of these cases, the looks of the highlighted item are determined when the Free Menu is built, and a bitmap of the item with these looks is created. This bitmap is stored on the item's HIGHLIGHT property, and simply displayed when a mouse event occurs. The value of the highlight property in the Item Description is copied to the userdata list, in case it is needed later for a label change.

---

## Free Menu Item Links

---

Links between items are useful for grouping items in abstract ways. In particular, links are used for associating Editstart items with their item to edit, and State items with their state display. The Free Menu Item property LINKS is a property list, where the value of each Link Name property is a pointer to another item.

In the Item Description, the value of the LINK property should be a property list as above. The value of each Link Name property is a Link Description.

A Link Descriptions can be one of the following forms:

- |                                           |                                                                                                                                                                                                                                                |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;ID&gt;</code>                   | Simply an ID of an item in the Free Menu. This is okay if items can be distinguished by ID alone.                                                                                                                                              |
| <code>(&lt;GROUPID&gt; &lt;ID&gt;)</code> | A list whose first element is a GROUPID, and whose second element is the ID of an item in that group. This way items with similar purposes, and thus similar ID's, can be distinguished across groups.                                         |
| <code>(GROUP &lt;ID&gt;)</code>           | A list whose first element is the keyword GROUP, and whose second element is an item ID. This form describes an item with ID, in the same group that this item is in. This way you don't need to know the GROUPID, just which group you're in. |

Then after the entire menu is built, the links are setup, turning the Link Descriptions into actual pointers to Free Menu Items. There is no reason why circular Item Links cannot be created, although such a link would probably not be very useful. If circular links are created, the Free Menu will not be garbage collected after it is not longer being used. The application is responsible for breaking any such links that it creates.

---

## Free Menu Window Properties

---

- |                 |                                                                                                                                                                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FM.PROMPTWINDOW | Specifies the window that Free Menu should use for displaying the item's messages. If not specified, PROMPTWINDOW is used.                                                                                                                                                              |
| FM.BACKGROUND   | The background shade of the entire Free Menu. This property can be set automatically by specifying a BACKGROUND argument to the function FREEMENU. The window border must be 4 or greater when a Free Menu background is used, due to the way the Window System handles window borders. |
| FM.DONTRESHAPE  | Normally Free Menu will attempt to use empty space in a window by pushing items around to fill the space. When a Free Menu window is reshaped, the items are repositioned in the new shape. This can be disabled by setting the FM.DONTRESHAPE window property.                         |

---

## Free Menu Interface Functions

---

|                                                             |                         |
|-------------------------------------------------------------|-------------------------|
| <code>(FREEMENU DESCRIPTION TITLE BACKGROUND BORDER)</code> | <code>[Function]</code> |
|-------------------------------------------------------------|-------------------------|

---

Creates a Free Menu from a Free Menu Description, returning the window. This function will return quickly unless new display fonts have to be created. See the example above.

## Accessing Macros

These Accessing Macros are provided to allow the application to get and set information in the Free Menu data structures. They are implemented as macros so that the operation will compile into the actual access form, rather than figuring that out at run time.

(FM.ITEMPROP *ITEM PROP {VALUE}*)

[Macro]

Similar to WINDOWPROP, this macro provides an easy access to the fields of a Free Menu Item. A handle on the item can be gotten from the Free Menu by the function FM.GETITEM, described below. *VALUE* is optional, and if not given, the current value of the *PROP* property will be returned. If *VALUE* is given, it will be used as the new value for that *PROP*, and the old value will be returned.

When a call to FM.ITEMPROP is compiled, if the *PROP* is known (quoted in the calling form), the macro figures out what field to access, and the appropriate Data Type access form is compiled. However, if the *PROP* is not known at compile time, the *function* FM.ITEMPROP, which goes through the necessary property selection at run time, is compiled.

The TYPE and USERDATA properties of a Free Menu Item are Read Only, and an error will result from trying to change the value of one of these properties.

(FM.GROUPPROP *WINDOW GROUP PROP {VALUE}*)

[Macro]

Provides access to the Group Properties set up in the PROPS list for each group in the Free Menu Description. *GROUP* specifies the ID of the desired group, and *PROP* the name of the desired property. If *VALUE* is specified, it will become the new value of the property, and the old value will be returned. Otherwise, the current value is returned.

(FM.MENUPROP *WINDOW PROP {VALUE}*)

[Macro]

Provides access to the group properties of the top-most group in the Free Menu, that is to say, the entire menu. This provides an easy way for the application to attach properties to the menu as a whole, as well as access the Group Properties for the entire menu.

(FM.NWAYPROP *WINDOW COLLECTION PROP {VALUE}*)

[Macro]

This macro works just like FM.GROUPPROP, except it provides access to the NWay Collections.

## Accessing Functions

(FM.GETITEM *ID GROUP WINDOW*)

[Function]

Get a handle on item *ID* in *GROUP* of the Free Menu in *WINDOW*. This function will search the Free Menu for an item whose ID property matches, or secondly whose LABEL property matches *ID*. If *GROUP* is NIL, then the entire Free Menu is searched. If no matching item is found, NIL is returned.

(FM.GETSTATE *WINDOW*)

[Function]

Return in property list format the ID and current STATE of every NWay Collection and item in the Free Menu. If an item's or Collection's state is NIL, then it is not included in the list. This provides an easy way of getting the state of the menu all at once. If the state of only one item or Collection is needed, the application

can directly access the STATE property of that object using the Accessing Macros above. Note that this function can be called when editing is in progress, in which case it will provide the label of the item being edited at that point.

## Changing Free Menus

---

Many of the following functions operate on Free Menu Items, and thus take the item as an argument. The *ITEM* argument to these functions can be the Free Menu Item itself, or just a reference to the item. In the second case, FM.GETITEM will be used to find the item in the Free Menu.

The reference can be in one of the following forms:

<ID> Specifies the first item in the Free Menu whose ID or LABEL property matches <ID>.

(<GROUPID> <ID>) Specifies the item whose ID or LABEL property matches <ID> within the group specified by <GROUPID>.

---

(FM.CHANGELABEL *ITEM NEWLABEL WINDOW UPDATEFLG*) [Function]

This function changes an item's label after the Free Menu has been created. It works for any type of item, and state items will remain in their current state. If the window is open, the item will be redisplayed with its new appearance. *NEWLABEL* can be an atom, a string, or a bit map (except for Edit items), and will be restricted in size by the MAXWIDTH and MAXHEIGHT Item Properties. If these properties are unspecified, the item will be able to grow to any size. *UPDATEFLG* specifies whether or not the regions of the groups in the menu are recalculated to take into account the change of size of this item. The application should not change the label of an Edit item while it is being edited.

The following Item Property is relevant to changing labels:

CHANGELABELUPDATE Exactly like *UPDATEFLG* except specified on the item, rather than as a function parameter.

---

(FM.CHANGESTATE *X NEWSTATE WINDOW*) [Function]

Programmatically changes the state of items and NWay Collections. *X* is either an item or a Collection name. For items *NEWSTATE* is a state appropriate to the type of the item. For NWay Collections, *NEWSTATE* should be the desired item in the Collection, or NIL to deselect. For Edit and Number items, this function just does a label change. If the window is open, the item will be redisplayed.

---

(FM.RESETSTATE *ITEM WINDOW*) [Function]

Set an item back to its initial state.

---

(FM.RESETMENU *WINDOW*) [Function]

Reset every item in the menu back to its initial state.

---

(FM.RESETSHAPE *WINDOW ALWAYSFLG*) [Function]

Reshapes the window to its full extent, leaving the lower-left corner unmoved. Unless *ALWAYSFLG* is T, the window will only be increased in size as a result of resetting the shape.

---

(FM.RESETGROUPS *WINDOW*) [Function]

Recalculate the extent of each group in the menu, updating group boxes and backgrounds appropriately.

(FM.HIGHLIGHTITEM *ITEM WINDOW*)

[Function]

This function provides a way of programmatically forcing an item to be highlighted. This might be useful for items which have a direct effect on other items in the menu. The item will be highlighted according to its HIGHLIGHT property, as described in the section **Free Menu Item Highlighting**. Note that this highlight is temporary, and will be lost if the item is redisplayed, by scrolling for example.

## Editor functions

(FM.EDITITEM *ITEM WINDOW CLEARFLG*)

[Function]

Start editing an Edit or Number item at the beginning of the item, as long as the window is open. This function will most likely be useful for starting editing of an item that is currently the null string. If *CLEARFLG* is set, the item is cleared first.

(FM.SKIPNEXT *WINDOW CLEARFLG*)

[Function]

This function causes the editor to jump to the beginning of the next Edit item in the Free Menu. If *CLEARFLG* is set, then the next item will be cleared first. If there is not another Edit item in the menu, this function will simply cause editing to stop. If this function is called when editing is not in progress, editing will begin on the first Edit item in the menu. This function can be called from any process, and can also be called from inside the editor, in a LIMITCHARS function.

(FM.ENEDIT *WINDOW WAITFLG*)

[Function]

Stop any editing going on in *WINDOW*. If *WAITFLG*, then block until the editor has completely finished. This function can be called from another process, or from a LIMITCHARS function.

(FM.EDITP *WINDOW*)

[Function]

If an item is in the process of being edited in the Free Menu *WINDOW*, that item is returned. Otherwise, NIL is returned.

## Miscellaneous

(FM.REDISPLAYMENU *WINDOW*)

[Function]

Redisplays the entire Free Menu in its window, if the window is open.

(FM.REDISPLAYITEM *ITEM WINDOW*)

[Function]

Redisplays a particular Free Menu Item in its window, if the window is open.

(FM.SHADE *X SHADE WINDOW*)

[Function]

*X* can be an item, or a group ID. *SHADE* is painted on top of the item or group. Note that this is a temporary operation, and will be undone by redisplaying. For more permanent shading, the application may be able to add a REDEDISPLAYFN and SCROLLFN for the window as necessary to update the shading.

(FM.WHICHITEM *WINDOW POSorX Y*)

[Function]

Gets a handle on an item from its known location within the window. If *WINDOW* is NIL, (*WHICHW*) is used, and if *POSorX* is NIL, the current cursor location is used.

(FM.TOPGROUPID *WINDOW*)

[Function]

Return the ID of the top group of this Free Menu.

## **Free Menu Changes:**

This document describes the incompatible changes from the old version to the new version of Free Menu. This document does not describe any of the new features of Free Menu. Some of the terminology used in these notes is introduced in the Free Menu documentation. You should read the Free Menu documentation first.

The function FREEMENU is used to create a Free Menu, replacing and combining the functions FM.MAKEMENU and FM.FORMATMENU.

## **In the Description of the Free Menu:**

There is no longer a WINDOWPROPS list in the Free Menu Description. Instead, the window properties TITLE and BORDER that used to be set in the WINDOWPROPS list can now be passed to the function FREEMENU. Other window properties (like FM.PROMPTWINDOW) can be set directly after FREEMENU returns the window using the system function WINDOWPROP. See the section in the documentation entitled **Free Menu Window Properties**.

Setting the initial state of an item is now done with the item property INITSTATE in the item description, rather than the STATE property.

## **Free Menu Items:**

3STATE items now have states OFF, NIL, and T (instead of a NEUTRAL state). They appear by default in the NIL state.

STATE items are general purpose items which maintain state, and replace the functionality of NCHOOSE items. To get the functionality of NCHOOSE items, specify the property MENUITEMS (a list of items to go in a popup menu), which instructs the STATE item to popup the menu when it is selected. STATE items do not display their current state by default, like NCHOOSE items used to. Instead, if you want the state displayed in the Free Menu, you have to link the STATE item to a DISPLAY item using a Free Menu Item Link named "DISPLAY". The current state of the STATE item will then automatically be displayed in the specified DISPLAY item. The item properties MENUFONT and MENUTITLE also apply to the popup menu.

NWAY items are declared slightly differently. There is now the notion of an NWay Collection, which is a collection of items acting as a single nway item. The Collection is declared by specifying any number of NWay items, each with the same COLLECTION property. NWay Collections have properties themselves, accessible by the macro FM.NWAYPROPS. These

properties can be specified in property list format as the value of the NWayPROPS Item Property of the first NWay item declared for each Collection. NWay Collections by default cannot be deselected (a state in which no item selected). Setting the Collection property DESELECT to any non-nil value changes this behavior. The state of the NWay Collection is maintained in its STATE property.

EDIT items no longer will stop at the edge of the window. Editing is either restricted by the MAXWIDTH property, or else it is not restricted at all. The EDITSTOP property is obsolete. Starting editing with the Right mouse button causes the item to be cleared first.

EDITSTART items now specify their associated edit item (there can only be one, now) by a Free Menu Item Link named "EDIT" from the EDITSTART item to the EDIT item.

TITLE items are replaced by DISPLAY items, which work the same way.

### **Free Menu Interface functions:**

(FREEMENU DESCRIPTION TITLE BACKGROUND BORDER) replaces FM.MAKEMENU and FM.FORMATMENU.

The desired format is not specified as the value of the FORMAT property in the group's PROPS list.

(FM.GETITEM ID GROUP WINDOW) replaces FM.ITEMFROMID.

Searches within GROUP for an item whose ID property is ID. ID is matched against the item ID and then the item LABEL. If GROUP is NIL, the entire menu is searched.

(FM.GETSTATE WINDOW) replaces FM.READSTATE.

Returns a property list of the selected item in the menu. This list now also includes the NWay Collections and their selected item.

(FM.CHANGELABEL ITEM NEWLABEL WINDOW UPDATEFLG) **new argument order.**

Now works by rebuilding the item label from scratch, taking the original specification of MAXWIDTH and MAXHEIGHT into account. NEWLABEL can be an atom, string, or bitmap. If UPDATEFLG is set, then the Free Menu Group's regions are recalculated, so that boxed groups will be redisplayed properly.

(FM.CHANGESTATE X NEWSTATE WINDOW) **new argument order.**

X is either an item or an NWay Collection ID. NEWSTATE is an appropriate state to the type of item. If an NWay collection, NEWSTATE is the actual item to be selected, or NIL to deselect. Toggle items take either T or NIL as NEWSTATE, and 3STATE items take OFF, NIL, or T, and STATE items take any atom, string, or

bitmap as their new state. For EDIT items, *NEWSTATE* is the new label, and FM.CHANGELABEL is called to change the label of the EDIT item.

(FM.RESETSHAPE WINDOW ALWAYSFLG) replaces FM.FIXSHAPE

(FM.HIGHLIGHTITEM ITEM WINDOW) replaces FM.SHADEITEM and FM.SHADEITEMBM.

FM.HIGHLIGHTITEM will programmatically highlight an item, as specified by its HIGHLIGHT property. The highlighting is temporary, and will be undone by a redisplay or scroll. To programmatically shade an item an arbitrary shade, use the new function FM.SHADE.

## ICONW

---

This is a package of functions for building small windows of arbitrary shape, principally for use as icons for shrinking windows; i.e., these functions are likely to be invoked from within the ICONFN of a window.

An icon is specified by supplying its image (a bit map) and a mask that specifies its shape. The mask is a bit map of the same dimensions as the image whose bits are on (black) in those positions considered to be in the image, off (white) in those positions where the background should “show through.” By using the mask and appropriate window functions, the icon package maintains the illusion that the icon window is nonrectangular, even though the actual window itself is rectangular. The illusion is not complete, of course. For example, if you try to select what looks like the background (or an occluded window) around the icon but still within its rectangular perimeter, the icon window itself is selected. Also, if you move a window occluded by an icon, the icon never notices that the background changed behind it.

Icons created with this package can also have “titles”; some part of the image can be filled with text computed at the time the icon is created, or even changed after creation.

---

## Creating Icons

---

(ICONW *IMAGE MASK POSITION NOOPENFLG*) [Function]

Creates a window at *POSITION*, or prompts for a position if *POSITION* is NIL. The window is borderless, and filled with *IMAGE*, as cookie-cut by *MASK*. If *MASK* is NIL, the image is considered rectangular (i.e., *MASK* defaults to a black bit map of the same dimensions as *IMAGE*). If *NOOPENFLG* is T, the window is returned unopened.

(TITLEDICONW *ICON TITLE FONT POSITION NOOPENFLG JUST BREAKCHARS OPERATION*) [Function]

Creates a titled icon at *POSITION*, or prompts for a position if *POSITION* is NIL. If *NOOPENFLG* is T, the window is returned unopened. The argument *ICON* is an instance of the record TITLEDICON, which specifies the icon image and mask, as with ICONW, and a region within the image to be used for displaying the title. Thus, the *ICON* argument is usually of the form

(create TITLEDICON *ICON\_someIconImage*  
*MASK\_iconMask TITLEREG\_someRegionWithinIcon*).

The title region is specified in icon-relative coordinates, i.e., the lower-left corner of the image bit map is (0, 0). The mask can be NIL if the icon is rectangular. The image should be white where it is covered by the title region (in any event, TITLEDICONW clears the region before printing on it).

The title is printed into the specified region in the image, using *FONT*, which if *NIL* defaults to the value of *DEFAULTICONFONT*, initially Helvetica 10. The title is broken into multiple lines if necessary; *TITLEDICONW* attempts to place the breaks at characters that are in the list of character codes *BREAKCHARS*. *BREAKCHARS* defaults to (CHARCODE (SPACE *Ÿ*)). In addition, line breaks are forced by any carriage returns in *TITLE*, independent of *BREAKCHARS*. *BREAKCHARS* is ignored as needed if a long title would not otherwise fit in the specified region. For convenience, *BREAKCHARS* = *FILE* means the title is a file name, so break at file name field delimiters.

The argument *JUST* indicates how the text should be justified relative to the region—it is an atom or list of atoms chosen from *TOP*, *BOTTOM*, *LEFT*, or *RIGHT*, which indicate the vertical positioning (flush to top or bottom) and/or horizontal positioning (flush to left edge or right). Where not indicated, the text is centered.

The argument *OPERATION* is a display stream operation indicating how the title should be printed. If *OPERATION* is *INVERT*, then the title is printed white-on-black. The default *OPERATION* is *REPLACE*, meaning black-on-white. *ERASE* is the same as *INVERT*; *PAINT* is the same as *REPLACE*.

For convenience, *TITLEDICONW* can also be used to create icons that consist solely of a title, with no special image. If the argument *ICON* is *NIL*, *TITLEDICONW* creates a rectangular icon large enough to contain *TITLE*, with a border the same width as a regular window. The remaining arguments are as described above, except that a *JUST* of *TOP* or *BOTTOM* is not meaningful.

---

## Modifying Icons

---

(*ICONW*.*TITLE* *ICON* *TITLE*)

[Function]

Returns the current title of the window *ICON*, which must be a window returned by *TITLEDICONW*. Additionally, if *TITLE* is non-*NIL*, makes *TITLE* be the new title of the window and repaints it accordingly. To erase the current title, make *TITLE* be a null string.

(ICONW.SHADE *WINDOW SHADE*)

[Function]

Returns the current shading of the window *ICON*, which must be a window returned by *ICONW* or *TITLEDICONW*. Additionally, if *SHADE* is non-NIL, paints the texture *SHADE* on *WINDOW*. A typical use for this function is to communicate a change of state in a window that is shrunk, without reopening the window. To remove any shading, make *SHADE* be *WHITESHADE*.

---

## Default Icons

---

When you shrink a window that has no *ICONFN*, the system currently creates an icon that looks like the window's title bar. You can make the system instead create titled icons by setting the global variable *DEFAULTICONFN* to the value *TEXTICON*.

(TEXTICON *WINDOW TEXT*)

[Function]

Creates a titled icon window for the main window *WINDOW* containing the text *TEXT*, or the window's title if *TEXT* is NIL.

DEFAULTTEXTICON

[Variable]

The value that *TEXTICON* passes to *TITLEDICONW* as its *ICON* argument. Initially NIL, which creates an unadorned rectangular window, but you can set it to a *TITLEDICON* record of your choosing if you would like default icons to have a different appearance.

---

## Sample Icons

---

The file <LispUsers>StockIcons contains a collection of icons and their masks usable with *ICONW*, including:

FOLDER, FOLDERMASK—A file folder

PAPERICON, PAPERICONMASK—A sheet of paper with the top right corner turned

FILEDRAWER, FILEDRAWERMASK—The front of a file drawer

ENVELOPEICON, ENVELOPEMASK—An envelope

TITLED.FILEDRAWER—A TitledIcon of the filedrawer front (Capacity, about three lines of 10-pt. text)

TITLED.FILEFOLDER—A TitledIcon of the file folder (Capacity, about three lines of 10-pt. text)

TITLED.ENVELOPE—A TitledIcon of the envelope (Capacity, one short line of 10-pt. text)

## APPENDIX B. SEDIT—THE LISP EDITOR

---

SEdit is the Xerox Lisp structure editor. It allows you to edit Xerox Lisp code directly in memory. This editor replaces DEdit in Chapter 16, Structure Editor, of the *Interlisp-D Reference Manual*. First introduced in Lyric, the SEdit structure editor has been greatly enhanced in the Medley release. Medley additions are indicated with revision bars in the right margin.

All symbols referenced in this appendix are external in the package named "SEdit", unless otherwise qualified.

---

### 16.1 SEdit - The Structure Editor

---

As a structure editor, SEdit alters Lisp code directly in memory. The effect this has on the running system depends on what is being edited.

For Common Lisp definitions, SEdit always edits a copy of the object. For example, with functions, it edits the definition of the function. What the system actually runs is the installed function, either compiled or interpreted. The primary difference between the definition and the installed function is that comment forms are removed from the definition to produce the installed function. The changes made while editing a function will not be installed until the edit session is complete.

For Interlisp functions and macros, SEdit edits the actual structure that will be run. An exception to this is an edit of an EXPR definition of a compiled function. In this case, changes are included and the function is unsaved when the edit session is completed.

SEdit edits all other structures, such as variables and property lists, directly. SEdit installs all changes as they are made.

If an error is made during an SEdit session, abort the edit with an Abort command (see Section 16.1.7, Command Keys). This command undoes all changes from the beginning of the edit session and exits from SEdit without changing your environment.

If the definition being edited is redefined while the edit window is open, SEdit redisplay the new definition. Any edits on the old definition will be lost. If SEdit was busy when the redefinition occurred, the SEdit window will be gray. When SEdit is no longer busy, position the cursor in the SEdit window and press the left mouse button; SEdit will get the new definition and display it.

### 16.1.1 An Edit Session

---

The List Structure Editor discussion in Chapter 3, Language Integration, explains how to start an editor in Xerox Lisp.

Whenever you call SEdit, a new SEdit window is created. This SEdit window has its own process, and thus does not rely on an Exec to run in. You can make edits in the window, shrink it while you do something else, expand it and edit some more, and finally close the window when you are done.

Throughout an edit session, SEdit remembers everything that you do through a change history. All edits can be undone and redone sequentially. When an edit session ends, SEdit forgets this information and installs the changes in the system.

The session ends with an event signalling to the editor that changes are complete. Three events signal completion:

- Closing the window.

Do this to terminate the edit session when you are finished.

- Shrinking the window.

Shrink the window when you have made some edits and may want to continue the editing session at a later time.

- Typing one of the Completion Commands, listed below.

Each of these commands has the effect of installing your changes, completing the edit, and returning the TTY process to the Exec. They vary in what is done in addition to completing. Using these commands the definition that you were editing can be automatically compiled, the edit window can be closed, or both.

A new edit session begins when you come back to an SEdit after completing. The change history is discarded at this point.

If the Exec is waiting for SEdit to return before going on, complete the edit session using any of the methods above to alert the Exec that SEdit is done. The TTY process passes back to the Exec.

### 16.1.2 SEdit Carets

---

There are two carets in SEdit, the edit caret and the structure caret. The edit caret appears when characters are edited within a single structure, such as an atom, string, or comment. Anything typed in will appear at the edit caret as part of the structure that the caret is within. The edit caret looks like this:

(a  b)

The structure caret appears when the edit point is between structures, so that anything inserted will go into a new structure. It looks like this:

(a  b)

SEdit changes the caret frequently, depending on where you are in the structure you are editing, and how the caret is positioned. The left mouse button allows an edit caret position to be set. The middle mouse button allows the structure caret position to be set.

### 16.1.3 The Mouse

In SEdit, the mouse buttons are used as follows. The left mouse button positions the mouse cursor to point to parts of Lisp structures. The middle mouse button positions the mouse cursor to point to whole Lisp structures. Thus, selecting the Q in LEQ using the left mouse button selects that character, and sets the edit caret after the Q:

```
(LEQ▲ n 1)
```

Any characters typed in at this point would be appended to the atom LEQ.

Selecting the same letter using the middle mouse button selects the whole atom (this convention matches TEdit's character/word selection convention), and sets a structure caret between the LEQ and the n:

```
(LEQ▲ n 1)
```

At this point, any characters typed in would form a new atom between the LEQ and the n.

Larger structures can be selected in two ways. Use the middle mouse button to position the mouse cursor on the parenthesis of the desired list to select that list. Press the mouse button multiple times, without moving the mouse, extends the selection. Using the previous example, if the middle button were pressed twice, the list (LEQ ...) would be selected:

```
(LEQ n 1)
```

Pressing the button a third time would cause the list containing the (LEQ n 1) to be selected.

The right mouse button positions the mouse cursor for selecting sequences of structures or substructures. Extended selections are indicated by a box enclosing the structures selected. The selection is extended in the same mode as the original selection. That is, if the original selection were a character selection, the right button could be used to select more characters in the same atom. Extended selections also have the property of being marked for pending deletion. That is, the selection takes the place of the caret, and anything typed in is inserted in place of the selection.

For example, selecting the E by pressing the left mouse button and selecting the Q by pressing the right mouse button would produce:

```
(LEQ□ n 1)
```

Similarly, pressing the middle mouse button and then selecting with the right mouse button extends the selection by whole structures. Thus, in our example, pressing the middle mouse button to select LEQ and pressing the right mouse button to select the 1 would produce:

This is not the same as selecting the entire list, as above. Instead, the elements in the list are collectively selected, but the list itself is not.

#### 16.1.4 Gaps

---

The SEdit structure editor requires that everything edited must have an underlying Lisp structure, even if the structure is not directly displayed. For example, with quoted forms the actual structure might be (**QUOTE** GREEN), although this would be displayed as 'GREEN. Even when the user is in the midst of typing in a form, the underlying Lisp structure must exist.

Because of this necessity, SEdit provides gaps to serve as dummy Lisp objects during typing. SEdit does not need a gap for every form typed in, but gaps are necessary for quoted objects. When something is typed that requires SEdit to build a Lisp structure and thus create a gap, as the quote character does, the gap will appear marked for pending deletion. This means it is ready to be replaced by the structure to be typed in. In this way it is possible to type special structures, like quotes, directly, while SEdit maintains the structure.

A gap looks like: -x-

A gap displayed after a quote has been typed in would look like this:

with the gap marked for pending deletion, ready for typein of the object to be quoted.

#### 16.1.5 Special Characters

---

A few characters have special meaning in Lisp, and are treated specially by SEdit. SEdit must always have a complete structure to work on at any level of the edit. This means that SEdit needs a special way to type in structures such as lists, strings, and quoted objects. In most instances these structures can be typed in just as they would be to a regular Exec, but in a few cases this is not possible.

##### Lists- ( and )

Lists begin with an open parenthesis character (. Typing an open parenthesis gives a balanced list, that is, SEdit inserts both an open and a close parenthesis. The structure caret is between the two parentheses. List elements can be typed in at the structure caret. When a close parenthesis, ) is typed, the caret will be moved outside the list (and the close parenthesis), effectively finishing the

list. Square bracket characters, [ and ], have no special meaning in SEdit, as they have no special meaning in Common Lisp.

## Quoted Structures:

SEdit handles the quote keys so that it is possible to type in all quote forms directly. When typing one of the following quote keys at a structure caret, the quote character typed will appear, followed by a gap to be replaced by the object to be quoted.

### Single Quote – ’

Use to enter quoted structures.

### Backquote – `

Use to enter backquoted structures.

### Comma – ,

Use to enter comma forms, as used with a Backquote form.

### At Sign – @

Use after a comma to create a comma-at-sign gap. This allows type-in of comma-at forms, e.g. ,@list, as used within a Backquote form.

### Dot – .

Use the dot (period) after a comma to create a comma-dot gap. This allows type-in of comma-dot forms, e.g. ,.list, as used within a Backquote form.

### Hash Quote – #'

Use this two character sequence to enter the **CL:FUNCTION** abbreviation hash-quote (#').

## Dotted Lists:

The dot, or period, character (.) is used to type dotted lists in SEdit. After typing a dot, SEdit inserts a dot and a gap to fill in for the tail of the list. To dot an existing list, point the cursor between the last and second to the last element in the list, and type a dot. To undot a list, select the tail of the list before the dot while holding down the SHIFT key.

## Escape- \ or %

Use to escape from a specific typed in character. Use the escape key to enter characters, like parentheses, which otherwise have special meaning to the SEdit reader. Press the escape key then type in the character to escape. SEdit uses the escape key appropriate to the environment it is editing in; it depends on the readtable that was current when the editor was started. The backslash key (\) is used when editing Common Lisp, and the percent key (%) is used when editing Interlisp.

## Multiple Escape- |

Use the multiple escape key, the vertical bar character (|), to escape a sequence of typed in characters. SEdit always balances multiple escape characters. When one multiple escape character is typed, SEdit produces a balanced pair, with the caret between them, ready for typing in the characters to be escaped. If you type a second vertical bar, the caret moves after the second vertical bar, and is still within the same atom, so that you can add more unescaped characters to the atom.

## Comments- ;

The comment key, a semicolon (;), starts a comment. When a semicolon is typed, an empty comment is inserted with the caret in position for typing in the comment. Comments can be edited like strings. There are three levels of comments supported by SEdit: single, double, and triple. Single semicolon comments are formatted at the comment column, about three-quarters of the way across the SEdit window, towards the right margin. Double semicolon comments are formatted at the current indentation of the code that they are in. Triple semicolon comments are formatted against the left margin of the SEdit window. The level of a

comment can be increased or decreased by pointing after the semicolon, and either typing another semicolon, or backspacing over the preceding semicolon. Comments can be placed anywhere in your Common Lisp code. However, in Interlisp code, they must follow the placement rules for Interlisp comments.

**Strings- "**

Enter strings in SEdit by typing a double quote ("). SEdit balances the double quotes. When one is typed, SEdit produces a second, with the caret between the two, ready for typing the characters of the string. If a double quote character is typed in the middle of a string, SEdit breaks the string into two smaller strings, leaving the caret between them.

---

**16.1.6 Commands**

---

SEdit commands are most easily entered through the keyboard. When possible, SEdit uses a named key on the keyboard, for example, the DELETE key. The other commands are either Meta, Control, or Meta-Control key combinations. For the alphabetic command keys, either uppercase or lowercase will work.

There are two menus available, as an alternative means of invoking commands. They are the middle button popup menu, and the attached command menu. These menus are described in more detail below.

---

**16.1.6 Editing Commands**

---

|                             |                  |
|-----------------------------|------------------|
| <b>Redisplay: Control-L</b> | [Editor Command] |
|-----------------------------|------------------|

Redisplays the structure being edited.

|                                 |                  |
|---------------------------------|------------------|
| <b>Delete Selection: DELETE</b> | [Editor Command] |
|---------------------------------|------------------|

Deletes the current selection.

|                               |                  |
|-------------------------------|------------------|
| <b>Delete Word: Control-W</b> | [Editor Command] |
|-------------------------------|------------------|

Deletes the previous atom or whole structure. If the caret is in the middle of an atom, deletes backward to the beginning of the atom only.

---

**16.1.7 Completion Commands**

---

|                      |                  |
|----------------------|------------------|
| <b>Abort: Meta-A</b> | [Editor Command] |
|----------------------|------------------|

Aborts. This command must be confirmed. All changes since the beginning of the edit session are undone, and the edit is closed.

The following commands signal completion of an edit session and install the structure you were editing.

|                  |                  |
|------------------|------------------|
| <b>Control-X</b> | [Editor Command] |
|------------------|------------------|

Signals the system that this edit is complete. The window remains open, though, so the user can see the edit and start editing again directly.

|                  |                  |
|------------------|------------------|
| <b>Control-C</b> | [Editor Command] |
|------------------|------------------|

Signals the system that this edit is complete and compiles the definition being edited. The variable \*compile-fn\* determines the

function to be called to do the compilation. See the Options section below.

---

**Meta-Control-X** [Editor Command]

---

Signals the system that this edit is complete and closes the window.

---

**Meta-Control-C** [Editor Command]

---

Signals the system that this edit is complete, compiles the definition being editing, and closes the window.

### 16.1.8 Undo Commands

---

---

**Undo: Meta-U or UNDO** [Editor Command]

---

Undoes the last edit. All changes since the beginning of the edit session are remembered, and can be undone sequentially.

---

**Redo: Meta-R or AGAIN** [Editor Command]

---

Redoes the edit change that was just undone. Redo only works directly following an Undo. Any number of Undo commands can be sequentially redone.

### 16.1.9 Find Commands

---

---

**Find: Meta-F or FIND** [Editor Command]

---

Finds a specified structure, or sequence of structures. If there is a current selection, SEdit looks for the next occurrence of the selected structure. If there is no selection, SEdit prompts for the structure to find, and searches forward from the position of the caret. The found structure will be selected, so the Find command can be used to easily find the same structure again.

If a sequence of structures is selected, SEdit will look for the next occurrence of the same sequence. Similarly, when SEdit prompts for the structure to find, you can type a sequence of structures to look for.

The variable *\*wrap-search\** controls whether or not SEdit wraps around from the end of the structure being edited and continues searching from the beginning.

---

**Reverse Find: Control-Meta-F** [Editor Command]

---

Finds a specified structure, searching in reverse from the position of the caret.

The variable *\*wrap-search\** controls whether or not SEdit wraps around from the beginning of the structure being edited and continues searching from the end.

---

**Find Gap: Meta-N or SKIP-NEXT**[Editor Command]

---

Skips to the next gap in the structure, leaving it selected for pending deletion.

---

**Substitute: Meta-S or SHIFT-FIND**[Editor Command]

---

Substitutes one structure, or sequence of structures, for another structure, or sequence, within the current selection. SEdit prompts you in the SEdit prompt window for the structures to replace, and the structures to replace with.

The selection to substitute within must be a structure selection. To get a structure selection, click with the middle mouse button (not the left), and extend it, if necessary, with the right mouse button. If you begin with the left button, you will get an informational message "Select the structure to substitute within", because the selection was of characters, rather than structures.

---

**Delete Structure: Meta-Control-S**[Editor Command]

---

Removes all occurrences of a structure or sequence of structures within the current selection. SEdit prompts the user in the SEdit prompt window for the structures to delete.

---

**16.1.9 General Commands**

---

---

**Arglist: Meta-H or HELP**[Editor Command]

---

Shows the argument list for the function currently selected, or currently being typed in, in the SEdit prompt window. If the argument list will not fit in the SEdit prompt window, it is displayed in the main Prompt Window.

---

**Convert Comments: Meta-;**[Editor Command]

---

Converts old style comments in the selected structure to new style comments. This converter notices any list that begins with an asterisk (\*) in the INTERLISP package (IL:\*) as an old style comment. Section 16.1.11, Options, describes the converter options .

---

**Edit: Meta-O**[Editor Command]

---

Edits the definition of the current selection. If the selected name has more than one type of definition, SEdit asks for the type to be edited. If the selection has no definition, a menu pops up. This menu lets the user specify either the type of definition to be created, or no definition if none needs to be created.

---

**Eval: Meta-E or Do-It**[Editor Command]

---

Evaluates the current selection. If the result is a structure, the inspector is called on it, allowing the user to choose how to look at the result. Otherwise, the result is printed in the SEdit prompt window. The evaluation is done in the process from which the edit session was started. Thus, while editing a function from a break window, evaluations are done in the context of the break.

---

**Expand: Meta-X or EXPAND**[Editor Command]

---

Replaces the current selection with its definition. This command can be used to expand macros and translate CLISP.

**Extract: Meta- /** [Editor Command]

Extracts one level of structure from the current selection. If the current selection is an atom, or if there is no selection, the next largest structure containing this atom, or caret, is used. This command can be used to strip the parentheses off a list or a comment, or to unquote a quoted structure.

**Inspect: Meta-I** [Editor Command]

Inspect the current selection.

**Join: Meta-J** [Editor Command]

Joins. This command joins any number of sequential Lisp objects of the same type into one object of that type. Join is supported for atoms, strings, lists, and comments. In addition, SEdit permits joining of a sequence of atoms and strings, since either type can easily be coerced into the other. In this case, the result of the Join will be an atom if the first object in the selection is an atom, otherwise the result will be a string.

**Mutate: Meta-Z** [Editor Command]

Mutates. This command allows the user to do arbitrary operations on a LISP structure. First select the structure to be mutated (it must be a whole structure, not an extended selection). When the user presses Meta-Z SEdit prompts for the function to use for mutating. This function is called with the selected structure as its argument, and the structure is replaced with the result of the mutation.

For example, an atom can be put in upper case by selecting the atom and mutating by the function U-CASE. You can replace a structure with its value by selecting it and mutating by EVAL.

**Quote: Meta-'**  
**Meta-'**  
**Meta-,**  
**Meta-.**  
**Meta-@ or Meta-2**  
**Meta-# or Meta-3** [Editor Command]

Quotes the current selection with the specified kind of quote, respectively, Single Quote, Backquote, Comma, Comma-At-Sign, Comma-Dot, or Hash-Quote.

**Parenthesize: Meta- ) or Meta-0** [Editor Command]

Parenthesizes the current selection, positioning the caret after the new list.

**Parenthesize: Meta- ( or Meta-9** [Editor Command]

Parenthesizes the current selection, positioning the caret at the beginning of the new list. Only a whole structure selection or an extended selection of a sequence of whole structures can be parenthesized.

### 16.1.10 Miscellaneous

---

**Change Print Base: Meta-B**

[Editor Command]

Changes Print Base. Prompts for entry of the desired Print Base, in decimal. SEdit redisplay fixed point numbers in this new base.

---

**Set Package: Meta-P**

[Editor Command]

Changes the current package for this edit. Prompts the user, in the SEdit prompt window, for a new package name. SEdit will redisplay atoms with respect to that package.

---

**Attached Menu: Meta-M**

[Editor Command]

Attaches a menu of the commonly used commands (the SEdit Command Menu) to the top of the SEdit window. Each SEdit window can have its own menu, if desired.

### 16.1.10 Help Menu

When the mouse cursor is positioned in the SEdit title bar and the middle mouse button is pressed, a Help Menu of commands pops up. The menu looks like this:

| Commands               |       |
|------------------------|-------|
| Abort                  | M-A   |
| Done                   | C-X   |
| Done & Compile         | C-C   |
| Done & Close           | M-C-X |
| Done, Compile, & Close | M-C-C |
| Undo                   | M-U   |
| Redo                   | M-R   |
| Find                   | M-F   |
| Reverse Find           | M-C-F |
| Remove                 | M-C-S |
| Substitute             | M-S   |
| Find Gap               | M-N   |
| Arglist                | M-H   |
| Convert Comment        | M-;   |
| Edit                   | M-O   |
| Eval                   | M-E   |
| Expand                 | M-X   |
| Extract                | M-/   |
| Inspect                | M-I   |
| Join                   | M-J   |
| Mutate                 | M-Z   |
| Parenthesize           | M-(   |
| Quote                  | M-'   |
| Set Print-Base         | M-B   |
| Set Package            | M-P   |
| Attach Menu            | M-M   |

The Help Menu lists each command and its corresponding Command Key. (In the menu, the letter C stands for CONTROL, while M indicates Meta.) The command selected is executed just as if the command had been entered from the keyboard. The menu remembers which command was selected last, and pops up with the mouse cursor next to that same command the next time the menu is used. This provides a very fast way to repeat the same command when using the mouse.

### 16.1.9 Command Menu

The SEdit Attached Command Menu contains the commonly used commands. Use the Meta-M keyboard command to bring up this menu. The menu can be closed, independently of the SEdit window, when desired. The menu looks like:

All of the commands in the menu function identically to their corresponding keyboard commands, except for Find and Substitute.

When Find is selected with the mouse cursor, SEdit prompts in the menu window, next to the Find button, for the structures to find. Type in the structures then select Find again. The search begins from the caret position in the SEdit window.

Similarly, Substitute prompts, next to the Find button, for the structures to find, and next to the Substitute button for the structures to substitute with. After both have been typed in, selecting Substitute replaces all occurrences of the Find structures with the Substitute structures, within the current selection.

To do a confirmed substitute, set the edit point before the first desired substitution, and select Find. Then if you want to substitute that occurrence of the structure, select Substitute. Otherwise, select Find again to go on.

Selecting either Find or Substitute with the right mouse button erases the old structure to find or substitute from the menu, and prompts for a new one.

### 16.1.11 SEdit Window Region Manager

SEdit provides user redefinable functions which control how SEdit chooses the region for a new edit window.

**(Get-Window-Region** *CONTEXT REASON NAME TYPE*)

**[Function]**

This function is called when SEdit wants to know where to place a window it is about to open. This happens whenever the user starts a new SEdit or expands an Sedit icon. The default behavior is to

pop a window region off SEdit's stack of regions that have been used in the past. If the stack is empty, SEdit prompts for a new region.

This function can be redefined to provide different behavior. It is called with the edit *CONTEXT*, a *REASON* for needing a region, the *NAME* of the structure to be edited, and the *TYPE* of the structure to be edited. The edit *CONTEXT* is SEdit's main data structure and can be useful for associating particular edits with specific regions. The *REASON* argument specifies why SEdit wants a region, and will be one of the keywords :CREATE or :EXPAND.

---

**(Save-Window-Region *CONTEXT REASON NAME TYPE REGION*)** [Function]

This function is called whenever SEdit is finished with a region and wants to make the region available for other SEdits. This happens whenever an SEdit window is closed or shrunk, or when an SEdit icon is closed. The default behavior is simply to push the region onto SEdit's stack of regions.

This function can be redefined to provide different behavior. It is also called with the edit *CONTEXT*, the *REASON*, the *NAME*, the *TYPE*, and additionally the window *REGION* that is being released. The *REASON* argument specifies why SEdit is releasing the region, and will be one of the keywords :CLOSE, :SHRINK, or :CLOSE-ICON.

---

**Keep-Window-Region** [Variable]

Default **T**. This flag determines the behavior of the default SEdit region manager, explained above, for shrinking and expanding windows. When set to **T**, shrinking an SEdit window will not give up that window's region; the icon will always expand back into the same region. When set to **NIL**, the window's region is made available for other SEdits when the window is shrunk. Then when an SEdit icon is expanded, the window will be reshaped to the next available region.

This variable is only used by the default implementations of the functions **Get-Window-Region** and **Save-Window-Region**. If these functions are redefined, this flag is no longer used.

---

### 16.1.12 Options

The following parameters can be set as desired.

---

**\*Wrap-Parens\*** [Variable]

This SEdit pretty printer flag determines whether or not trailing close parenthesis characters, ), are forced to be visible in the window without scrolling. By default it is set to **NIL**, meaning that close parens are allowed to "fall off" the right edge of the window. If set to **T**, the pretty printer will start a new line before the structure preceding the close parens, so that all the parens will be visible.

---

**\*Wrap-Search\*** [Variable]

This flag determines whether or not SEdit find will wrap around to the top of the structure when it reaches the end, or vice versa in the case of reverse find. The default is **NIL**.

**\*Clear-Linear-On-Completion\***

[Variable]

This flag determines whether or not SEdit completely re-pretty prints the structure being edited when you complete the edit. The default value is NIL, meaning that SEdit reuses the pretty printing.

**Convert-Upgrade**

[Variable]

Default 100. When using Meta-; to convert old-style single- asterisk comments, if the length of the comment exceeds **Convert-Upgrade** characters, the comment is converted into a double semicolon comment. Otherwise, the comment is converted into a single semicolon comment.

Old-style double-asterisk comments are always converted into new-style triple-semicolon comments.

**16.1.13 Control Functions****(Reset)**

[Function]

This function recomputes the SEdit edit environment. Any changes made in the font profile, or any changes made to SEdit's commands are captured by resetting. Close all SEdit windows before calling this function.

**(Add-Command KEY-CODE FORM &OPTIONAL KEY-NAME COMMAND-STRING HELP-STRING)**

[Function]

This function allows you to write your own SEdit keyboard commands. You can add commands to new keys, or you can redefine keys that SEdit already uses as command keys. If you mistakenly redefine an SEdit command, the function Reset-Commands will remove all user-added commands, leaving SEdit with its default set of commands.

*KEY-CODE* can be a character code, or any form acceptable to il:charcode.

*FORM* determines the function to be called when the key command is typed. It can be a symbol naming a function, or a list, whose first element is a symbol naming a function and the rest of the elements are extra arguments to the function. When the command is invoked, SEdit will apply the function to the edit context (SEdit's main data structure), the charcode that was typed, and any extra arguments supplied in *FORM*. The extra arguments do not get evaluated, but are useful as keywords or flags, depending on how the command was invoked. The command function must return T if it handled the command. If the function returns NIL, SEdit will ignore the command and insert the character typed.

The optional arguments are used to add this command to SEdit's middle button menu. When the item is selected from the menu, the command function will be called as described above, with the charcode argument set to NIL.

*KEY-NAME* is a string to identify the key (combination) to be typed to invoke the command. For example "M-A" to represent the Meta-A key combination, and "M-C-A" for Meta-Control-A.

*COMMAND-NAME* is a string to identify the command function, and will appear in the menu next to the *KEY-NAME*.

*HELP-STRING* is a string to be printed in the prompt window when a mouse button is held down over the menu item.

After adding all the commands that you want, you must call **Reset-Commands** to install them.

For example:

```
(add-command "↑U" (my-change-case t))
(add-command "↑Y" (my-change-case nil))
(add-command "l,r" my-remove-nil
 "M-R" "Remove NIL"
 "Remove NIL from the selected structure"))
(reset-commands)
```

will add three commands. Suppose *my-change-case* takes the arguments *CONTEXT*, *CHARCODE*, and *UPPER-CASE?*. *UPPER-CASE?* will be set to T when *my-change-case* is called from Control-U, and NIL when called from Control-Y. *my-remove-nil* will be called with only *CONTEXT* and *CHARCODE* arguments when Meta-R is typed.

Below are some SEdit functions which are useful in writing new commands.

---

**(Reset-Commands)****[Function]**

This function installs all commands added by **Add-Command**. SEdits which are open at the time of the **Reset-Commands** will not see the new commands; only new SEdits will have the new commands available.

---

**(Default-Commands)****[Function]**

This function removes all commands added by **Add-Command**, leaving SEdit with its default set of commands. As in **Reset-Commands**, open SEdits will not be changed; only new SEdits will have the user commands removed.

---

**(Get-Prompt-Window *CONTEXT*)****[Function]**

This function returns the attached prompt window for a particular SEdit.

---

**(Get-Selection *CONTEXT*)****[Function]**

This function returns two values: the selected structure, and the type of selection, one of NIL, T, or :SUB-LIST. The selection type NIL means there is not a valid selection (in this case the structure is meaningless). T means the selection is one complete structure. :SUB-LIST means a series of elements in a list is selected, in which case the structure returned is a list of the elements selected.

---

**(Replace-Selection *CONTEXT STRUCTURE SELECTION-TYPE*)****[Function]**

---

This function replaces the current selection with a new structure, or multiple structures, by deleting the selection and then inserting the new structure(s). The *SELECTION-TYPE* argument must be one of T or :SUB-LIST. If T the *STRUCTURE* is inserted as one complete structure. If :SUB-LIST, the *STRUCTURE* is treated as a list of elements, each of which is inserted.

### 16.1.13 Programmer's Interface

This programmer's interface to SEdit provides a way to call SEdit directly. This interface is sketchy and will change in the future.

**\*Getdef-Fn\*** [Variable]

This function is called with the arguments *NAME*, *TYPE*, and *OLDDEF*, when SEdit needs to refetch the definition for the named object being edited. When SEdit is first started it gets passed the structure, so this function doesn't get called. But after completion, SEdit refetches because it doesn't know if the Edit Interface (File Manager) changed the definition upon installation. The function returns the new definition.

**\*Fetch-Definition-Error-Break-Flag\*** [Variable]

This flag, along with the error options listed below, determines what happens when the Getdef-Fn errors. The default value is NIL, causing errors to be suppressed. When set to T, the break will be allowed.

**\*Getdef-Error-Fn\*** [Variable]

This function is funcalled with the arguments *NAME*, *TYPE*, *OLDDEF*, and *PROMPT-WINDOW*, when the Getdef-Fn errors, independent of whether or not the break is suppressed. This function should return the structure to be used in place of the unavailable new definition.

**\*Edit-Fn\*** [Variable]

This function is funcalled with the selected structure as its argument from the Edit (M-O) command. It should start the editor as appropriate, or else generate an error if the selection is not editable.

**\*Compile-Fn\*** [Variable]

This function is funcalled with the arguments *NAME*, *TYPE*, and *BODY*, from the compile completion commands. It should compile the definition, *BODY*, and install the code as appropriate.

**(SEdit STRUCTURE PROPS OPTIONS)** [Function]

This function provides a means of starting SEdit directly. *STRUCTURE* is the structure to be edited.

*PROPS* is a property list, which may specify the following properties:

:name - the name of the object being edited

:type - the file manager type of the object being edited. If NIL, SEdit will not call the file manager when it tries to refetch the

definition it is editing. Instead, it will just continue to use the structure that it has.

:completion-fn - the function to be called when the edit session is completed. This function is called with the *CONTEXT*, *STRUCTURE*, and *CHANGED?* arguments. *CONTEXT* is SEdits main data structure. *STRUCTURE* is the structure being edited. *CHANGED?* specifies if any changes have been made, and is one of NIL, T, or :ABORT, where :ABORT means the user is aborting the edit and throwing away any changes made. If the value of this property is a list, the first element is treated as the function, and the rest of the elements are extra arguments that the function is applied to following the main arguments above.

:root-changed-fn - the function to be called when the entire structure being edited is replaced with a new structure. This function is called with the new structure as its argument. If the value of this property is a list, the first element is treated as the function, and the rest of the elements are extra arguments that the function is applied to following the structure argument.

*OPTIONS* is one or a list of any number of the following keywords:

:fetch-definition-suppress-errors - If this option is provided, any error under the Getdef-Fn will be suppressed, regardless of the :fetch-definition-allow-errors option or the value of **\*Fetch-Definition-Error-Break-Flag\***.

:fetch-definition-allow-errors - If this option is provided, any error under the Getdef-Fn will be allowed to break.

:dontwait - This option specifies that the call to **SEdit** should return as soon as the editor is started, rather than waiting for a completion command.

:close-on-completion - This option specifies that SEdit cannot remain active for multiple completions. That is, the SEdit window cannot be shrunk, and the completion commands that normally leave the window open will in this case close the window and terminate the edit.

:compile-on-completion - This option specifies that SEdit should call the \*Compile-Fn\* to compile the definition being edited upon completion, regardless of the completion command used.

---

## Fixed ARS

**AR 7471** ---- You no longer have to Ctrl-X out of SEdit to compile. To compile, select either of two new SEdit commands. The C-C command (Ctrl -C) compiles and leaves the SEdit window open. The M-C-C command (Meta-Ctrl- C) compiles and closes the window.

**AR 7783** ---- After typing Meta-O, you are prompted to "Select a type of dummy definition to install." The first option is "Optimizers". This title refers to XCL:DEFOPTIMIZERS, and has nothing to do with CL:OPTIMIZE.

**AR 7786** ---- Square bracket characters '[' and ']' are not treated as special characters by SEdit, just as in Common Lisp.

[This page intentionally left blank]

Test script for SEdit version February 24, 1987

SEE CHANGE CONTROL FOR THE FILE SEDIT

FIXED:

7692 M-E breaks on numbers  
7682 Ctrl-W with pending delete selection breaks  
7705 M-H with extended selection breaks  
7717 M-J breaks when nothing selected  
7759 forgets package of mutator candidate  
7731 M-J breaks with a sequence of numbers  
7509 SEDIT.RESET needs IP fonts  
7576 SEDIT.RELOAD should not be part of SEdit

Select a number and hit M-E, the result will be the number.

CTRL-W when there is a pending delete selection will do nothing. The easy test case is single-quote then ctrl-w.

Make an extended selection and hit M-H (help). Sedit will now say "Select function you want the arguments for"

Just after Starting SEdit, or any other time nothing is selected and/or there is no point, M-J used to break. Will now say "Select items to join."

SEdit now remembers the package of the mutate function candidate. Type in the atom abc. Get into the LISP package (M-P, LISP). Select the atom abc. Hit M-Z, and type IL:U-CASE, cr. Now hit M-Z again, the old SEdit would prompt with U-CASE, the new sedit will prompt with IL:U-CASE.

Select a sequence of numbers, or any sequence with a number first. Hit M-J. SEdit will say "Can't join numbers". SEdit will join AB 123 CD, though, as it used to.

With INTERPRESSFONTDIRECTORIES set to NIL, call SEDIT.RESET. It won't try to create IP fonts, and thus won't break.

The function SEDIT.RELOAD is not longer in the sysout.

„ wasn't recognized as a quote type. (SEdit '(BQUOTE (A (\, FOO) B) used to display as '(A (\, FOO) B) and now will display as '(A „FOO B).

And now for all the shift selecting stuff:

Weren't able to Move select a structure into a pending delete selection. Now you can unless the structure overlaps the pending delete selection in some way. SEdit will say "Can't move a structure which overlaps the selection" if you try.

Can move select an object out of a quote, into any destination (exec, same sedit, different sedit), and the object will be replaced by a gap, which is selected pending delete.

Shift selecting something into a string didn't use to be completely undoable. Try Move selecting an atom into a string, then hit undo.

Move selecting something into a different destination when there is a main selection used to leave the selection messed up. Now it doesn't.

---

---

## TWODINSPECTOR

---

---

By: Jan Pedersen (Pedersen.PA @ Xerox.ARPA)

The TWODINSPECTOR package provides a two-dimensional inspector window abstraction, very similar in form to the standard one-dimensional inspector but laid out in rows and columns, instead of just rows.

The top level function is TWODINSPECTW.CREATE

```
(TWODINSPECTW.CREATE DATUM ROWPROPS COLUMNPROPS FETCHFN ^
 STOREFN VALUECOMMANDFN ROWPROPCOMMANDFN ^
 COLUMNPROPCOMMANDFN TITLE TITLECOMMANDFN
 WHERE TOPRIGHT) [Function]
```

Datum is the object to be inspected. Rowprops is a list of properties of the datum which will be laid out vertically, or a function which will be called with datum as an argument and returns such a list. Similarly, columnprops is a list of properties of the datum which will be laid out horizontally, or a function which will be called with datum as an argument and returns such a list. Each pair (rowprop, columprop) specifies a cell of the twodimensional inspector window. Fetchfn is a function which if called with arguments datum, rowprop, and columprop returns the value in that cell. Storefn is a function which if called with arguments newvalue, datum, rowprop, and columprop stores newvalue in the cell.

The cells of the inspector window are selectable. If valuecommandfn is given, it must be a function which will be called with arguments cellvalue, rowprop, columprop, datum, and twodinspectwindow when the cell specified by (rowprop, columprop) is selected. A default valuecommandfn is provided which allows the cellvalue to be inspected, set, or bound to the litatom IT.

Similarly the rowprops and the columnprops themselves are selectable. If rowpropcommandfn is given it must be a function which will be called with args rowprop, datum, and twodinspectwindow when rowprop is selected. If columpropcommandfn is given it must be a function which will be called with args columprop, datum, and twodinspectwindow when columprop is selected. No default rowpropcommandfn or columpropcommandfn is provided. If rowpropcommandfn is not given, the rowprops will not be selectable. Similarly, If columpropcommandfn is not given, the columnprops will not be selectable.

Title will be the title for the window -- a default is provided. Titlecommandfn is a function which will be called with the single argument twodinspectwindow if the middle button is depressed in the title bar of the window.

Where may be a window, in which case it will be used as at least part of the twodinspector (the twodinspector is composed of five window), This is especially useful if where is the result of a previous

call to `TWODINSPECTW.CREATE`. The dimensions of `where` will not be used to position the `twodinspector` unless `topright` is `NIL`.

`Where` may also be region or a position specifying the lower left hand corner of the `twodinspector`. If `where` is `NIL`, the user will be prompted for a position.

`Topright` allows the user to specify the top right-hand corner of the `twodinspector`. `Topright` must be a position, and if given overrides any specification which may have been provided by the argument `where`.

Returns the main window of an attached window group.

The arguments to `TWODINSPECTW.CREATE` are cached on windowprops of the same name on the returned main window.

Several functions are provided for use in the various command functions.

(`TWODINSPECT.REDISPLAY` *TWODINSPECTW* *SOMEROWPROPS* ^  
*SOMECOLUMNPROPS*) [Function]

Redisplay selected cells of `twodinspectw`. `Somerowprops` may either be a single rowprop, a list of rowprops, or `NIL`. `Somecolumnprops` may either be a single columnprop, a list of columnprops, or `NIL`. If either are `NIL` the entire `twodinspectw` is recomputed and redisplayed. Otherwise, the cells specified by the cross product of `somerowprops` and `somecolumnprops` are redisplayed, possibly forcing the entire `twodinspectw` to redisplay if the printed representation of a cell overflows its column width.

(`TWODINSPECT.REPLACE` *TWODINSPECTW* *ROWPROP* *COLUMNPROP* ^  
*NEWVALUE*) [Function]

Replaces the cell specified by (`rowprop`, `columnprop`) with `newvalue` and updates the display.

(`TWODINSPECT.SELECTITEM` *TWODINSPECTW* *ROWPROP* *COLUMNPROP*) [Function]

Selects the cell specified by (`rowprop`, `columnprop`). That cell is inverted and put on the window prop `SELECTION` of `twodinspectw`. If either of `rowprop` or `columnprop` is `NIL`, then the current selection is simply deselected.

(`TWODINSPECT.SELECTROWPROP` *TWODINSPECTW* *ROWPROP*) [Function]

Selects `rowprop`. If `rowprop` is `NIL`, then the currently selected `rowprop` is deselected.

(TWODINSPECT.SELECTCOLUMNPROP *TWODINSPECTW* COLUMNPROP) [Function]

Selects columnprop. If rowprop is NIL, then the currently selected columnprop is deselected.

Note: there is no provision for redisplaying selected row or column props -- although this may be effected by redisplaying the entire twodinspectw.

Since the Twodinspector windows differ stylistically from the standard inspector windows, a stylistically similar onedinspector window is also provided.

(ONEDINSPECTW.CREATE *DATUM PROPS FETCHFN STOREFN VALUECOMMANDFN ^  
PROP COMMANDFN TITLE TITLECOMMANDFN WHERE TOPRIGHT*) [Function]

Datum is the object to be inspected. Props is a list of properties of the datum which will be laid out horizontally, or a function which will be called with datum as an argument and returns such a list. Each prop specifies a cell of the onedimensional inspector window. Fetchfn is a function which if called with arguments datum, and prop returns the value in that cell. Storefn is a function which if called with arguments newvalue, datum, and prop stores newvalue in the cell.

The cells of the inspector window are selectable. If valuecommandfn is given, it must be a function which will be called with arguments cellvalue, prop, datum, and onedinspectwindow when the cell specified by prop is selected. A default valuecommandfn is provided which allows the cellvalue to be inspected, set, or bound to the litatom IT.

Similarly the props themselves are selectable. If propcommandfn is given it must be a function which will be called with args prop, datum, and onedinspectwindow when prop is selected. No default propcommandfn is provided. If propcommandfn is not given, the props will not be selectable.

Title will be the title for the window -- a default is provided. Titlecommandfn is a function which will be called with the single argument onedinspectwindow if the middle button is depressed in the title bar of the window.

Where may be a window, in which case it will be used as at least part of the onedinspector (the onedinspector is composed of three window), This is especially useful if where is the result of a previous call to ONEDINSPECTW.CREATE or TWODINSPECTW.CREATE. The dimensions of where will not be used to position the onedinspector unless topright is NIL.

Where may also be region or a position specifying the lower left hand corner of the onedinspector. If where is NIL, the user will be prompted for a position.

Topright allows the user to specify the top right-hand corner of the onedinspector. Topright must be a position, and if given overrides any specification which may have been provided by the argument where.

Returns the main window of an attached window group.

The arguments to ONEDINSPECTW.CREATE are cached on windowprops of the same name on the returned main window.

(ONEDINSPECT.REDISPLAY *ONEDINSPECTW SOMEPROPS*) [Function]

Redisplay selected cells of onedinspectw. Someprops may either be a single prop, a list of props, or NIL, in which case the entire onedinspectw is recomputed and redisplayed. Otherwise, the cell(s) specified by the someprops are redisplayed, possibly forcing the entire someprops to redisplay if the printed representation of a cell overflows the column width.

(ONEDINSPECT.REPLACE *ONEDINSPECTW PROP NEWVALUE*) [Function]

Replaces the cell specified by prop with newvalue and updates the display.

(ONEDINSPECT.SELECTITEM *ONEDINSPECTW PROP*) [Function]

Selects the cell specified by prop. That cell is inverted and put on the window prop SELECTION of onedinspectw. If prop is NIL, then the current selection is simply deselected.

(ONEDINSPECT.SELECPROP *ONEDINSPECTW PROP*) [Function]

Selects prop. If prop is NIL, then the currently selected prop is deselected.

**BACKGROUND-MENU-BUTTONS**

---

---

By: Doug Cutting (Cutting.PA@Xerox.COM)

This document last edited on January 28, 1988.

**INTRODUCTION**

BACKGROUND-MENU-BUTTONS makes it easy for the Rooms user to make buttons which do the same things as entries on the background menu.

**EXPLANATION**

When this module is loaded a button labelled "Make Background Button" is placed on the screen. When this button is pressed a menu which looks just like the background menu is raised. Selecting an entry from this menu will create a button which does the same thing as this entry.

September, 1988

Dear ROOMS User:

Attached is the documentation for the Rooms User's modules.

Note that most of these modules include source code. Thus besides being useful in themselves, these modules provide good examples of programmatic use of ROOMS.

Rooms User modules are user-contributed software, and as such are not supported Envos products. We merely distribute these modules in hope that they will prove useful.

Please direct questions, suggestions and problems with Rooms User's modules directly to their authors. We have included the ARPAnet addresses of the authors in the documentation for this purpose.

We encourage you to contribute more Rooms User's modules. The same policies which apply to Lisp User's modules apply here. For more information see the Lisp User's guidelines distributed with the Medley release.

**INTRODUCTION**

>>This paragraph should be replaced by an overview of your module.<<

**MODULE EXPLANATIONS****>>Functions, Variables, and Lisp Code Examples<<**

It is usual to first give the name of a function, then describe its purpose and each of its arguments. When the name of a function is first given, it is set off like this:

(IMAGEFNSCREATE *DISPLAYFN IMAGEBOXFN PUTFN GETFN COPYFN*) [Function]

The function name is in 10-point regular Modern, all caps. Arguments are in 10-point italic Modern, in all caps, mixed case, or lowercase, as they appear in the system. Variables look like functions, except that the word "Variable," enclosed in **square brackets**, follows the variable name. Please note that these are the characters [], not the parentheses

This is an example of code. It is in 10-point Terminal font.

Function names, commands, file names, and the like are in 10-point modern.

Be sure to include the following information in any module explanations:

- any file dependencies
- definitions of all arguments
- module, function variable, etc. limitations
- a liberal number of examples for all functions, variables, etc.

## HYPERDESK and HYPERDESK-INIT

The HyperDesk (or "MobyDesk") sysout is a "Swiss Army Sysout" that includes much of the best local functionality. This includes Sketch, DictTool, PCL, CommonLens, Rooms, and Notecards. The HyperDesk-INIT file provides a powerful init file for HyperDesk Users as well as those that may use other sysouts but would like convenient access to HyperDesk functionality. This Init file can make life easier for those who don't hack their own init files by making it easier on those that are called in to do so. A reasonable goal is that users of this class wouldn't need separate init files and instead will be able to tailor thier environment through a control panel and automatic profile saving.

HYPERDESK

Author: Ramana Rao  
Filed on: {EG:PARC:XEROX}<RAO>HYPERDESK>HYPERDESK.TEDIT;5  
Last filed: April 26, 1988 14:14 PDT (Tuesday)  
Copyright © 1987 by Xerox Corporation. All rights reserved.

**\*DRAFT\***

## HYPERDESK

The HyperDesk.SYSOUT is available from <LISP>LYRIC>BASICS> on your favorite Lisp Servers (i.e. IE: and PHYLUM). It contains the SKETCH, DICTTOOL, ROOMS, PCL, COMMON-LENS, and NOTECARDS.

\CC-HYPERDESK-MSG

[Variable]

When HYPERDESK is greeted, it automatically sends a LAFITE message to the maintainer. By default this message is CC'ed to the person using the sysout; this CC'ing can be disabled by setting the variable \CC-HYPERDESK-MSG to NIL in the users Init File.

Loading HYPERDESK-INIT

## Loading HYPERDESK-INIT

The HYPERDESK-INIT file is available to PARC users of the Lyric release of Xerox Lisp. It can be found on the directory {EG:PARC:}<RAO>HYPERDESK>. Including the file command

```
(FILES (FROM LISPUSERS)
 "HYPERDESK-INIT")
```

in your personal INIT file will automatically load HYPERDESK-INIT when you start up a new Lisp.

HYPERDESK-INIT is essentially wrapping around GENERIC-INIT, so users of HYPERDESK-INIT should understand the essentials of GENERIC-INIT. Documentation for it is available from {EG:}<LANNING>LISP>USERS>GENERIC-INIT.TEDIT. Both of these centralized init files set variables and invoke operations that tailor the environment. Much of this behavior can be controlled or preempted by setting user parameters or special control variables either before or after the load of HYPERDESK-INIT. Two variables, LOGINHOST/DIR and HOME-MACHINE-NAME, must be set before the load of HYPERDESK-INIT (or at least setting them should be considered explicitly). These are used as control variables to GENERIC-INIT and are documented there.

An example of a minimal init file can be found on {EG:}<RAO>HYPERDESK>LYRIC-INIT. Any of these INIT files (HYPERDESK-INIT, GENERIC-INIT, LYRIC-INIT, my {EG:}<RAO>LISP>INIT-LYRIC or Stan's {EG:}<LANNING>LISP>LYRIC-INIT) can be

loaded prop into your sysout without any thing happening so you can see what would happen. The one caveat is that they will smash filecoms of files with the same name.

Tailoring HYPERDESK-INIT

## Tailoring HYPERDESK-INIT

There are a number of variables that can be set before and after loading HYPERDESK-INIT to tailor its behavior to ones liking. In addition, users can also tailor GENERIC-INIT by setting variables documented in the GENERIC-INIT documentation. A few of the GENERIC-INIT variables (\*LOAD-UTILITY-OPTIONS\*) are used by HYPERDESK-INIT, so users should use the variables provided by HYPERDESK-INIT as described below before resorting to GENERIC-INIT variables. Unless otherwise noted, all symbols described are in the INTERLISP package.

### Things you MAY do before loading

**\*HYPERDESK-FULL-INIT-P\*** [Variable]

When HYPERDESK-INIT is loaded, it will ask if it should do a full initialization. By default this message will time out, set this variable and continue to a full initialization. This is especially convenient for starting non-hyperdesk sysouts where you don't want to wait for special status hyperdesk functionality to be loaded.

**\*HYPERDESK-BASE-MODULES\*** [Variable]

**\*HYPERDESK-MODULES\*** [Variable]

**\*HYPERDESK-EXTRA-MODULES\*** [Variable]

These variables control what modules are loaded automatically by GENERIC-INIT. HYPERDESK-INIT initvars \*LOAD-UTILITY-OPTIONS\* to the append of these three variables in the order listed. \*HYPERDESK-MODULES\* is initialized to the special status hyperdesk modules (ROOMS, PCL, and COMMON-LENS, and a bunch of window types for ROOMS) unless \*HYPERDESK-FULL-INIT-P\* is NIL in which case \*LOAD-UTILITY-OPTIONS\* will not be touched. Note that these should all be lists of strings where the strings are the name of the package as seen on the Load Utility Menu (i.e. the name of the top level or only file of the module e.g. LoadPCL or COMMON-LENS). See GENERIC-INIT \*LOAD-UTILITY-OPTIONS\*.

## HYPERDESK

|                           |            |
|---------------------------|------------|
| *HYPERDESK-SUITES-P*      | [Variable] |
| *HYPERDESK-AX-POCKETS-P*  | [Variable] |
| *HYPERDESK-AX-ORIGINAL-P* | [Variable] |
| *HYPERFLOOR-SUITE-P*      | [Variable] |
| *HYPERDESK-SUITE-P*       | [Variable] |
| *HYPERDESK-USER-SUITES*   | [Variable] |

HYPERDESK-INIT provides some mechanisms for setting up initial suites. Setting \*HYPERDESK-SUITES-P\* to NIL will disable this facility altogether. Setting \*HYPERDESK-AX-POCKETS-P\* and \*HYPERDESK-AX-ORIGINAL-P\* to NIL will disable deletion of POCKETS and ORIGINAL rooms respectively. Setting \*HYPERFLOOR-SUITE-P\* and \*HYPERDESK-SUITE-P\* to NIL will disable loading of these two default suites respectively (note that disabling HYPERFLOOR suite will also disable the HYPERDESK Suite). Finally \*HYPERDESK-USER-SUITES\* should be a list of fully qualified file names that determine which suites get loaded initially.

Hyper Suites

## HyperFloor and HyperDesk Suites

HyperFloor and HyperDesk Suites provide a basic framework for working with Rooms and other HyperDesk functionality.

HyperFloor provides three rooms: HyperPanel which is basic inclusion room, Help where eventually various buttons for getting documentation will be put, and the Boiler Room where buttons for fixing things and dealing with the HyperDesk in general will be put. One particularly important button in the Boiler Room is one that allows you to reload the HyperFloor so you can import any recent additions to the Boiler or Help Rooms.

HyperDesk provides two rooms: Mail Room and Office. Users should copy these rooms to make suites of their own and avoid working in these if they want to build their own suite.

---

## LAFITE-WINDOW-TYPES

---

---

By: Doug Cutting (Cutting.PA@Xerox.COM)

This document last edited on January 28, 1988.

### **INTRODUCTION**

This module provides window types for Lafite windows. Lafite is the Interlisp-D mail program. Loading this module enables you to save Lafite windows in your suite files.

### **EXPLANATIONS**

We provide window types for Lafite browsers and for the Lafite status window.

Note: we do not provide window types for message windows, as these are far more transient than the status window and browsers.

---

---

**OFFICE.SUITE**

---

---

By: Doug Cutting (Cutting.PA@Xerox.COM)

This document last edited on January 28, 1988.

**INTRODUCTION**

This is a sample suite file.

Beginning Rooms users might load this, augment it as desired, and then use the "Dump Suite" command to save their own version of it.

This suite also gives some ideas about how one might use the facilities which Rooms provides.

**INSTALLATION**

Load the file OFFICE.SUITE. This file (like all suite files) will load ROOMS if it is not already loaded. It will then create the rooms in the OFFICE suite. Use the Overview to see these rooms.

---

---

**RANDOM-WINDOW-TYPES**

---

---

By: Doug Cutting (Cutting.PA@Xerox.COM),  
Stan Lanning (Lanning.PA@Xerox.COM) and  
Ramana Rao (Rao.PA@Xerox.COM)

This document last edited on April 21, 1988.

This module contains window type definitions for many LispUsers modules.

These definitions serve two purposes. Their primary purpose is to allow one to save windows created by these modules in suites. Secondly they provide good examples of window type definitions for the programmer attempting to define his own.

Modules covered are:

WHO-LINE  
CALENDAR  
PRINTERMENU  
CROCK  
BICLOCK  
ADDRESSBOOK  
PHONE-DIRECTORY  
GRID-ICONS

In addition, support is provided for the FILEWATCH LispUsers module. This works by adding a property to each room which notes whether FILEWATCH is on in that room. This property is not inherited, i.e. including a room in which FILEWATCH is does not turn FILEWATCH on.

A listing of RANDOM-WINDOW-TYPES can be found in Appendix A of this document.

# ROOMS™

## Overview

ROOMS is a powerful interface to the Medley lisp environment window management system. ROOMS effectively increases the size of the screen and allows you to organize the work environment to facilitate management of complex parallel tasks.

For example a user may be developing and debugging a program, writing a paper, doing background research, reading mail, and filing all more or less at the same time. With limited screen space a user performing all these activities loses productivity shuffling through windows, icons, and other assorted screen clutter in order to reestablish the context of a task. ROOMS solves this problem of context switching by allowing users to create workspaces (called rooms), each one analogous to another screen, and containing only those tools needed for a specific task. Moreover, ROOMS provides methods for easily moving from one room to another and customizing the "look" of each room further aiding in efficient task-switching.

By providing dedicated workspaces, ease of navigation between workspaces, and a graphical link between each workspace and its related task, ROOMS helps users minimize context recovery time caused by task switching. In addition ROOMS provides an easy means to develop highly graphical custom interfaces for

end-user applications. The overall result of this seamless integration of form and functionality is increased productivity in performing tasks in the Envos Software Development Environment.

## Research Background

The ROOMS system design resulted from the following observations by members of the Xerox Palo Alto Research Labs:

- 1) Most intellectual work requires coordinating many sources of information, e.g. notes, drafts, spreadsheets, program listings, etc.
- 2) Before the widespread dissemination of desktop workstations and personal computers, knowledge workers typically spread paper containing these items out on a desk (or dining room table). But the small screens of computer workstations do not allow such a lavish use of space when working on many concurrent tasks. For example, it takes 22 average PC screens or 10 19" workstation screens to equal the area of a typical desk.
- 3) The result for overlapped windows systems is a kind of electronic messy desk, where the user spends large amounts of time moving, shrinking, and resizing windows in order to switch tasks.
- 4) An interface designed to assist a user to work on concurrent tasks rather than assume linear work habits would have the following features:
  - Fast task switching and fast task resumption
  - Easy to re-acquire mental task context
  - Access to a large amount of information
  - Fast Access to information
  - Low user overhead
  - Engaged tools shareable among several tasks
  - Collections of engaged-tools shareable among tasks
  - Task-specific presentation of shared-engaged tools.

How Envos' implementation of ROOMS accomplishes these goals is described in the next section "The ROOMS Design".

## The ROOMS Design

Rooms solves the problem of user task switching by allowing users to create a number of screen-sized workspaces called Rooms. The figure below shows two Rooms.

Two example Rooms (a) used for programming and (b) used for reading mail

In each room, there are a number of small icon-like objects called Doors. When a door is selected with the mouse, the user has the illusion of transiting to a new room containing windows. Each room is related to a different major task, such as working on a particular project, reading mail or file management. In the room are a number of engaged tools related to the task. When a user re-enters a room it appears exactly as when it was left.

The basic notion of the Rooms scheme is simple. But in order for this basic notion to be successful the ROOMS system design has many features to help manage window interaction among rooms and to keep the user from getting lost.

## Task Interaction

---

When working in ROOMS, there are usually a number of engaged tools that the user wants to share among different tasks. Examples of these might include a code editor, a text editor or a clock. The following ROOMS design features allow for the sharing of engaged tools:

**Placements** A window in a room has a specific location and shape. This is known as a Placement. The same window can exist in several rooms, with different locations, shapes, etc., in each room. Actions done on a shared window in one room are reflected in another room. Note that the black promptwindow in the Mail and Project rooms has a different location and shape in each room.

**Inclusions** Rooms can be included within other rooms. This allows collections of rooms to share a common set of windows, known as Inclusions. The band of windows and icons common in both parts of the Mail and Project rooms is a control panel, shown below, implemented as an included room.

Example of an included room called Office Panel

**Baggage** When moving between rooms you may carry windows with you. For example, you may wish to bring program code from one workspace to a workspace where you are doing documentation. This is accomplished by holding down the Move or Copy key when selecting a door. You will then be prompted to select the windows you wish to carry with you to the next room. The windows will have the same presentation in the new room.

**Pockets** You can also have a constant piece of baggage called a Pocket. A Pocket is a room dynamically included in all rooms. Whichever windows are placed in your Pocket ( a clock say) will automatically occur (at the same location and presentation attributes) in all rooms.

## Navigation

---

The organization of the user's workspace into a number of workspaces creates a potential navigational problem. ROOMS solves this problem with a number of navigational aids.

- Doors** Doors provide the basic link mechanism between rooms. Selecting a door with the mouse "moves" you to the new room containing windows associated with that room.
- Back Doors** Rooms allows you to create a Back Door in a room. If you have created a Back Door you can easily move back to the task you were previously working on before you entered the present room.
- Rooms Menu** Selecting the Go To Room sub-item from the ROOMS background menu presents you with a list of Room names. Selecting one will move you to that Room.
- Overview** The main feature of the Overview is a set of Room pictographs as shown in the opening diagram. From the Overview you can see the overall layout of a room and the tools it contains. The room pictographs can be instantly expanded one at a time, allowing you to browse through the windows in the entire set of rooms. In addition you can enter any room directly via the Overview.

## Tailorability

---

Several mechanisms are provided to help users tailor rooms. First, simply creating, moving, deleting and shaping windows in the usual way causes things to exist in rooms. Thus ROOMS preserves the natural interaction with the user. Second, special background entries are provided to allow the user to create new doors and other conveniences of construction. Below is an example of the standard set of Doors available to users.

At the Overview level, it is possible to copy, move or delete window pictographs within a room and between rooms and have the changes reflected in the rooms themselves. And finally, Rooms has a simple layout language for creating unique backgrounds for Rooms. By using the structure editor, SEdit, on this layout language, users can run arbitrary procedures on the entrance and exit of a room and can compute

specialized backgrounds for rooms. Below is an example of a SEdit of a rooms layout expression for the Project room shown earlier.

```
SEdit Project Package: XCL-USER
(:INCLUSIONS ("Office Panel") :BACKGROUND
 ((:REGION (0 1/4 1.0 3/4) :SHADE
 (:EVAL ROOMS:RENAISSANCE-BITMAP)
 :BORDER 2)
 (:TEXT "Project" :FONT
 (IL:HELVETICA 36 IL:BOLD)
 :POSITION (10 . 10))))
```

### Suites

Having designed an environment to suit your needs, ROOMS allows you to restore that state if there is a need to reload your system. Subsets of rooms can be grouped together to form Suites. Suites can be saved to a file and later restored to a new environment or shared with other users. Most system windows have a ROOMS window-type specification which allows them to be saved and restored from a suite. Thus a Filebrowser window that you have open on a particular system can be saved and the window placement and contents will be restored when you reload the suite onto a new system.

### Buttons

Buttons are a unique user-interface device that provides for the execution of any lisp command at the click of the mouse. Buttons can be of any shape and size. Doors are examples of buttons that move you from one room to another. For example selecting the following button will perform a directory listing of the local disk.

The button definition is shown below:

```
SEdit Directory Package: XCL-USER
(:TEXT "Directory" :FONT
 (IL:HELVETICA 12
 (IL:BOLD IL:REGULAR
 IL:REGULAR)))
:SHADOWS :ARK :TYPE :STRETCHY-ROUND-ARK
:HELP "Bring up local disk directory"
:ACTION (DIR "{dsk}<lispfiles>")
:INVERTED? NIL)
```

### Customization of Rooms

When used as the interface to an application, ROOMS provides you with a complete programmatic interface to allow application specific customization. This includes the ability to have applications create and switch rooms under programmatic control as well as enable users to design custom buttons and window-types.

## ROOMS USERS' RULES

---

---

This document describes the rules and procedures for "Rooms Users" modules. This document is mainly for Rooms Users' module writers, but users should also understand the rules.

### **DEVELOPING A ROOMS USERS' MODULE**

A Rooms Users' module is a useful program made available to the general Rooms community. Neither the author nor the custodian of Rooms Users' imputes any warranty of suitability or responsibility for errors.

Rooms Users' modules should be easily distinguishable from released library and Lisp Users' modules. In particular, this means that a Rooms Users' module may not have the same name as a Library or Lisp Users' module and should be visibly different. Rooms Users' modules derived from released software should be announced to the public only after communicating with the organization responsible for that released software.

Testing is important. If you make significant changes to a Rooms Users' module, enlist users at your site as alpha testers. A Rooms Users' module is not shoddy software; it is software made available outside the regular release channels.

### **ROOMS USERS' MODULE OWNERSHIP**

A module submitted for Rooms Users' remains the "property" of the submitter. Others may not make changes, except for their own private use, without negotiating with the owner (who may already be making similar or incompatible changes).

As the owner of a module, you are not required to fix bugs, but if not, you must be willing to transfer ownership (permanently) to someone who volunteers to fix them. Ownership may pass back and forth among several people as long as they agree.

### **SUBMITTING ROOMS USERS' MODULES**

If you are not an internal user, you should submit your new module to us through e-mail or on a floppy or tape. External users should make sure that they include all relevant information, such as documentation containing an e-mail or US mail address where he/she can be reached.

### **SUBMITTING FILES TO ROOMS USERS'**

As with released software, it is important to submit not just the resulting product, but all the files needed to build and maintain a Rooms Users' module:

1. the file to load ( .LCOM or .dfasl or .SUITE)
2. documentation describing it, following the formatting rules (see below)
3. a source file that can be released (optional)
4. data files, if needed

Modules submitted once are released once. Do not assume that a module submitted for one release will be automatically released in subsequent releases.

**DOCUMENTATION**

No modules will be released without documentation. Documentation can be as simple as a paragraph describing what the module does and how to use it, or it can be as extensive as a dozen-page user manual. All modules should have a file with a .TEDIT extension. Formatting should be done according to the rules outlined in the Rooms Users' Template, included on the Rooms Users floppy or tape as EASYTEMPLATE.TEDIT and also printed in this document. All users, external users included, should follow the Rooms Users' Template rules. If the documentation is large and formatting time consuming, you can also produce an interpress file (with the .ip extension), as well as submitting a .TEdit file. (Be sure to update the interpress file if you update the documentation!) Documentation should include the full address of the submitter.

**COMPATIBILITY**

Any submitted Rooms Users' files should be compilable in a "vanilla" Rooms environment. The file itself should load in any auxiliary modules when necessary.

Thanks for your cooperation.

## TOUCHY BUTTONS

---

---

By: Ramana Rao (Rao.pa)

Uses: Rooms

This document last edited on January 22, 88.

### INTRODUCTION

This Rooms Users Package provides a number of "touchy" buttons i.e. buttons that visually depend on the state of the world and change the state of the world when touched. Right now I provide three types of touchy buttons: `includer`, `toggler`, and `once-only`. You can make a touchy button by calling `rooms::make-<touchy-type>`. I will take suggestions for any others that people think may be useful since I'm trying to abstract the touchy technology.

### BUTTON CONSTRUCTORS

(ROOMS::MAKE-INCLUDER *ROOM-NAME*) [Function]

Includers allow you to conveniently mixin or mixout rooms. For example, you can have "Notecards-Mixin" and "Programming-Mixin" Rooms and have includer buttons in your personal "Pockets." Then you can include these functionality traits whenever you need them no matter the room.

(ROOMS::MAKE-TOGGLER *VARIABLE-NAME*) [Function]

Toggle buttons allow you to toggle boolean variables. This should obviously be generalized to something that allows you to select or circulate through value settings.

(ROOMS::MAKE-ONCE-ONLY *FORM INITIAL-TEXT FINAL-TEXT*) [Function]

A once-only button evaluates a form exactly once in a sysout and then displays that it is exhausted. For Example:

```
(ROOMS::MAKE-ONCE-ONLY (IL:PROMPTPRINT "Hello, World") "Fire..."
 "Exhausted")
```

---

---

## UN-HIDE-TTY

---

---

By: Doug Cutting (Cutting.PA@Xerox.COM)

This document last edited on April 28, 1988.

ROOMS changes the window system such that open windows are not always visible. Some applications presume that open windows are visible. This module attempts to amend this situation.

Often when an application decides to start using a window which is not visible it gives that window the caret. CHAT is an example of such an application. When IL:CLOSECHATWINDOWFLG is NIL (the default) CHAT windows are left open after their connection is closed. If one leaves such a CHAT window in another room and then attempts to open a CHAT connection, CHAT will merrily re-use the hidden window. But as CHAT takes the caret when it opens a connection, we can identify that window and pull it into the current room.

(ROOMS:UN-HIDE-TTY)

[Function]

If the window with the caret is not in the current room, it is brought into the current room with a call to ROOMS:UN-HIDE-WINDOW. If the window with the TTY is already visible on the screen then it is flashed. If there is no TTY window (i.e. the process with the keyboard has no TTY window) then a message to this effect is printed to the prompt window.

One can use this function in the action of a button, e.g.:

```
(ROOMS:MAKE-BUTTON-WINDOW
 (ROOMS:MAKE-BUTTON :TEXT "Un-Hide TTY" :ACTION '(ROOMS:UN-HIDE-TTY)))
```

Control-Y

[Interrupt]

Brings the window with the caret into the current room by calling ROOMS:UN-HIDE-TTY. This interrupt is installed when UN-HIDE-TTY is loaded. This will not work with applications which have their own interrupt tables, e.g. TEdit and CHAT.

---

---

### ROOMS USERS' MODULES

---

---

#### INTRODUCTION

ROOMS User's modules are written by users of Envos ROOMS. They are supported by the individuals who wrote them, not by Envos. Envos takes no responsibility for the reliability and maintenance of these modules.

Each module is documented, some in detail, others with only enough information to get the user started. At the top of each document, the name of the author is written, along with his electronic mail or U.S. mail address. Please contact the author with any problems you may have.

Note that most of these modules include source code. Thus besides being useful in themselves, these modules provide good examples of programmatic use of ROOMS.

This document contains explanations of each module, written by the author of each. It also contains an explanation of how to submit your own ROOMS User' module. Please read these instructions carefully if you wish submit a module.

---

---

## WALLPAPER

---

---

By: Doug Cutting (Cutting.PA@Xerox.COM) and  
Larry Masinter (Masinter.PA@Xerox.COM)

Uses: SCREENPAPER

This document last edited on August 8, 1988.

### INTRODUCTION

This module provides an easy way to create distinctive backgrounds for your rooms.

All symbols described in this document are in the package ROOMS.

### FUNCTIONS

(MAKE-WALLPAPER-WINDOW &OPTIONAL REGION) [Function]

Makes and returns a Wallpaper window. When the LEFT or MIDDLE mouse button is pressed over Wallpaper windows the user is asked to select a tile size, then a position for the tile. Positions are selected with the LEFT button. Each tile is displayed in the window. If the user presses the MIDDLE button then the background of the current room is changed to be the current tile. The user can abort this process at any time by pressing the RIGHT mouse button.

There is a window type definition for Wallpaper windows so they may be saved in Suites.

(HACK-BACKGROUND SHADE &OPTIONAL ROOM) [Function]

Changes the first background shade specified for ROOM to be SHADE. If ROOM does not paint the background then this function adds a command to the background specification for ROOM which paints the whole screen with SHADE. ROOM defaults to the current room.

## Lyric Manual Test procedures

Filed as: {Eris}<Test>Admin>ManualManual.tedit

This document is a part of the procedures describing how to run tests on the Xerox Lisp Environment. The following is a list of the tests that must be run by hand. These are of two types. 1. Those that are run via the do-test software and thus automatically log errors. These are denoted by a .u extention. 2. Those that must be manually logged.

### Running interactive regression tests using do-test

1. Bring up the LISP.SYSOUT to be tested.
2. In an XCL executive window, load DO-TEST by typing (LOAD "{ERIS}<LISPCORE>INTERNAL>LIBRARY>DO-TEST.DFASL")
3. To run tests using DO-TEST, type (DO-ALL-TESTS :PATTERNS '("filenames") :RESULTS "{Eris}<Test>SubSystemName>SubSystemName.log")

For example, to run all the interactive tests for the debugger and put the results in a file named debugger.log, do the following:

```
(DO-ALL-TESTS
 :PATTERNS '("{Eris}<Test>Env>Debugger>Hand>*.u;")
 :RESULTS "{Eris}<Test>Env>Debugger>Logs>Debugger.log")
```

**Note the importance of using the terminating semicolon on test file names.** Not supplying the semicolon makes it run all versions of that file name!

See {eris}<lispcore>internal>library>do-test.tedit for the full list of features.

### Helpful utilities:

(IL:FILESLOAD WHO-LINE) ;each field is active to help change them.  
(IL:FILESLOAD FILEWATCH) ;use background menu to turn on a monitor of what files you have open

### SUCCESS / FAILURE prompt windows

Some tests will pop up a prompt window requesting certain actions and to look for certain results. At the top of the window are the words SUCCESS and FAILURE. If the results of the test are as prompted, select SUCCESS otherwise select FAILURE. You may move and shrink this window, but do not close it.

Before this window is popped up, you will be asked if you want a SHORT, MEDIUM, or LONG test and you will be presented with a menu. A short test will only test high priority items. LONG will test all cases.

### Reporting results

After running a test for a subsystem, shift-select the log file into a message and address it to: John Sybalsky, the appropriate developer, and the test writer.

Here is a lafite-form for this purpose:

Subject: Test results for >>subsystem name<<  
To: >>developer<<, >>test writer<<, >>documenter<<  
cc: Sybalsky.pa

>> test log <<

### LIST OF MODULES TO BE TESTED:

**EXEC - Tests written by John Park**

Location of Old Detailed Test Procedures: {eris}<test>env>exec>hand>test.proc  
 Approximate time to run test: < 1 hr.

Note:

You cannot use do-all-tests with the Exec test suite. You must instead:

(DO-TEST-FILE '{Eris}<Test>Env>exec>Hand>FOO.u)

where FOO is the name of each .u file in the directory.

These are automatic tests, which feed the input into exec via bksysbuf. Test results are automatically logged in {eris}<lispcore>test>exec>test.report, but you must make sure a new version of the file exists before you run the tests.

Be sure the exec is in the XCL-TEST package.

While running these tests you must not place the caret outside of the exec or do any other work while the tests are running.

*1108 Regression tests assigned to Norm Schuster, 3/18/87.*

### **DEBUGGER - Tests written by Kirk Kelley**

Relevant developer: Andy Daniels

(DO-ALL-TESTS

:PATTERNS '("{Eris}<Test>Env>Debugger>Hand>\*.u;")

:RESULTS "{Eris}<Test>Env>Debugger>Logs>Debugger.log")

Approximate time to run test: < 1 hr.

Note: These are a mixture of automatic tests and those that require interaction. Some of them intentionally pop up break windows since this tests break windows. If in the process of testing you get a break window that is not obviously part of the test, uparrow out of it (type an ↑ or use the one from the title menu) and the next test should appear.

These tests were generated (and run) on an 1108.

*Regression tests assigned to Masa Tateno, 3/18/87.*

### **DEDIT - Tests written by Henry Cate**

Location of test file: {eris}<test>env>DEdit>hand>\*.u

Location of log file: {eris}<test>env>DEdit>logs>DEdit.log

Approximate time to run test: < 1 hr.

*1108 Regression tests assigned to Albert Sahim, 3/18/87.*

### **DISPLAY - Tests written by Peter Reidy**

Location of test procedure: {eris}<test>i/o>display>hand>cursor.proc

Location of test source code (used by both cursor.proc and cursor.test:

{eris}<test>i/o>display>hand>cursor.test

Location of log file: {eris}<test>i/o>display>logs>cursor.log

### **HARDCOPY - Tests written by Peter Reidy**

Location of test plans: {erinyes}<test>lisp>lyric>plans>fx80driver.plan, 4045xlpstream.plan, press/interpress.plan

Location of test procedure files: {eris}<test>i/o>hardcopy>hand>fx80driver.proc, 4045xlpstream.proc, press/interpress.proc

Location of log files: {eris}<test>i/o>hardcopy>hand>fx80driver.log, 4045xlpstream.log, press/interpress.log

Location of test code: {eris}<test>i/o>hardcopy>hand>streamtests.u

Location of test cases: {eris}<lispcore>test>streams>

*Regression tests assigned to >>NAME<<, >>DATE<<.*

**KEYBOARD - Tests written by Henry Cate**

Location of test file: {eris}<test>i/o>Keyboard>hand>\*.u  
 (As of march 10th, there are 4 tests.)

Location of log file: {eris}<test>i/o>Keyboard>logs>Keyboard.log

Approximate time to run test: about 15 minutes.

*Regression tests assigned to Albert Sahim, 3/26/87.*

**PROGRAM ANALYSIS - Tests written by John Park  
(Subsystems: Masterscope, Databasefns, Browser, and Inspector)****Masterscope**

Location of test files: {eris}<test>env>program-analysis>hand>masterscope.u

Location of log file: {eris}<test>env>program-analysis>logs>masterscope.report

Approximate time to run test: 7 minutes.

**Databasefns**

Location of test files: {eris}<test>env>program-analysis>hand>databasefns.u

Location of log file: {eris}<test>env>program-analysis>logs>databasefns.report

Approximate time to run test: 3 minutes.

Note: The data file used by this test is in {eris}<test>env>program-analysis>hand>databasefns.data

**Browser**

Location of test files: {eris}<test>env>program-analysis>hand>browser-part1.u

{eris}<test>env>program-analysis>hand>browser-part2.u

Location of log file: {eris}<test>env>program-analysis>logs>browser.report

Approximate time to run test: 8 minutes.

Note: There are two test files for browser testing. Part 2 must be executed after Part 1.

The data file used by this test is in {eris}<test>env>program-analysis>hand>browser. graph

**Spy**

Location of test files: {eris}<test>env>program-analysis>hand>spy.u

Location of log file: {eris}<test>env>program-analysis>logs>spy.report

Approximate time to run test: 5 minutes.

**Inspector**

Location of test files: {eris}<test>env>program-analysis>hand>inspect.u

Location of log file: {eris}<test>env>program-analysis>logs>inspect.report

Approximate time to run test: 8 minutes.

Note: A fatal bug was discovered - Inspect never returns when \*random-state\* is inspected (AR # 8203).

*Regression tests assigned to Norm Schuster, 3/26/87.*

**PROGRAM SUPPORT - Tests written by John Park  
(Subsystems: DWIM, and PRETTYPRINT)****DWIM**

Location of test files: {eris}<test>env>program-support>hand>dwim.u

Location of log file: {eris}<test>env>program-support>logs>dwim.report

Approximate time to run test: 2 minutes.

Note: The DWIM test is executed by entering (DWIM-TEST). SEE the test file for more info.

**Printing Out Function Definitions (PRETTYPRINT)**

This test is covered by PP and other subsystems of Executative Test .

(See {eris}<test>env>exec>hand>pp.u and also see.u, see-without-comment, ty.u and type.u in the same directory)

**PROCESS CONTROLS (PSW) - Tests written by John Park**

Location of test files: {eris}<test>env>process-controls>hand>psw.u

Location of log file: {erinyes}<test>env>process-controls>logs>psw.report

Approximate time to run test: 2 - 10 minutes.

**SEdit - Tests written by Henry Cate**

For SEdit test, load TEdit. Then change packages with: (cl:in-package 'xcl-test)  
 For do-all-tests, it may work better if the semicolon is not used.

Location of test file: {eris}<test>env>code-editor>hand>\*.u  
 (As of march 2nd, there are 21 tests.)

Location of log file: {eris}<test>env>code-editor>logs>SEdit.log

Approximate time to run test: about a day.

*1108 Regression tests assigned to Albert Sahim, 3/18/87.*

**INSPECTOR - Tests written by Lois Lew**

Location of test files:{eris}<test>env>env>inspector>hand>inspect-allrec.tedit

{eris}<test>env>inspector>hand>inspect-defstruct.tedit

{eris}<test>env>inspector>hand>inspect-macro.tedit

{eris}<test>env>inspector>hand>inspectw.tedit

{eris}<test>env>inspector>hand>inspect-code.tedit

{eris}<test>env>inspector>hand>inspectfieldflg.tedit

Location of log file:create one at:

{eris}<test>env>inspector>logs>inspect-allrec.log

{eris}<test>env>inspector>logs>inspect-defstruct.log

{eris}<test>env>inspector>logs>inspect-macro.log

{eris}<test>env>inspector>logs>inspectw.log

{eris}<test>env>inspector>logs>inspect-code.log

{eris}<test>env>inspector>logs>inspectfieldflg.log

Approximate time to run test: ?

Note: use shift select to copy the material marked to be typed into the appropriate exec window.

*Regression tests assigned to Masa Tateno, 3/26/87.*

# Running AR Test Cases & Recording the Results

## The Pass and Fail commands

The "Pass" and "Fail" commands are defined on <Lispcore>Internal>Library>RELEASETOOLS. The form of use is

**Pass** AR#1 AR#2 AR#3 . . . ;Records the fact that AR Test Cases for the ARs named were run and succeeded.

**Fail** AR#4 AR#5 AR#6 . . . ; Records the fact that AR Test Cases for the ARs named were run and failed.

These two commands record each AR in a log file, along with your user name (so we know who ran it), and the current time (so we know when). These log entries will be used to

- 1) Track the current status of the AR test cases, and
- 2) Prepare the alpha-test log for Beta-test readiness review.

## Running a test

When you run an AR test case, please use the Pass or Fail command to record the fact!

# AR Test Case Status Summary

## As of >>Date<<

>>AR Test &  
Status<<

# Special Files on <Test>ARs>

## **AR-TEST-CASE.Auto-log;1**

This is the file where the "Pass" and "Fail" commands record the results of running an AR test case.  
See {Eris}<Test>Admin>Running-AR-Test-Cases.TEdit for details.

>><<  
>><<

>><<

>><<

## **SEdit test report**

This report is for tests written and executed up to February 28, 1987 on the <Lyric>Basics>Full.Sysout generated 21-Jan-87.

The following tests are for the integration of the new error system into the Interlisp environment.

The test plan for this report is {Erinyes}<Test>Lisp>Lyric>Plans>SEdit.NoteFile

### **Groups of tests were written and executed on the 1186 for the following commands:**

INTERRUPTS

ABORT  
BASE  
COMMENT  
EVAL  
EXPAND  
EXTRACT  
FIND  
HELP  
JOIN  
MENU  
EDIT DEFINITION  
MUTATE  
PACKAGE  
PARENTHESIZE  
REDO  
SKIP-NEXT  
SUBSTITUTE  
UNDO

DELETE PREVIOUS WORD  
DONE  
REDISPLAY

These require user interaction. They are stored at {Eris}<Lispcore>Test>SEdit>\*.u

### **Still to be formally tested**

The mouse, (shift selection (copy, delete, move) to and from each source:

1. The same SEdit
2. A different SEdit
3. TEdit
4. Exec (each type/profile)

Window. Test each window operation with SEdit in each of stand selection/caret situations. SEdit should reappear in the same situation.

Completion. Make sure SEdit completes properly for each type of definition being edited.

1. def-types
2. fns
3. vars
4. property lists
5. records and datatypes.

Edit interface:

1. ed and editdef
2. df, dv, dc, dp
3. multiple edit drivers: editfromfile, editcallers, masterscope, etc...

## New ARs generated

7553 Not able to parenthesize part of an litatom  
 7604 SEdit, Meta-B does not work with decimals  
 7607 SEdit, problem with Base, change base and try placing edit caret, break  
 7624 SEdit, Attach Menu, come up with incorrect Print-Base  
  
 7629 SEdit, meta-E has trouble evaluating a number, breaks  
 7631 SEdit, meta-E, evaluates all, even when only part is selected  
 7642 SEdit, meta-E, something ought to happen with extended selection  
 7682 SEdit, control-W after single quote breaks  
 7688 SEdit, CASE on a string or litatom doesn't change the case  
  
 7699 SEdit, help, if nothing is selected, nothing happens, should give some feedback  
 7703 SEdit, meta-H, no response against a string  
 7705 SEdit, meta-H, break window when have an extended selection  
 7717 SEdit, meta-J, new, nothing selected, type meta-J, break window  
 7729 SEdit, documentation says prompt window, confusing  
  
 7731 SEdit, try meta-J against an extended selection of numbers, breaks  
 7733 SEdit, meta-J can join atoms and strings, different types  
 7783 SEdit, meta-O, optimizers, cann't use cl:optimize  
 7784 SEdit, meta-O, lets the user get started then says no way  
 7792 SEdit, meta-O some times the message overflows  
  
 7842 SEdit, meta-; documentation on old format, need il:  
 7851 SEdit, combination of meta-0, & meta-/ builds break window  
 7878 SEdit, meta-s, cann't substitue in extra items in a list  
 7879 SEdit, meta-S cann't substitute in a comment  
 7880 SEdit, meta-s, cann't substitute for an extended selection of a number  
  
 7889 SEdit-, meta-n give some feedback when don't do anything  
 7907 SEdit, meta-n, select vs extended selection give different results

## Debugger, Error System, and Unwinder test report

This report is for tests written and executed up to March 24, 1987 on the <Lyric>Basics>Full.Sysout generated 11-Mar-87.

The following tests are for the integration of the new error system into the Interlisp environment.

The source for this report is {Erinyes}<Test>Lisp>Lyric>Plans>Debugger.NoteFile

The print version of this test report is filed at {Eris}<Lispcore>Test>Debugger>Report.IP

The test plan is filed at {Erinyes}<Test>Lisp>Lyric>Plans>Debugger.NoteFile and IP.

Groups of tests were written and executed on the 1109 for all the commands in the Debugger document in the Xerox Common Lisp implementation notes.

These are stored on {eris}<Lispcore>Test>Debugger>BreakWindow.u

Groups of tests were written and executed on the 1109 for most of the functions in IRM chapter 15: Breaking, Tracing, and Advising.

These are mostly automatic tests but some require user interaction. They are stored in {Eris}<Lispcore>Test>Debugger>Debugger.u

For tests of the Xerox extensions to the CML error system, see {Eris}<Lispcore>cml>test>24-\*. {Eris}<Lispcore>cml>test>cl-error.x and {Eris}<Lispcore>cml>test>errorsystem.notefile which is the source for {Eris}<Lispcore>cml>test>24-errorsystem.x.

## Regression Test for ARS

### ARS tested 21-Jan-87 <Lyric>basics>full.sysout

7152 passed  
7780 new  
7797 new  
6503 passed

### New ARs generated

Several problems were discovered and reported as ARs. Each of these have tests. The following are only new ARs generated up to February 28.

#### DEBUGGER.NEWARS

7486 debugger "eval:" undocumented

7522 missing second param causes random error reporting

7601 unnamed proceed cases break compute-proceed-cases

7679 Version .01 Error System documentation edits

7780 argument names of broken fns unbound in debugger

7797 breaking/tracing advised fns does not update brokenfns

7845 exec il:settopval il:helpflag serious-condition attempt-to-change-constant

7848 (IL:NLSETQ (CL:SIGNAL 'ERROR)) breaks

7868 bad package fix readtable change screws up fix

7873: Common functions should be safe to break

AR 7923 il:brkinfolst no longer exists

AR 7908 untrace also unbreaks

AR 7919 TRACE no longer works for undefined subfunctions

AR 7932: (unbreak (sub-fn in super-fn)) has two problems

## Original List of ARs

## **DEdit test report**

This report is for tests written and executed up to February 28, 1987 on the <Lyric>Basics>Full.Sysout generated 21-Jan-87.

The test plan for this report is {Erinyes}<Test>Lisp>Lyric>Plans>DEdit.tedit.

### **Groups of tests were written and executed on the 1186 for the following commands:**

After, Before, Delete, Replace, SWitch, (), () out, Undo, Find, Swap, Reprint, Edit, EditCom, Break, Eval, Exit.

These require user interaction. They are stored at {Eris}<Lispcore>Test>DEDIT>high-level.u

### **New ARs generated**

None

Scripts for testing the record package (assuming currently in **Common Lisp User** package)

## Record type - Record

## Record type - Subrecords

**type:**

```
(il:record record-test-name (alpha bravo gamma) (il:synonym alpha a) (il:type? (oddp (length
il:datum))))
(il:record record-test-name1 (xray zebra record-test-name)
(il:subrecord record-test-name))
(setq record-test-record (il:create record-test-name1 alpha il:_ '(a b c) bravo il:_ "some
string" zebra il:_ "hi"))
```

**type:**

```
(inspect record-test-record)
```

**choose "inspect"**

*--should produce a window with three numbered elements 1 nil 2 "hi" and 3 the list ((a b c) "some string" nil)*

```
(nil hi ((a b c) some string nil)) Inspector
1 nil
2 "hi"
3 ((a b c) "some string" nil)
```

**type:**

```
(inspect record-test-record)
```

**choose "as a record"**

**choose "record-test-name1"**

*--should produce a window with three elements the first one of which is a list of a list, a string and nil .*

```
(nil hi ((a b c) some string nil)) Inspector
record-test-name ((a b c) "some string" nil)
zebra "hi"
xray nil
```

**type:**

```
(inspect record-test-record 'record-test-name1)
```

*--should produce a window identical to the one in the previous step.*

**type:**

```
(ed 'record-test-name1 'records)
```

delete zebra from the element list.

type cntl-x to save edit.

**type:**

```
(inspect record-test-record 'record-test-name1)
--should produce a window with no zebra and the value that used to be zebra is now record-test-name.
```

**return to the edit window and type zebra back in where it belongs.**

**type cntl-x to save again.**

**type:**

```
(inspect record-test-record 'record-test-name1)
--should produce a window with three elements the first one of which is a list of a list, a string and nil and
zebra is returned to the list
```

**close the edit window**

**type:**

```
(in-package 'interlisp)
```

**type:**

```
(inspect user::record-test-record 'user::record-test-name1)
--should produce a window with three elements where all the values not in quotes are qualified as user.
```

The screenshot shows a window titled "(nil hi ((a b c) some string nil)) Inspector". Inside the window, the following structure is displayed:

```
user::record-test-name ((user::a user::b user::c)
user::zebra "hi"
user::xray nil)
```

**type:**

```
(cl:in-package 'user)
```

```

-- an inspect window appears

select a name (first,second, third or fourth) with the left button, then press the middle button - select set.

type in a new value for the selected element, confirm that the value changes.

Type ALIST on the exec window and notice that the list has changed.

**type:**

```
(INSPECTW.CREATE 'ALIST ' (FIRST SECOND THIRD FOURTH) 'FETCHFROMLIST 'STOREINLIST 'PROPCOM)
```

select a name (first, second, third or fourth) with the left button, then press the middle button. It should appear as if nothing has happened. Position the mouse in the title bar of the inspect window, press down the middle button - select refetch. *The values of Alist should be reversed.* Type ALIST on the exec window and notice that the list has changed.

**Close all inspector windows**

**type:**

```
(INSPECTW.CREATE 'ALIST '(FIRST SECOND THIRD FOURTH) 'FETCHFROMLIST 'STOREINLIST "HELLO THERE GUESS WHO?" 'VALCOM 'TITLECOM "Having Fun?" 'SELECTF WIND 'PROPP)
```

- the inspector window should appear where you placed the first one. Shape the window so you can view all of it. It should look like this (notice the new title):

**select something from the left-hand column**

-a window will appear telling you what you selected and that it is a property.

**press the middle button on the same selection**

- a message "HELLO THERE GUESS WHO" will appear in the prompt window

**select something from the right hand column**

-a message will appear in the same window that appeared two steps back telling you what property the value you selected belongs to and that it is a value.

**press the middle button on the same selection**

-the values reverse themselves again

**Put the mouse in the title bar and press the middle button**

-The values have all changed to be the following.

## Testing Report

### Tested:

- different ways of creation: using, copying, reusing, smashing
- type?, typenamep, typename are tested for each type of record that maintains typename info: typerecord, arrayrecord, datatype
- for record types with and without typename info, provided a test form, and made sure it works via type?
- field name synonyms
- typenamep.- on an 1109
- records which turn into datatypes with type#>255 The sysout has more than 255 datatypes already, so this is well tested.
- defstruct's with types on the slots.
- checked that type number (as built by \typeglobalvariable) are in the current package.
- Similarly, tested the interaction of packages with Interlisp records. (i.e. that the record name and the field names are in the same package.) Made sure that package qualified versions of things work with fetch and replace.
- recursive records with above.
- new record types: confirmed that the irm is correct.
- editing of records with SEdit (multiple completion).
- inspected any type of object the system can create
- specified type in ASTYPE arg to INSPECT
- user options INSPECTALLFIELDSFLG, MAXINSPECTCDRLEVEL, MAXINSPECTARRAYLEVEL, INSPECTPRINTLEVEL
- extensibility via INSPECTMACROS
- confirmed programmatic interface to INSPECTW's
- code inspectors on frames (both \realframep frames and others.),
- inspected values in frame variables.
- the setters on defstruct slots (including readonly-ness) for lists, vectors, :named and otherwise.
- examples of propprintfn

### Left to be tested:

- typenamep should be tested on each machine. and was only tested on the 1109
- code inspectors on frames (both \realframep frames and others.), should be tested from both compilers
- all tests should be run compiled and interpreted on each machine.

### Outstanding bugs and comments

7630 Smashing-arrayrecord fails

6950 WITH doesn't compile correctly. (new)

6606 re: record redeclaration.

4007 want to have - in record field names (closed)

1046 ensure that the editors can be successfully invoked from the inspector.

1820 make sure you can edit terminal tables

2019 problem with \applyinspectmacro (open)

2613 try inspecting processes (running and dead), other system types.

Note: there is no interaction between the inspector and \*print-circle\* and \*print-pretty\*

### 3. How to Create Sketch Elements

---

The elements a sketch consists of are text, boxed text, lines, boxes, polygons, curves, closed curves, circles, ellipses, arcs, arrowheads, and bit maps. This chapter explains how to create and change each kind of element, and how to change the way new elements will look.

---

#### To Use Text in a Sketch

---

In Sketch, text is provided by text elements. Each text element has some characters, a control point that positions it, and properties that determine the way it looks (e.g., boldness, font family) and how it is justified relative to its position (e.g., left, right, or center justification). A new text element is added by typing it in (see the section “To Type In Text,” below). You edit existing text elements by selecting within them and typing (see the sections “To Insert Characters Into a Piece of Existing Text” and “To Replace Characters in a Piece of ExistingText”). The size, font family, boldness, and italic properties, and the location of the text relative to its position, are changed using the Change command (see the section “To Change the Way Text Looks”).

In a sketch window, the three mouse buttons provide quick access to text editing and line drawing. Figure 8 summarizes these mouse button functions.

*Figure 8. Mouse button text-editing and line-drawing functions*

---

#### To Type In Text

---

Move the cursor to where you would like the text to be and press the left mouse button. The caret shape (I) will appear. Type the text. Typing a carriage return will start another line.

If a vertical bar  appears instead of a caret, the position you selected is in existing text (see the following sections). You cannot create a new text element in the middle of an existing text element. Any characters you type will be added to the existing text. To create a new text element, hold down the left button and move the cursor until the vertical bar  changes into the caret shape . At this point you can create a new text element by typing new text.

1. Put the cursor where the new text should be.

2. Type the text.  
In this case, "a box."

*Figure 9. Steps to insert new text*

When characters are typed, a new piece of text is centered around the position of the caret. The alignment of the text relative to this position can be changed. For example, the text can be changed so that this position is its left edge. See the sections "To Change the Justification of Text" and "To Change the Properties of New Text."

---

## To Insert Characters Into a Piece of Existing Text

---

Move the cursor to the place in the text where you want to insert the characters and click the left button. When you press the left button, the vertical bar  will appear between the characters. Type the characters. The typed characters will appear where the vertical bar is. If you hold the left button down while moving the cursor, the vertical bar will follow.

If you place the cursor over a piece of text and the vertical bar does not appear, the text may be contained in a group or it may be overflow from a text box. If it is in a group, you can edit this text only by ungrouping it first. See the section "To Use Groups." If it is overflow from a text box, you can reshape the text box to make it large enough to hold the text. See the section "To Change the Size of a Text Box."

You can insert characters at the beginning of a text element by selecting the left half of the first character. The vertical bar will appear in front of the first character when the cursor is positioned correctly. If you move out of the text, the vertical bar will change to a caret shape . If you type when the caret shape is visible, you will create a new text element rather than inserting characters into the existing one. You can insert characters at the end of a text element by selecting the right half of the last character.

## To Replace Characters in a Piece of Existing Text

---

Move the cursor to in front of the first character to be replaced; press and release the left button. A vertical bar (|) will appear in front of that character. Move the cursor to the last character to be replaced; press and release the right button. After you press the right button, the text that will be replaced when you type is shown white-on-black. Type the new characters (see figure 10).

*Figure 10. Steps to edit existing text*

## To Delete Characters in a Piece of Existing Text

---

Select the characters using the left and right buttons as described above in the section "To Replace Characters in a Piece of Existing Text" and press the delete key.

## To Delete Text During Type-in

---

When you are typing text, you can use the backspace (BS) key to delete the previous character, and control-W to delete the previous word.

## To Change the Way Text Looks

---

You can change the properties of text by using the Change command. After selecting the Change command, select a piece of text or a collection of pieces of text (see the section "To Select Sketch Elements") that you wish the change to apply to. You will then be presented with a menu (see figure 11) of possible ways of changing the text.

## To Change the Bold and Italic Properties of Text

---

Select the Change command, move the cursor to the control point of the text (which will be marked with a ) and press and release the left button. The menu shown in figure 11 will appear. Select one of the items Bold, Unbold, Italic, or Unitalic.

Bold will make the selected text element appear in bold letters. Unbold will remove the bold property from the text if it was previously bold. Italic will make the selected text element appear in italics. Unitalic will change italic text to roman text.

Figure 11. Menu offered for changing text elements

---

## To Change the Size of Text

Select the Change command, move the cursor to the control point of the text (which will be marked with a ) and press and release the left button. The menu shown in figure 11 will appear. Select one of the items Smaller Font, Larger Font, or Set Font Size.

Smaller Font will make the characters appear in the next smaller font. Larger Font will make the characters appear in the next larger font. Set Font Size will prompt you for a size to make the text.

Note: The font size is changed at the scale in which the text was originally entered. If you are viewing the text from a *zoomed view* (a window that has had its scale changed) the text size may not change. Or it may change more than a single size. If you have difficulty getting the size you want, enter a new piece of text, adjust its size, make the original piece of text have the same size (see the section "To Make Several Pieces of Text Look Alike"), and then delete the new text.

---

## To Change the Font Family of Text

Select the Change command, move the cursor to the control point of the text (which will be marked with a ) and press and release the left button. The menu shown in figure 11 will appear. Select the item Different Font. A menu of the known font families and the item Other will appear. Select the name of the family you want or, if it is not there, select Other. If Other is selected, a small window with

the message "New family:" will appear above the sketch window. The caret will be blinking in it. Type the name of a font family, ending with a carriage return. If the selected or entered font family is not available in the size of the selected text element, a message is printed and nothing is changed.

When selecting the control point of the text, you can also select more than one text or text box element (see the section "To Select Sketch Elements"). If more than one text element is selected, any that have the same size as the first selected text element are changed to the new font family.

Note: the search for fonts encompasses any directories on DISPLAYFONTDIRECTORIES and may take a few minutes. (If font file servers are down or slow, it may take even longer.) If Sketch doesn't find a font that you believe exists, you can make that font the default font, both family and size (see the section "To Change the Properties of New Text") and retry the change.

## To Change the Justification of Text

Select the Change command, move the cursor to the control point of the text (which will be marked with a ) and click the left button. The menu shown in figure 11 will appear. Select one of the items Left Justify, Center Justify, Right Justify, Top Justify, Bottom Justify, Middle Justify, or Baseline Justify. These commands will change where the text appears relative to its control point. Table 1 shows the effects of the different commands on horizontal and vertical justification.

| Vertical<br>Horizontal | Baseline Justify  | Middle Justify    | Top Justify       | Bottom Justify    |
|------------------------|-------------------|-------------------|-------------------|-------------------|
|                        | Center Justify    | Left Justify      | Right Justify     |                   |
| Center Justify         | Play              | Play              | Play <sup>+</sup> | Play <sub>+</sub> |
| Left Justify           | <sub>+</sub> Play | <sup>+</sup> Play | <sup>+</sup> Play | <sub>+</sub> Play |
| Right Justify          | Play <sub>+</sub> | Play <sup>+</sup> | Play <sup>+</sup> | Play <sub>+</sub> |

<sup>+</sup> - control point of the text

*Table 1. How the justification properties affect the position of text relative to its control point*

## To Make Several Pieces of Text Look Alike

Select the Change command, hold down one of the shift keys, move the cursor to the control point of the text that looks the way you want, and click the left button. Using the procedure described

in the section “To Use Menus and Submenus,” select the text elements you want to change to look like this one. When finished, release all the mouse buttons and the shift key. The menu shown in figure 11 will appear. Select the item Look Same. This will make all the selected text items be the same font size, face, and alignment as the one you selected first. The change is made to both boxed and unboxed text. This command is convenient for making text that was entered at different scales look the same.

---

## To Use Boxed Text

---

Sketch has the capability of framing text and justifying text within the frame. The element that supports this is called a text box. Whenever the caret is inside a text box, the characters typed become part of the text within the box. The text in a box is broken into lines between words so that each line fits within the width of the box. If a single word in the text is wider than the box, it spills over. If there are more lines than fit in the height of the box, they spill over also. The characters outside the box cannot be selected for editing; the box must be enlarged to allow these to be edited.

A text box can be created by boxing a text element (see “To Put a Box Around Existing Text”), by typing a control-carriage return (see “To Create a Box to Put Text In”), or by using the **TEXT BOX** command (see “To Create a Sized Box to Put Text In”). The justification properties of the text specify the position of the text within the box (see “To Reposition the Text Within a Box”). The text inside a text box has the same looks properties as a text element (see the sections “To Use Text in a Sketch” and “To Change the Way Text in a Box Looks”).

The frame around the text is called its box. It has control points at its upper-right and lower-left corners. Moving one of these changes the size of the box (see “To Change the Size of a Text Box”). The box has thickness and dashing pattern properties that affect the frame (see “To Change the Border Thickness of a Text Box” and “To Make a Dashed Border Around a Text Box”) and a filling property that shades the part of the box not occupied by text (see “To Change the Filling of a Text Box”). Figure 12 shows some examples of text boxes.

Figure 12. Examples of text boxes

---

## To Put a Box Around Existing Text

Select the Change command from the command menu, move the cursor to the control point of the text you wish to box, and press and release the left button. A large menu titled Change Text How? will appear (see figure 11). Select the Box the Text item. The text will become part of a text box.

---

## To Create a Box to Put Text In

Hold down the control key and press the return key. If the caret is inside a text box, a new text box of the same size will appear below it. Any characters typed will now go into the new box. If the caret is not in a text box, a new box will appear at the current cursor position. Note: you should hold down the control key until the new box appears.

---

## To Create a Sized Box to Put Text In

Select the **Text Box** command from the command menu, move the cursor to one corner of the desired box location, press and hold the left button, move the cursor to the diagonally opposite corner, and release the button. While you are moving to the opposite corner, a gray outline of the box will be shown. When you release the button, the gray outline will be replaced by a solid one. You can stop this command by releasing the button when the cursor is outside the window.

---

## To Change the Size of a Text Box

Move either control point of the text box using one of the point-moving methods described in the section "To Move Elements."

---

## To Change the Border Thickness of a Text Box

Select the Change command, move the cursor to one of the corner points of the text box (which will be marked with a ) and press and release the left button. The menu shown in figure 14 will appear. Select the item Box Thickness. This will bring up a menu titled Change Size How? that contains the items Smaller Line, Larger Line, and Set Line Size. Selecting Smaller Line will

make the box outline be one size smaller than it is. Selecting Larger Line will make it one size larger than it is. Selecting Set Line Size will bring up a number pad menu (see figure 13). In this case, you should enter the size in screen points (1/72 of an inch) that you want the box thickness to be. The box thickness can be set to zero with the Set Line Size command, but the Smaller Line command will not make it less than one. If the thickness is zero, the box around the text won't appear, but any filling will remain and the text will still justify itself within the box's boundary.

Figure 13. The number pad menu for entering line thickness

---

## To Make a Dashed Border Around a Text Box

You can make the border of a text box dashed by specifying a *dashing pattern* (see the section "To Make a Dashed Line"). A dashing pattern is a sequence of numbers that indicates how many brush marks should be on and off. To specify a dashing pattern, first select the Change command, then move the cursor to one of the corner points of the text box (which will be marked with a ) and press and release the left button. The menu shown in figure 14 will appear. Select the Dashing item. This will bring up a menu titled New Dashing Pattern?, similar to the one shown in figure 34, that contains several dashing patterns and the items Other and No Dashing. Selecting one of the dashing patterns will make the border have that pattern. Selecting the Other item will bring up a series of number pad menus in which you enter, alternatively, the size of the black portion of the pattern and the size of the white portion of the pattern. The pattern can have as many alternations as you like. Number pad menus will continue to appear until you enter zero. When you enter zero, a menu is brought up showing what your new dashing pattern looks like and requesting confirmation. If you like the pattern, select Yes. If you don't like it, select No. If you select No, you will be given a chance to enter another series of sizes. If you select Yes, the box outline will be dashed according to your pattern. The pattern you entered will be remembered and will appear in the dashing menu next time you change the dashing.

Figure 14. Change menu for text boxes

## To Change the Filling of a Text Box

Select the Change command, move the cursor to one of the control points of the text box (which will be marked with a ) and press and release the left button. The menu shown in figure 14 will appear. Select the Filling item. From this point, follow the procedure given in the section "To Change the Filling of a Box."

## To Change the Way Text in a Box Looks

Select the Change command, move the cursor to one of the corner points of the text box (which will be marked with a ) and press and release the left button. The menu shown in figure 14 will appear. Select the item The Text. The menu shown in figure 15 will appear. Select one of the items Different Font, Smaller Font, Larger Font, Set Font Size, Bold, Unbold, Italic, or Unitalic. The action of these items is described in the section "To Change the Way Text Looks."

Figure 15. Menu offered for changing boxed text elements

## To Remove a Box From Around Text

---

Select the Change command, move the cursor to one of the corner points of the text box (which will be marked with a  and press and release the left button. The menu shown in figure 14 will appear. Select the item Unbox the Text. The box and all of its properties (such as filling) will be removed. If you want to keep the filling but not display the box, set the border thickness to zero (see the section “To Change the Border Thickness of a Text Box”).

## To Reposition the Text Within a Box

---

Select the Change command, move the cursor to one of the corner points of the text box (which will be marked with a  and press and release the left button. The menu shown in figure 14 will appear. Select the item The Text. The menu shown in figure 15 will appear. Select one of the items Left Justify, Center Justify, Right Justify, Top Justify, Bottom Justify, Middle Justify, or Baseline Justify. Left Justify will move each line of the text to the left edge of the box. Right Justify will move lines to the right edge. Center Justify will cause each line to be centered between the left and right edges. Top Justify will move the text so that the first line is at the top edge of the box. Bottom Justify will move it so that the last line of text is at the bottom edge. Middle Justify will move it so that the middle of the middle line of text is halfway between the top and bottom edges. Baseline Justify will move it so that the baseline position of the middle line of text is halfway between the top and bottom edges.

## To Make the Text in Several Text Boxes Look Alike

---

The procedure is the same as the one described in the section “To Make Several Pieces of Text Look Alike.”

---

## To Add Lines to a Sketch

---

Most sketch elements other than text, such as boxes, circles, and curves, are made up of lines. This section describes all the methods for adding lines, but does not tell you how to change their properties. The line properties are thickness, brush shape, and dashing, and you can change them using the information in the section “To Change the Way Lines in Elements Look.”

## To Add a Line

---

To add a single line to a sketch, move the cursor into the sketch window and press the middle mouse button. While the middle button is held down, the cursor changes to . A mark will

follow the cursor on grid points, described in the section “To Use the Grid Display”). Move the cursor to where you want one end of the new line and release the middle button. Press and hold the middle button again and move the cursor to where you want the other end. A line will be stretched from the first position to the cursor position and will follow it. When the line is in the right place, release the middle button. If you move outside the window, the stretched line will disappear. If you release the button while the cursor is outside the window, no line is added. This provides a way of aborting if you change your mind while placing the second end of a line. If you move back into the window with the button still down, the line will reappear. If you want to change the position of the first point, click the left button while inside the sketch window, then start this procedure over.

*Figure 16. Two examples of connected lines with control points highlighted*

---

## To Add a Series of Connected Lines

You can add a series of connected lines using either the mouse or the  command. Using the mouse enables you to see and reposition the lines as you draw them, while using the  command may sometimes be faster.

---

### With the Mouse

Move the cursor to over the Defaults menu command in the Sketch command menu, press and hold the left button, and slide the cursor out the right side through the triangle. A menu that includes the item Line will appear. Move the cursor over the Line item and slide out its right side. A menu that includes the item Mouse Line Specs will appear. Move the cursor over the Mouse Line Specs item and release the left button. A fourth (and final) menu with the title Connect Middle Button Lines? will appear. Select the Yes item from this menu. This procedure (which you only have to do once) has changed the mode of adding lines with the middle button to construct a series of lines. If you now draw lines as before, a new line will be stretched to the cursor position from the end of the previous line. To start a new series of lines, press either the left or the right mouse button in the sketch window. (A new series of lines is also started when you select a menu command.) You can stop the drawing of an individual line segment by moving the mouse cursor outside the window.

This does not start a new series of lines; moving back into the window and pressing the middle button picks up where the last line ended.

If you want to change the mode from entering connected lines back to unconnected lines, follow the above procedure but select the No item from the Connect Middle Button Lines? menu.

---

### With the Command

---

Select the  from the Sketch command menu. The cursor will change to  and an  will follow the cursor. Move the cursor to each point that the lines go through and click the left mouse button. Each time you specify an endpoint, it is marked with a . After all the points have been specified, move the cursor outside the window and press the left mouse button. After you click outside the window, the line will be drawn connecting the . Figure 16 shows two examples of connected lines.

---

### To Add Boxes to a Sketch

---

Sketch boxes can be either filled or unfilled; in addition, their borders may vary in thickness and brush shape, or be dashed. To add a box to a sketch, select the  command from the Sketch command menu. The cursor will change to . Move the cursor to one corner of the rectangle where you want the box. Press the left button. Holding the left button down, move the cursor to the opposite corner and release the button. While the left button is down, the rectangle will be highlighted in gray. When you release the button, a box will be added. To abort, move the cursor outside the window and click the left button. Note: the specified box must be entirely within the window. Figure 17 shows some examples of boxes.

*Figure 17. Three examples of boxes.  
The left one has its control points highlighted*

## To Change the Filling of a Box

Select the Change command from the command menu, then select the box or boxes whose filling you wish to change using the procedure described in the section "To Select Sketch Elements." You can include elements other than boxes as long as the first element you select is a box. The menu shown in figure 18 will appear.

Figure 18. Menu of properties you can change for boxes

Select the Filling item. A menu titled New Filling? similar to the one shown in figure 19 will appear.

Figure 19. Menu of textures that can fill boxes

If the filling you want is shown on the menu, select it. If you want to remove the filling from a box, select the No Filling item. To create a shade that is not on the menu, select either the 4x4 Shade or the 16x16 Shade item. Selecting either item will cause the shade editor to appear (see figure 20). The 4x4 Shade item will allow you to create a 4-bit-by-4-bit shade. The 16x16 Shade item will allow you to create a 16-bit-by-16-bit shade. Construct the shade you want in the lower part of the window by turning points black with the left button and white with the middle button. Selecting Quit will cause the box to be filled with the newly constructed shade. The shade you created will be added to the menu for future selection. Advanced user note: the function (SK.CACHE.FILLING SHADE) can be called to add a filling to the menu.

Figure 20. The shade editor

To change the thickness, dashing, or brush shape of a box's border, see the section "To Change the Way Lines in Elements Look."

---

## To Add Polygons to a Sketch

---

Select the  command from the Sketch command menu. The cursor will change to  and an  will follow the cursor. Move the cursor to each vertex of the polygon and click the left button. When you select a point, it is marked with a . When you have selected all the points, move the cursor outside the window and click the left button. The points you selected will become the control points of the polygon. To abort, move the cursor outside the window and click the left button before selecting any points. Figure 21 shows some examples of polygons.

Figure 21. Three examples of polygons with control points highlighted

You can move any of the control points (using one of the point-moving commands described in the section "To Move Elements," below) to change the polygon.

## To Add Curves to a Sketch

There are two kinds of curves you can add to a sketch: open curves and closed curves. This section tells you how to add each kind of curve.

### To Add an Open Curve

Select the  command from the Sketch command menu. The cursor will change to  and an  will follow the cursor. Move the cursor to the points you want the curve to go through and click the left button. When you select a point, it is marked with a . When you have selected all the points, move the cursor outside the window and click the left button. The points where you clicked will become the control points of the curve. To abort, move the cursor outside the window and click the left button before selecting any points. Figure 22 shows some examples of curves.

Figure 22. Four examples of curves with control points highlighted

You can move any of the control points (using one of the point-moving commands described in the section “To Move Elements”) to change the shape of the curve. In general, when you construct a curve, the closer together the points are the sharper the curve is; the farther apart they are, the smoother it is. The best way to learn how the control points affect the shape is to enter lots of different curves and move their points around.

### To Add a Closed Curve

Select the  command from the Sketch command menu. The cursor will change to  and an  will follow the cursor. Move the cursor to the points you want the curve to go through and click the left button. When you select a point, it is marked with a . When you have selected all the points, move the cursor outside the window and click the left button. The points where you clicked will become the control points of the closed curve. To abort, move the cursor outside the window and click the left button before selecting any points. Figure 23 gives some examples of closed curves.

Figure 23. Three examples of closed curves with control points highlighted

You can move any of the control points (using one of the point-moving commands) to change the shape of the closed curve.

---

## To Add Circles to a Sketch

---

Select the  command from the Sketch command menu. The cursor will change to . Move the cursor to the point you want to be the center of the circle and click the left button. The selected point is marked with  and the cursor changes to . Move the cursor to a point you want to be on the radius of the circle and click the left button. The circle will be added. The two points you selected are the control points of the circle. Either can be moved using one of the point-moving commands to change the radius and location of the circle. To abort this command, move the cursor outside the window and click the left button. Figure 24 shows two examples of circles.

Figure 24. Two examples of circles with control points highlighted

## To Add Ellipses to a Sketch

Select the  command from the Sketch command menu. The cursor will change to . Move the cursor to the point you want to be the center of the ellipse and click the left button. The selected point is marked with  and the cursor changes to . Move the cursor to the point you want to determine one radius and the orientation of the major axis of the ellipse (see figure 25). Click the left button. The selected point is marked with  and the cursor changes to . Move the cursor to any point that is the same distance from the center as you want the second radius to be and click the left button. The ellipse will be added.

The control points of the ellipse are the center and first radius point you selected and the point on the ellipse at the minor radius. Any of them can be moved using one of the point-moving commands to change the size, orientation, and location of the ellipse. To abort this command, click the left button with the cursor outside the window.

Figure 25. The control points for an ellipse

## o Use Arcs in a Sketch

In Sketch, partial circles are provided by the arc command. An arc is characterized by three control points (see figure 26) and a direction. The shape and angle of the arc can be changed by moving any of the control points (using one of the point-moving commands). The angle of the arc can also be changed by setting the number of degrees the arc spans. (See the section "To Set the Number of Degrees an Arc Spans," below.) The direction determines whether the arc is traversed in a clockwise or a counterclockwise direction from the starting point. An arc has

thickness (size), brush shape, and dashing properties; it can also have arrowheads.

Figure 26. The control points of an arc

## To Add an Arc

Select the  command from the Sketch command menu. The cursor will change to . Move the cursor to the center of the arc and click the left button. The selected point is marked with  and the cursor changes to . Move the cursor to one end of the arc and click the left button. This point determines the radius of the arc and its first end (see figure 26). The arc will begin at this point.

The selected point is marked with  and the cursor changes to . Move the cursor to the other end of the arc and click the left button. The arc will be added. To abort this command, click the left button with the cursor outside the window.

## To Set the Number of Degrees an Arc Spans

Select the Change command, move the cursor to one of the control points of the arc (which will be marked with a ) and click the left button. The menu shown in figure 27 will appear.

Figure 27. Menu of ways to change an arc

Select the Angle item. A number pad menu titled Enter Arc Angle in Degrees will appear (see figure 28). Enter the number of degrees that the arc should span by selecting digits from the number pad. When you are done, select the OK item. The selected arc (or arcs) will be changed to span the indicated number of degrees. The third control point (the angle point) is moved to accomplish this. To abort the command, select the Abort item from the number pad.

Figure 28. Number pad menu for changing the angle of an arc

## To Reverse the Direction of an Arc

Select the Change command, move the cursor to one of the control points of the arc (which will be marked with a ) and click the left button. The menu shown in figure 27 will appear. Select the Direction item. A menu titled Which Way Should the Arc Go? with the items Clockwise and Counterclockwise will appear. Select Clockwise if you want the arc to go in a clockwise direction. Select Counterclockwise if you want the arc to go in a counterclockwise direction. Figure 29 shows the same arc with different directions.

Figure 29. The direction of an arc

## To Use Arrowheads in a Sketch

Arrowheads can be added to lines, open curves, and arcs. An arrowhead can be added to either or both ends of an element. It is then a property of the element and moves with it if it moves.

An arrowhead has a shape, a size, and an angle (see figure 30). The default arrowhead shape, size, and angle specify what a newly added arrowhead looks like. If you want to add several arrowheads that look alike, it is easiest to change the default arrowhead properties (see the section "To Change the Properties of New Arrowheads") before you add the arrowheads. The shape, size,

and angle of arrowheads on existing elements can be changed using the Change command.

Figure 30. Sample arrowheads

## To Add an Arrowhead to an Existing Element

Select the Change command from the command menu, then select the element or elements you wish to add an arrowhead (or arrowheads) to using the procedure described in the section "To Select Sketch Elements." You can include elements that do not allow arrowheads (such as text or circles) as long as the element first selected does. A menu will appear that contains all of the properties that can be changed in the first element you selected. It will include the item Arrowheads. Select it. The menu shown on the left in figure 31 will appear.

Figure 31. The menus for changing arrowheads.  
The left one specifies which end of the line or curve will be changed.  
The right one specifies how it changes

This menu allows you to specify the end or ends of the selected element(s) to which the arrowhead(s) will be added. Selecting Left will add the arrowhead to the leftmost end of the element (or the topmost if both ends have the same x position). Selecting Right will add the arrowhead to the rightmost end of the element (or the bottommost if both ends have the same y position). Selecting Both will add the arrowhead to both ends of the element. Selecting First will add the arrowhead to the end of the element that was entered first when this element was added. Selecting Last will add the arrowhead to the end of the element that was entered last.

After you select one of these items, the menu shown on the right in figure 31 will appear. Select the item Add Arrow. Arrowheads will be added to the specified ends of the selected elements that do not

already have arrowheads. To abort this operation, click the left button outside any menu instead of selecting an item.

## **To Remove an Arrowhead**

---

Select the Change command from the command menu, then select the element or elements you wish to remove an arrowhead (or arrowheads) from using the procedure described in the section “To Select Sketch Elements.” You can include elements that do not have arrowheads as long as the element you select first does allow them. A menu will appear that contains all the properties that can be changed in the first element you selected. It will include the item Arrowheads. Select it. The Which End? menu shown in figure 31 will appear. Select the item that describes the end or ends (Left, Right, Both, First, or Last) from which the arrowhead(s) should be removed. (These items are described in the section “To Add an Arrowhead to an Existing Element.”) After you select one of these items, the Specify Change menu shown in figure 31 will appear. Select the item Remove Arrow. Arrowheads will be removed from the specified ends of the selected elements that have arrowheads. To abort this operation, click the left button outside any of the menus instead of selecting an item.

## **To Change the Way an Arrowhead Looks**

---

Select the Change command from the command menu, then select the element or elements whose arrowhead(s) you wish to change using the procedure described in the section “To Select Sketch Elements.” You can include elements that do not have arrowheads as long as the first element you selected allows them. A menu will appear that contains all the properties that can be changed in the first element you selected. It will include the item Arrowheads. Select it. The menu shown on the left in figure 31 will appear. Select the item that describes the end or ends on which the arrowheads to be changed occur. (These items are described in the section “To Add an Arrowhead to an Existing Element.”) After you select an item, the menu shown on the right in figure 31 will appear. See figure 30 for some examples of arrowheads that may help you understand the following instructions.

Selecting the item Wider will increase the angle of the specified arrowhead by 10 degrees. Selecting the item Narrower will decrease the angle of the specified arrowhead by 10 degrees. Selecting the item Larger will increase the length of the specified arrowhead by two screen points. Selecting the item Smaller will decrease the length of the specified arrowhead by two screen points. Selecting the item Triangle will add a base to the arrowhead. Selecting the item V-Shape will remove the base from the arrowhead. To abort this operation, click the left button outside any menu instead of selecting an item.

If you want to change several properties of some arrowheads, it may be easier to set the default arrowhead specifications to be like the arrowhead you want (see the section “To Change the Properties of New Arrowheads”), remove the existing arrowheads, and then add the arrowheads again. The newly added arrowheads will have the default properties.

## To Indicate That New Elements Should Have Arrowheads

---

Move the cursor over the Defaults command, press and hold the left button, and slide the cursor out the right side of the menu. Another menu will appear. In this new menu, with the left button still held down, position the cursor over the Line item and roll out its right side. A third menu will appear. In this menu, position the cursor over the Add Arrowhead item and release the left button. Two of the menus will disappear, and the menu titled Which End? shown on the left in figure 31 will appear. From this menu select the end of the elements you want to have arrowheads. Usually you will want to select Last. After selecting an item, whenever you add a line, curve, or arc, it will have an arrowhead on the specified end or ends.

To indicate that arrowheads should no longer be added to newly created elements, follow the above procedure but select the Neither item from the Which End? menu.

---

## To Change the Way Lines in Elements Look

---

Lines, polygons, curves, closed curves, boxes, ellipses, circles, and arcs have thickness (size), brush shape, and dashing properties. You change these properties using the Change command. Figure 32 shows some examples of different-sized lines.

Figure 32. Examples of different sizes of lines

---

## To Change the Size of a Line

---

Select the Change command from the command menu, then select the element(s) you wish to change using the procedure described in the section "To Select Sketch Elements." You can include elements that do not contain lines as long as the element first selected does; the change will not affect the others. A menu will appear that contains all the properties that can be changed in the first element you selected. Select the item Size. The menu shown in figure 33 will appear. Selecting the item Smaller Line will make all the lines one point thinner. Selecting the item Larger Line will make all the lines one point thicker. Selecting the item Set Line Size will bring up a number pad menu with the title Enter the New Line Thickness. Enter the size you want the lines to be by selecting the digits as you would on a calculator. When you have entered the number, select OK; all the lines will be made that

thickness. To abort the command, select the item Abort from the number pad.

Figure 33. The menu of ways to change the line size of an element

## To Make a Dashed Line

Select the Change command from the command menu, then select the element(s) you wish to change using the procedure described in the section "To Select Sketch Elements." You can include elements that do not contain lines as long as the element first selected does; selected elements without lines will be unaffected by the command. A menu will appear that contains all the properties that can be changed in the first element you selected. Select the item Dashing. A menu similar to the one shown in figure 34 will appear.

Figure 34. The menu of dashing patterns

Selecting one of the dashing patterns will make all the lines in the selected element(s) dashed with that pattern. Selecting the item No Dashing will make all the lines be solid; that is, it will remove the dashing from them. Selecting the item Other will prompt you for a new dashing pattern.

A dashing pattern is a sequence of numbers that indicates how many brush marks should be on and off. For example, the pattern (1 4 3 8) is , that is one on, four off, three on, eight off, repeated. When you select Other, a number pad menu with the title Number of Points On will appear. Enter the number of points you want to have on. When you have finished, select OK. A number pad menu with the title Number of Points Off will appear. Enter the number of points you want to have off. When you have finished, select OK. Number pads will continue to appear, giving you a chance to specify as long a dashing pattern as you like. After you have entered the last number in your dashing pattern, select OK when the number pad display has zero in it. A menu with the title Is This Pattern OK?, similar to the one shown in figure 35, will appear.

Figure 35. The menu presented to confirm a new dashing pattern

The first item will show the pattern you entered. If this is what you wanted, select the item Yes or the pattern; all the lines in the selected elements will change to that pattern. This pattern will also appear in the menu of dashing patterns the next time you change the dashing of an element. If you want to enter a different pattern, select the item No and you will be prompted for another dashing pattern. If you want to abort, select No and then select Abort from the number pad that appears. Selecting Abort from any number pad will abort the command.

Figure 36. Examples of different dashing patterns for lines

Note: most printers do not support the dashing of splined curves, so curves, circles, ellipses, and arcs will not have dashed lines on hard copy. The effect will only be visible on the display.

---

## To Change the Brush Shape of a Line

Select the Change command from the command menu, then select the element(s) you wish to change using the procedure described in the section "To Select Sketch Elements." You can include elements that do not contain lines as long as the first element you selected does. A menu will appear that contains all the properties that can be changed in the first element you selected. Select the item Shape. The menu titled Pick a Shape shown in figure 37 will appear. Select the brush shape you want. When you have selected one, all of the lines will be painted with that brush. To abort the command, select outside any of the menus.

Figure 37. The menu of brush shapes

Note: because most printers do not support all of the available brush shapes, the effect may be visible on the display only.

## To Change the Way New Elements Look

The properties an element has when it is first added to a sketch are called the *default* properties. For example, there is a default size that determines how wide newly added lines, curves, boxes, etc., will be. All these defaults can be changed using the Defaults command and subcommands (see figure 38). If you want to add a collection of elements that are different from the standard, changing the default is often the easiest way to do it. For example, if you want a bunch of extra-thick arrows, you could change the default properties of new lines to have a thickness of two and an arrowhead on the last point specified before you enter the lines for the arrows. Any defaults that you change are saved when the sketch is saved.

Figure 38. Submenu for the Defaults command

TO

### Change the Properties of New Text

**1** Move the cursor over the Defaults command, press the left button, and slide out the right side through the triangle. The middle menu shown in figure 39 will appear. Move the cursor over the Text item and slide out the right through the triangle. The right menu shown in figure 39 will appear.

Error in IMAGEOBJ  
(GETFN: HRULE.GETFN)

Selecting the item Font Size will prompt you for the size that new text should have; supply it using the same procedure described in the section "To Change the Size of Text." Selecting the item Font Family will prompt you for the family that new text should have, which you specify using the procedure described in the section "To Change the Font Family of Text." If the specified font cannot be found in the current default size, an error message is printed and the default is not changed. Selecting the item Horizontal Justification will prompt you for whether the new text should be left, right, or center justified. Selecting the item Vertical Justification will prompt you for whether the new text should be top, bottom, middle, or baseline justified. For more information about text justification, see the section "To Change the Justification of Text." Selecting the item Bold and/or Italic will prompt you for the bold and italic properties that new text should have.

### To Change the Properties of New Text Boxes

Move the cursor over the Defaults command, press the left button, and slide out the right side through the triangle. The middle menu shown in figure 40 will appear. Move the cursor over the Text Box item and slide out the right through the triangle. The right menu shown in figure 40 will appear.

Selecting the item Horizontal Justification will prompt you for whether the text in new text boxes should be left, right, or center justified. Selecting the item Vertical Justification will prompt you for whether the text should be top, bottom, middle, or baseline justified. For more information about text justification, see the section "To Reposition the Text Within a Box." The font size, family, and bold and italic properties for new text boxes are the same as for text. See the section "To Change the Properties of New Text." The line thickness of the box is the same as the thickness of lines, so to change it see the section "To Change the Properties of New Lines."

Figure 40. Submenu to set the default position of text inside a text box

---

## To Change the Properties of New Lines

Move the cursor over the Defaults command, press the left button, and slide out the right side through the triangle. The menu shown in figure 38 will appear. Move the cursor over the Line item and slide out the right through the triangle. A menu containing the items Size, Shape, Add Arrowhead, and Mouse Line Specs will appear. Selecting the item Size will prompt you for a number that will become the thickness of any new lines, curves, circles, etc. Selecting the item Shape will prompt you for a brush shape that will become the shape of any new lines, curves, circles, etc. Selecting the item Add Arrowhead will prompt you for which end or ends, if any, of new lines, curves, and arcs should automatically get arrowheads. To change the characteristics new arrowheads have, see below. Selecting the item Mouse Line Specs enables you to choose whether lines created by middle buttoning in the window should be connected.

---

## To Change the Properties of New Arcs

Move the cursor over the Defaults command, press the left button, and slide out the right side through the triangle. A menu that contains (among others) the item Arc will appear (see figure 41). Still holding down the left button, move to over Arc and slide out the right side through the triangle. A menu with the items Clockwise and Counterclockwise will appear (see figure 41). Selecting Clockwise will make new arcs go from their radius point to their angle point in a clockwise direction. Selecting Counterclockwise will make new arcs go from their radius point to their angle point in a counterclockwise direction.

The line thickness of arcs is the same as the thickness of lines. See "To Change the Properties of New Lines" if you want to change arc thickness.

Figure 41. Submenu to change the default direction of arcs

## To Change the Properties of New Arrowheads

Move the cursor over the Defaults command, press and hold the left button, and slide the cursor to the right through the triangle. The menu shown in figure 42 will appear. In this new menu, with the left button still held down, position the cursor over the Arrowhead item and slide it to the right again. A menu containing the commands Size, Angle, and Type will appear (see figure 42).

Figure 42. Menu of ways to change the default properties of arrowheads

From this new menu, select the arrowhead property you want to change. Selecting Size will bring up a number pad menu titled New Arrowhead Size in Screen Pts and giving the current default arrowhead size (length of the edges). Enter the number you want to become the size of new arrowheads, then select OK. You can abort the Size command by selecting Abort from the number pad menu.

Selecting Angle will bring up a number pad menu titled New Head Angle in Degrees, which gives the current number of degrees of the angle between the edges of new arrowheads. Enter the angle you want, then select OK. To abort, select the Abort item from the number pad menu.

Selecting the item Type will bring up a menu with the items V-Shape and Triangle, from which you can select the type of end you want new arrowheads to have. If you select V-Shape, your arrowheads will consist of two lines from the head. If you select

Triangle, new arrowheads will be triangles (two lines from the head and a line connecting their endpoints).

After this, whenever you add an arrowhead it will have the specified property.

---

## To Use Bit Maps in a Sketch

---

You can include bit maps and other types of image objects in Sketch drawings. This section describes the procedures for dealing with bit maps because they are a particularly useful kind of image object, but many of the procedures described here apply to other image objects as well. You can place a bit map in a sketch with the standard copy-select mechanism. A bit map has a single control point at its lower-left corner and can be moved, copied, and deleted like other elements. Advanced user note: applying the Change command to an image object or pressing a button down while over its image in the sketch window calls that object's `BUTTONEVENTINFN`, which is often an editor for the object.

---

## To Insert a Bit Map From the Screen

---

Move the cursor into the sketch window and click the left button. A caret () will appear. (If it doesn't appear, click again.) Move the cursor into the background (i.e., so it is not in a window). Hold down the copy key. On 1108 and 1186 keyboards, this can be either shift key or the Copy key; on Alto-style keyboards, it is either shift key. A menu with the single item Snap will appear. Select it.

The cursor will change to . Move the cursor to one corner of the region of the screen you want to include in the sketch. Press the left button. Holding the left button down, move the cursor to the opposite corner and release the button. While the left button is down, the region will be highlighted in gray. When you release the button, the message "Move the figure into place and press the left button" will appear in a small window above the sketch window. If this doesn't happen, you probably forgot to click in the sketch window first, and the bit map was inserted into whatever window was active. When the message appears, move the cursor into the sketch window and place the bit map image where you want it. When it is positioned, click the left button to insert the bit map.

---

## To Insert a Bit Map of a Pop-Up Menu

---

Images of pop-up menus are often useful in illustrating documentation (see, for example, figures 38 and 42). To insert a pop-up menu in a sketch, you must break the process that is popping it up using the following procedure. While the pop-up menu is visible, type the help interrupt character. Initially this is control-G (that is, hold the control key down and type G); however some systems move it onto control-H. When you have typed the help interrupt character, a menu containing the names of all the current processes will appear. Select the process that has popped up the menu, which is usually marked with an asterisk. It is often

the process Mouse. If you selected the correct process, a break window will appear and the menu will still be on the screen. If the menu disappears, you broke the wrong process; move the cursor into the break window that appeared, press the middle button, and select OK from the menu that appears. This will continue the process you did break. Bring up the pop-up menu again, type the help interrupt character, and select a different process from the menu. When you get the pop-up menu image to stay up, follow the procedure described above in "To Insert a Bit Map From the Screen." Important: when you have finished getting the image, move the cursor into the break window that appeared, press the middle button, and select OK from the menu that appears. This will continue the process that popped up the menu. If you forget this, strange things will happen when you next use the pop-up menu.

It is often helpful to consider the background onto which the pop-up menu will appear. This is because you often get parts of the background when you copy a menu image. And the bit map editor Trim command (see below and figure 43) only trims away white space. So if there are black background bits, you will have to edit them out using the bit map editor (see the next section). This step can sometimes be avoided by changing the background to white (by typing (CHANGEBACKGROUND WHITESHADE) into the executive window). It is also helpful to move other windows away from the area where the pop-up menu will appear.

---

## To Touch Up a Bit Map

---

Move the cursor over the bit map's image in the sketch window and press the left button. The menu shown in figure 43 will appear.

Select the Hand Edit item. The cursor will change into  and a large box outline will appear. This outline is the region the bit map editor will occupy. Move the box to the place on the screen where you want the bit map editor window to reside and click the left button. The bit map editor window will appear at that location (see figure 44).

*Figure 43. Menu of commands to edit a bit map.  
You obtain this menu by pressing the left button  
when the cursor is over a bit map image in a sketch window*

Edit the image by pressing the left or middle button in the large area at the bottom of the window. The image can be scrolled using the normal scroll bars if not all of it appears in the editing area. To quit, press the middle button while in the gray area at the upper-right part of the window. A menu will appear. Select OK to have the changes you made put back into the sketch. Select Stop if you want your changes disregarded. After you exit the bit map editor, the image in the sketch window is often incorrect. See the section "How to Clean Up the Display" for instructions on making it pretty again.

Figure 44. A bit map editor window

Another useful bit map editor command is Trim, available from the Operations on Bitmaps menu shown in figure 43. Trim will remove all the edge rows and columns that contain only white bits, making it easier to place lines and text around the bit map and saving storage space.

---

## To Put a Border Around a Bit Map

---

Move the cursor over the bit map's image in the sketch window and press the left button. The menu shown in figure 43 will appear. Select the Add Border item. This will prompt you for the number of bits you want in the border, then allow you to edit a four-by-four shade that will be put in the border. You can add multiple borders. For example, many of the bit maps in this document have two points of white surrounded by one point of black.

For a complete description of the bit map editor, see the EditBitMap documentation in the *Lisp Library Packages Manual*.

## File Naming

### —**.test**

A file of DO-TEST forms, suitable for running with DO-TEST-FILE or DO-ALL-TESTS. Within a directory, files are named x-y-z-w....test, with more general descriptions to the left, and more specific naming to the right. For example, there might be several tests of Lists: LIST-CREATION.TEST and LIST-MODIFICATION.TEST. It is poor form to include the words REGRESSION, TEST, or such like in the file name: Regression tests should be folded into the main test file, and all of these files are tests, so that's redundant.

### —**.u**

A script to be followed during hand testing. Within a directory, files are named x-y-z-w....u, with more general descriptions to the left, and more specific naming to the right. For example, the Exec might have several test files, e.g., Exec-PL.u, Exec-DIR.u, etc.

### —**.plan**

A plan for testing a section of the system, a new product like PCE, etc.

### —**m-d-y.log**

The results of running a test or series of tests.

This msg is stored on {eris}<lispcore>internal>library>do-test.tedit  
The tester is on {eris}<lispcore>internal>library>do-test.dcom.

### The main entries are the following:

(DO-TEST *name forms*)

A test succeeds if the final *form* returns a non-nil result. *Name* is just the name which can be an atom or string; strings are preferred. Forms are presumed to be read with the Common Lisp reader in package XCL-TEST, which uses LISP and XCL. If a test fails or an error occurs during evaluation, a message is printed to \*ERROR-OUTPUT\*.

(DO-TEST-GROUP *name&options forms*)

For associating a group of tests. For instance, a group of tests may all require the same setup and cleanup. If there are any options (see below) then the CAR of *name&options* is the name and the CDR is a keyword/value list. All *forms* must be DO-TEST forms.

(EXPECT-ERRORS *error-types forms*)

*Error-types* is a list of errors that may occur while executing the *forms*. If one of the listed errors occurs, EXPECT-ERRORS returns (values t error-that-occurred), otherwise NIL. Normal use of this form is:

```
(DO-TEST "a test"
 (EXPECT-ERRORS (type-of-error)
 (THIS-FORM 'SHOULD 'ERROR)))
```

(DO-TEST-FILE *filename*)

Reads and executes a file of tests. All forms in the file are read before any are executed. The file should be clear text (clearput in TEdit) and terminate with a STOP. The format for test names is Chap#[-sec#[-subsec#]]-comment.TEST

(CL-READFILE *filename*)

Reads all forms in *filename* and returns a list of them. This function is used by DO-TEST-FILE to read test files; test writers who want to see if their files are syntactically valid should first see if CL-READFILE will read them, then see if DO-TEST-FILE will execute them.

```
(DO-ALL-TESTS &key (results *test-batch-results*)
 (patterns *test-file-pattern*)
 (sysout-type nil)
 (resume nil))
```

Calls DO-TEST-FILE on each file that matches *patterns*, which is a list of directory patterns, and prints the results to a new version of a file named *results*. If *results* is T, results are printed to the window where DO-ALL-TESTS is running. The header of the results file is a message of the date and time the tests are being run and the MAKESYSDATE of the sysout; if *sysout-type* is supplied, a line for it goes out too. If *resume* is non-NIL, DO-ALL-TESTS attempts to resume an interrupted test sequence, appending the results onto the latest version of *results*.

TEST-SETQ, TEST-DEFUN, TEST-DEFMACRO

These work like SETQ, DEFUN, and DEFMACRO, except that if they are executed within a DO-TEST-GROUP, their effects are manually undone (old values are saved and then restored) upon leaving the DO-TEST-GROUP. Use these in :BEFORE forms that a whole group of DO-TESTs want to see. DON'T use TEST-SETQ on locally-bound variables or in loops.

### Relevant variables:

\*TEST-MODE\*

Default is :batch, which means to report test failures and errors on \*ERROR-OUTPUT\* (which is usually a file), and continue. Other values possible are:

:interactive which means to print a message before running each test, print another message for test failures, and produce a break window on errors.

:batch-verbose which means to generate all the messages of :interactive and do not break on errors.

\*TEST-BATCH-RESULTS\*

Defaults to "{eris}<lispcore>cml>test>test-results"

\*TEST-FILE-PATTERN\*

Defaults to ("{eris}<lispcore>cml>test>\*.test;" "{eris}<lispcore>cml>test>\*.x") which runs all the internal tests.

**\*TEST-COMPILE\***

If this switch is non-nil, DO-TEST compiles its forms before testing them. DO-ALL-TESTS will print a message in its header if this switch is on.

**\*ALL-FILES-REMAINING\***

While DO-ALL-TESTS is running, this variable contains a list of all the files remaining to be processed; files are removed from it AFTER they are read and executed. To restart a test run that somehow crashes the test driver, first clean up whatever blew up the run (if necessary, dump \*ALL-FILES-REMAINING\* to a file and get a new sysout), then do  
(DO-ALL-TESTS :RESUME T [:RESULTS "wherever"]).

**Options to do-test-group.**

:before        allows for a setup form for a group of tests.  
:after        allows a form to be run after the tests without affecting results.

The normal form of a DO-TEST-GROUP using all its features is:

```
(DO-TEST-GROUP
 ("a test group"
 :BEFORE (progn (before-form-1) (before-form-2) ...)
 :AFTER (progn (after-form-1) (after-form-2))
)
 (DO-TEST "first test")
 (DO-TEST "second test")
)
```

Add new abbreviation characters below, with a tab between. To test, expand the right-hand instance of each, and print the result.

## Introduction

AGAST is an attempt to produce a program that can write intelligent stories. With an eclectic combination of ideas from the work of both computer scientists and writers, we have produced the flexible core of what could be a very intelligent story teller.

Work being done in cognitive science, natural language processing, and other areas that are closely based on human actions fits neatly into the project. Story-telling is not one isolated behavior, but a combination of many; work from text generation, decision-making, story-planning, character development and other areas is needed.

AGAST uses a formula similar to those developed by various professional writers to teach beginning authors how to write stories\*. This formula (described in detail in Part II) divides stories into five sections. AGAST attempts to model this formula by creating stories in the form of five inter-related sections.

AGAST is flexible because it "writes" stories in two stages. The first stage creates a story tree, where every action that happens is stored. As the tree is generated, the internal representation of the physical world (including locations, objects, and characters) is affected, which in turn affects the progress of the story.

A straight-forward depth-first traversal of the story tree produces a "chronological" account of the story. The second part, the text generator, walks the tree this way and thus tells the story. This part is extremely simple now; it just writes a sentence for each and every action, telling the story in excruciating detail. But since the story structure is unaffected by the telling, a different text

---

\* i.e. to capture what is essential in a story as opposed to a random collection of sentences, or some other form of prosaic writing such as a newspaper article or master's thesis

generator could easily be used before, after, or instead of the one used now. Sequences of events could be summarized to different levels as needed, events could be told in varying orders, or two stories could be meshed together.

The fact that the story exists as a tree after its generation means also that actions can be undone and the story can take a new direction in the retelling. AGAST uses this feature to handle stories that end in story-telling failure. Like a human writer, AGAST can "change its mind" and rewrite the story to end successfully. This also means that AGAST doesn't need to plan every detail of the plot ahead of time. It can randomly generate complications for the plot, handle them using any sort of decision making process, and know that if it paints itself into a corner, it can either undo the actions that got it into trouble, or change the situation so that the characters can successfully handle the problem.

## **Related Work**

### **A. James Meehan's "TALE-SPIN"**

"Tale-Spin" [Meehan 76] seems to be the grandparent of computer story writing--at least, everyone who does work in the field must refer to James Meehan's ground-breaking work.

Like Tale-Spin, AGAST has a physical world, with objects and locations. Both have actions, although AGAST's actions are arranged in a writerly (GIVE, PICK-UP) rather than a formal (PTRANS, MTRANS) fashion.

Tale-Spin's stories are generated by goal stacks--the original goal puts other goals on the stack, the achievement of all of which completes the original goal. AGAST's stories have this feature as well. However, like AGAST actions, AGAST goals are arranged in a writerly fashion, each broken down into story parts. In addition there is the possibility of having multiple goals, all being solved simultaneously.

One example of this is when a character is looking for two different objects. First one object is sought, and when it is found, the other is sought. However, if the second object is run across in the search for the first, it is picked up and the search for it is never initiated. Although it isn't yet implemented in AGAST, characters can have other character's goals as subgoals, thus helping friends achieve their major goals.

Also, in storing actions and their side-effects as they occur, AGAST allows story revision and backpatching, which aren't conceivable in Tale-Spin.

Tale-Spin does have some level of social interaction, which AGAST is at present totally missing.

## **B. Natalie Dehn's thesis**

Natalie Dehn [Dehn 81] makes the point that in writing a story, authors have a goal: to write an interesting story. Her project concentrates on author intentionality. AGAST attempts to emulate this goal with the plot formula that drives the story, and with backpatching that "saves" the story when it plots its way into a dead end.

However, there is also the point that characters must have goals. If they start without a specific goal, they are quickly given one, from simply staying alive to saving the universe. Dehn points this out (but not in terms of character goals) when she mentions justifying the situation a character finds him or herself in. A story goes wherever the author intends, but it won't be a very good story if the characters seem to be acting only on the author's whim. They should be following their own goals; their actions should make sense to them, not just to "The Story," of which characters generally aren't aware, anyway. AGAST attempts to combine the internal logic of goal-driven behavior of Tale-Spin with the author-intention-driven stories that Dehn promotes.

## **C. Michael Dyer's "BORIS"**

Michael Dyer's work [Dyer 81] is more on story understanding than on story generation. Dyer's BORIS attempts to understand stories not only by general semantic, grammatical and lexical knowledge but by discerning the context that the story creates. AGAST creates and stores its context, but so far makes only a limited use of it. One example in which AGAST uses the context of an event is when an accident occurs (a character is injured--they trip, or some

such accident). If the character is just travelling or exploring, they can cure themselves (but only if they're carrying a medikit). However, if they are fighting or escaping, they can't take the time to do anything about the injury.

While it would surely be interesting to have BORIS read in AGAST stories and answer questions about them, it would be more interesting to have a BORIS-like program enhance the context that AGAST builds. A memory of past events would allow characters to "learn" and would make social interaction easier to simulate. For instance, suppose Frank killed Libby's cat. When Libby next meets Frank, the past event might make her want to get revenge on Frank, and thus would influence what she did during the meeting. As in Tale-Spin, she would know Frank was not to be trusted--but she would conclude it rather than knowing it from the start. From the examples in Dyer's paper, it would seem possible to use such a system to determine characters' attitudes toward other characters and their current emotional states.

#### **D. Eduard H. Hovy's "PAULINE"**

The actual text of AGAST stories is generated very simply--every object in a story tree knows how to print a description of the action it represents. This produces very lengthy, boring text (see sample stories).

Eduard H. Hovy [Hovy 87] discusses a much better text generation model. His program, PAULINE, groups related actions together and summarizes them, specifically mentioning only the "high points" of the event. PAULINE interprets the actions, draws conclusions, and adds them to its knowledge of the event. PAULINE can also "shade" what it tells, adding evocative words that can slant the meaning of the text, although the event is still accurately portrayed.

These abilities would greatly enhance the "story-ness" of AGAST's stories.

Instead of:

**Libby swung her sword at the giant centipede, injuring its leg.**

**The giant centipede bit Libby, injuring her arm.**

...and so on, each exchanging many blows and ending with:

**Libby swung her sword at the giant centipede, injuring its head. Its head was severed and dropped to the floor. The giant centipede was killed.**

A program such as PAULINE might be able to produce more writerly text:

**Libby drew her sword as the giant centipede attacked. She slashed at the slaver creature as it bit at her. Howling with rage, the giant centipede sank its mandibles into Libby's left arm. Libby raised her sword and with a cry of desperation cut off the centipede's head.**

Since AGAST's actions are already grouped and catalogued (a series of "injure" actions that constitute a "fight" are stored in a slot of a "fight" event), summarizing events and choosing weighted words that fit the situation (desperate, rage) and the characters in it ("slaver", since giant centipedes are defined as non-intelligent animals) should be relatively easy to do.

## **E. Michael Lebowitz's "UNIVERSE"**

Michael Lebowitz's UNIVERSE program generates plots for soap-opera-like stories. This is different from most other work in the field in that stories in UNIVERSE are deliberately constructed not to end, but to have continuing characters moving from mishap to mishap. Below we examine two versions of UNIVERSE which have appeared in the literature.

[Lebowitz 83]

While AGAST is action-heavy, Lebowitz is primarily concerned with character consistency and development. Past events affect the personality (and thus actions taken) of characters. Like UNIVERSE, AGAST creates important

characters--the protagonist, the antagonist, anyone directly involved in the main goal--before the story starts. Unimportant characters--attacking monsters, for instance--are created on the fly.

AGAST reaches for this ideal with the Background section of the story providing the motivation for the story. However, UNIVERSE goes much further, with each character carrying around a changing history. Like Dyer's BORIS, a UNIVERSE-like program could significantly help the character development of AGAST's stories.

UNIVERSE also keeps track of character relationships in a more consistent way than AGAST. AGAST's characters can be related to one another (e.g. Libby is Frank's mother, and Frank is Libby's son), but if Frank is Stella's brother, all Libby knows is that she is somehow related to Stella. Relationships that change with time, such as marriage, exist, but are assumed permanent, with no history of past divorces or whatever.

[Lebowitz 87]

Using goal precedence and mutual-achievement criteria for goal selection, UNIVERSE nicely manages the interweaving of plots that is important for a complex, interesting story. AGAST currently has only one form of subplot implemented, the substory. Here the main goal is temporarily suspended while a subgoal (with a "subprotagonist") is "written" in a "meanwhile, back at the ranch..." type of story. The conclusion of the subgoal, usually with the subprotagonist and the protagonist joined as companions, then allows the completion of the major goal. The nesting of substories, however, can produce quite complex stories (Libby rescues Fred; they both rescue John; all three join with Natasha to continue the search for the Lost Ark of the Covenant...).

The "churning" of plots that UNIVERSE uses as one of its author goals is somewhat emulated by the introduction of obstacles and problems into the path of the protagonist. Plans have particular problems associated with them, and goals (which determine the type of story, such as the "quest") can also have special problems associated with them, especially at the climax of the story (which is a concept UNIVERSE doesn't have, since it writes "slice of life" narratives).

## **F. Schank and Abelson's scripts**

Schank and Abelson [Schank and Abelson 77] discuss many of the methods used in story writing programs. One important idea is that of scripts--an outline of how to behave in particular situations. They allow both understanding and generation of simple stories involving frequently done events, such as eating in restaurants or taking the bus.

Actions in the AGAST story tree are grouped and stored in PLAN objects. Many plans are similar to scripts in that they generate a restricted series of actions that constitute a type of event. For instance, if the event is a FIGHT between two parties: first, a character (randomly chosen from the first party) injures one (randomly chosen from the second party), then a return injury is done. These actions are repeated until one of the parties has no one left who can continue fighting.

## LESSON A7: FETCHING A NEW SYSOUT ON A DANDELION

B. Burwell December 7, 1987

Filed on : {Phylum}<ISLDOC>A07■DaybreakSysoutFetch

**Objective:** This document provides a recipe for the installation of a new copy of an Xerox Lisp "Sysout" (i.e., the main Xerox Lisp software), on a Daybreak which resides on a local network. You will be retrieving a new copy of the Xerox Lisp software from a network-based file. This document does not tell you how to load a new sysout from floppy disks.

### Discussion:

The Xerox Lisp software machine uses various resources, primary memory in particular, during its life cycle. Not all of these resources are relinquished and deallocated when no longer needed, and the machine tends to "fill up" after prolonged use. To avoid problems when running low on the available memory that Xerox Lisp will want to use, the software on the machine (i.e. sysout) should be periodically restored to its prior initial state. This is accomplished by loading into the computer a fresh copy of the software, which reflects a full complement of the resources that are supposed to be available. The frequency of such need varies according to use: busy programmers may require a new copy daily, while casual users using only the mail and editing facilities may survive several weeks or more. The need to load a new copy of the sysout may be heralded by seeing such error messages as "ARRAYS FULL". Also, when the system starts to get sluggish and it takes longer than usual for processes to complete this is generally an indication that a new sysout is needed.

Sometimes your machine may crash with an error that is unrecoverable until you get a new sysout. If you get a 0217, 1185 or some other error in the cursor, please refer to Lesson L5. If you are really stuck just get a new sysout.

The following assumes you have a working Dandelion that has an Xerox Lisp system installed and running. Additionally, this machine should be connected to an Ethernet and able to access the appropriate file server designated for your use. When you have completed the sequence of steps listed you should have a fresh copy of the Xerox Lisp sysout running and ready for service. All of your local disk files and permanently stored files on file servers will remain unchanged. Your personal additions may not change, unless you have previously modified your "user init file", which directs Xerox Lisp to customize your machine according to your individual specifications. (See Lesson H for more on Init files.)

In the following, comments are in *Italicized print*; you type the things that are underlined, and normal print represents statements issued by the computer.

## Procedure:

### 1. Saving your work and running the Lisp Installer

*IF THE MACHINE IS ALREADY ON and running Xerox Lisp, first save your work by doing the following: put any TEdit or Sketch files that you have made changes to, save any functions that you have defined, close any mail folders that you have open. Now logout by doing the following:*

(LOGOUT)

*IF THE MACHINE IS OFF, turn it on by moving the rocker switch on the main unit front panel toward the 1 position.*

*After a few seconds a number of icons will appear which will correspond with the function keys. Press the F1 key immediately followed by the 0 (zero) key. Do not hold both keys down at once.*

*This will look for and boot from a specific Mesa boot file on your local hard disk.*

*The Daybreak will come alive as a Mesa machine (i.e. running under the Pilot operating system).*

### 2. Installer Version 1.0

Copyright (C) 1984, 1985 by Xerox Corporation. All rights reserved.

Processor = 0AA007B74H = 25200075564B = 2■852■158■324

Memory size = 1536K bytes

Shall I try to find remote scripts? (Y / N): N <CR>

>Online

Drive Name: RD0 <CR>

*Pressing the carriage return at this point will bring the rigid disk (RD0) online.*

### 3. Installing a new sysout

*There are two choices for installing a new sysout. Since retrieving a new sysout from a file server on the Ethernet can take up to ten minutes, some people stash a fresh copy on*

*their LispFiles volume to save time. The sysout does take up space, though. If you already have a sysout on your LispFiles volume that you want to use, skip to step 5.*

*In this step you will actually fetch a new sysout onto the local disk. You will need to know ahead of time exactly which sysout you want and where it is stored. Refer to lesson M1 for a discussion about possible sysouts to load. The sysout is either on an NS file server or an IFS.*

*First you will open a connection to the file server and then fetch the sysout from that file server.*

### **For a sysout on an NS file server**

*If the sysout is on an NS file server (e.g. IE:PARC:Xerox) then you need to make sure you are logged in with your NS id (you were previously when connected to Starfile Public).*

> login  
User: your NS id (e.g. Joe Public:PARC:Xerox) <CR>  
Password: your NS password <CR>

> open  
connection to: your NS file server (e.g. IE:) <CR>

### **For a sysout on an IFS:**

*If the sysout is on an IFS (e.g. Phylum or qv) you will first need to login with your Grapevine name.*

> pup login<CR>  
User: your Grapevine id (e.g. Jones.pa) <CR>  
Password: your Grapevine password <CR>

> pup open  
connection to: your IFS (e.g. Phylum) <CR>

*Note: even if you give the name of an IFS that is running, it is possible to get an error returned. If you will get the message "No Route to host" simply execute the pup open command again until you get a connection. Alternatively, if you get the message "connection rejected by host" this means that the file server is very busy. The pup open command will keep trying to make a connection.*

4. *You now have a connection open to a file server. You want to ask the Installer to fetch the sysout onto a partition on the disk.*

> Lisp Sysout Fetch

Logical volume: volume name where you want sysout stored (e.g. Lisp) <CR>

Source: directory on file server where sysout is located (e.g. <Lisp>Lyric>Basics>Full.sysout) <CR>

Expand volume: (answer Y unless you are fetching the sysout to be a fresh Lisp sysout) Y <CR>

expanding. . . . (unless you said N above)

Shall I make this the physical volume: N <CR>

*Fetching a sysout usually takes 5 to 10 minutes.*

## 5. **Copying a fresh lisp sysout:**

*If you didn't fetch the sysout into a fresh lisp sysout then go onto step 6. You will now copy the fresh lisp sysout from the partition you fetched it into to the partition that you want to run Lisp in. After that you will expand the destination partition.*

> copy vmem

Source volume: your fresh lisp sysout volume (e.g. LispFiles) <CR>

Destination volume: your working lisp partition (e.g. Lisp) <CR>

copying.....done.

> expand volume

Logical volume: your working Lisp partition (e.g. Lisp) <CR>

expanding..... done.

6. **N.B. Unlike a Dandelion, the Daybreak requires that there be Lisp microcode in each volume that you want to run Lisp in.** You must have the right version of Lisp microcode which corresponds with the release of Lisp. For example, to run Lyric, you must use Lyric microcode. The Lisp microcode is available on Phylum, IE:PARC:Xerox and Starfile Public. In the following example, Lisp Lyric microcode will be retrieved from Phylum. Refer to Lesson A6 if Phylum isn't available. **If you are just getting a new sysout and are staying with the same release then continue on to step 7.**

> pup login<CR>

User: your Grapevine id (e.g. Jones.pa) <CR>

Password: your Grapevine password <CR>

> pup open  
connection to: Phylum<CR>

> Lisp Microcode Fetch  
Logical Volume Name: (the name of the volume e.g. Lisp) <CR>  
Source: <Lisp>Lyric>Basics>LispDove.db  
Shall I make this the physical volume? N <CR>

**7. Starting Lisp:** *You are now ready to go into Lisp.*

> Start Lisp  
Logical volume: your lisp volume (e.g. Lisp) <CR>  
Are you sure: Y <CR>

8. The screen will go dark and possibly display an odd pattern on the screen. The cursor will stop on 199 for a number of seconds and finally go to 1186. If the maintenance panel hangs on some other number refer to lesson L5.

*As Xerox Lisp looks for and activates different tools, the screen may change slightly. This process will be complete when the Xerox Lisp prompt "1>" returns to the 'TTY' window.*

*At this point you should now be in possession of a fully functional Xerox Lisp machine, and it is ready for you to resume your work.*

```

# File Naming

### —.test

A file of DO-TEST forms, suitable for running with DO-TEST-FILE or DO-ALL-TESTS. Within a directory, files are named x-y-z-w....test, with more general descriptions to the left, and more specific naming to the right. For example, there might be several tests of Lists: LIST-CREATION.TEST and LIST-MODIFICATION.TEST. It is poor form to include the words REGRESSION, TEST, or such like in the file name: Regression tests should be folded into the main test file, and all of these files are tests, so that's redundant.

### —.u

A script to be followed during hand testing. Within a directory, files are named x-y-z-w....u, with more general descriptions to the left, and more specific naming to the right. For example, the Exec might have several test files, e.g., Exec-PL.u, Exec-DIR.u, etc.

### —.plan

A plan for testing a section of the system, a new product like PCE, etc.

### —m-d-y.log

The results of running a test or series of tests.

## AUTOMATED TEST HARNESS INTERFACES

This document specifies the interfaces to the automated tester harness. The harness is composed of two parts: the **top-level tester** and the **individual test handlers**. The name of the file to load for this is AUTOTEST.LCOM in the top level of the {MEDLEY}internal/test directory.

The top-level tester is set up similarly to the package FileBrowser. Items are selected in the same manner as FileBrowser, and are displayed similarly. The portions of the display are as follows (from top to bottom):

1. A prompt window for displaying messages and getting new input.
2. A command menu with the following commands:

TEST Tests sequentially each of the items selected in the test files window. Testing consists of loading the file containing the test suite, calling a function which has the same name as the NAME field of the filename (this function must return NIL iff the test suite is not successful), then undoing (as best as possible) the side-effects of loading and running the test suite. The function which is called is passed one argument: the name of the directory that the test suite came from (including the host name). If this item is selected with the middle button, then first it asks for the name of the file to direct output to (selecting this item with the left button will direct output to T, the process TTY display stream), before running the test suites. All output directed to NIL, the default output stream, will go to this file, including all error messages generated by the automated test harness and by TEST-MESSAGE (see below). It is assumed that no other activity is being performed while testing is in progress.

ABORT Aborts any tests in progress. Confirmation (via clicking the left mouse button) is required. New tests can be selected, tests can be re-run, etc. after an abort.

PAUSE Temporarily pauses any tests in progress. Any pause time does not count in the computation of timeouts (see below).

RESUME Resumes PAUSED testing.

DIRECTORY Does a directory of files (the directory pattern is prompted for in the prompt window) and puts them in the test files window in order to have a new set of test suites to select from.

PRINT Prints the results of testing the selected files. Selecting this item with the left button will print on the default printer. Selecting this item with the middle button will put up a menu asking whether to print to a printer or a file. If a printer is selected, then a menu asking for the printer to print to (gotten from DEFAULTPRINTINGHOST plus the selection "Other"; the latter will ask for the name of a new printer to print to) is up. Otherwise, if a file is selected, then the user will be prompted for the name of a file to print to (also, if the type of output is not obvious, i.e. PRESS or INTERPRESS, then the user will be prompted for the type of output). When the Hardcopy item of the right button menu is selected for this window, then this command is performed (except that selecting the main item does the default, while selecting either the printer or the file sub-item starts the sequence of questions at the intuitive place).

SUMMARIZE Similar to PRINT, except that it prints only those tests (out of the selected tests) which failed.

c. **QUIT** Quits testing, closing the window and throwing away all test results, test names, et stored in the window. If any tests are currently in progress, then confirmation (via clicking the left mouse button) is required in order to quit (in this case an ABORT is performed before quitting). When the tester window is closed, this command is performed.

3. A status window, which has the following fields:

**Suite** The name of the test suite currently running.  
**ID** The ID of the current test being performed by SINGLE-TEST.  
**Start** The time that the current test was started.  
**End** The time that the current test will time out at, or blank if none.

4. A summary window, which has the following fields:

**Files** The number of files in the test files window.  
**Selected** The number of files (test suites) selected in the test files window.  
**Completed** The number of test suites completed.  
**Successful** The number of test suites which were successful.

5. The directory pattern used to select the test suite files. Unless otherwise overridden, the directory pattern by default only selects the latest version of each test suite file. Also, unless otherwise overridden, the directory pattern by default only selects .LCOM files (if a source file is more recent than the corresponding compiled file, then an error message is displayed).

6. A heading line which identifies each column in the test files window.

7. The test files window which has a line for each test suite file which matches the directory pattern. The left button on an entry selects only that entry. The middle button on an unselected entry adds that entry to the selected entries. The middle button on a selected entry removes that entry from the selected entries. The right button in the left portion of an entry will extend the current entries to include this entry and all the entries inbetween (the mouse cursor will change to a right pointing arrow when this action is enabled). This window is also scrollable (both vertically and horizontally). When each test is completed, a line is drawn through the entry. This window has the following columns:

**Result:** The result of testing using the corresponding test file. The following can appear in this column:

? The test suite has not been completed or possibly even initiated, so no results are known.  
pass The test suite completed successfully.  
FAIL The test suite did not complete successfully. This could be because a test in the test suite returned bad results, a test in the test suite aborted, a test in the test suite ti out, etc..

med

**Name:** The NAME portion of the test suite file name.

**File:** The full name of the test suite file (except for the host name).

When the tester is loaded, a new entry is added to the background menu, labelled AutomatedTester. When this is selected, an automated tester process is started, which will prompt (in the system prompt window) for a directory pattern which is used to initialize the test files window.

The individual test handler is a function which is called by the top-level function of each test suite (the function which was called by the top-level tester). This function has the following interface (all arguments must be supplied):

Name: SINGLE-TEST (LAMBDA function).

Arguments:

IDENTIFIER The integer identifier of this test. Identifiers are assigned manually and are unique across all tests in all test suites. [We need to set up an index file for this purpose, in the standard test directory.]

ht EXPRESSION The expression to evaluate (e.g. (PLUS 2 3)). Note that in order to get the right results, this argument would normally be quoted with QUOTE (or ') or be an expression such as (QUOTE (fn)), where fn is a separately defined function (and is therefore compiled code, instead of interpreted code).

5)) PREDICATE The (one argument) predicate to check the result (e.g. (LAMBDA (X) (EQP X or NULL)). This must be NIL iff the result was not correct (non-NIL indicates that the result was correct). If more than one error can occur, then output identifying the specific error should be printed (to NIL). Note that this argument would normally be quoted with QUOTE (or ') or FUNCTION in order to get the right results.

he TIMEOUT The maximum elapsed (wall) time (in milliseconds) that the expression EXPRESSION should take to complete (NIL implies that no timeout is to be used). With the current Interlisp-D process mechanism, this will only work if the expression (or anything it calls) does a BLOCK, so that another process can check to see whether a timeout has occurred. Also, the timing is not exact, so the actual timeout used will be no less than the value supplied. Time elapsed while the test was PAUSED is not counted in checking for a timeout.

Result: NIL iff the test was not successful (due to PREDICATE returning NIL, a NOBIND being returned, a timeout occurring, or a deep exit (such as an abort) occurring). Non-NIL indicates success.

Description: This function evaluates the expression EXPRESSION and checks the result with the predicate PREDICATE, returning the result from calling PREDICATE. If NOBIND is returned from either EXPRESSION or PREDICATE, then an error message is printed (to NIL) and a NIL is returned from SINGLE-TEST. If the timeout is exceeded (and timeouts can be checked) then the evaluation of the expression is aborted and an error message is printed (to NIL) and a NIL is returned from SINGLE-TEST. If a deep exit occurred in either EXPRESSION or PREDICATE (e.g. from aborting of the expression), then an error message is printed (to NIL) and a NIL is returned from SINGLE-TEST.

Side Effects: A message can be printed (to NIL).

Assumptions: Deep exits completely out of EXPRESSION or PREDICATE are not part of the successful behaviour of either EXPRESSION or PREDICATE (any such exits must be caught internally within EXPRESSION or PREDICATE). Note that deep exits are caught via ERRORSET, so RETFROM, RETTO, RETEVAL, RESUME, etc. are not caught.

There is a function available which prints out an easily identifiable error message in a standard format to the standard output. This function has the following interface (all arguments must be supplied):

Name: TEST-MESSAGE (LAMBDA function).

Arguments:

IDENTIFIER The integer identifier of this test (as given to SINGLE-TEST).

TEXT The text of the error message.

INFO Information specific to this instance of this error.

Result: Not useful.

Description: The error message along with the test identifier and the specific information is printed to NIL in a standard, easy to notice format.

Side Effects: A message is printed (to NIL).

Assumptions: None.

Some side-effects of the automated test harness are:

1. The History List for the Programmer's Assistant is used, therefore old items are lost and a REDO, etc. immediately after testing will redo the last command that the automated test harness performed, not the last item printed in the top level typescript window.
2. The top level value and the value in the Programmer's Assistant of `HELPFLAG` are change for the duration of running a test suite.
3. Extra processes are run to perform the testing.

Known deficiencies with the implementation are:

1. ABORTing and PAUSEing can only be done between individual tests.
2. If a test is aborted between individual tests, but not between tests suites, then the effects LOADing and running that test suite are not UNDOne.
3. Some errors are not caught, and some side effects are not undone if errors occur.

Some possible extensions to this package are:

1. Utilities to help with testing for deliberate errors.
2. Utilities to help with automating input which would normally be manual.

Running DSKTEST  
The Disk-file-system test utility

1. Load the file DSKTEST.DCOM from whichever directory & server it is stored on.
2. Type  
(DSKTEST ' {DSK} <LISPFILES>

# # Medley

## ## What File to Load

Load the file {MEDLEY}internal>DO-TEST.DFASL

All the symbols mentioned in this document are in both the IL: and XCL-TEST: packages, unless otherwise noted.

## Main Testing Entry Points

(DEFTEST *name&options forms*)

[Definer]

This is the definer for tests, allowing them to be saved on file-managed files. The test succeeds if the final *form* returns a non-NIL result. If *name&options* isn't a list, then it's just the name which can be a symbol or string; symbols are preferred for DEFTEST tests. If you specify options, the CAR of *name&options* is the name. If you specify :COMPILED in *name&options*, the test will run only when it has been compiled. Since this test is stored as structure rather than as plain text, any symbols will be package-qualified appropriately. If a test fails or an error occurs during evaluation, a message is printed to '\*ERROR-OUTPUT\*'.<sup>1</sup>

Unless you have DFNFLG set to PROP, the act of defining a test also causes it to be run (so you'll see if your test fails right away).

Examples:

'''

```
(DEFTEST ISSUE-1000 ;use issue number in test name
 (= 3 (+ 1 2)))
```

```
(DEFTEST (+-OPT :COMPILED) ; A test of the compiler, only makes sense to run compiled.
 (= 3 (+ 1 1 1))) ; Checking that +'s optimizer does the right thing.
```

```
(DEFTEST (MS-TEST :INTERPRETED) ; A test of Masterscope, only makes sense interpreted.
 (TEST-DEFUN FN (X) (FOO X))
 (\. IS FOO CALLED BY FN))
```

'''

(DEFTESTGROUP *name&options forms*)

[Definer]

This is the definer for groups of tests, allowing them to be saved on file-managed files. For associating a group of tests. For instance, a group of tests may all require the same setup and cleanup. If there are any options (see below) then the CAR of *name&options* is the name and the CDR is a keyword/value list. All *forms* must be DEFTEST or DO-TEST forms.

Unless you have DFNFLG set to PROP, the act of defining a test group also causes it to be run (so you'll see if your tests fail right away).

:before allows for a setup form for a group of tests.

:after allows a form to be run after the tests without affecting results.

For example, a DEFTESTGROUP using all its features is:

```
(DEFTESTGROUP
 (UNWIND-OPCODE-TESTS
 :BEFORE (progn (before-form-1) (before-form-2) ...)
 :AFTER (progn (after-form-1) (after-form-2))
)
 (DEFTEST "first test")
 (DEFTEST "second test")
)
```

## ## Functions You'll Find Useful When Building Tests

(EXPECT-ERRORS (*error-types*) *forms*)

[Macro]

*Error-types* is a list of errors that may occur while executing the *forms*. If one of the listed errors occurs, EXPECT-ERRORS returns (values t error-that-occurred), otherwise NIL. If all you want to do is make sure that an error is signalled somewhere in the test, you can specify an *error-types* of T. Normal use of this form is:

```
(DEFTEST ERROR-CHECK
 (EXPECT-ERRORS (T)
 (THIS-FORM 'SHOULD 'ERROR)))

(DEFTEST (+-DETECTS-NILS :INTERPRETED)
 (EXPECT-ERRORS (XCL:TYPE-MISMATCH)
 (+ 3 NIL)))
```

(TEST-SETQ *Variable Value*)

(TEST-DEFUN *name (arglist) forms*)

(TEST-DEFMACRO *name (arglist) forms*)

[Macros]

These work like SETQ, DEFUN, and DEFMACRO, except that if they are executed within a DEFTEST or DEFTESTGROUP, their effects are manually undone (old values are saved and then restored) upon leaving the test. Use these in :BEFORE forms that a whole group of DEFTESTs want to see. **DON'T** use TEST-SETQ on locally-bound variables or in loops.

## Commands and Functions for Running Tests

run *Test-name*

[EXEC Command]

Once *Test-name* has been defined using DEFTEST or DEFTESTGROUP, you can run the test with the run command.

(DO-TEST-FILE *filename*)

Reads and executes a file of tests. All forms in the file are read before any are executed. The file should be clear text (clearput in TEdit) and terminate with a STOP. The format for test names is

'''

Chap#[-sec#[-subsec#]]-comment.TEST

```
(DO-ALL-TESTS &key (results *test-batch-results*)
 (patterns *test-file-pattern*)
 (sysout-type nil)
 (resume nil))
```

'''

Calls DO-TEST-FILE on each file that matches *patterns*, which is a list of directory patterns, and prints the results to a new version of a file named *results*. If *results* is T, results are printed to the window where DO-ALL-TESTS is running. The header of the results file is a message of the date and time the tests are being run and the MAKESYSDATE of the sysout; if *sysout-type* is supplied, a line for it goes out too. If *resume* is non-NIL, DO-ALL-TESTS attempts to resume an interrupted test sequence, appending the results onto the latest version of *results*.

' \*TEST-MODE\*'

[Variable]

Default is :batch, which means to report test failures and errors on \*ERROR-OUTPUT\* (which is usually a file), and continue. Other values possible are: :interactive which means to print a message before running each test, print another message for test failures, and produce a break window on errors. :batch-verbose which means to generate all the messages of :interactive and do not break on errors.

' \*TEST-BATCH-RESULTS\*'

[Variable]

Defaults to "{MEDLEY}tmp>test>test-results"

' \*TEST-FILE-PATTERN\*'

[Variable]

Defaults to "{MEDLEY}internal>test>\*.TEST "

'\*TEST-COMPILE\*'

[Variable]

If this switch is non-nil, DO-TEST compiles its forms before testing them. DO-ALL-TESTS will print a message in its header if this switch is on.

'\*ALL-FILES-REMAINING\*'

[Variable]

While DO-ALL-TESTS is running, this variable contains a list of all the files remaining to be processed; files are removed from it AFTER they are read and executed. To restart a test run that somehow crashes the test driver, first clean up whatever blew up the run (if necessary, dump \*ALL-FILES-REMAINING\* to a file and get a new sysout), then do

```
(DO-ALL-TESTS :RESUME T [:RESULTS "wherever"])
```

## ## internal Functions

(DO-TEST *name&options forms*)

[Macro]

This is the obsolete, plain-test-file testing macro; it is still around so that old tests work (and because DEFTEST uses it). A test succeeds if the final *form* returns a non-nil result. If *name&options* isn't a list, then it's just the name which can be an atom or string; strings are preferred. If you specify options, the CAR of *name&options* is the name. If you specify :COMPILED in *name&options*, the test will run only when it has been compiled. Forms are presumed to be read with the Common Lisp reader in package XCL-TEST, which uses LISP and XCL. If a test fails or an error occurs during evaluation, a message is printed to \*ERROR-OUTPUT\*.

(DO-TEST-GROUP *name&options forms*)

[Macro]

This is the obsolete, plain-test-file testing macro; it is still around so that old tests work (and because DEFTESTGROUP uses it). For associating a group of tests. For instance, a group of tests may all require the same setup and cleanup. If there are any options (see below) then the CAR of *name&options* is the name and the CDR is a keyword/value list. All *forms* must be DO-TEST forms.

:before allows for a setup form for a group of tests.

:after allows a form to be run after the tests without affecting results.

An example of a DO-TEST-GROUP using all its features is:

```
'''
(DO-TEST-GROUP
 ("a test group"
 :BEFORE (progn (before-form-1) (before-form-2) ...)
 :AFTER (progn (after-form-1) (after-form-2))
)
 (DO-TEST "first test")
 (DO-TEST "second test")
)
'''
```

(CL-READFILE *filename*)

Reads all forms in *filename* and returns a list of them. This function is used by DO-TEST-FILE to read test files; test writers who want to see if their files are syntactically valid should first see if CL-READFILE will read them, then see if DO-TEST-FILE will execute them.

(MUNG-TEST-FILES *filepattern* &key (*compiler* 'compile-file)  
(*startinglist* NIL))

Compiles test files so they can be run by just loading them. Compiles all files matching *filepattern* (which is fed to directory) using *compiler* and writes them out to the directory they came from with an extension appropriate to *compiler*. If you want to explicitly specify the list of files to compile, hand a list of pathnames to *startinglist*. Prints an error message for files that fail to compile. You have to use this function (instead of just compiling the test files) because it prefaces the test files with

'''

```
(in-package "XCL-TEST")
(setq *test-file-name* "NAME-OF-FILE")
, , ,
```

so the compiler will read them properly and the files will know their names for error reporting purposes. **NOTE:** tests that fail should not be compiled; the resulting compiled code may not be a valid test.

## THE INTERLISP-D TESTING SYSTEM

The Interlisp-D testing system is an integrated system built for creating, managing and using a large set of programmed tests for testing the correctness and the performance of the Interlisp-D programming environment.

The system is consisted of three parts : The test driver, the data base management system, and a graphic control tool. In addition, there are various tools for helping the test builders in the process of creating new tests.

All parts of the system assumes the structure of a TEST which is a data type consists of several fields, of which the most important are the expression which has to be evaluated, and a predicate which takes the results of this evaluation and determines whether the test was a success or a failure (i.e. whether the actual result is the same as the expected result).

The test driver is in principal a function which gets an object of type TEST, performs the test, and return either success or failure plus some additional information. It includes facilities for monitoring the test execution, tracing and recording the testing process to enable reproducing tests, Remote Eval protocols to enable performing tests with two machines and more.

The data base management system works in two levels. In the low level, the "test cluster" level, the system manages and organizes the tests in the file system, enable retrieving tests through a caching system, and allows concurrent access to test files using a simple locking scheme.

In the high level, the system enables each user to manipulate the database using its own VIEW of the system. This view is implemented through the CONCEPT SPACE which is a directed acyclic graph that will usually reflect the logic structure of the system as seen by the user.

The graphic control tool displays a concept space as a graph and allows the user to perform most of the Test system operations by selecting nodes from the graph.

The tools for building and manipulating tests include test inspector (and editor), a random generator which can generate random specified Lisp objects, Indirect reference to other tests in TEST fields for shrinking the space of the tests themselves and avoiding redundant work when creating tests which share some of their fields, and more .

In the next sections the different parts of the system will be described as well as the interaction between them.

## The TEST data type

The TEST is the data type of test objects. Its structure reflects the various properties that tests have. It includes the following fields:

TestID : The tests are identified by an integer.

Input : This field contains an expression that, when evaluated, will generate the list of arguments on which the tested expression will be applied. There are several tools which help in creating this entry. The random generator helps in generating random objects with specified restrictions. The SYSTEMATIC operation helps in generating systematically all the combinations over finite ranges.

Expression: It can contain a function name, a lambda expression or arbitrary sexpression. In the first two cases it will be applied on the input.

Success Predicate: This field contains a lambda expression with two arguments - the ACTUAL input for the test, and the result of the evaluation. It returns one of the two atoms: Success or Failure. When performing tests with random input, some tricks may have to be used as demonstrated in the examples in the end.

Timeout :This is a lambda expression which gets the ACTUAL input as an argument, and produces an upper limit to the estimated time of evaluation.

EvalBefore and EvalAfter: expressions to be evaluated before and after the test execution. usually, before the test we may want to set the appropriate environment for the test (like loading certain files), and after the test we may want to clean up the environment (like deleting files which the test created).

Pretests: Contains a list of links to other tests. These links may influence the order of an execution of a set of tests. Currently there are two types of links. A STRONG link to other test means that whenever the current test is going to be executed, the pretest must be executed first. An example for such pretest may be tests for the tests themselves. If a test generates a few thousands combinations of some arguments, it may be useful to test first if the test itself works correctly by executing a simplified test which works only on one set of arguments, and check that the test outcome is reasonable. A WEAK link to other test means that whenever a SET of tests is being executed, and both the test and pretest are in this set, the pretest will be executed before the test (thus it defines a partial order on any set of tests). This link may be used in cases where there is logical order on the execution of tests - for example, it is reasonable to test opening a file before testing writing to a file.

## The Test Driver

The test driver accept a test as its input and returns either success or failure. It will evaluate the input and the tested expression itself on a remote machine if requested, or on the local machine otherwise. All the process of the testing is recorded on a trace file, such that as much information as possible will be available if needed.

The driver evaluates the EVALBEFORE form, evaluates the input expression to generate the input for the tested expression, applies the tested expression on the generated input, applies the success predicate on the result and the generated input, and evaluates the EVALAFTER form. After some of the above stages the appropriate information is written on the trace file. The most important one is the input generated, especially in cases of random input.

All the evaluation done by the driver uses the Interlisp-D ERRORSET command, thus allowing evaluation that will not break under error condition. The error type may be used by the success predicate to determine if the result is a success or a failure. Thus one test for many arithmetic functions can be to supply them with non numeric arguments and to check that the error reported will be the right one.

The evaluation of the tested expression is done as a separated process, such that the driver will be able to try to interrupt it in case where the time of execution is larger than the value of TIMEOUT field of the test. This interrupt will work only if the test execution process will release voluntarily the cpu (when waiting on I/O for example) since Interlisp-D uses non preemptive scheme for process scheduling.

Remote evaluation will not benefit us much in this type of problems. If the remote machine is in infinite loop for example, it will not listen to interrupt attempts as well. The advantages of using remote machine are two: If a long sequence of tests are executed, and the machine "freezes", a remote test will freeze the remote machine and the local machine will be able to call for help and resume operation (as soon as the remote machine does not respond for more than some estimated limit of time, the local machine sends messages to a preset distribution list and asking for human help). A second benefit of remote evaluation is when we need to evaluate the tested expression in a different environment than the Testing system resides. We will want the testing system to work in considerably different environment (software release), while we are testing an experimental different environment.

### **The data base management system: the "test cluster" level.**

The user can retrieve a test by calling the GetTest function. The low level of the dbms is responsible for performing the appropriate operations to retrieve the requested test. If the test is not already loaded it will be loaded from its file. There is a limit on the number of the tests that are loaded, and if this number is exceeded a replacement will take place and a test will be removed. The replacement policy is LRU (least recently used) and is implemented by moving each test being referenced to the front of the list of the loaded tests. Thus the last test in the list will be the one to be removed. The limit on the number of loaded tests is dynamically modified according to the amount of the available memory.

The Interlisp-D testing system is designed to work with several users who use it concurrently. There are no problems if the users were only retrieving tests from the data base. Problems may occur if two users modify the same part of the data base in the same time.

For such cases a locking scheme was integrated into the system. There is a special designated file which is the "gate" for the data base. Users can obtain write LOCKS on tests. The file contains the list of users with their locked tests. The basic locking function is ObtainDatabaseWriteLock(testnumber) which checks the LOCK file, and registers the tests that are not already locked. The user has the option of

automatically generated messages that will be sent to the locking users, inform them that somebody is waiting for their locked tests and request them to release them as soon as they are not needed.

Thus, either automatically or manually, whenever a user edits a test, he will first obtain LOCK on tests. The locking scheme will work only if the users will follow the rules and will not try to access tests not through the testing system.

The basic operation - ObtainDatabaseWriteLock is "atomic" in the sense that the LOCK file is opened for read and write throughout the execution of this procedure, and thus no other user will be able to open it. The time interval in which the file is opened is very short.

Another problem that may arise from concurrent access to the data base is test numbering. As mentioned above, each test has a unique integer as an ID. Thus there is a file which contains the last ID issued, and the procedures for creating new tests will access and update this file.

### **The "Concept Space" level.**

What is the "thing" which is being tested by the test? it may be a specific low level system function, a library package, or a new representation scheme for integers. It is hard to find a common class to which all these entities belong. Thus the testing system assumes that it is some CONCEPT of the Interlisp-D system that is being tested.

While it is true that when a test is CREATED, its creator intent to test a specific concept, the test itself is not necessarily a test only for this concept. A test that was built for testing the READ function, may actually test also the NS communication protocols, the OPENFILE function etc.

For this reason the tested concept is not considered to be a part of the test itself. There is a separated knowledge space which is the way that the user views the test cluster. A concept space is an acyclic directed graph of CONCEPTS. Each node of the graph is of type CONCEPT which has four fields: The concept name, the tests that tests this concept, the subconcepts and the superconcepts.

The main purpose of the concept space is to enable the user to group tests in a logical way and to perform operations on these sets of tests. The semantic of a concept node is : "the tests which tests this concept are the tests of the concept itself plus the tests that tests its subconcepts (recursively)".

Such a definition allows us to build concept spaces which view the tests from different points of view. We may have a concept named "Arithmetic system" with subconcepts "Integer arithmetic", "Float arithmetic" and "Arithmetic functions". The "Arithmetic functions" will have as subconcepts, the concepts "IPLUS", "FPLUS", "PLUS" etc. "IPLUS" is also a subconcept of "Integer arithmetic", and "FPLUS" of "Float arithmetic". Thus, if a new representation for the integers was introduced to the system, we will test the "Integer Arithmetic" concept, while in other cases we may want to test the "Arithmetic Functions".

From the above example and from the more detailed example at the end, we can conclude that the organization of the test system should be very flexible, since there can be many parallel views into the same part of the system. We can also see why a tree structure would not be sufficient as a representation scheme. The Testing system supports the co-existence of several concept spaces, and thus each user can build and use his own concept space(s) to reflect his view of the system.

## THE CONCEPT SPACE BROWSER

Most of the operations of the Interlisp-D testing system are done through the "Concept Space Browser". The browser is a graphic tool which is applied on a concept space.

It has a few types of operations. Any operation that require a concept as an argument will get it by a selection from the displayed graph.

The first type of operations are operations for modifications of the concept space itself. There are commands to add new concept, to delete a concept, to add and delete a link and to add and delete a test to a concept.

Second type of operations are data base operations. The user can edit a test selected from specific concept, can hardcopy all (or part of) the tests of a selected concept, and can request to lock all (or part of) the tests of a concept.

A third type are display op can be specified, a browser of a subgraph can be created, and the tests can be dre are commands to execute all (or part of) the tests of a certain concept, with different modes of execution .

The browser also allows to copy subgraphs between two displayed concept spaces, and to get all the tests of a node by a copy selection so that functions that are not available in the browser can use the concept space as well.

.

### Test creation tools and misc tools

There are several tools that were created to help the tests builders in their task.

In each field of a test the user can write (& n) when n is a test number. This tells the system that to retrieve the value for this field it should refer to the same field in test n. This was done since many tests share values for some of their fields.

The test inspector is built on the top of the Interlisp-D inspector. The user can inspect and modify the various fields of a test. In addition he can call the inspector on indirect referenced tests.

There are functions which keep tracks of changes done to tests, and functions which stores modified tests.

The Random Generator is a very important tool for creating a test. It has many entries for different Lisp objects which he can generate randomly. These set of possible entries will grow constantly as test builders will need more types of random objects.

The random generator function gets as an argument an object type and a list of modifiers. The test builder can specify in the input field of a test a call like `(GenerateRandom 'LARGE-INTEGER)`, or `(GenerateRandom 'WINDOW)` or `(GenerateRandom '(LIST-OF-ITEMS WINDOW 50 100))` to get a random list of length between 50 and 100 of windows.

From the experiments done with the Testing system it was clear that random tests are an important part of any testing and can discover bugs that would be hard to find otherwise.

Another tool is the SYSTEMATIC input generator. Many times we want to test a function if it works right with all the possible combinations of values of its arguments, or to find out whether an library package works with all possible settings for its flags. For such cases the test builder can specify in the input field that he wants a systematic test, and supply the expressions that produces the ranges of values to combine.

## TEST EXAMPLES:

## EXAMPLE 1

```

Test number 18
PRETESTS :NIL
TESTCOMMENT :(* * Generates systematically all the pairs of all
 the "special" bignums
 (stored in TEST.BIGNUM-SPECIAL-NUMBERS in file

## TEST APPRENTICE

This is the preliminary documentation for the first experimental version of the Test Apprentice. The purpose of this tool is to help with testing. It is eventually intended to generate and execute tests (it would be an AI application). In its current state it is just learning by watching what other testers do. But it is useful in this state because it can repeat exactly what other testers have done before.

The Test Apprentice is easy to use, you just type in the commands that you would use for doing the test the first time, with only an occasional extra command. To repeat a test, you only need to specify a special Test Apprentice function giving it the name of the test to re-perform.

The Test Apprentice groups test steps (commands) into tests, and groups tests into test suites. A test is a group of highly related test steps which are used to test a (small) portion of the system and which can be run independently from other tests (e.g. NS Filing directory enumeration). A test suite is a group of related tests which can be run together for convenience (e.g. NS Filing).

The Test Apprentice has the following limitations:

1. It can only record and repeat commands to the (standard) Lisp Executive, it does not record mouse operations or commands typed into other windows. It also cannot in general record input which is non-commands typed to the Lisp Executive (e.g. responses to the FILES? function's questions), but some commands record responses on the history list, so they are recorded (e.g. responses to the COMPILE function's questions). The rule of thumb to use here is if a REDO would re-perform those inputs, then the Test Apprentice has recorded them.
2. The number of test steps recorded for a particular test is limited to the size of the history list (usually 100 entries).

The following are the commands and functions available in the Test Apprentice:

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ST  | Start Test. A Lisp Executive command which starts the Test Apprentice recording the test steps of a test. An implicit ST is performed after an ET command or an ADD-TO-TEST-SUITE function. An ST can be performed at any time to restart recording of a test (and forget any recording in progress).                                                                                                                                                                                                                                                        |
| ET  | End Test. A Lisp Executive command which completes the recording of the test steps of a test. This must have the name of the test as its single parameter (e.g. "ET NSFiling-1"). Test names only have to be unique within a test suite.                                                                                                                                                                                                                                                                                                                     |
| ITS | Ignore Test Step. A Lisp Executive command which ignores test steps in the current test. Currently this will only ignore the previous step, but in the future it will ignore specified steps. This is useful for removing mistakes from a test or removing miscellaneous commands not directly related to the tests. If you need to delete anything other than the last test step, then you must edit the test suite manually or restart the test using ST (the former can only be done after an ET, while the latter can only be done before an ET).        |
| ITR | Ignore Test Result. A Lisp Executive command which ignores test results from test steps in the current test. Currently this will only ignore results from the previous step, but in the future it will ignore results from specified steps. This is useful for ignoring intermediate results. The Test Apprentice will check to see if the results from re-running tests are EQUAL to the results obtained when the test was recorded. For example, one test step may have returned a window as a result, then the next merely see if the type of the result |

is WINDOW. In this case two different instances of a window will not be EQUAL, so the result of the first step should be ignored. If this becomes a problem EQUALALL may be used in a future version of the Test Apprentice, but even this does not always work (e.g. it does not work on windows).

**ADD-TO-TEST-SUITE** An NLAMBDA function which adds a test to a test suite. Its one required argument is the name of the test suite. If the test suite did not exist before, then it is created. Test suites are just variables that contain a list in a specified format, they can be saved in files by the File Package command VARS (or UGLYVARS if data structures are used in test results or HORRIBLEVARS if there are circular pointers). This function must be called before any test steps are started. It sets up all future tests to be part of this test suite until changed by another ADD-TO-TEST-SUITE.

**EXECUTE-TEST-SUITE** A LAMBDA function which executes all tests in a test suite. Its one required argument is the test suite to execute. This returns a true (non-NIL) value iff all tests executed successfully. An error message is printed out for each test which fails.

**EXECUTE-TEST** A LAMBDA function which executes one specific test in a test suite. Its required arguments are the test suite and the name of the test in the test suite to execute. This returns a true (non-NIL) value iff the test executed successfully.

The following are recommendations on using the Test Apprentice effectively:

1. Don't use absolute command number references, use relative ones (e.g. use "(VALUEOF -2)" not "(VALUEOF 36)" if you are on command number 38). This is so the test will run correctly when it is re-run (if it were re-run and the VALUEOF was done on command number 67, then you would get some unexpected command's result instead of what you wanted).
2. Two different data structures (defined with DATATYPE, ARRAY, etc., such as windows) will never compare EQUAL, even if they contain the same values. This means these should never be used as (non-ignored) test step results. Use ways of looking at the contents of the data structures instead.

The following is an example of a normal session with the Test Apprentice for recording a test suite:

```

34_(ADD-TO-TEST-SUITE NSFiling)
NSFiling
35_ST
Start-of-test-block
36_<test 1 step 1>
<test 1 step 1 result>
37_<test 1 step 2>
<test 1 step 2 result>
...
40_ET NSFiling-1
End-of-test-block
41_ST
Start-of-test-block
42_<test 2 step 1>
<test 2 step 1 result>
43_<test 2 step 2>
<test 2 step 2 result>
...
65_ET NSFiling-2

```

```

End-of-test-block
66_(FILES?)
the variables: NSFiling...to be dumped.
want to say where the above go ? Yes
(variables)
NSFiling File name: NSFiling
NIL
66_(MAKEFILE '{Erinyes}<Test>Tests>OS>NSFiling)
{Erinyes}<Test>Tests>OS>NSFiling.;1

```

The following is an example of a normal session with the Test Apprentice for repeating a test suite:

```

19_(EXECUTE-TEST-SUITE NSFiling)
Executing NSFiling-1
Executing NSFiling-2
T

```

# THE INTERLISP-D TESTING SYSTEM - USER GUIDE

This document should be used as a guide for users of the testing system, and it assumes that the reading of "The InterlispD Testing System" document.

## LOADING THE TESTING SYSTEM

The testing system resides on the directory {Eris}<test>tools>. To load the testing system, LOAD the file TESTERLOADER. This file contains the correct loading sequence for the testing system files.

FILES:

TESTER.DCOM - Contains the main part of the tester program.

TESTERVARS - Contains most of the tester global variables.

TEST-REMOTE-EVAL.DCOM -Contains the functions for executing remote eval.

RANDOM-GENERATOR.DCOM - Contains functions and variables for random generation.

VARBROWSER.DCOM - A user package for manipulating the programs global variables.

THERMOMETER.DCOM - A user package for displaying the progress of a program in execution.

INTERLISPD-SYSTEM.CONCEPTSPACE - The file contains the global concept space of the system.

## EXECUTING TESTS

Usually execution of tests will be done through the Concept Space Browser. The basic function which is called by the browser is:

(TEST.PERFORM-TEST TEST TIMES LOCATION TRACE-FILE TRACE-MODE) [function]

Only the first argument is necessary. TEST must be of type TEST. TIMES is the number of times that the test will be performed and is defaulted to the value of the field TIMES of TEST. If this value is NIL it will be executed once. LOCATION can be either the atom "Local" or the atom "Remote" and is defaulted to the value of the global variable TEST.DEFAULT-LOCATION. TRACE-FILE is the name of the file on which the test execution process should be traced. The default name is the value of the global variable TEST.TRACE-FILE-NAME. TRACE-MODE can be the atom "On" or the atom "Off". It is defaulted to the value of the global variable TEST.DEFAULT-TRACE-MODE. When TRACE-MODE is "On" every testing step will be recorded on the trace file as soon as possible. The tracing will be done in a "careful" way - as soon as a new information is available (The input was generated, the result from the tested expression evaluation is returned, etc. ) , the trace file will be opened the information will be written and the file will be closed. If the trace mode is Off, the function will check at the end of each iteration of the function to see if the outcome was a failure and only in such a case it will write it down on the trace file.

There are two ways in which the PERFORM-TEST function can iterate. One way is if the TIMES argument is greater than one (or the times field of the test is greater than one). The other way is when the input expression is a list starts with the atom SYSTEMATIC. In such a case each of the elements of the CDR of the list will be evaluated. The tester expects them to produce sets (lists) which are the ranges of the arguments. It will then collect all the possible combinations of the elements in these finite ranges and perform the test on each of these combinations.

The function returns the name of the trace file.

(TEST.HARDCOPY-TRACE-FILE TRACE-FILE OUTPUT-FILE FAILURES-ONLY)

The default for TRACE-FILE is the value of TEST.TRACE-FILE-NAME. The default for OUTPUT-FILE is the value of TEST.DEFAULT-HARDCOPY-DEVICE (usually {LPT}). The trace file is written in a way that is hard for reading. This function prints the trace file in a "pretty" way. If FAILURES-ONLY is non-NIL only the trace of tests that failed will be printed out.

## Manipulating Concept Spaces

Concept spaces are stored in files, each concept space in its own file. Usually the name of the file can be XXX.CONCEPTSPACE where XXX is the name of the concept space. This name can be retrieved by calling

(TEST.CANONICAL-CONCEPT-SPACE-FILE-NAME CONCEPT-SPACE-NAME)

Returns XXX.CONCEPTSPACE where XXX is the value of CONCEPT-SPACE-NAME.

A concept space is of type CONCEPTSPACE which is a record with the fields CONCEPTSPACENAME, ROOTCONCEPT and CONCEPTLIST. ROOTCONCEPT is the name of the root concept. CONCEPTLIST is a list of concepts. A concept is an instance of the record CONCEPT which has the fields CONCEPTNAME, TESTS, SUBCONCEPTS and SUPERCONCEPTS. SUBCONCEPTS and SUPERCONCEPT are NAMES of concepts. TESTS is a list of tests ids. Usually the initial concept space will be created by the function

(TEST.CREATE-NEW-CONCEPT-SPACE CONCEPT-SPACE-NAME ROOT-CONCEPT-NAME)

which returns an instance of CONCEPTSPACE with one concept. The rest of the concept space will be most conveniently built using the Concept Space Browser.

The system maintains a global list of the concept spaces that are "known" to the system. It is convenient to work with concept spaces that appear in that list since this will enable the user to perform certain operations on the concept space using the background menu. The global list is stored in the global variable TEST.CONCEPT-SPACES. This variable can be manipulated directly or by calling the function

(TEST.ADD-CONCEPT-SPACE-TO-CONCEPT-SPACES CONCEPTSPACE)

If a concept space with the same name is already in the list, it will be removed and the new one will be added. The function

(TEST.GET-CONCEPT-SPACE NAME)

Returns the concept space with name NAME (if there is one in TEST.CONCEPT-SPACES).

Concept spaces that are on the TEST.CONCEPT-SPACES can be stored by calling the function

(TEST.STORE-CONCEPT-SPACE CONCEPTSPACE-NAME)

The function will prompt for a file name, suggesting the canonical name. If the concept space was loaded before through the TEST.LOAD-CONCEPT-SPACE function then the candidate file name will be the same as the one that it was loaded from (but with higher version). The user can also choose the subitem "Store Concept Space" from the background menu.

(TEST.LOAD-CONCEPT-SPACE CONCEPT-SPACE-FILE-NAME)

Loads the concept space from the specified file, adds it to TEST.CONCEPT-SPACES and keeps the file name in the property CONCEPTFILE of the concept space name.

## Building and manipulating tests

(TEST.CREATE-NEW-TEST )

[function]

Creates an instance of the record TEST with the default values which are obtained by calling the function TEST.GET-DEFAULT-FIELD-VALUE. The new instance is then added "officially" to the world by calling TEST.ADD-TEST . Then the test editor is called on the new test to allow the user insert values to its fields. It does NOT store the test in a file, and this should be done later by calling either TEST.STORE-TEST or TEST.STORE-CHANGED-TESTS. The test, after created is not assigned to any concept, and it is recommended to assign it as soon as possible to at list one concept.

(TEST.ADD-TEST TEST-RECORD)

[function]

Assigns a new ID to the test record instance by calling TEST.GET-AND-INCREASE-NEXT-TESTID and adds the test to the list of loaded tests.

( TEST.EDIT-TEST TEST)

[function]

TEST should be a test or a test number. If the global flag TEST.OBTAIN-LOCK-WHEN-EDIT is non NIL the function will try to obtain write lock on the test. If it fails to obtains such a lock it will exit without editing. The user can get the name of the locking users and automatically send release requests as described in the "accessing the database" section.

The test inspector will be called and the test will be marked as changed.

(TEST.GET-TEST TEST-NUMBER)

This function is the user interface to the database management system. The user calls this function and gets the test with the TESTID TEST-NUMBER. Actually the system will search for the test in the list of the loaded tests. If it will not be found a "test fault" will occur and the system will look for the file for this test and load the test from there. If by adding the test to the list of loaded tests an "overflow" occurs (the number of tests is more then the maximum allowed), the last test on the list (the least recently used will be deleted from the list.

(TEST.GET-FIELD-VALUE FIELD DATUM)

Gets the "Actual value" of a test field. If the field value is indirect reference to other test, the field value will be retrieved from there (using TEST.GET-FIELD-VALUE thus enable chaining), otherwise it will return the field value of DATUM.

( TEST.GET-DEFAULT-FIELD-VALUE FIELD-NAME)

FIELD-NAME is a TEST field name. The function will return the global default value for this field.

The following functions can be useful when building a test for use within the actual test fields:

(TEST.TEST-SINGLE-TIME TEST-NUMBER)

There are tests which have the TIMES field greater than one. Such tests will be executed more than one time. There are also tests which have as their INPUT field a list that starts with the atom SYSTEMATIC. Such tests will be applied on all the combinations of the elements of sets in their INPUT field. Such tests can run for hours only to discover that something in the test itself was not correct, and the trace file is full of garbage. To avoid such a case it is recommended to create for such tests a "Testing test" which will perform the tested test once and will only check that the outcome is meaningful (i.e. The result is either "success" or "failure" etc). Such a test can be built easily by having as its Expression field a call to this function with the tested test as TEST-NUMBER. It may be also useful to add a WEAK or STRONG link in the tested test PRETESTS field.

(TEST.ERRORP EXPR) [function]

If an error occurred during the evaluation of the evaluated expression, the returned result will be a list of two elements, the first is the atom ERROR!, and the second is the error number. This is a simple predicate that checks if an expression is of the form described above. It is useful for building the success predicate. For example, a test may have as the EVAEXPR the function ADD1, as its INPUT field some non-numeric atom, and as its success predicate, the expression (LAMBDA (RES ARGS) (IF (AND (TEST.ERRORP RES)(EQP (CADR RES) 10)) THEN 'SUCCESS ELSE 'FAILURE) . This test tests whether the function ADD1 breaks with non-numeric arg error.

(TEST.ALL-COMBINATIONS SET-OF-SETS) [function]

Produces the Cartesian product of the sets in the list SET-OF-SETS . (TEST.ALL-COMBINATIONS '((a b)(1 2 3))) will return the list ((a 1)(a 2)(a 3)(b 1)(b 2)(b 3)). This function is used by the tester when it encounters an INPUT field that starts with the atom SYSTEMATIC. It is useful in any case that the user wants to build tests that try all the combinations of possible values of a function arguments, or to have all the possible settings for flags and global variables for some subsystem or library package.

(TEST.LOCAL-EVAL-FORM FORM) [function]

Evaluates the form FORM using ERRORSET, thus the evaluation will not break even if an error condition occurs. If an error did not occur the function will return the result of the evaluation of form. If an error condition was entered, the function will return a list with the first element ERROR!, and the second element the number of the error (as described in Interlisp-D manual).

(TEST.PERFORM-TIMED-EVALUATION FORM TIMEOUT.ms) [function]

Evaluates FORM using TEST.LOCAL-EVAL-FORM (thus it will not break). If the evaluation will take time which is longer then the value of TIMEOUT.ms, the function will return the error expression (ERROR! TIMEEXPIRED). This function is used by the test driver if the TIMEOUT field of a test is non NIL, thus an evaluation that will take more time that the designated time will be considered as returning with error condition. The function create a seperate process to perform the evaluation, and set a timer for the designated time (plus some time for overhead). The user should note that since the Interlisp-D process scheduling algorithms are non-preemptive, the function is not guarantied to halt. An infinite loop may not release the CPU and then only keyboard interrupt will work.

(TEST.GET-NEXT-AVAILABLE-TESTID ) [function]

The test ids should be unique. That's why the system maintains a file which holds the next available test id. This function access this file and returns the id.

(TEST.GET-AND-INCREASE-NEXT-TESTID ) [function]

This functions returns the next available id as the one above, but also increase this number on the file. this function is called by the function TEST.ADD-TEST which adds a test "officially" to the world.

## The Random Generator

The random generator resides on the file RANDOM-GENERATOR.DCOM. The main function is

(TEST.GENERATE-RANDOM OBJECT-SPECIFICATION) [function]

This function is planned to be constantly expanded by the tests builders according to their needs. The OBJECT-SPECIFICATION can be an atom, which should be one of the objects known by the random generator. It can also be a list where the first element is an atom which is one of the known objects, and the rest of the list are modifiers according to the object type. The current list of known objects is : (INTEGER, SPECIAL-INTEGER, BOUND-INTEGER, LARGE-INTEGER, SMALL-INTEGER, BIGNUM, POSITIVE-BIGNUM, SPECIAL-BIGNUM, POSITIVE-POWEROF10-BIGNUM, WINDOW, REGION, SHORT-SIMPLE-LIST, SHORT-SIMPLE-NON-NULL-LIST, SHORT-LIST, LIST-OF-CHARACTERS, CHARACTER, LIST-OF-ITEMS and some more.

Some of the objects have modifiers, like short list which can have a maximum depth as a modifier. A very important object is LIST-OF-ITEMS which can have as its modifier another object specification, thus enable recursive use of the function. Thus you can write (TEST.GENERATE-RANDOOM '(LIST-OF-ITEMS REGION 100 200)) which will produced betwween 100 and 200 random regions.

Database access

(TEST.GET-LOCKING-USERS TEST-LIST) [function]

TEST-LIST is a list of test numbers or the atom DATABASE. Will return the list of all the users that kas locks to tests in TEST-LIST together with the tests in TEST-LIST that they are locking. If TEST-LIST is the atom DATABASE, the function will return the names of all the users that have locks to any test.

(TEST.OBTAIN-DATABASE-WRITE-LOCK TEST-LIST) [function]

TEST-LIST is as above. The function tries to obtain locks on the list of tests in TEST-LIST. If TEST-LIST is the atom DATABASE, it will try to obtain lock on the whole data base. A lock on a test can be obtained if there is no other user locking the test. A lock to the whole data-base can be obtained if there is no user that locks any test. The function returns the list of all tests that it was able to lock.

(TEST.RELEASE-DATABASE-WRITE-LOCK TEST-LIST) [function]

As above, but releases the locks to the tests in TEST-LIST that are locked by the user. Returns all the tests that it succeeded to release.

(TEST.SEND-RELEASE-REQUESTS TEST-LIST) [function]

TEST-LIST is as above. Sends automatic messages to all the users with locks to the tests in TEST-LIST to release their locks.

(TEST.MARK-AS-CHANGED TEST-NUMBER) [function]

The number of the tests that are being modified using the programs editor are added to the global list TEST.LIST-OF-MODIFIED-TESTS. This can be done by calling this function.

(TEST.UNMARK-AS-CHANGED TEST-NUMBER) [function]

As above, but remove the test from the list.

(TEST.STORE-CHANGED-TESTS) [function]

Stores all the tests in the list of modified tests.

(TEST.STORE-TEST TEST-NUMBER) [function]

Stores the test TEST-NUMBER in the file with the name returned by the function TEST.TEST-NUMBER-TO-FILE-NAME, and removes it from the list of changed tests.

(TEST.TEST-NUMBER-TO-FILE-NAME TEST-NUMBER) [function]

Returns a file name on which the test TEST-NUMBER is stored. The directory is the value of the global variable TEST.TEST-DATA-BASE-DIRECTORY. The the root name for test number 45 will be TEST00045.

## The Concept Space Browser

To browse a concept space you can either select the submenu "Browse Concept Space", or by calling the function

(TEST.DISPLAY-CONCEPT-SPACE-BROWSER CONCEPT-SPACE REGION/POSITION DEPTH INCLUDE-TESTS) [function]

CONCEPT-SPACE must be of type CONCEPTSPACE. REGION/POSITION can be either a region or a position for the browser window. DEPTH is the depth of the lattice that will be displayed. If INCLUDE-TESTS is non NIL, the tests will be included as part of the displayed graph. Only the first argument is necessary.

All the operations on concepts are done in PREFIX form - first you select the operation and then the argument (like all Lisp operations). Copy selection from a node will push the list of test numbers belong to this node into the current tty stream. The operations that are available using the concept space browser are:

**Copy subtree** : Allow you to copy a subtree from one displayed concept space to another one. Will prompt for selection of the new parent node and the root of the subtree.

**Add Concept** : Prompts for the parent of the new concept and for the name of the new concept.

**Delete concept** : Deletes the concept selected, and all its children which have the deleted concept as they only parent (and so on recursively).

**Add Link** : prompts for the superconcept and the subconcept and creates a link between them.

**Delete Link** : prompts for the superconcept and the subconcept and deletes the link between them.

**Add test** : Adds a test to a concept. Prompts for selection of the concept and for a test number. The test number can be a list of numbers, thus you can copy select tests from any node on any browser window.

**Delete test** : Will ask you to select a node and will add a menu with all the tests of the node so that you can select those you want to delete.

**Edit test** : Will ask you for selection of a node and will pop up a menu of all the tests in the selected concept. Will apply the test editor on the selected test.

**Display - Display tests on/off** : will switch the mode of display. You can either display the graph with the tests as part of it or only with the concepts.

**Display - Browse subtree** : Will ask you to select a concept and will apply the concept space browser on the subgraph for which the selected node is the root.

**Display - Change depth** : Will pop up a menu of integers. You can select the depth of the graph being displayed.

**Display - Update** : Recomputes the graph of the concept space and redisplay it.

**Execute tests** : Will execute all of the tests or part of the tests of the selected concept. Will pop up a menu to set the execution modes.

**Hardcopy tests** ; Sends a pretty printed hardcopy of all the tests (or the selected tests) of the selected concept.

**data base - obtain lock** : Tries to obtain lock on all the tests of the selected concept.

**data-base - Release lock** : Releases all the locks that the user has to tests belongs to the selected concept

## Test Utilities

The following are a useful set of utilities for the testing group. They all reside in the TestUtils file on the Tools subdirectory of the standard test directory.

**PRINT-TEST-ARS**      A lambda function which prints out the AR number and subject fields from an AR query. This function has a window and a file as arguments. The window is the main window of an AR query form (labelled "AR Query Window"). The file is the file to print output on (NIL goes to standard output). The query must already have been performed to select those items which are to be printed and the query should have been sorted by status (as the first sort item in the sort list). In order for this to work correctly, you must scroll the "AR Query Browser" window through all the items before using this function. As an example of use, say that you had previously specified a query list of "(System: IS Operating% System) (Subsystem: IS Generic% File% Operations)" and a sort list of "Status:" in an AR query window (and performed the query and scrolled through all the items), then you could point the cursor to the window labelled "AR Query Window" and do "(PRINT-TEST-ARS (WHICHW) '{DSK}<LISPFILES>TEMP)". This would print a list of the ARs in the file {DSK}<LISPFILES>TEMP.
